Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 1

Economics and the environment

The implementation challenge of the Water Framework Directive

COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 1

Economics and the Environment – The Implementation Challenge of the Water Framework Directive

Produced by Working Group 2.6 - WATECO

Disclaimer:

This technical document has been developed through a collaborative programme involving the European Commission, all the Member States, the Accession Countries, Norway and other stakeholders and Non-Governmental Organisations. The document should be regarded as presenting an informal consensus position on best practice agreed by all partners. However, the document does not necessarily represent the official, formal position of any of the partners. Hence, the views expressed in the document do not necessarily represent the views of the European Commission.

A great deal of additional information on the European Union is available on the Internet.
It can be accessed through the Europa server (http://europa.eu.int).

Introduction - A Guidance Document: What For?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – 'the Directive'). It focuses on the implementation of its economic elements in the broader context of the development of integrated river basin management plans as required by the Directive.

TO WHOM IS THE GUIDANCE DOCUMENT ADDRESSED?

We believe the Guidance will help you in *doing the job,* whether you are:

- Undertaking the economic analysis yourself;
- Leading and managing experts undertaking the economic analysis;
- Using the results of the economic analysis for aiding decision making and supporting the development of river basin management plans; or
- Reporting on the economic analysis to the European Commission as required by the Directive.

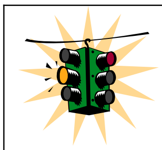
WHAT CAN YOU FIND IN THIS GUIDANCE DOCUMENT?

- **The role of economics in the Water Framework Directive.** What are the key economic elements of the Water Framework Directive? Where in the Directive are these elements made explicit or referred to? How do these elements fit with the Directive's overall river basin planning process?

- **Planning the economic analysis.** How should the process of conducting the economic analysis be planned and organised? When and how should economic expertise be integrated with non-economic expertise? How can adequate financial and human resources be allocated to the economic analysis? Which role could stakeholders and the public play in the economic analysis? How to deal with limited information and expertise? How can external consultants and advisers be used to provide external support? Which elements of the analysis should be undertaken by 2004?

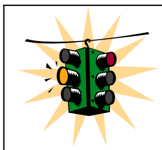
- **Methodologies for undertaking the economic analysis.** What methodology should be used to integrate economics in the preparation of river basin management plans? How can cost-effective measures be selected to build a programme of measures? How can costs and cost-recovery levels be assessed? When is it necessary to assess benefits? How and when can economics be used to support the justification for derogation?

- **Reporting the results of the economic analysis**. How should the different results of the economic analysis be reported? Which results of the economic analysis should be reported by 2004? Which indicators and variables should be computed to inform and consult the public?



Look out! The methodology from this Guidance Document must be adapted to national and regional/local circumstances

The Guidance Document proposes an overall methodological approach. Because of the diversity of circumstances within the European Union, the way to deal with the logical approach and address specific issues will vary from one river basin to the next. This proposed methodology may therefore need to be tailored to specific circumstances.



Look out! What you will not find in this Guidance Document

The Guidance Document focuses on the economic analysis required for supporting the development of River Basin Management Plans, with specific attention to the 2004 requirements of the Directive. The Guidance does not focus on:

- How to develop incentive pricing policies according to Article 9;
- How to develop and implement other economic and fiscal instruments as mentioned in Annex VI;
- How to develop an economic analysis for supporting the development of penalties that provide incentive according to Article 23.

…AND WHERE?

The role of economics in the Water Framework Directive

Section 2 – Which role for economics in the Directive?; **Annex B1** – The economic elements of the Water Framework Directive, original legal text; **Annex B2** – Glossary;
Also: **Section 3** – Roadmap to implementing the Directive's economic elements.

Planning the economic analysis

Section 5 – Ensuring coherency with the overall implementation process;
Section 4 – 2004: the first milestone for the economic analysis;
Annex C – Illustrative terms of reference for *scoping* activities and *stakeholder analysis*;
Also: **Section 3** – Roadmap to implementing the Directive's economic elements; **Annex A1** – The joint activities and working groups of the Common Implementation Strategy; **Annex A2** – Lists and contacts of the WATECO group.

Methodologies for undertaking the economic analysis

Section 3 – Roadmap to implementing the Directive's economic elements;
Annex D1 – Information sheets; and **Annex D2a** - Analysis for derogation;
Also: **Annex D3** – List of references; **Annex A1** – Relevant references and Guidance from other working groups of the Common Implementation Strategy.

Reporting the results of the economic analysis

Section 5 – Ensuring coherency with the overall implementation process;
Section 4 – 2004: the first milestone for the economic analysis;
Annex C – Key summary and reporting tables

Section 1 – Implementing the Directive: Setting the Scene

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

DECEMBER 2000: A MILESTONE FOR WATER POLICY

A Long Negotiation Process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that today form the foundation of the Water Framework Directive.

NEW CHALLENGES IN EU WATER POLICY

What is the Purpose of the Directive?

The Directive establishes a framework for the protection of all water bodies (including inland surface waters, transitional waters, coastal waters and groundwater) which:

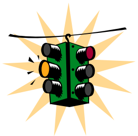
- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes a sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

… and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

What Are the Key Actions that Member States Need to Take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs), and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);
- To carry out the inter-calibration of the ecological status classification systems by 2006 (*Article 2(22); Annex V*);
- To make operational the monitoring of water status by 2006 (*Article 8*);
- Based on sound monitoring and on the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*); and
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).



Look out!
Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be made explicit in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage in two further six- year cycles of planning and implementation of measures.

Developing the Right Process – Information, Consultation and Participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007; and
- The draft river basin management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

Integration of environmental objectives, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;

Integration of all water resources, combining fresh surface water and groundwater bodies, wetlands, transitional and coastal water resources **at the river basin scale**;

Integration of all water uses, functions, values and impacts into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good, investigating both point-source and diffuse pollution, etc.;

Integration of disciplines, analyses and expertise, combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;

Integration of water legislation into a common and coherent framework. The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;

Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;

Integration of stakeholders and the civil society in decision-making, by promoting transparency and information to the public, and by offering a unique opportunity for involving stakeholders in the development of river basin management plans;

Integration of different decision-making levels that influence water resources and water status, be local, regional or national, for an effective management of all waters; and

Integration of water management from different Member States, for river basins shared by several countries, existing and/or future Member States of the European Union.

WHAT IS BEING DONE TO SUPPORT IMPLEMENTATION?

Activities to support the implementation of the Water Framework Directive are under way both in Member States and in countries candidate for accession to the European Union. Examples of activities include public consultation, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

May 2001 – Sweden: Member States, Norway and the European Commission Agree on a Common Implementation Strategy

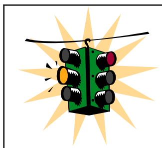
The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance (see *Annex A*). A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of the overall decision body for the Common Implementation Strategy.

The WATECO Working Group

A working group has been created for dealing specifically with economic issues. The main short-term objective of this working group named *WATECO* (for *WATer and ECOnomics*) was the development of a non-legally binding and practical guidance for supporting the implementation of the economic elements of the Water Framework Directive with emphasis on its 2004 requirements. The members of *WATECO* are economists, technical experts and stakeholders from European Union Member States and from a limited number of candidate countries to the European Union.

To ensure an adequate input and feedback during the Guidance development phase from a wider audience, and to evaluate earlier versions of the Guidance Document, the *WATECO* group has organised several discussions and feedback events such as meetings, workshops and conferences.



Look out! You can contact the experts involved in the *WATECO* activities

The list of *WATECO* members with full contact details can be found in *Annex A.* If you need input into your own activities, contact a member from *WATECO* in your country. If you want more information on specific scoping and testing pilot studies, you can also contact directly the persons in charge of carrying out these studies.

Developing the Guidance Document: An Interactive Process

Within a very short time period, a large number of experts and stakeholders have been involved at varying degrees in the development of this Guidance Document. The process for their involvement has included the following activities:

- **Regular meetings** of around 40 experts and stakeholder members of *WATECO*;
- Organisation of **two workshops** to present and discuss the activities and preliminary output of *WATECO*:
    - ***With a larger number of stakeholders (May 2001 - Bruxelles, Belgium);***
    - ***With experts from candidate countries (November 2001 - Szentendre, Hungary).***
- A series of **scoping and testing pilot studies** to assess the feasibility of the overall economic approach (e.g. in terms of information and expertise requirements) and of specific elements of this approach (see *Annex E*).
    - ***In national river basins*** in the United Kingdom, Germany, Spain, Portugal, Sweden, Greece and France;
    - ***In the international basin of the Scheldt River*** as part of a collaborative effort between the Netherlands, France and the three Belgium regions of Wallonia, Flanders and Bruxelles.
- Regular **interactions with experts from other working groups of the Common Implementation Strategy**, mainly those dealing with the assessment of pressures and impacts, designation of heavily modified water bodies and river basin planning. For example, key to many of the above-mentioned pilot studies has been the involvement of non-*WATECO* experts and the integration between economic and technical expertise, e.g. for testing the feasibility of applying cost-effectiveness methods.

Two events for discussing and evaluating draft versions of the Guidance Document:

- A **conference** (March 2002 – Lille, France) to present and discuss the preliminary output of the *WATECO* group (draft Guidance Document, results of scoping and testing activities) to a wide range of **experts and stakeholders;** and
- A **workshop with a small group of water managers** (April 2002 – Bruxelles, Belgium) that are leading the development of river basin management plans in their respective countries, in order to evaluate expectations from water managers *vis-à-vis* the economic analysis and adapt the Guidance to ensure a better integration of the output of the economic analysis into the decision making process.

Section 2 – Which Role for Economics in the Directive?

This Section outlines the economic elements of the Water Framework Directive. It aims at: (i) providing an understanding of the role of economics in water policy making; (ii) critically reviewing the references to economics and economic requirements in the Water Framework Directive; and (iii) integrating these into the decision making process aimed at developing river basin management plans.

WHICH ROLE FOR ECONOMICS IN WATER POLICY?

With increasing scarcity of both water resources and financial resources allocated to the water sector, economic analysis and expertise is increasingly called for in supporting water management and policy decisions. Overall, a sound economic analysis can help in:

- Understanding the **economic issues and tradeoffs at stake** in a river basin – restoring water quality can impact on economic sectors that can have significant role and importance in the local, regional and national economy (be it in terms of overall economic output, trade or employment). Also, different economic sectors are often competing for the same (good quality) water resources;
- Assessing the **least-costly way** for the economy or for specific economic sectors **achieving well-defined environmental objectives** for water resources. Clearly, this ensures best use of limited financial resources allocated to the water sector;
- Assessing the **economic impact of proposed programmes of measures** aimed at improving water status (i.e. who are the *losers*, who are the *gainers*). In some cases, this assessment may stress the need for developing specific accompanying measures that would (partially) compensate *losers*, and thus facilitate the implementation of proposed measures;
- Assessing regions or water bodies where **environmental objectives need to be made less stringent to account for economic and social impacts** in a search for overall sustainability; and
- Supporting the **development of economic and financial instruments** (e.g. water prices or supplementary measures such as pollution charges or environmental taxes), that may be effective in reaching environmental objectives.

Overall, the economic analysis is a **process of providing valuable information to aid decision-making** and should be an essential part of the overall approach for supporting decisions. The economic analysis is also a source of information of interest to stakeholders and the public in the context of information and consultation activities. For example, discussing significant water management issues in a river basin is likely to require information on who pollutes, who uses, which environmental impact occurs, but also on what it costs, who pays, who gains and who suffers from the current situation.

THE ECONOMIC ELEMENTS OF THE WATER FRAMEWORK DIRECTIVE

The Water Framework Directive clearly integrates economics into water management and water policy decision-making. To achieve its environmental objectives and promote integrated river basin management, the Directive calls for the application of economic principles (for example, the *polluter-pays principle*), economic approaches and tools (e.g. cost-effectiveness analysis) and instruments (e.g. water pricing). *Table 1* summarises the key functions of the economic analysis that are referred to in the Water Framework Directive text (see *Table 2*).

Table 1 – Different functions of the economic analysis in the Water Framework Directive

- To carry out an *economic analysis of water uses* in each River Basin District;
- To assess *trends* in water supply, water demand and investments;
- To identify areas designated for the protection of *economically significant aquatic species;*
- To designate heavily modified water bodies based on the assessment of changes to such water bodies and of the *impact* (including economic impact) on existing uses and *costs* of alternatives for providing the same beneficial objective;
- To assess current levels of *cost-recovery;*
- To support the selection of a programme of measures for each river basin district on the basis of *cost-effectiveness* criteria;
- To assess the potential role of *pricing* in these programmes of measures – implications on cost-recovery;
- To estimate the need for potential (time and objective) derogation from the Directive's environmental objectives based on assessment of *costs and benefits* and *costs* of alternatives for providing the same beneficial objective;
- To assess possible derogation resulting from new activities and modifications, based on assessment of *costs and benefits* and costs of alternatives for providing the same beneficial objective;
- To evaluate the costs of process and control measures to identify a *cost-effective* way to control priority substances.

Integrating Economics into Environmental Policy: The Novelty of the Water Framework Directive

Costs, discount rate, prices, taxes… The use of economic terms in the water sector in Europe has increased over recent years – and not only on the part of economists. Economic issues affect all people – as consumers who pay for water supply and sewerage services; as taxpayers for supporting heavy investments in the water sector; and increasingly as human beings, eager to protect water resources for themselves and for future generations.

Since the 1970s, advocating the *polluter-pays principle* in water policy has become the norm rather than the exception, although the level of application of this principle remains highly heterogeneous. Furthermore, the focus was on financial aspects rather than on economic costs. It is only in the early 1990s (not long before the Directive's negotiations were initiated) that attention started switching to the economic value of water.

This led to the production of many academic studies and analyses, but with limited emphasis placed on creating a link between empirical research and policy-making. With the Water Framework Directive, it is the first time in EU environmental policy that economic principles, tools and instruments are explicitly integrated into a piece of legislation, thus opening up an unique opportunity of making that link a reality.

Table 2 – Overview of the Economic Elements in the WFD

Reference	Summary Provisions
Preambles 11, 12, 31, 36, 38 and 43	• That the **polluter should pay;** • Take into account the **economic** and social development of the Community; • Lower objectives justified if **unreasonably expensive** to achieve good status; • Carry out an **economic analysis of water uses;** • Use **economic instruments** as part of the **programmes of measures;** • Apply the **principle of cost recovery of water services (including environmental and resource costs)** in accordance with the **polluter pays principle;** • Identifying **cost-effective** combination of measures for reducing pollution of priority substances.
Article 2: Definitions 38 and 39	Definition of water services – Definition of water use
Article 4: Environmental objectives *Designation of Heavily Modified Water Bodies (4.3)* *Environmental objectives and derogations (4.4, 4.5 and 4.7)*	An economic justification can be provided for designating Heavily Modified Water Bodies (*'….for reasons of technical feasibility and **disproportionate costs**….* '). Possible economic justification for derogation: • Time derogation if … *completing the improvements within the time scale would be disproportionately expensive… ;* • Objectives derogation if … *the achievement of these objectives would be infeasible or disproportionately expensive…* and there are *no other means which are a significantly better environmental option not entailing disproportionate cost;* • Derogation for new modification or sustainable economic activity, if benefits of this activity outweigh benefits from good water status and there are *no other means which are significantly better environmental option not entailing disproportionate cost.*
Article 5: Characteristics of the river basin district, review of the environmental impact of human activity and economic analysis of water use *Annex III: Economic Analysis*	As part of the analysis of the River Basin characteristics, an **economic analysis of water uses** must be conducted. According to specifications in Annex III, *the economic analysis shall contain enough information in sufficient detail to*: • Make the relevant calculations necessary for taking into account **cost recovery of water services**, *taking account of long term forecasts of supply and demand for water in the RBD and, where necessary:* *a) Estimates of the volume, prices and costs associated with water services:* b) *Estimates of relevant investment including forecasts of such investments.* • Make judgements about the most **cost effective combination of measures** in respect of water uses to be included in the programme of measures under Article 11 based on estimates of the potential costs of such measures.
Article 6: register of protected area & Annex IV: Protected areas	Designation of areas for the protection of **economically significant aquatic species**.
Article 9: Recovery of costs for water services	Take account of the principle of **recovery of the costs of water services**, including **environmental and resource costs**, according to the ***polluter pays principle*** *Member states shall ensure by 2010* • *that **water pricing policies** provide adequate incentives for users to use water resource efficiently, and thereby contribute to the environmental objectives of this Directive »* • *An adequate contribution of the different water uses, disaggregated into at least industry, households and agriculture, to the recovery of the costs of water services…* Possibility to account for social, environmental and **economic effects** in defining pricing policy
Articles 11: Programme of measures & Annex VI: Lists of measures to be included within the programme of measures	Establishment of programme of measures with references to the analysis performed based on Article 5 (thus, the **economic analysis** of water use according to Annex III) and including as basic measure (b) **measures deemed appropriate for the purposes of Article 9** (i.e. recovery of costs for water services) Annex VI – part B (iii) mentions ***economic or fiscal instruments***
Article 13: River Basin Management Plans & Annex VII: River basin management plans	The river basin management plan shall cover: • A **summary of the economic analysis of water use** as required by Article 5 and Annex III.
Article 16 "Priority Substances"	Use of **cost-effectiveness criteria** for identifying best combination of product and process controls for controlling priority substances
Article 23 "Penalties"	Defining penalties may build on economic input, as these penalties have to be …*effective, proportionate and dissuasive…*

Note: the text in *italics* is the exact wording of the Directive. An exhaustive list of economic references in the Directive is given in *Annex B* and can be used as support to this Section.

WHICH ECONOMIC ANALYSIS FOR SUPPORTING IMPLEMENTATION?

The Water Framework Directive includes a specific Annex dealing with the economic analysis, i.e. Annex III. However, the comparison between the economic elements of the Directive reviewed above and the content of Annex III shows that not all components of the economic analysis required to support the implementation of the economic elements of the Directive are specifically spelt out in Annex III.

A difference is made between the ***explicit*** and ***implicit*** functions of the economic analysis, the term *explicit* referring to the economic components that are specifically outlined in Article 5 and Annex III (see *Figure 1*), and the term *Implicit* referring to references made to economic issues in other parts of the Directive text that will also require some economic analysis which has not been mentioned in Article 5 and Annex III (see *Figure 2*).

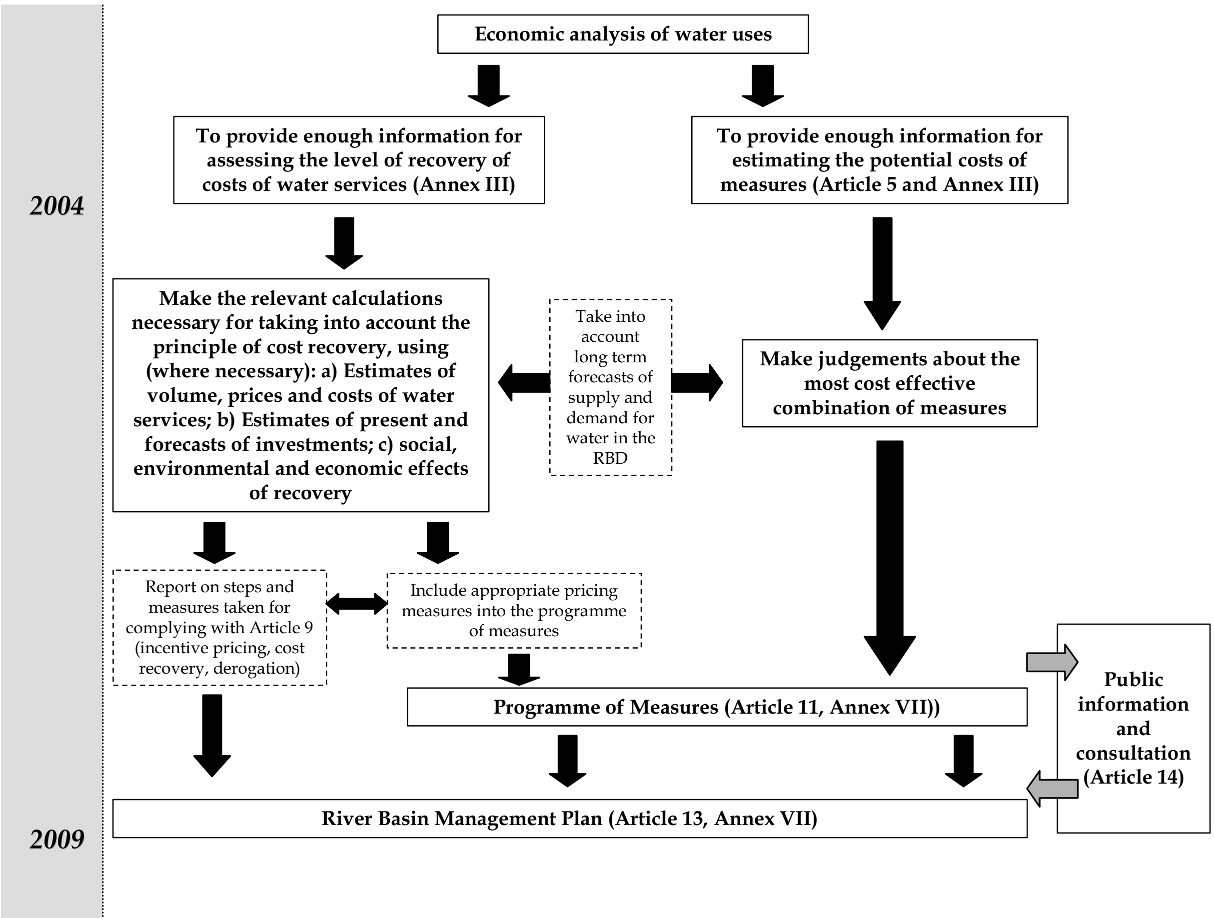


Figure 1 – The *Explicit* Economic Functions of the Economic Analysis

Look out!

Annex III indicates that the economic analysis conducted by 2004 should support the assessment of the most cost-effective combination of measures to be included in the Programme of Measures (Article 11). Such cost-effectiveness analysis requires an identification of environmental objectives for each water body, an assessment of possible measures to meet these objectives, an estimate of their costs and of their impact on the status of water bodies.

➢ *The economic analysis to be carried out by 2004 should pave the way for carrying out the cost-effectiveness analysis for the preparation of the programme of measures. Testing the cost-effectiveness of proposed measures will be carried out during the phase 2004-2009;*

➢ *The economic analysis undertaken by 2004 being the basis for output to be delivered at a later stage, it is important to ensure the information collected and analysis performed for 2004 already account for following requirements, such as the overview of significant water management issues (by 2007) or the development of integrated river basin management plans (by 2009). This may have implications, for example, on the spatial scale at which variables are computed (river basin district scale for the 2004 reporting versus more disaggregated scale for the overview of significant water management issues).*

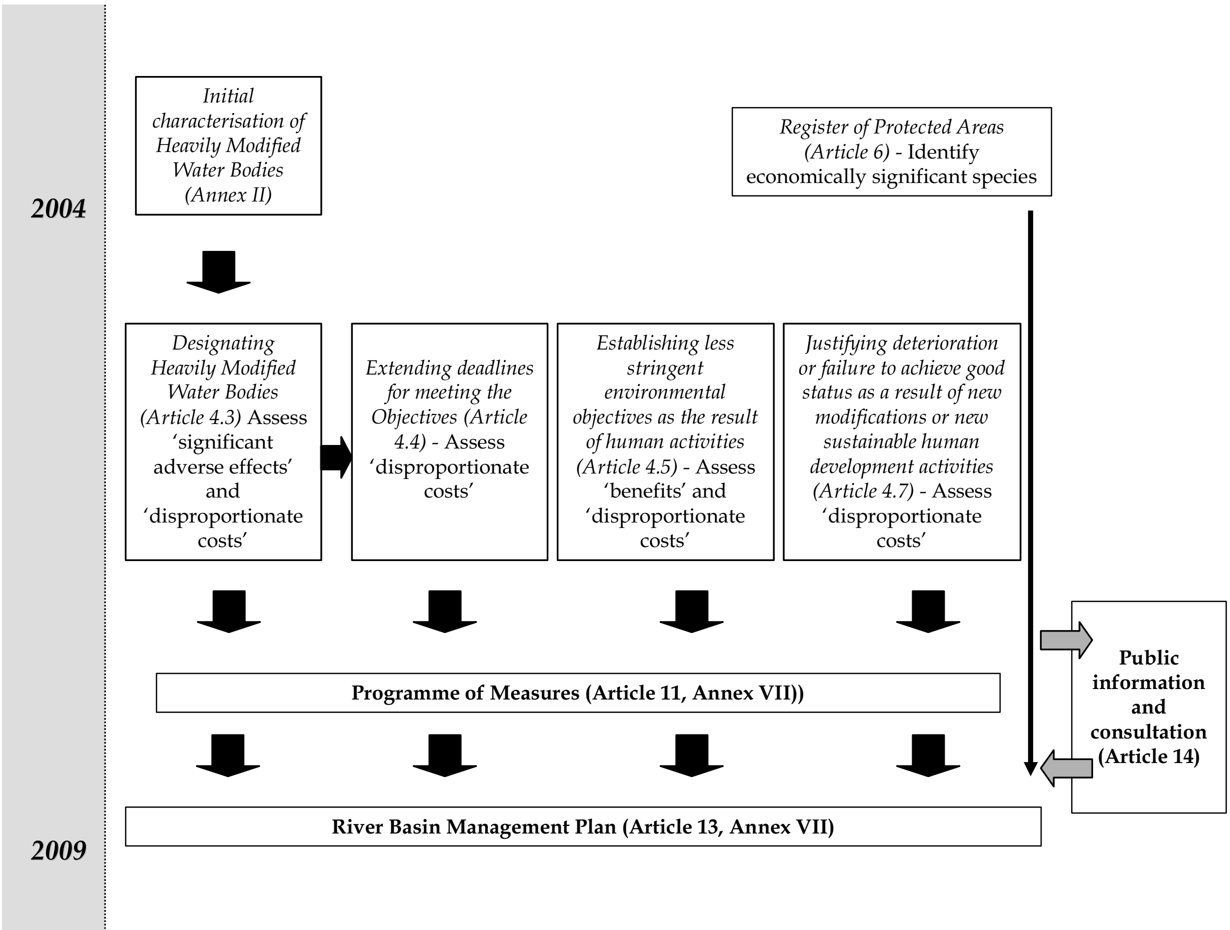

Figure 2 – The *Implicit* Economic Functions of the Economic Analysis

HOW CAN THIS GUIDANCE DOCUMENT HELP YOU?

This Guidance Document will help you to make the economic analysis a reality and to:

- Know when to establish 'knowledge links' with other disciplines for the preparation of the economic analysis and the programme of measures (*Section 3* and *Section 5*);
- Understand which information will be needed for carrying out the analysis and to fill the gaps once they have been identified (*Section 3* and *Section 5*);
- Estimate costs on the basis of common definitions (*Annexes A2* (Glossary) and *D1* (Estimating costs (and benefits)), and in particular to identify methods for estimating environmental and resource costs;
- Understand how to evaluate the role of pricing as an economic instrument (*Annex D1* (Pricing as an Economic Instrument)), but not how to develop these (*Section 3*);
- Provide some common tools for estimation of disproportionate costs (*Annex D1* (Disproportionate costs));
- Understand the timing requirements for submitting requests for derogation (*Section 3* and *Section 5*).

Dealing with economic issues and analyses: which tasks for the European Commission?

The economic analysis for supporting the development of river basin management plans and the assessment and development of pricing policies is clearly the responsibility of Member States. But the European Commission is mentioned at a few places in the Water Framework Directive in relation to economic analysis. More specifically:

- In the context of the submission of proposals of controls for priority substances (Article 16), the Commission *shall identify the appropriate* ***cost-effective*** *and proportionate level and combination of product and process controls for both point and diffuse sources…*;
- It shall also **publish a report** based (Article 18) on the summary reports submitted by Member States on the analysis required under Article 5 (Article 15), i.e. **including the economic analysis of water uses and subsequent analyses referred to in Annex III**;
- A Commission statement was added to the Directive's text at the time of adoption, stressing that *the Commission in his report will, with the assistance of the Member States, include a* ***cost-benefit study*****.**

Although scattered along the Directive's text, the different economic elements should be well integrated in the policy decision and management cycle (see *Figure 3*) to ensure it effectively aids and informs decision-making.

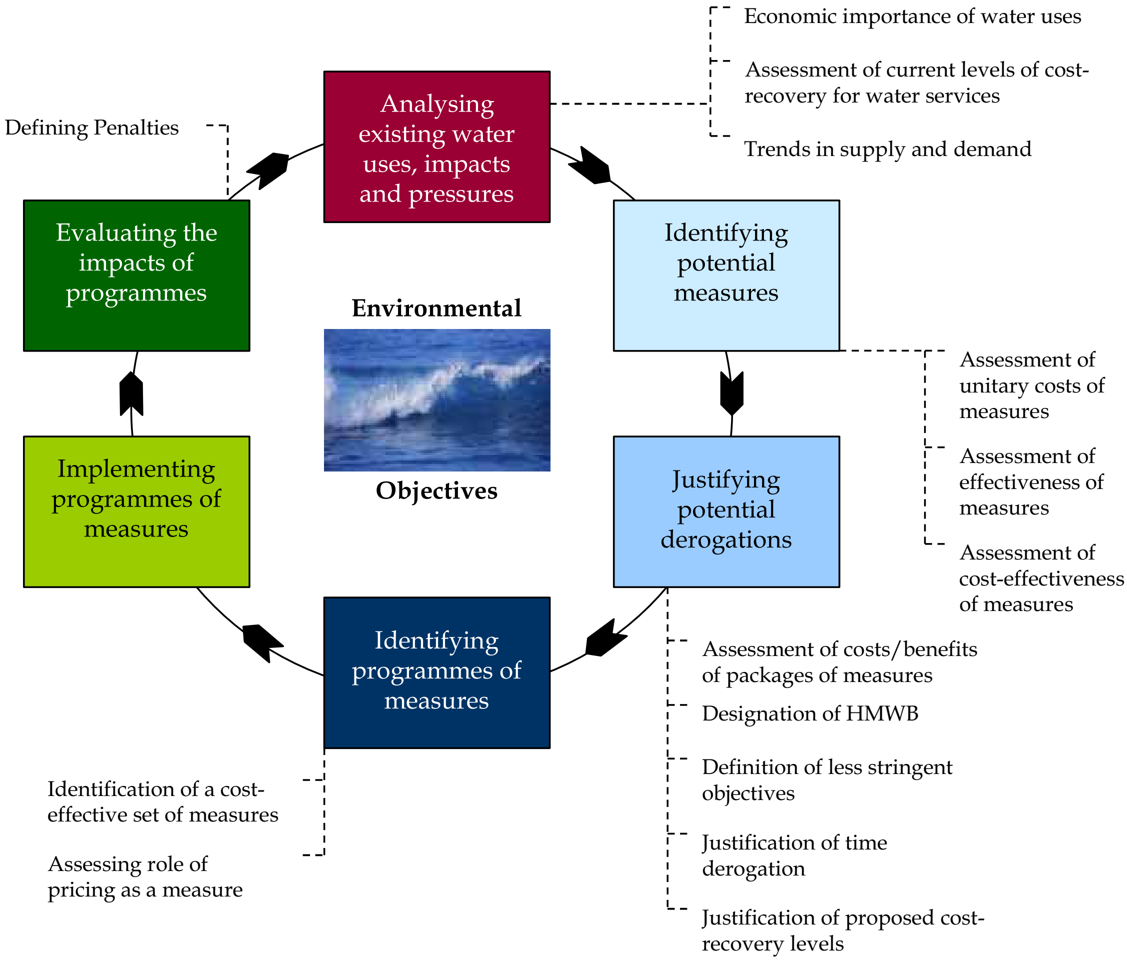

Figure 3 – Economic Elements are linked and must be integrated

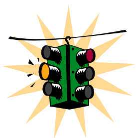
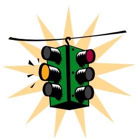


Look out! There is no straight line on the economic analysis path…

Figure 3 illustrates in a simple manner the role economics can play in developing and implementing river basin management plans. In practice, however, the distinction between different tasks and the chronological order in which tasks take place is more complicated. For example, designating heavily modified water bodies requires looking simultaneously at environmental objectives, pressures and impacts, and measures for improving environmental quality.



Look out! Economics is only there to inform decision makers

Bear in mind: whether it is based on cost-effectiveness, cost-benefit assessment or any other economic method, the economic analysis does not *take the decision*! Similarly to other disciplines and expertise, it helps in taking better decisions by accounting for their economic dimensions and impact. Thus, it is important to ensure the economic analysis and its output is well integrated with other analyses and expertise aimed at supporting policy and management decisions.

Section 3 – Roadmap to Implementing the Directive's Economic Analysis

This Section lays out the key steps that you should consider going through to carry out the economic analysis to aid decision making for developing river basin management plans. This is only a roadmap: each Member State will need to find its own way based on local circumstances.

To support the development of river basin management plans, a three step economic analysis is proposed in this Section. This 3-step approach aims at providing a coherent framework to the different functions of the economic analysis required for the Water Framework Directive and identified in Section 2. It clearly integrates economic and technical issues, expertise and tools in:

- **Step 1 - Characterising the river basin** in terms of the economics of water uses, trends in water supply and demand and current levels of recovery of the costs of water services;
- **Step 2** - Identifying water bodies or group of water bodies not achieving the environmental objective of the Directive (i.**e. identifying gaps or risks of failure** in achieving objectives); and
- **Step 3** - Supporting the development of the **programme of measures** to be integrated in river basin management plans **through cost-effectiveness analysis** and justifying from an economic point of view possible (time, objective) derogation.

The objective of this Section is to set out these steps you might want to follow to carry out the economic analysis in a logical way. Section 4 will summarise what needs to be done to meet the 2004 requirements of the Water Framework Directive.

For each step, you find in this Section:	
Objective	The objective of the Step, also pointing out to the outputs to be produced in that Step.
Process	Each Step has been broken down in sub-steps and key actions. This Section distinguishes between actions to be undertaken by economists, those dealt with by technical experts (in ***green***) and those undertaken jointly (in *violet*).
Methodological Scope	For each step, there is a range of options for conducting the analysis, ranging from what is practical in the short-term to what is required by the Directive and what would constitute an economic best practice. The latter might not always be achievable due to data or human resource limitations or because of too-high supplementary costs (see *Annex C*).
References in this Guidance Document	Links with other documents in the Guidance that give you more in-depth description and illustration of what actually needs to be done.
Links with other tasks	Links with other tasks with which coordination is required for the development of integrated river basin management plans.
Likely information requirements	List of information (non-exhaustive, non-compulsory) likely to be required for the activities described in the process, from both the economic analysis and from other tasks (in ***green***). Overall, only the information that is required for the specific purpose of the economic analysis and for supporting management decision should be gathered – data should not be gathered for the sake of gathering data.

OVERALL APPROACH

In accordance to the specifications of the Water Framework Directive, the overall objectives of the three-step approach are:

- To aid decision making in selecting programmes of measures for achieving the environmental objectives of the Directive – an economic appraisal is made to rank measures and identify those that are the most cost-effective in achieving these objectives; and
- To ensure transparency in the real costs of water management interventions and help making informed decisions on the recovery of these costs for providing incentives to achieve the environmental objectives of the Directive.

In Figure 4, the graph and the timing charts on the right hand-side focus on the logical flow of the three step approach that should be followed to implement the economic aspects of the Water Framework Directive whilst respecting the Directive's own deadlines. In particular, the Figure 4 presents for each step its objectives, the type of analysis to be carried out, what the economic analysis feeds into and key deadlines. Although presented linearly, the analysis is iterative in nature: initial analysis will be based on existing information, but will be upgraded as new information and knowledge is obtained. This figure includes two areas where economic issues are at stake but that are more difficult to position in time and within this logical framework:

- The identification and designation of heavily modified water bodies (Article 4.3 of the Directive, see *Annex D2b*); and
- The assessment and justification of objective derogation because of new morphological modification, over-abstraction of aquifers or new sustainable economic activities (Article 4.7 of the Directive, see *Annex D2a*).

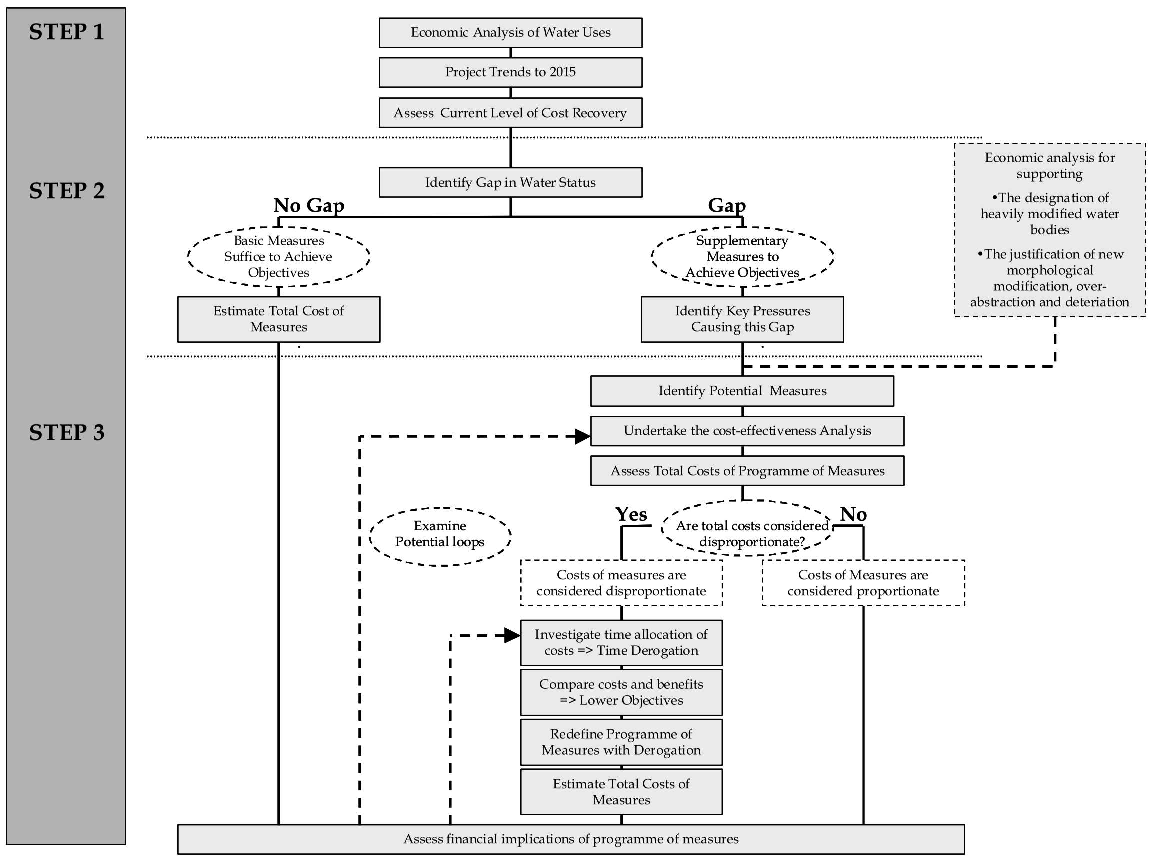
Although required in the Directive for 2008 as part of the draft river basin management plan put for consultation to the public, the designation of heavily modified water bodies and the justification for derogation resulting from new modifications and sustainable economic activities will be needed when developing the programme of measures. Thus, additional input from the economic analysis on these matters is likely to be required earlier on the basis of costs and benefits assessment.

Overall, it is important to stress that the deadlines for implementation are influenced by several drivers: (i) the Directive's own deadlines: these have been discussed in *Section 2*; (ii) logical steps for the analysis: this is what this *Section 3* focuses on (see also the critical path analysis presented in *Section 6*); (iii) interaction with other fields of competencies and with the consultation and participation process: see more on this in *Section 5*.

Before engaging in the 3-step approach, make sure to know where you are going!

Conducting a ***feasibility study*** (see *Section 5*) is recommended to assess whether the proposed approach can be made operational under actual conditions. It is important to do this assessment for future data requirements, as collecting (or creating) additional data can be long and resource-intensive. This feasibility study may include nation-wide and region-wide elements to assess the scale at which activities could best be performed.

Objective	The Three Steps	Feed Into	Timing
To characterise River Basins	STEP 1	• Economic Analysis of Water Uses • Identification of protected areas	By 2004
To identify significant water management issues and risk of non-compliance	STEP 2	• Preparatory documents for RBMP • Interim Overview of Significant Water Management Issues	By 2006 By 2007
To help identify a cost-effective programme of measures To assess cost-recovery and incentive pricing and their economic impact	STEP 3	• Draft RBMP • River Basin Management Plan • Adequate pricing and cost-recovery	By 2008 By 2009 By 2010



Is that it?

No, most of the steps of the economic analysis will need to be repeated at later stages as further management cycles are required and proposed. Furthermore, the Directive sets out very clear timeframes for each of these repetitions, timed slightly differently from this first iteration. Thus, be careful to respect future deadlines! The different interim evaluations specified by the Directive will be key in updating information and assumptions made doing the earlier analyses and will ensure better information is obtained for aiding decision-making.

Figure 4 - A Bird's View to the Three-Step Approach

STEP 1 – CHARACTERISING RIVER BASINS

Objectives		Look out!
To prepare an economic analysis of water use in order to analyse: ➢ Current water uses and their economic importance; ➢ Future trends in key economic drivers up to 2015; ➢ Current cost-recovery levels of water services.		This step will require a high level of coordination with other experts and stakeholders to build a common knowledge and representation of the River Basin.

Process	Look out!
STEP 1.1 – ASSESSING THE ECONOMIC SIGNIFICANCE OF WATER USES	
➢ Identify human pressures on water bodies; ➢ Localise water uses in the river basin district; ➢ Identify water uses and services by socio-economic sector (agriculture, industry, households and recreation); ➢ Assess the relative socio-economic importance of water uses; ➢ Identify areas designated for the protection of economically significant aquatic species.	*Potential indicators of importance:* ➢ ***Income, employment…;*** ➢ ***Volumes of water demands;*** ➢ ***Expression of economic and social preferences, via public consultation.***
STEP 1.2 – PROJECTING TRENDS IN KEY INDICATORS AND DRIVERS UP TO 2015	
➢ Assess trends of key hydrological and socio-economic factors/*drivers* that are likely to affect pressures (demography, climate, sector policies, e.g. common agricultural policy, technological development…); ➢ Identify proposed measures and planned investments for implementing existing water legislation; ➢ Forecast changes in pressures based on changes in economic and physical drivers and proposed water-related measures; ➢ Construct a *Business As Usual* scenario for pressuresConduct a sensitivity analysis on the baseline scenario and identify optimistic and pessimistic scenarios.	*Ensure coherence with projections and trends used for other river basins for national and EU policies and climate change.* *The business as usual scenario may first build on certain changes and thus need to be updated beyond 2004 in order to integrate changes in uncertain parameters.*
STEP 1.3 – ASSESSING CURRENT COST-RECOVERY	
➢ Estimate costs of water services, including financial, environmental and resource costs; ➢ Estimate the price/tariff currently paid by the users; ➢ Assess the extent of cost recovery by water service and sector; ➢ Assess the contribution to cost recovery from key water uses; ➢ If felt necessary, initiate review of incentive pricing properties of existing tariffs.	***This is needed to evaluate the effort needed to meet the 2010 deadline. Principles for allocating costs of water services to categories of water users will need to be defined in a coherent manner.***
	… Feed into
Key indicators of economic significance of water uses Baseline scenario and trends up to 2015 Current extent of cost-recovery } Areas designated for the protection of economically significant aquatic species	Economic Analysis of water uses by 2004. Register of Protected Areas.

Methodological Scope
➢ At the minimum, the economic role of water uses should be identified at the River Basin District (RBD) level, which is also the level of reporting to the Commission. However, this may be of little use for follow-up analyses and consultation required for developing river basin management plans that are likely to require lower disaggregation for economic information and indicators (e.g. sub-regions of the basin or sub-economic sectors); ➢ Initiating the integration of economic and technical information for developing an adequate integrated information base will be key to the activities aimed at characterising RBDs; ➢ If initiated at this stage, consultation would focus on seeking views on key issues and concerns in the RBD and on informing about the appraisal process.

References in this Guidance Document	**Links with other Tasks**
Annex D1: *Estimating costs, Reporting on Cost-recovery, Baseline scenario, Pricing as an Economic Instrument* ***Section 4***	Determination of Pressures and Impacts Characterisation of water bodies (e.g. transitional and coastal waters) Development of geo-referenced databases Overall River Basin Planning

Likely information requirements	**Look out!**
Step 1.1	
➢ Water abstractions and discharges by socio-economic categories and localisation; ➢ Economic importance of main water uses: turnover, employment, income, number of beneficiaries; ➢ Information (for example, quantity, prices or turnover, depending on availability) for characterising economically significant aquatic species.	*Key is to collect information that is relevant to water management issues in the river basin and to key economic sectors likely to be affected by the Directive Implementation. Combining biophysical and economic information will require agreement on common spatial scale of analysis and reporting.*
Step 1.2	
➢ Prospective analyses of likely development of key economic sectors/economic drivers influencing significant pressures; ➢ General information on population growth, economic growth, sector growth patterns, future policies and forecasts of the impact of climate change; ➢ Studies on existing and projected water balance; ➢ Inventory of existing measures (and costs) for complying with existing water legislation; ➢ Identification of technological developments in the water sector.	*A good understanding of regional planning issues will also be required for this step.* *Risk assessment is key: try to specify the degree of confidence when forecasting data.*
Step 1.3	
➢ Estimation of financial costs (broken down in operating, maintenance and capital costs); ➢ Evaluation of tax transfers, administrative costs and any other costs; ➢ Evaluation of environmental and resource costs as required; ➢ Extent of financial and environmental cost-recovery; ➢ If activities initiated for reviewing incentive pricing: current pricing structure and price elasticity, affordability criteria.	*Assessing incentive pricing properties of existing tariffs might be difficult in practice: it should be done so as to inform the future introduction of incentives in tariffs by 2009.* *Affordability is seen as key in some countries (e.g. candidate countries to the European Union).*

Illustration - Assessing the economic significance of water uses

The pilot projects undertaken in the context of developing this Guidance have illustrated the diversity of economic indicators that can be computed for assessing the economic significance of water uses.

- In the **Corfu** case study (see *Annex E*), tourism represents a key water use sector. Its economic importance was illustrated with absolute and relative (as compared to national values) values for mean annual employment (direct and indirect) and total number of nights spent by tourists in the island during the year;
- For the characterisation of the Scheldt estuary, undertaken as part of the **Scheldt** case study (see *Annex E*), the analysis concentrated mainly on navigation and harbour economic activities (leading to deepening and maintenance of the shipping channel) and economic land use in the area (agriculture, industry or harbour development leading to in-poldering and construction of dikes); and
- In addition to urban development and linked water services, the **Cidacos** case study (see *Annex E*) emphasised agricultural water use with the view to assess the indirect economic impact potential measures aimed at improving water status would have on the agricultural sector.

Water services, water uses and cost-recovery

The Water Framework Directive requires Member States to take account of the principle of recovery of the costs (including environmental and resource costs, see Article 9.1) of water services, also taking into account the *polluter pays principle*.

The assessment of cost recovery is relevant to water services (according to Article 2.(38)) but not to the wider circle of water uses (according to Article 2.(39)). However, the different water uses shall deliver an adequate contribution to the recovery of the costs of water services (Article 9.1), stressing the need to link water uses and services developed for mitigating the negative environmental impact of these uses.

Further issues on water services to be included in the analysis (based on transparency, effectiveness and proportionality criteria) and related implications are further developed in *Annex B3*.

STEP 2 – IDENTIFYING SIGNIFICANT WATER MANAGEMENT ISSUES

Objectives		Look out!
➢ To identify the gaps between the water status resulting from the baseline scenario and the Directive's objectives (good water status); ➢ To identify significant water management issues in each River Basin; ➢ To pave the way for the preparation of a programme of measures to address these issues.		Here, the economic analysis will use a high level of input from more technical analysis. However, sufficient economic elements should be provided to organise meaningful stakeholder consultation.

Process	Look out!
STEP 2.1 – WILL THERE BE GAPS IN WATER STATUS BY 2015?	
➢ Translate the forecast analysis of pressures and investments in the water sector into a forecast of impact; ➢ To assess the gap between the Directive's objectives with respect to water status and the water status achieved with the baseline scenario and optimistic and pessimistic variations: o If *gap* in water status ➢ ***Go to Step 2.2.a***; o If *no gap* in water status➢ ***Go to Step 2.2.b.***	***Assessing the gap in water status is equivalent of the more rigorous assessing risk of non-compliance.***
STEP 2.2.a – WHAT TO DO WHEN A "GAP" HAS BEEN IDENTIFIED?	
➢ *Gap*: identify water bodies where there is a gap; ➢ Define the main drivers of pressures (particularly, in terms of socio-economic groups) in order to facilitate the selection of appropriate measures in Step 3; ➢ Start identifying main options/measures likely to be investigated in subsequent steps as guide; ➢ Evaluate how socio-economic groups may be affected by main options/measures taken to reduce the gap.	*Public consultation is clearly specified in this Step. It will be important to have preliminary assessments of cost and socio-economic impacts to provide a basis for consultation.*
STEP 2.2.b – WHAT TO DO WHEN "NO GAP" HAS BEEN IDENTIFIED?	
➢ *No gap*: measures for complying with existing water legislation are sufficient to meet the Directive's objectives; ➢ In the preparatory documents, propose to confirm those objectives and the programme of measures required by existing water legislation; ➢ If considered necessary, estimate the costs of these basic measures and provide a first assessment of the impact of these measures on socio-economic sectors and cost-recovery ➢ Go to ***Step 3.4.***	***In Step 3, it might be necessary to reconfirm the costs of these basic measures and their cost-recovery impact in order to incorporate them in the final River Basin Management Plan.***
Key Outputs…	**… Feed into**
➢ Total costs of basic measures if *no gap* is identified; ➢ Identification of water bodies where gap is identified; ➢ Identification of the key sectors causing the gap and that might be affected and initial estimation of costs of additional measures for reaching good water status.	➢ Preparatory documents for the RBMP by 2006; ➢ Interim Overview of Significant Management Issues by 2007.

Methodological Scope
➢ Once gaps or risks of non-compliance have been identified for specific water bodies within a river basin, more detailed analysis might need to be carried out at the level of the concerned water bodies. For example, to obtain a better hand on pressures and their impact on the status of these specific water bodies; ➢ The assessment of the gap will require a good understanding of the hydrological cycle and relationships between, on one side, pressures and measures and, on the other side, impacts. The scale at which this assessment is required will be influenced by the identification of water bodies where gaps occur in the concerned river basin.

References in this Guidance Document	**Links with Other Tasks**
Annex D1: *Estimating costs* *Reporting for cost-recovery* ***Section 4***	Determination of Pressures and Impacts Overall River Basin Management

Information requirements	**Look out!**
Step 2.1	
➢ Methods and tools for transforming trends in pressures into trends in water status; ➢ Potential role of environmental modelling.	***Information for this Sub-Step will mostly come from other competencies at river basin level, such as from the experts in charge of determining pressures and impacts.***
Step 2.2.a	
➢ Identification of additional measures, including new investments, sector policies, economic instruments; ➢ Initial estimation of the costs of these additional measures; ➢ Preliminary (qualitative) assessment of socio-economic impacts on specific target groups.	***Economic analysis may play a role in the identification of key drivers for pressures. And socio-economic indicators are likely to be of interest to stakeholders and the public in the context of consultation.***
Step 2.2.b	
➢ Costs of basic measures; ➢ Estimation of the impact of basic measures on socio-economic groups.	*See for example reports of specific European water directives (e.g. Urban Waste Water Treatment Directive).*

Is that it?

Article 14 specifies that preparatory documents for the River Basin Management Plan will need to be produced three years before each future RBMP for adequate information and consultation of key stakeholders and the public. This requirement applies to the interim overview of the significant water management issues required for 2007 (and at least two years before each future plan in following planning cycles). Thus, ensuring results of the analysis respond to the demand for information from stakeholders and the public will be key to the type of information to be delivered and to the reporting format.

Illustrations - Using simulation models for assessing the gap in water status and supporting the cost-effectiveness analysis

Computer-based simulation models can prove useful for assessing the impact of pressures on water status and investigating the effectiveness/likely environmental impact of different measures:

- A mathematical hydrodynamic model was used in the **Alsace** case study (see *Annex E*) for investigating problems of salt (NaCl) intrusion into the groundwater aquifer. The model helped quantify the impact of planned measures on water quality, showing these measures would not be sufficient for achieving good water status;
- A simple mass balance model was developed for assessing the effectiveness of measures in the **Cidacos** case study (see *Annex E*). This model integrates sub-models for specific river reaches, and provided input into the cost-effectiveness analysis of measures targeting various economic sectors (agriculture, household, etc) and environmental issues (water quality, water quantity and over-abstraction).

Clearly, models should be used with caution, i.e. the user must understand the assumptions and information used for building and calibrating the model, and uncertainties in model prediction. However, properly developed and handled in interaction with stakeholders, they can provide effective platforms for analysis, understanding and discussion aimed at supporting decision.

STEP 3 – IDENTIFYING MEASURES AND ECONOMIC IMPACT

Objective		Look out!
➢ To provide an economic input into the definition of the programme of measures and help ranking possible measures based on cost-effectiveness criteria; ➢ To provide economic support to the assessment of derogation; ➢ To assess the potential impacts and financial implications of the programme.		This step is the key economic input into the preparation of the RBMP (*Article 13*). It is important efforts are targeted to areas and issues required for aiding decision making.

Process	Look out!
STEP 3.1 – EVALUATING THE COSTS and EFFECTIVENESS of POTENTIAL MEASURES	
➢ Identify potential measures to achieve the Directive's objectives, including basic and supplementary measures; ➢ Estimate the costs of each measure; ➢ Estimate the effectiveness (environmental impact) of each measure.	*Given potential interaction between measures, it is important to assess the effectiveness of basic measures and integrate them into the cost-effectiveness analysis.*
STEP 3.2 – CONSTRUCTING A COST-EFFECTIVE PROGRAMME of MEASURES	
➢ Assess and rank cost-effectiveness of measures; ➢ Select the most cost-effective programme of measures that can reach environmental objectives; ➢ Calculate range for the total discounted costs of this programme; ➢ Undertake a sensitivity analysis to assess robustness of results.	***Uncertainty on costs, effectiveness and time-lagged effects of measures needs to be considered in the cost-effectiveness analysis.***
STEP 3.3 – EVALUATING WHETHER COSTS ARE DISPROPORTIONATE	
➢ If total costs are judged to be proportionate ➢ Go to ***Step 3.4;*** ➢ If the total costs of the proposed programme are judged to be disproportionate, estimate whether a derogation might be needed from an economic point of view and on which basis: 1. Compare total costs to financial resources – if costs can be reduced or better managed over longer time horizon, propose time derogation; 2. Assess total costs and benefits (including water-related environmental benefits) – if total costs disproportionate as compared to benefits, propose less stringent environmental objectives – account for socio-economic and distributional implications if considered necessary. ➢ Redefine programme of measures accordingly and propose water bodies for derogation; ➢ Calculate total discounted costs of revised programme.	***How to "judge" whether costs are disproportionate is not developed here, as it encompasses many complex decisional, institutional and socio-economic elements. Judgement needs to be made prior the analysis to decide whether to embark into the analysis or not. Estimating the need for derogation will be resource intensive and will require co-ordination with other experts and consultation of key stakeholders and the public.*** ***➢ Plan it well and start early!***
STEP 3.4 – ASSESSING THE FINANCIAL IMPLICATIONS OF PROGRAMME OF MEASURES	
➢ Assess socio-economic and distributional impact of the selected programme; ➢ Assess financial and budgetary implications of the selected programme, establish alternative financial plans; ➢ Identify accompanying (financial, technical, institutional) measures for implementing the selected programme; ➢ Assess potential impact on cost-recovery and incentive pricing.	*This analysis will feed into the definition of pricing policies by 2010. It may also require loops to earlier steps of the cost-effectiveness analysis, e.g. if resulting price changes are likely to change pressures and thus the cost-effectiveness analysis.*

Key Outputs…	… Feed into
➢ Estimation of Total Costs of Programme of Measures; ➢ Economic justification for possible derogation; ➢ Financial and budgetary implications of selected programme; ➢ Assessment of cost-recovery levels with proposed measures.	Programme of measures and River Basin Management Plan

References in this Guidance Document	Links with Other Tasks
Annex D1: *Scale issues,* *Estimating costs,* *Cost-effectiveness analysis,* *Cost and benefit assessment,* *Pricing as an Economic Instrument,* *Disproportionate costs*	Definition of programme of measures Estimation of the effectiveness of measures Justification of derogation

Information requirements	Look out!
Step 3.1	
➢ Costs of potential measures, e.g.: investing to increase available supplies, demand management, wetland restoration, limiting abstractions with permits ➢ Effectiveness of potential measures	*If demand management and pricing measures are used, the effectiveness of the programme of measures might need to be revisited to account for elasticity issues.*
Step 3.2	
➢ Compile information gathered in Step 3.1.	
Step 3.3	
➢ Costs are proportionate: compile total costs of programme ➢ To assess whether costs are disproportionate: o Estimate financial resources available; o Estimate costs and environmental benefits which relate to the water body level.	***The economic analysis can only formulate recommendations: estimating the need for derogation will ultimately remain a political decision.***
Step 3.4	
➢ Forecasts of prices by 2010 based on ongoing tariff policies; ➢ Allocation of costs by water uses; ➢ Information on price elasticity (effectiveness).	

Methodological Scope
➢ The cost-effectiveness analysis is best performed at the river basin scale. Undertaking the analysis at lower scale requires an adequate integration between analyses undertaken for sub-units of the river basin; ➢ Specific care needs to be given to the choice of the effectiveness indicator. Indeed, different effectiveness indicators may lead to a different outcome for the ranking of measures. Furthermore, specific attention may be required as the effectiveness of measures can often be assessed (qualitatively) for a few environmental indicators only, and not for the range of environmental issues encompassed in the definition of water status; ➢ Care is to be given to the assessment of the different costs considered in the cost-effectiveness analysis. Often, information may not be available for specific cost types. Thus, it is important to remember the cost-effectiveness analysis is only partial and to stress the possible uncertainty existing with the ranking of measures obtained.

SELECTED ISSUES FOR CONCLUDING SECTION 3

Methodological Scope for the economic analysis	
Scale	Even though reporting in the RBMP is at the river basin district level, different types of analysis should be conducted at different scales: • Cost-effectiveness analysis should best be conducted at the *river basin level*; • In some cases, it may be more practical to undertake the analysis for *sub-basins*. However, the hydrological integrity of the basin needs to be kept, starting for example with the most up-stream sub-basin and working downwards; • Derogations can be justified (based on the assessment of costs and benefits) at the *water body level*; • Reporting on cost-recovery should be done by *socio-economic sector* (water use) or sub-sector.
Integration	Already said before, but worth repeating…. Integration between economists and other experts from the start, i.e. from the characterisation of the river basin, is key to the usefulness and effectiveness of the economic analysis in supporting decisions.
Uncertainty	Uncertainty on costs, effectiveness and time-lagged effects of measures needs to be dealt with throughout the economic analysis process, and more generally throughout the process of identifying measures and developing the river basin management plan. Sources for uncertainty are highly diverse according to situations and river basins, but will exist with regards to the assessment of pressures, impacts, baseline, costs or effectiveness. It is important that key areas of uncertainty and key assumptions made for the analysis are clearly spelt out and reported along the results of the analysis. Thus, comparison between analyses undertaken in different river basins and regular updates of the analysis will always be possible.
Sensitivity analysis	Sensitivity analysis is required for assessing the robustness of the results of the analysis (i.e. whether results are modified or not) if some parameters vary within certain acceptable limits. Sensitivity is seen as key to the development of the baseline scenario and the cost-effectiveness analysis.
Information	The collection of economic-related information should be well thought through and targeted. Apart for the specific reporting and analytical requirements of the Water Framework Directive, it is important to ensure data collection is targeted to where it is useful for supporting the decision making process, be it for the decision itself or for informing and consulting the public on this decision.
An iterative process	Although the right information may not be available today, it is important to start the analysis and develop it in iterations. Thus, as important as the results of the analysis for the different steps is the assessment of the most significant information gaps and the development of activities aimed at filling these gaps.

Illustrations - Selecting the "right" scale for the analysis?

The scoping and testing projects undertaken to support the development of this Guidance Document illustrate the importance of selecting the 'right' scale for the economic analysis:

- The economic significance of water uses can be assessed at scales that account for the hydrological functioning of the river basin, socio-economic characteristics of economic sectors, land planning and land use. Identifying homogenous units for these criteria was performed in the **Rhône-Méditterranée-Corse** case study (see *Annexes D1* and *E*). These units are often recognised by stakeholders and the public, and thus particularly important for consultation and participation. The combination of economic and biophysical information for identifying management units to which the economic analysis should concentrate was also stressed in the analysis of groundwater issues in the **Scheldt** case study (see *Annexes D1* and *E*);
- The forecast of water demand in **England and Wales**[1], undertaken by the Environment Agency, showed the importance of adopting a disaggregated approach to demand forecasting, in order to identify the key drivers of demand and in particular, the key sectors having an impact on demand. Such disaggregation is required to introduce sufficient confidence into the supply-demand balance assessments that are key to establishing a baseline water use estimation;
- The **Cidacos** case study (see *Annexes D1* and *E*) showed the importance of undertaking the cost-effectiveness analysis at the river basin scale, accounting for the hydrological functioning of the river basin. As an illustration, undertaking cost-effectiveness analyses independently for three different river reaches led to total costs estimates for the selected programme of measures that were significantly higher than the estimated costs obtained for a cost-effectiveness analysis undertaken for the three river reaches in combination;
- Activities undertaken in the **Ribble**, **Cidacos** and **Daugava**[2] (see *Annexes D1* and *E*) case studies investigated measures of relevance to different spatial scales and decision-making levels. They stressed the need for consistent approaches and feedback between scales and levels.

[2] Ilona Kirhensteine. 2002 (forthcoming). Developing river basin management plans in the Daugava river basin (Latvia). Proceedings of the Lille III Conference. (see also Annexes IV.I and V.II).

Section 4 – 2004: The First Milestone for the Economic Analysis

This Section brings together the economic analyses Member States should undertake by 2004 to be on track for complying with the requirements of the Water Framework Directive.

The Water Framework Directive specifies a series of reporting dates (see *Section 1 - Introduction*) for key tasks and activities aimed at the development of river basin management plans. And 2004 is the first major deadline directly following the designation of the river basin districts and competent authorities (required for 2003). The overall objective of the 2004 deadline is a description or characterisation of the river basins as referred to primarily in Article 5 of the Directive and relevant Annexes.

Thus, 2004 is also the first milestone for the economic analysis and for economists involved in the development of river basin management plans. The present Section provides a synthesis of the economic analysis required for 2004:

- To comply with the main reporting obligations of the Directive for 2004, and identify reporting requirements to the European Commission; and
- To ensure adequate economic input into the initial steps of preparing the cost-effectiveness analysis of measures and thus support the development of river basin management plans.

This Section does not repeat the elements of the process required for developing the economic analysis as described in the previous and following Sections (see ***Section 3*** and ***Section 5***). The focus is on the main economic elements to be investigated, i.e.:

- Undertaking **the economic analyses of water uses** (*Article 5*);
- Investigating the dynamics in the river basin **– development of the baseline scenario** (*Article 5, Annex III*);
- Assessing current levels of **cost-recovery of water services** (*Annex III, Article 9*);
- Preparing for the **cost-effectiveness analysis** (*Annex III*); and
- Proposing activities for **enhancing the information and knowledge base** (*Annex III*).

It is important to ensure that the economic analyses described below are integrated with other technical analyses such as the analysis of pressures and impacts. This will ensure a common description and characterisation of the river basin is obtained, basis for the identification of the programme of measures and the development of the river basin management plan.

For many elements of the analysis proposed below (e.g. extent of recovery of environmental costs), information will not be directly available for undertaking a robust analysis by 2004. However, undertaking the analysis with existing data and information will allow Member States to identify practical steps to be followed after 2004 for improving the information and knowledge base. This will ensure that the analysis developed in following the steps effectively supports decision-making and complies in time with the requirements of the Water Framework Directive.

In addition to these economic analyses, economic input may be required in analyses and activities which timing is less well defined in the Directive. For example, the designation of heavily modified water bodies will require early economic input. This has not been specified here and will be dealt with in the respective Guidance on the identification and designation of heavily modified water bodies (see *Annex D2b*) and in the overall Guidance on best practices in river basin planning.

UNDERTAKING THE ECONOMIC ANALYSES OF WATER USES

The primary objective of the economic analysis of water uses is (i) to assess **how important water is for the economy and socio-economic development of the river basin**, and (ii) to **pave the way for the assessment of significant water uses and analysis of disproportionate costs.**

(i) The **economic analysis of water uses** is used to construct the general economic profile of the river basin and of its key water uses and significant pressures in terms of:

- Economic analysis of water uses, e.g. collating information for significant water uses on gross income, turnover, number of beneficiaries, agricultural and industrial area or employment, etc as considered relevant;
- Stressing the importance of water for economic and regional development and the evidence of this importance provided in existing economic strategies and plans; and
- Areas designated for the protection of *economically significant aquatic species*, as input into the register of protected areas required under *Article 7* and *Annex IV* of the Directive.

These general economic indicators will be computed at the **scale of the river basin or river basin district**. For economically significant aquatic species, further desegregation according to location within the river basin may be provided consistently with the maps prepared for *Article 7*. This analysis is mainly based on easily available statistics and information. Specific approaches may be used to transform existing information (often available for administrative regions or water service areas) to the scale of the river basin or river basin district.

(ii) In parallel, the economic analysis of water uses needs **to pave the way for the assessment of the significant water uses** to be reported to the public by 2007 and related understanding of the likely tradeoffs and conflicts between socio-economic development, environment and water protection that can be fed into the public information and participation process regarding the development of river basin management plans.

The indicators computed are similar to the ones listed above, complemented with variables and indicators that are specific to the significant water uses identified for the river basin considered, e.g. cropping pattern for specific irrigated schemes that impose high pressures on water resources, turnover and main products of industrial sub-sectors that are highly polluting rivers, etc. However, the computation scale or desegregation level is the **area linked to a given significant pressure or to specific economic sectors/sub-sectors.**

Overall, the analysis should remain proportionate and not entail extensive collection of new data, i.e. dealing primarily with clear conflicts/water management issues based on information of relevance to significant water uses. The spatial scale or region at which the analysis should be undertaken will be defined by both the analysis of pressures and impacts developed for the characterisation of the river basin, and the outcome of the participation process and stakeholders input/request for specific further desegregation.

INVESTIGATING THE DYNAMICS IN THE RIVER BASIN DEVELOPMENT OF THE BASELINE SCENARIO

Feeding into the **identification of significant water management issues** for 2007, the analysis needs to complement the characterisation of the river basin today by an assessment of its future likely trends and baseline scenarios. This assessment is the basis for analysing the gap between likely water status and good water status (**risk of non-compliance**) and for undertaking the subsequent **cost-effectiveness analysis of measures**.

Being a joint activity between different expertise and disciplines (see *Section 3*), the specific role of the economic analysis in the development of baseline scenarios and the analysis of the dynamics of the river basin is the assessment of forecasts in **key (non-water related) policy and economic drivers** likely to influence pressures and thus water status.

Focus is likely to be on foreseen trends in (non-exhaustive list):

- General socio-economic indicators and variables (e.g. population growth);
- Key sector policies that influence the significant water uses identified in the river basin investigated (e.g. agricultural policy);
- Production or turnover of main economic sectors/significant water uses in the river basin;
- Land planning and its effects on the spatial allocation of pressures and economic sectors;
- Implementation of existing water sector regulation and directives; or
- Implementation of environmental policies likely to affect water (e.g. *NATURA* 2000).

Some of these forecasts will be developed jointly with technical experts (see for example the implementation of water sector directives and other environmental legislation). Complemented by analysis of changes in the hydrological cycle, e.g. for accounting for climate change, it will feed into an overall assessment of changes in key pressures, including water demand, and resulting impact on water status as key input into the identification of significant water management issues for 2007.

It is important to stress that **some analyses can be organised at the national or European scale** as all river basins of a given country or of Europe will face similar changes (this is for example the case for changes in EU policies such as the Common Agricultural Policy). Other analyses such as changes in production and turnover of significant water uses and economic sectors will need to be developed **at the scale of the river basin or for parts of the river basin** according to the scale at which related pressures take place.

ASSESSING CURRENT LEVELS OF COST-RECOVERY OF WATER SERVICES

The assessment of the current levels of cost-recovery of water services is the **basis for the implementation of Article 9 of the Water Framework Directive and for ensuring transparency** on costs, prices, subsidies, cross-subsidies, etc. As such, this analysis is less directly linked to the identification of the programme of measures and the development of integrated river basin plans. But it will be called for when assessing the financial implications of the chosen programme. Key elements to be investigated may include:

- Status of key water services (e.g. number of persons connected/using the service);

- Costs of water services (financial costs, environmental and resource costs);
- Institutional set-up for cost-recovery (prices and tariff structure, subsidies, cross-subsidy);
- Resulting extent of cost-recovery levels (for financial costs, for environmental and resource costs);
- Extent of contribution of key water uses to the costs of water services (link with pollution and use information collected for the analysis of pressures and impacts); and
- Complementary information whenever relevant (e.g. affordability for key water users).

The basic **scale of analysis is linked to the water service area** or combined water service area when services are combined. However, this will be very dependent on the structure of the water service sector and related information base.

PREPARING FOR THE COST-EFFECTIVENESS ANALYSIS

Although referred to in Annex III of the Directive in the context of the 2004 deadline, it will not be possible to perform the cost-effectiveness analysis in 2004 as environmental objectives and potential measures will not be identified yet. **To ensure the cost-effectiveness analysis can be performed** at a later stage, and **because of the limited cost-information available today in a coherent format** in most countries/river basins, it is proposed to develop a cost-database for a wide range of measures likely to be investigated:

- This database should not focus solely on cost information of infrastructure (the easiest to collect). Measures such as wetland restoration, demand management measures, new pricing, voluntary agreements, etc should be included. A key first step will be to provide an initial specification of the sort of measures that might be included in river basin management plans;
- A range of costs should be collated (minimum, average, maximum) as opposed to single average values. Key parameters influencing costs should be identified to facilitate extrapolation of figures to specific sites/conditions;
- Costs to be collected should include all costs that are non site-specific, e.g. limited to financial costs of the measures or specific environmental costs (e.g. air-related), and also indirect economic costs whenever considered relevant; and
- Wider economic benefits that are non-site specific may also be added to the database whenever considered relevant. This information would facilitate follow-up disproportionate cost analysis and support to derogation.

The information should be **collected for individual measures or units of measures**, thus at a spatial or desegregation scale depending on the scale at which the measure is applied or implemented. Such efforts may be best co-ordinated at the national or European scale, especially for measures linked to policies and programmes that have a more regional or national focus.

PROPOSING ACTIVITIES FOR ENHANCING THE INFORMATION AND KNOWLEDGE BASE

Along with results of the different components of the economic analysis, it will be important to **systematically report** on:

- **Information, assumptions and approaches** used for computing key indicators. It is important that this is made transparent (i) to ensure easy updating/upgrading of results as new information is made available and (ii) to facilitate comparisons between results obtained in different river basins or sub-basins (especially in transboundary river basins).

Practical steps and measures will be identified and proposed for **filling key information and knowledge gaps:**

- Identified during the first analysis aimed at **characterising the river basin in economic terms** - for ensuring key indicators (e.g. cost-recovery levels) can be **further improved and refined**; and

- **Likely to arise when developing integrated river basin management plans –** for ensuring the **cost-effectiveness analysis can be performed at a later stage**. This indeed requires **undertaking the *feasibility study*** (see *Section 5*) for the entire economic analysis process (which information to be collected, at which scale, which data collection or computation method, which periodicity, etc).

Although it is too early to specify the main focus of such activities, as they will be based on both general and local assessments of information and knowledge needs, likely candidates that will require further work combining economic and technical expertise include:

- The assessment of water-related environmental costs (benefits) and the development/strengthening of environmental costs databases;

- Methods for assessing the direct economic impact of range of measures for key economic sectors (e.g. industrial sub-sectors, agricultural sub-sectors);

- Methods for assessing the effectiveness of measures or combination of measures.

The costs of activities proposed for enhancing the information and knowledge base will be assessed and reported. Feedback to research programmes may also be developed to ensure research needs are tackled in a timely manner.

DOING AND REPORTING THE ECONOMIC ANALYSIS FOR 2004 – A SUMMARY

Table 3 summarises the different economic analyses and activities to be performed by 2004. It stresses reporting obligation to the European Commission defined in the Water Framework Directive. Clearly, these reporting obligations will need to be complemented by, integrated with, existing regional or national reporting obligations. Further reporting requirements may also arise from the participatory process developed by Member States for developing river basin management plans.

Table 3 - Summary of the different economic analyses and activities to be performed by 2004

Title	Addressing	Likely elements of the analysis	Reporting to the European Commission in the management plan of the river basin district	Feeding into
Undertaking the economic analysis of water uses	**What is the economic importance of key water uses in the river basin?**	• The economic importance of the main water uses is analysed for the river basin district. Relevant economic indicators are computed; • Further analysis is performed for lower disaggregation levels according to scale of significant pressures (jointly with pressures and impacts analysis); • Areas designated for the protection of *economically significant aquatic species* are investigated.	• Economic analysis of water uses at the river basin district scale.	**Characterisation of the river basin.** **Overview of significant water management issues.** **Register of protected areas.**
Investigating the dynamics of the river basin – developing the baseline scenario	**How will key policy and economic drivers evolve up to 2015?**	• Forecast in key economic drivers are investigated (different scale of analysis for different drivers); • The impact of these forecasts on key pressures is estimated (at the scale of significant water management issues, at the scale of the district).	• Trends in key economic and policy drivers at the river basin district scale.	**Overview of significant water management issues/ water status gap/risk of non-compliance.**

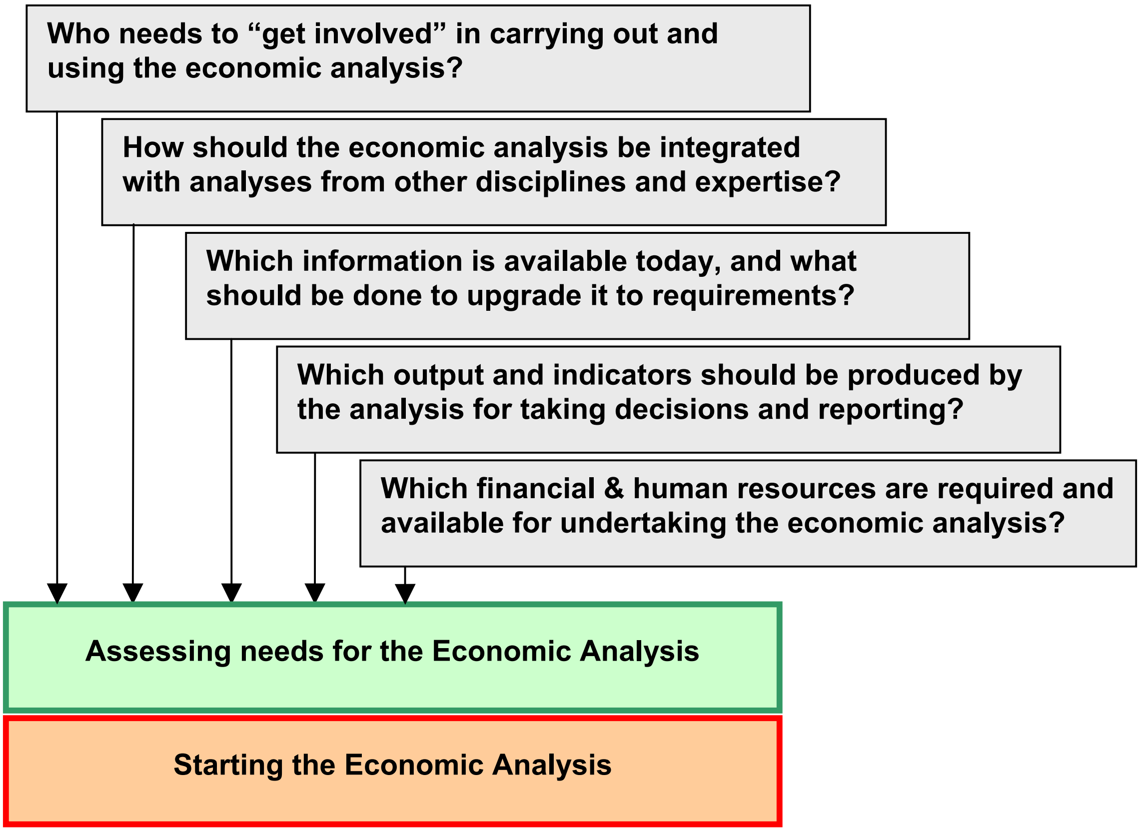
Title	Addressing	Likely elements of the analysis	Reporting to the European Commission in the management plan of the river basin district	Feeding into
Assessing current levels of cost-recovery **Assessing current levels of cost-recovery (continued)**	**What are current levels of recovery of costs of water services?** **Which contribution to the costs of water services from key water uses?**	• Collection of information on costs, prices, subsidies (water services, combined services, regional areas, etc) as seen appropriate; • Analysis of information and assessment of the extent of (financial, environmental and resource) cost recovery; • Description of the institutional mechanisms in place for cost recovery; • Analysis of the extent key water uses contribute to the recovery of costs of water services (linking with information on pressures and impacts).	• Financial cost-recovery; • Environmental and resource cost recovery; • Institutional mechanism for cost-recovery; • Contribution from key water uses (agriculture, households, industry) to the recovery of the costs of water services.	**Implementation of Article 9** **Financial implications of the selected programme of measures**
Preparing for the cost-effectiveness analysis	**What are costs of potential measures that will feed into the cost-effectiveness analysis?**	• Existing cost information is collected for a range of measures. A database easily accessible is developed.		**Selection of the programme of measures, cost-effectiveness analysis.**
Proposing activities for enhancing the information and knowledge base	**What are current information and knowledge gaps that need to be filled for taking decision?**	• Key assumptions and information sources, computation methods and uncertainty are made transparent for all elements of the analysis; • Identification of key information and knowledge missing for developing the economic analysis for the programme of measures and development of the integrated river basin plan; • Proposed data collection activities for filling gaps; • Assessment of the costs of data collection.	• Key assumptions and information sources, computation methods and uncertainty are made transparent for all elements of the analysis; • Identification of key information missing for developing economic analysis for integrated river basin plans; • Proposed data collection activities and related costs.	**Refining the economic analysis of water uses, ensuring the cost-effectiveness analysis can be performed and aid decision making.**

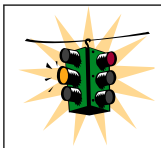
Section 5 – Making the economic analysis operational and ensuring Coherency with the Overall Implementation Process

This Section brings attention to key issues related to developing the economic analysis and the need to ensure coherency and integration with the process of preparing River Basin Management Plans.

Before starting the economic analysis itself (see *Section 3*), it is important to ensure that you have defined the right process for undertaking this analysis. You will need to carefully review a series of issues so that you can deliver what is expected from the economic analysis so it aids decision-making. Some of these issues are rather straightforward; others will need further elaboration and discussions with experts, water managers or stakeholders. Overall, most of what is described in this Section will need to be co-ordinated with other experts and disciplines involved in the development of river basin management plans.

ISSUES TO FOCUS ON INCLUDE…





Look out! Before starting the economic analysis, make sure:

- That you know who is going to use the information you produce, for which purpose, and what are the expectations *vis-à-vis* the economic analysis;
- That you have enough financial and human resources for undertaking the required economic analysis and meet expectations.

WHO NEEDS TO GET INVOLVED IN CARRYING OUT AND USING THE ECONOMIC ANALYSIS?

Assessing "who needs to get involved" requires addressing some of the following questions:

- Who will be responsible for the economic analysis?
- Who will undertake the economic analysis?
- Who will provide input into the economic analysis?
- Who will control the quality of the economic analysis?
- Who will use the results of the economic analysis?
- Who will pay for the economic analysis?

Answers to these "*Who*" questions are likely to include a wide range of organisations, stakeholders and individuals according to questions. For example, experts from the Ministry of Environment or other ministries (land planning, economic affairs, agriculture, etc), experts from river basin agencies or regional authorities, managers in charge of developing river basin management plans, ministry heads of water departments, researchers and consultants, economists and non-economists, the public and a wide range of stakeholders that have developed expertise in specific fields (see *Table 4*) and are involved in water management.

Developing a *stakeholder analysis* with possible involvement of key stakeholders can be an appropriate step for finding answers to these questions (see *Annex C2*). It also helps in identifying key steps in the analytical process when involvement or input from specific stakeholders is required (different "*Who*" for different steps).

Information, consultation and participation is a requirement of the Directive – it will also make implementation more effective

Article 14 promotes the *active participation of all interested parties* in the development of River Basin Management Plans, and requires Member States to *inform and consult the public*. Stakeholder participation is important as it can fulfil many functions:

- Developing a process agreed by all will increase the legitimacy of its outcome;
- Stakeholders can be a useful source of information and have expertise of direct use for the economic analysis (see *Table 4*);
- Surveys of the public can be useful to understand how people value improvements in the environment and quality of our waters, and how far they are ready to pay for environmental improvements;
- Public involvement and the network of partners developed through participation can be useful to develop a sense of ownership over the River Basin Management Plans and may increase the effectiveness of measures taken to meet the Directive's objectives.

The Directive only specifies key dates for consultation, but rightly does not specify dates for the participation process, as this will depend on local institutions and socio-economic set-up. However, it will be important to start the participation process early (eg. as part of the characterisation of the river basin before 2004) to improve its effectiveness.

Table 4 – Key Stakeholders can be a Very Important Source of Information and Expertise

Key Stakeholders	Where they can help with information and expertise
Water Service Suppliers	➢ Characterising water services; ➢ Assessing costs & recovery of financial costs; ➢ Developing trends in water service investments.
Experts from Ministries (agriculture, transport, planning, finance…) -	➢ Characterising water uses and their economic importance; ➢ Assessing changes in key national and regional policies and drivers for the trend analysis; ➢ Defining coherent methodologies for assessing key variables at Member State level.
Environmental NGOs	➢ Identifying key environmental issues; ➢ Assessing environmental impacts and costs; ➢ Developing methodologies for estimating environmental costs and benefits.
Economic sectors (farmers, industrialists, etc)	➢ Assessing trends in economic sectors; ➢ Identifying possible measures and assess their costs; ➢ Providing input into the assessment of disproportionate costs.
Researchers/Experts	➢ Assessing key policies/drivers for the trend analysis; ➢ Assessing impact of such policies on pressures; ➢ Assessing impact of climate change; ➢ Assessing the impact of pressures on water status (e.g. via modelling); ➢ Assessing effectiveness of measures; ➢ Assessing environmental and resource costs.
Stakeholders/civil society/public	➢ Assessing changes in key policies/drivers for the trend analysis; ➢ Assessing (local, regional, national) priorities *vis-à-vis* water quality improvements; ➢ Providing input into the assessment of disproportionate costs and analysis aimed at explaining derogation; ➢ Providing input into the assessments of socio-economic impacts and costs.

Illustrations - Building on the knowledge from stakeholders and the public for undertaking the economic analysis

There are different approaches for integrating stakeholders' and public concerns and knowledge into the economic analysis.

- Questionnaire surveys and stakeholder focus groups have been used for investigating the economic values placed on a wetland surrounding Kalloni Bay on the Island of **Lesvbos**[3] in Greece (see *Annex E*);
- Public forums followed by individual interviews (around 1,500) have been organised by the French Water Agency **Artois-Picardie**[4] in 1999/2000. The main objectives were the identification of key water management issues in the river basin (as part of the assessment of a baseline scenario), the identification of the main potential costs linked to future water policy and the ranking of possible future policy options;
- A stakeholder analysis was performed in two research projects in **France**[5,6] as the preliminary step of the economic analysis in a watershed to map actors, the main interest at stake and existing conflicts over water use. The knowledge and information obtained from stakeholders proved useful in identifying specific water management issues and potential measures of direct relevance for a follow-up cost-effectiveness analysis but that had not been envisaged by experts;
- From the scoping activity in the **Ribble** case study (see *Annex E*), key issues of relevance for implementing the consultation and participation were identified. Overall, it is essential to: (i) focus on why, when, where and how stakeholders should be consulted and involved; (ii) to relate the consultation process to the specific decision-making contexts and processes in the WFD (be it national, regional or local); (iii) To take account of the boundaries these different decision making levels place on the consultation; (iv) to take account of resource constraints, both for the authorities and stakeholders, to carrying our the consultation process; and
- Input from stakeholders was collected in the **Cidacos** (see *Annex E*) case study for discussing whether costs estimated as a result of the cost-effectiveness analysis could be considered as disproportionate. Along similar lines, a panel of experts was used in the **Scheldt** (see *Annexes D1* and *E*) case study to assess whether the costs of measures for reaching the ecological objectives in the Scheldt estuary were disproportionate or not.

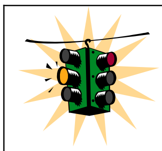
HOW SHOULD THE ECONOMIC ANALYSIS BE INTEGRATED WITH ANALYSES FROM OTHER DISCIPLINES AND EXPERTISE?

Up until recently, economic analyses, if at all developed, are often undertaken in isolation from other analyses and expertise. By contrast, the Water Framework Directive requires that economics be integrated with other disciplines and expertise for developing River Basin Management Plans. This means the economic analysis will build on key inputs from other disciplines and expertise, as shown in the Table 5 below.

Table 5 - Integration of economics with other disciplines and expertise for developing River Basin Management Plans

Key Inputs from the Economic Analysis	Steps	Key inputs from other Disciplines
➢ Economic analysis of water uses; ➢ Assess trends and baseline scenario; ➢ Assess cost-recovery levels.	*Step 1* Characterising River Basins	➢ Assess key pressures and impacts (*Annex II*); ➢ Analyse point source and diffuse pollutions; ➢ Investigate future trends in key pressures.
➢ If no gap, estimate total costs of basic measures of baseline.	*Step 2* Identifying Significant Water Management Issues	➢ Assess the impact of trends in pressures on water status; ➢ Assess environmental objectives and physico-chemical, hydromorphological and biological indicators; ➢ Assess gap in water status; ➢ Identifying key pressures causing this gap.
➢ Identify potential measures and assess their costs; ➢ Cost-effectiveness analysis; ➢ Economic input into the justification of derogation; ➢ Assess cost-recovery levels; ➢ Economic/financial impact of proposed programme of measures.	*Step 3* Identifying Measures and Economic Impact	➢ Identify potential measures and assess their technical feasibility; ➢ Assess the effectiveness of individual measures/combined measures; ➢ Assess the remaining environmental impact.



Look out! Designating heavily modified water bodies and justifying derogation

The designation of heavily modified water bodies or the justifications of derogation from the Directive's objectives are areas where the interaction between technical/biophysical and economic expertise are key to the analysis. For example, the designation of heavily modified water bodies requires (see *Annex D2b*):

- An assessment of the impact on existing uses of returning to natural conditions; and
- The comparison between the existing modification and alternatives for providing the same beneficial objectives in terms of their technical feasibility, their environmental impact and their economic impact (investigating the costs of different alternatives versus the existing modification).

What does "integrating economics with other disciplines" mean in practice?

- **Understanding each other!!**

- **Agreeing on common definitions;**

- **Agreeing on a common representation (i.e. characterisation) of the river basin investigated**, i.e. the spatial structure of the river basin, the key spatial units (either based on hydrological or economic variables) and the level at which biophysical and economic indicators will be computed and can be compared;

- **Developing a common baseline scenario for the river basin**, i.e. how will the river basin and its key pressures evolve up to 2015 taking account of policies and measures already planned. The development of the baseline will require economic expertise (e.g. analysis of changes in macro-economic/sectoral policies, trends in investments, trends in water demand) and technical/biophysical expertise (e.g. changes in key pressures and land-use, impact on water status of changes in pressures and planned investment). See for example the **Oise** case study (see *Annexes D1* and *E*) that deals with the development of baseline scenario;

- **Undertaking the appraisal of measures jointly,** e.g. the cost-effectiveness analysis as illustrated by the **Scheldt**, the **Cidacos**, the **Ribble** (see *Annexes D1* and *E*) or the **Daugava**[7] (see *Annex D1*) case studies, or the disproportionate cost analysis and the assessment of possible objective derogation as illustrated by the **Scheldt** or the **Alsace** (see *Annexes D1*and *E*) case studies;

- **Developing common information and databases** that are geo-referenced (use of Geographic Information Systems) – This is rather new for most economists that rarely integrate spatial dimensions into their analysis and databases. See for example the **Corfu** case study (see *Annex E*) that has integrated biophysical and economic data into a common Geographic Information System (GIS).

[7] Ilona Kirhensteine. 2002 (forthcoming). *Developing river basin management plans in the Daugava river basin (Latvia)*. Proceedings of the Lille III Conference.

The economics Guidance Document should be linked with other Guidance Documents produced by working groups of the Common Implementation Strategy

Several working groups created in the context of the Common Implementation Strategy are developing or have developed Guidance Documents for supporting experts in European Union Member States and candidate countries in their implementation tasks. It is important that these Guidances are used in a coherent and co-ordinated manner. Of particular relevance to the economic analysis and its integration with other disciplines and expertise are:

- The Guidance on ***Best practices in river basin planning*** (WFD Technical Report No. 2) that provides the overall framework for developing integrated river basin management plans;
- The Guidance on ***Information, consultation and participation of the public and stakeholders*** (WFD CIS Guidance Document No. 8) that provides methodological and illustrative elements of direct use for involving stakeholders and ensuring the economic analysis produces pertinent results for information and consultation of the public;
- The Guidance of the ***Analysis of pressures and impacts*** (WFD CIS Guidance Document No. 3) that needs to link with the present Guidance Document for producing by 2004 a joint and coherent characterisation of the river basin as required by Article 5 of the Water Framework Directive; and
- The Guidance on the ***Identification and designation of Heavily Modified Water Bodies*** (WFD CIS Guidance Document No. 4) where technical, biophysical and economic expertise and analyses are combined for designating heavily modified water bodies.

See *Annex A* for a list of Working Groups and Guidance Documents.

WHICH INFORMATION IS AVAILABLE TODAY, AND WHAT SHOULD BE DONE TO UPGRADE IT TO REQUIREMENTS?

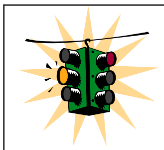
The availability of economic information is key to the usefulness of the economic analysis in the characterisation of river basins and the development of River Basin Management Plans.

Checklist for assessing existing information, its quality and existing gaps

- Which information is available?
- Who has collected the information?
- Who has the information? (organisation, person)
- Is it accessible? To everybody, to selected experts/government departments?
- At which costs?
- At which spatial scale is the information available?
- For which year(s) or period?
- What is the quality of the information?
- What are the levels of confidence attached to the available information?

Although the Water Framework Directive provides clear deadlines for reporting, the economic analysis remains an iterative process with constant improvements in the information base, methodology and expertise. If the "right" information (i.e. the required variable at the required spatial and temporal scales with an "acceptable" uncertainty) is not available today for supporting decisions, proxies or benchmark values should be used to provide first rough answers. However, as important as undertaking the analysis itself are:

- To be transparent and clearly report on the quality and uncertainty of the information used and on the assumptions made for doing the analysis; and
- To identify key data gaps and plan activities for collecting missing information and improving the analysis. For example, the economic analysis of water uses delivered for 2004 will likely need to be updated and upgraded at a later stage for supporting a robust cost-effectiveness analysis for defining the programme of measure.



Look out! Information for the economic analysis may be difficult to access due to confidentiality requirements

The area of water services is becoming increasingly competitive with large water service providers competing across borders. Information about water demand and investments might be considered commercially sensitive and will therefore risk not being provided, even though they represent key input for the economic analysis.

- ***Early in the process, it is important to identify who is holding exclusive commercial information and whether confidentiality issues are at stake. The identification of aggregation levels/scales where confidentiality is not an issue anymore but where information is still relevant for water management will be key to discussions with relevant stakeholders. Also, the signing of non-disclosure agreements may help lifting confidentiality constraints.***

However, accessing publicly owned information may also be a difficult task requiring specific agreements with organisations or individuals.

Illustrations - Which information for the economic analysis? From existing constraints to filling the gaps

Case studies undertaken in the different countries for supporting the development of the present Guidance have shown that the availability of economic-information is likely to represent a short-term constraint for undertaking the economic analysis. This is particularly true for environmental and resource costs information (e.g. not available at all in the **Corfu** (see *Annex E*) and **Vouga** (see *Annex E*) case studies), but it is also valid for more general cost information that remains incomplete, piecemeal and unevenly spread in space and time.

Of importance, however, is to carefully review existing information sources prior to launching any new data collection (as this may prove costly). The **Middle-Rhein** case study (see *Annex E*), for example, illustrated that information required for assessing cost-recovery is available with existing statistics in the pilot area considered. Similarly, effectiveness information for measures aimed at reducing water demand for households and industry was collected for the **Scheldt** case study (see *Annex E*) from relevant water supplier, industry and environmental NGOs.

In many cases, different elements of economic information are not available at spatial scales of relevance to water management. Most economic information linked to water services in the **Vouga** case study (see *Annex E*) is available for different administrative units (municipal, regional). Thus, consistent criteria must be developed to partition municipal and regional values into river basin/sub-basins values. Moreover, as stressed for example by the **Daugava** case study[8], it may be difficult and time-consuming to collect the information available for countries with a wide range of private and public organisations.

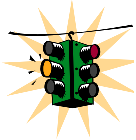
The **Corfu** case study (see *Annex E*) illustrated how a Geographic Information System could be developed to combine biophysical, climatic, land use and economic information. In addition to their presentation and analytical capabilities, such systems may help allocating values obtained for administrative units into information of relevance for water/river basin units.

WHICH FINANCIAL AND HUMAN RESOURCES ARE REQUIRED AND AVAILABLE FOR UNDERTAKING THE ECONOMIC ANALYSIS?

Collecting information, analysing it, involving stakeholders, integrating experts and disciplines, producing reports and providing input into information and consultation activities is likely to require money and people, both resources being scarce in many water administrations of both European Union Member States and candidate countries.

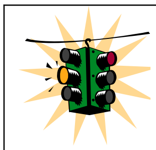
Ensuring that available resources match required ones is key to avoid false expectations and disappointments. If resources are not there, it is important to clearly assess and agree on priorities with other experts, stakeholders and organisations involved in/responsible for the development of river basin management plans and the implementation of the Water Framework Directive.

[8] – Ilona Kirhensteine. 2002 (forthcoming). *Developing river basin management plans in the Daugava river basin (Latvia)*. Proceedings of the Lille III Conference.



Look out! Conducting the economic analysis can be costly

Do not underestimate the resources required for developing the right process for the economic analysis, i.e. assessing the demand for economic input into the decision-making process and information/consultation activities. However, financial resources for developing the economic analysis will remain minimal as compared to those required for implementing measures for achieving the environmental objectives of the Directive!



Look out! Capacity-building will be key to ensuring success

Applied and practical economic expertise is rare, both in European Union Member States and in candidate countries! Thus, capacity-building activities may be required very early in the Water Framework Directive implementation process for ensuring timely delivery of the economic analysis requirements of the Directive.

WHICH OUTPUT AND INDICATORS SHOULD BE PRODUCED BY THE ECONOMIC ANALYSIS FOR TAKING DECISIONS AND REPORTING?

The Water Framework Directive has specific reporting obligations with regards to the economic analysis (Table 6). Most of these obligations refer to computed indicators at the scale of the river basin or river basin district. The assessment of the demand from policy makers and the public (i.e. which information and output do you want from the economic analysis) is likely to yield complementary reporting requirements in terms of the type of indicators and the spatial and temporal scale at which these indicators need to be computed.

Table 6 - WFD reporting obligations with regards to economic analysis

Component of the economic analysis	Reporting requirements defined in the Water Framework Directive	Possible interest from water managers, policy makers, stakeholders and the public
Characterisation and trend analysis	• Economic importance of water uses (RB); • Trends in key drivers and pressures, e.g. water supply and water demand (RB); • When required: trends in investments (RB).	• Current economic importance and likely trends of key economic sectors and policy driver in the river basin (RB, SRB, SES, SWU).
Economic analysis for selecting measures	• Total costs of cost-effective set of measures (RB); • Benefits and costs of alternatives measures in case of derogation (WB, possibly SRB).	• Benefits (economic, social, environmental) of proposed measures (RB/SRB/ES/SES); • Budgetary requirements (RB); • Impact on specific economic and social groups (SES, specific users).
Assessing cost-recovery and pricing	• Cost-recovery for water services (RB); • Contribution of water uses (agriculture, industry, households) to cost-recovery (RB/ES); • Social, economic and environmental impact for justifying proposed cost-recovery (RB/ES).	• Cost-recovery for key sub-sectors (e.g. a specific polluting industrial sector or sub-agricultural sector) (SRB, SES); • Current and proposed role of pricing as incentive (SES, specific users).
Key assumptions and information use	• Quality and uncertainties of information used and assumptions made (RB); • Proposed data collection (and related costs) for filling key information gaps (RB, possibly national proposals).	

Scale issues for reporting — RB = river basin; SRB = sub-river basin or coherent group of water bodies; ES = economic sector; SES = sub-economic sector; WB = specific water body; SWU = significant water use

Assessing the feasibility of the economic analysis: a pre-requisite to the economic analysis for increasing chances of success?

The objectives of a ***feasibility study*** are to prepare the economic analysis through:

- Assessing whether the proposed economic approach can be made operational;
- Evaluating the consistency of the proposed approach with other activities and processes developed for supporting the development of river basin management plans;
- Identifying key steps that need to be followed for removing constraints and problems likely to be faced when undertaking the economic analysis.

Key issues investigated during the activity include (list non-exhaustive):

1. Information and knowledge

- What are the information and knowledge requirements for undertaking the economic analysis?
- Which output (e.g. indicators computed at specific spatial scales) is expected from the economic analysis and for which purpose (taking a decision, informing, reporting, etc)?
- Which information and knowledge is currently available and accessible?
- How is economic and technical information integrated?
- What are the current gaps in information and knowledge for undertaking the analysis?
- What are possible means (short-term, long-term) for reducing these gaps?

2. Resources required for undertaking the economic analysis

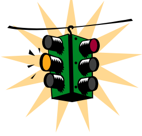
- Which human and financial resources are required for undertaking the economic analysis within the required timeframe?
- Which are the human and financial resources effectively available?
- What are the gaps in human and financial resources?
- What are possible means (short-term, long-term) for overcoming these gaps?

3. Information and consultation of the public, participation of stakeholders

- Which consultation and participation means are required for undertaking the economic analysis and disseminating its results?
- What are the existing information, consultation and participation means?
- What are the gaps in information, consultation and participation means?
- What are possible options (short-term, long-term) for overtaking existing constraints?

This assessment should be based on reviews of existing reports, documents and information/databases and on interviews with key experts, stakeholders and decisions makers. It can focus on a single representative river basin or have a more national focus. Workshops for sharing results of this assessment with a wider audience can prove useful in validating the results, identifying other solutions for removing constraints and announcing the forthcoming economic analysis.

Examples of Terms of Reference for a feasibility study are presented in Annex C.



Look out! The *feasibility study* should be a shared activity

Although proposed here in relation to the economic analysis, economists and non-economists should be undertaking this assessment jointly for the entire appraisal system aimed at developing integrated River Basin Management Plans.

Section 6 – Conclusion: What lies ahead?

As a way of conclusion, this Section looks at what remains to be done for implementing the Directive and by when, both by Member States in each River Basin and in a cooperative manner, at the European level.

A CRITICAL PATH ANALYSIS TO DETERMINE KEY LANDMARKS

2004 is the next key date for the implementation of the economic elements of the Directive. It may feel that it is a long time away, but it really is already tomorrow. When looking at what needs to be done by then and walking backwards, one might quickly realise that some of the steps should have really been initiated… the day before yesterday!

A big task lies ahead: start early!

To make sure they meet the Directive's deadlines, Member States and candidate countries may want to carry out a "critical path analysis", to identify what needs to be done by when and to logically link the economic analysis with other activities required for the River Basin Management Plans.

Figure 5 lays out a generic framework for such critical path analysis. The time needed for gathering information and consulting the public would of course depend on local circumstances, on the availability of information and on existing institutional structures. Therefore, each country would need to tailor this framework to its needs.

Figure 5 highlights a number of important points about the Directive's timing:

- To meet the 2004 requirements, significant economic analysis will have to take place. Some of this analysis feeds into each other: for example, the prospective analysis of pressures needs to be completed by 2004 to enable the determination of the *business as usual* (BAU) scenarios and identify water bodies where risk of non-compliance is likely to occur. This co-ordination with experts in charge of determining impacts and pressures will be crucial and planning ahead the scheduling of those tasks will allow avoiding any undue delays;

- Deadlines for the completion of the economics tasks required by the Directive are skewed towards the end the River Basin Management Plan (RBMP) period (2009). However, long lead times are required to complete these tasks and a number of important activities must be carried out well in advance to achieve those ultimate deadlines; and

- For some types of analysis (such as the *business as usual*, cost-effectiveness and disproportionate costs analyses), it might be preferable to first carry out a simple analysis, followed by a more in-depth analysis in the most contentious cases. This means that the simplest analyses might need to be carried out early on, which raises again timing issues.

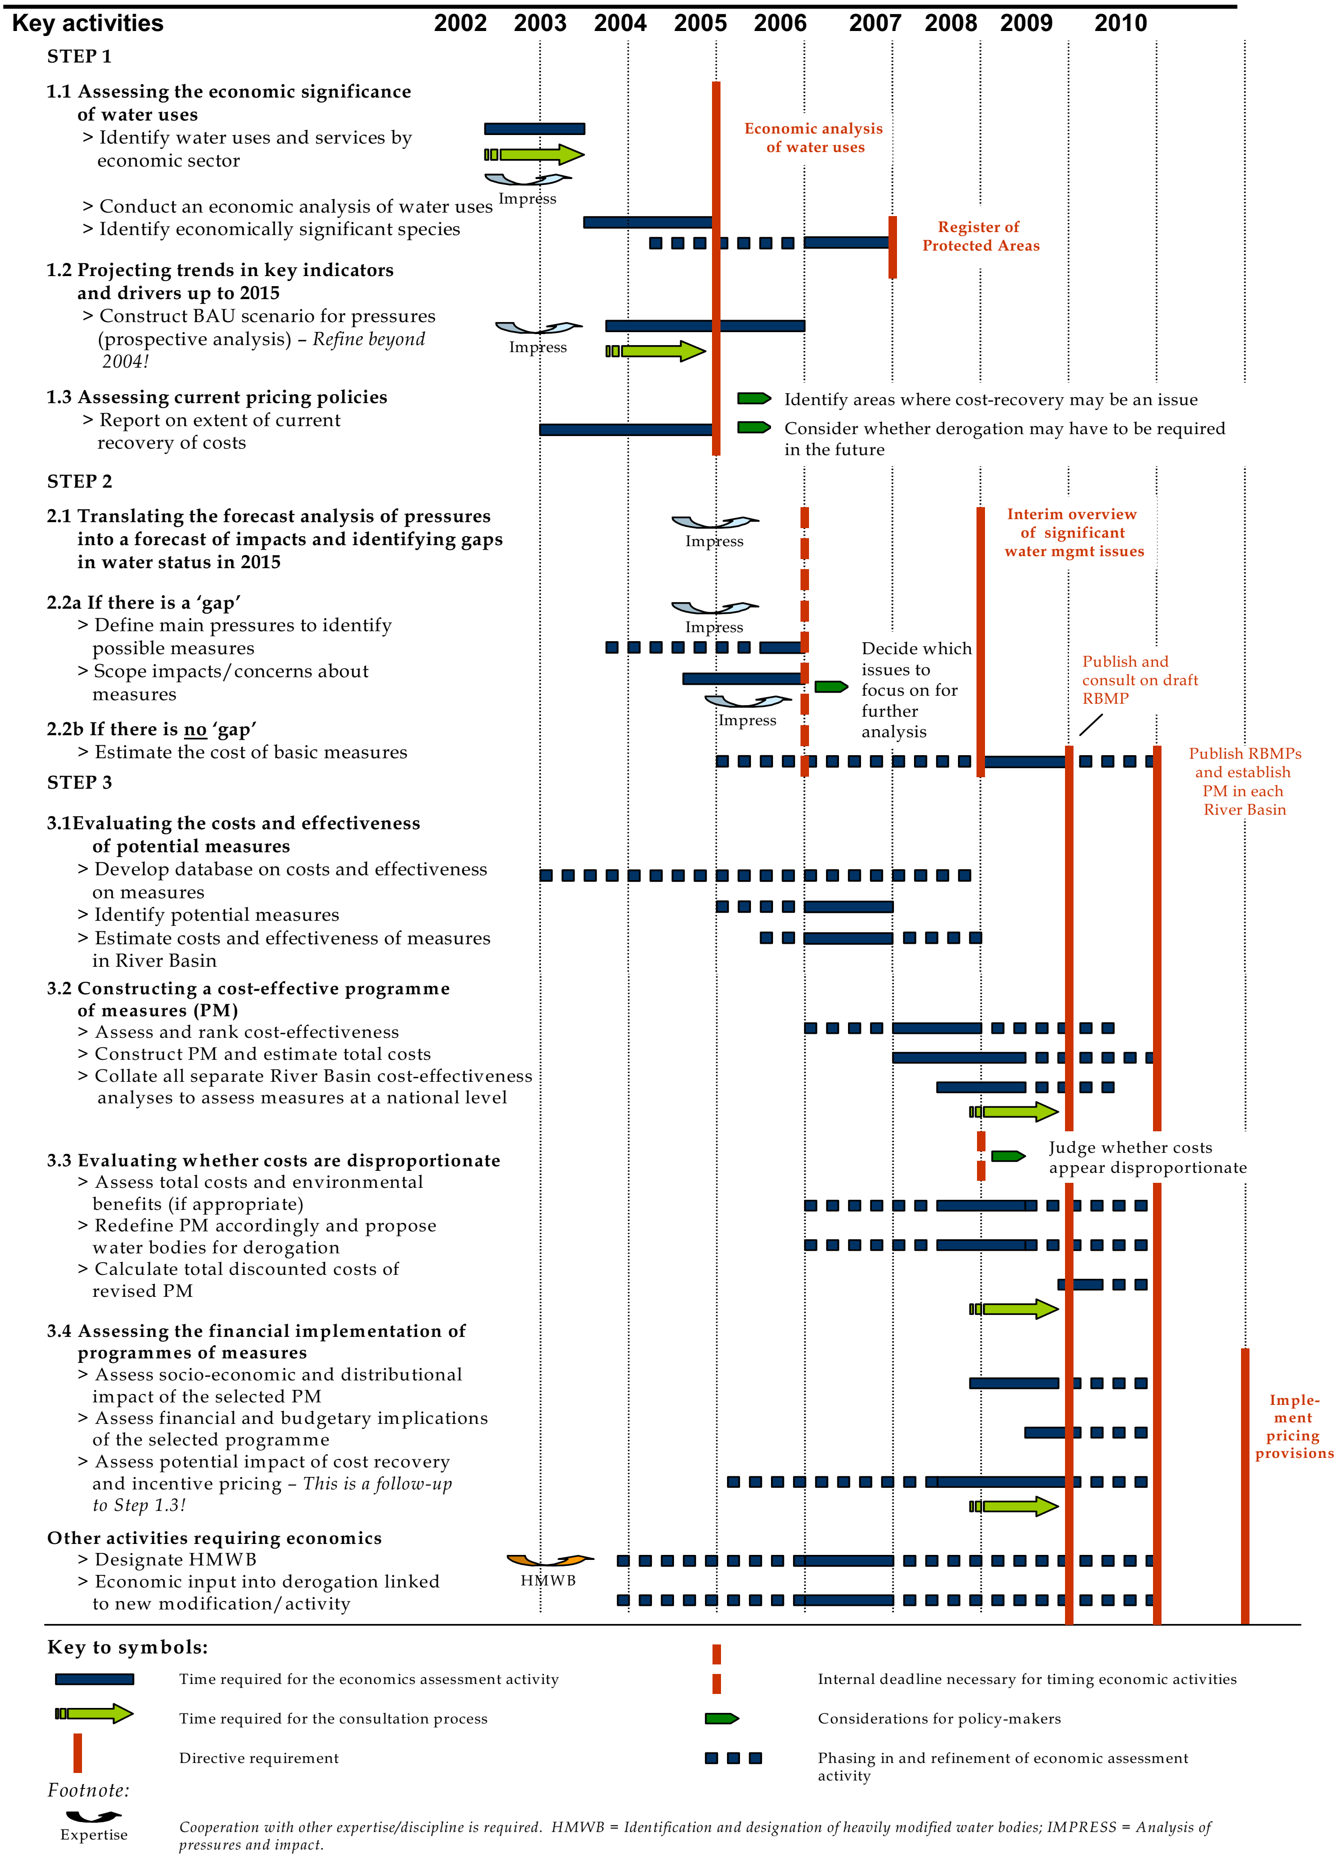


Figure 5 - Proposed Key Steps of the Critical Path

KEY ISSUES REMAIN TO BE EXPLORED…

The preparation of this Guidance Document has highlighted some outstanding issues that will need to be further examined in the years leading up to the river basin management plans. Although the application of the Guidance and the carrying out of the economic analysis by 2004 will help develop a practical knowledge base, some methodological issues are likely to require more time for in-depth research and analysis integrating technical and economic expertise. Selected issues can already be identified as requiring further methodological development, for example:

- How to assess **environmental and resource costs**: how can methods for assessing environmental costs (developed at an academic level) be made operational in the context of the development of river basin management plans?

- How to deal with **uncertainty:** which approaches can be proposed to water managers for integrating uncertainty into decision making, and for developing adequate communication on uncertainty towards the public and stakeholders?

- How to assess the **effectiveness** of measures or combination of measures: clearly, this issue departs from the scope of pure economics. But it will need to be solved to ensure cost-effectiveness analysis can be performed;

- How to assess the **direct and indirect economic impact** of a range of measures on key economic sectors? (e.g. industrial and agricultural economic sectors/sub-sectors).

…AND BEFORE YOU JUMP, REMEMBER: YOU ARE NOT ALONE!

Overall, using the present Guidance will help in developing practical experience, will increase the knowledge base and will develop capacity in the integration of economics into water management and policy. As much work lies ahead, the process that has been launched at the European level will not end with the production of this Guidance. Continuing this collaborative effort will be instrumental in moving forward and ensuring progress is made for an effective implementation of the Water Framework Directive.

Such collaborative efforts will include:

- Providing **support to the use of the Guidance** and implementation process and collating feedback and lessons from this process;

- Ensuring **integration** between economics and other expertise (working groups) through specific joint activities for integrated testing of guidance in pilot river basins; and

- Making operational specific economic **methodologies and approaches** (e.g. development of databases on water-related environmental costs/benefits).

Collaborating at European level to ensure integration with other expertise

Further co-operation with other areas of expertise remains essential for addressing a number of issues:

- How can economic information be used in order to take part in the process of identifying the need for **derogation**?
- What is the role of economics in the designation of **Heavily Modified Water Bodies** and how should the process of designation be carried out?
- What information on **pressures** is required for the economic analysis and how should the *Business as Usual* scenario be built by combining technical and economic expertise?

Integration with other expertise will be fostered at the European level through integrated testing of the Guidance Documents produced by the various working groups set up through the Common Strategy.

Integrated testing of guidance in pilot river basins

A specific working group of the Common Implementation Strategy (see Annex A) has been established for undertaking an integrated testing of all Guidance Documents in pilot river basins. The aim is to ensure coherence amongst Guidance Documents and their cross-applicability. A series of pilot river basins have been proposed by Member States and testing activities are presently being launched. Pilot projects will also be developed in candidate countries to the European Union with support from the European Commission.

Collaborating at European level to develop methodological tools and databases

On all of those issues, Member States might wish to collaborate in order to join their forces. Methodological developments are likely to be costly and information can be usefully shared and transferred in order to avoid duplication. In parallel with the implementation of the Directive at Member States level, activities are likely to continue at the European level in order to develop methodologies and shared databases.

Developing common databases on key data for the analysis

The development of common databases is likely to be instrumental in speeding up the process of data collection, providing some points of reference for the analysis and reducing the costs of carrying out full studies. It might be useful, for example, to develop databases on the costs and effectiveness of measures before 2004, as basis for undertaking the cost-effectiveness analysis by 2008. It would be necessary to identify the types of measures to be examined and what sort of cost data could already be collected. This data would need to be updated as information from monitoring systems start coming in from 2006 onwards. Similar efforts may be launched for developing environmental costs/benefits databases.

And finally…

Improving and updating this Guidance Document might be required at a future stage, after the 2004 deadlines have been met and new information and experience has been gained. This possibility will be examined depending on lessons collated from the use of the Guidance and from the information that will have emerged.

Annex A – Implementation of the Water Framework Directive

Annex B - Definitions

ANNEX B1 Economic elements of the Water Framework Directive: Legal text

Title	Specification	Provision
Preambles		
	No. 11	'[...] environmental damage should, as a priority, be rectified at source and the polluter should pay.'
	No. 12	'[...] the Community is to take account of available technical data, environmental conditions in the various regions of the Community, and the economic and social development of the Community as a whole and the balanced development of its regions as well as potential costs and benefits of action or lack of action.'
	No. 29	'[...] Member States may phase implementation of the programme of measures in order to spread the costs of implementation.'
	No. 31	In cases where a body of water is so affected by human activity or its natural condition is such that it may be infeasible or unreasonably expensive to achieve good status, less stringent objectives may be set [...] and all practicable steps should be taken to prevent any further deterioration of the status of waters.'
	No. 36	'It is necessary to undertake analyses of the characteristics of a river basin and the impacts of human activity as well as an economic analysis of water use [...]'
	No. 38	'The use of economic instruments by Member States may be appropriate as part of a programme of measures. The principle of recovery of the costs of water services, including environmental and resource costs associated with damage or negative impact on the aquatic environment should be taken into account in accordance with, in particular, the polluter pays principle. An economic analysis based on long-term forecasts of supply and demand for water in the RBD will be necessary for this purpose.'
	No. 43	'Pollution through the discharge, emission or loss of priority hazardous substances must cease or be phased out. The European Parliament and Council should [...] agree [...] on the substances to be considered for action as a priority and on specific measures to be taken against pollution of water by those substances, taking into account all significant sources and identifying the cost-effective and proportionate level and combination of controls.'
	No. 53	'Full implementation and enforcement of existing environmental legislation for the protection of waters should be ensured. It is necessary to ensure the proper application of the provisions implementing this Directive [...] by appropriate penalties [...]. Such penalties should be effective, proportionate and dissuasive.'
Article 2	*Definitions*	
	Paragraph 38	"Water services" means all services which provide, for households, public institutions or any economic activity: (a) abstraction, impoundment, storage, treatment and distribution of surface water or groundwater (b) waste water collection and treatment facilities which subsequently discharge into surface water.'
	Paragraph 39	"Water use" means water services together with any other activity identified under Article 5 and Annex II having a significant impact on the status of water. This concept applies for the purposes of Article 1 and of the economic analysis carried out according to Article 5 and Annex III, point (b).'

Title	Specification	Provision
Article 4	*Environmental objectives*	
	Paragraph 4.3	'Member States may designate a body of surface water as artificial or heavily modified, when: (a) the changes to the hydromorphological characteristics of that body which would be necessary for achieving good ecological status would have significant adverse effects [...].'(b) the beneficial objectives served by the artificial or modified characteristics of the water body cannot, for reasons of technical feasibility or disproportionate costs, reasonably be achieved by other means, which are a significantly better environmental option. Such designation and the reasons for it shall be specifically mentioned in the RBMPs required under Art. 13 and reviewed every six years.'
	Paragraph 4.4	'The deadlines established under paragraph 1 may be extended for the purposes of phased achievement of the objectives for bodies of water, provided that no further deterioration occurs in the status of the affected body of water when all of the following conditions are met: (a) Member States determine that all necessary improvements in the status of bodies of water cannot reasonably be achieved within the timescales set out in that paragraph for at least one of the following reasons: [...] (ii) completing the improvements within the timescale would be disproportionately expensive (b) Extension of the deadline, and the reasons for it, are specifically set out and explained in the RBMP required under Art. 13 [...].'
	Paragraph 4.5	'Member States may aim to achieve less stringent environmental objectives than those required under Paragraph 1 for specific bodies of water when they are so affected by human activity, as determined in accordance with Art. 5.1, or their natural condition is such that the achievement of these objectives would be infeasible or disproportionately expensive and all of the following conditions are met: (a) the environmental and socio-economic needs served by such human activity cannot be achieved by other means, which are a significantly better environmental option not entailing disproportionate costs; (b) Member States ensure, - for surface water, the highest ecological and chemical status possible is achieved, given impacts that could not reasonably have been avoided due to the nature of the human activity or pollution; - for groundwater, the least possible changes to good groundwater status, given impacts that could not reasonably have been avoided due to the nature of the human activity or pollution; [...] (d) the establishment of less stringent environmental objectives, and the reasons for it, are specifically mentioned in the RBMP required under Art. 13 and those objectives are reviewed every six years.'
	Paragraph 4.6	'Temporary deterioration in the status of bodies of water shall not be in breach of the requirements of this Directive if this is the result of circumstances of natural cause [...] or the result of circumstances due to accidents [...] when all of the following conditions have been met: (a) all practicable steps are taken to prevent further deterioration in status and in order not to compromise the achievement of the objectives of this Directive in other bodies of water not affected by those circumstances; (b) the conditions under which circumstances that are exceptional or that could reasonably have been foreseen may be declared, including the adoption of the appropriate indicators, are stated in the RBMP; [...] (d) [...] all practicable measures are taken with the aim of restoring the body of water to its status prior to the effects of those circumstances as soon as reasonably practicable; (e) a summary of the effects of the circumstances and of such measures taken or to be taken in accordance with paragraphs (a) and (d) are included in the next update of the RBMP.'
	Paragraph 4.7	'Member States will not be in breach of this Directive when: failure to achieve good groundwater status, good ecological status or, where relevant, good ecological potential or to prevent deterioration in the status of a body of surface water or groundwater is the result of new modifications to the physical characteristics of a surface water body or alteration to the level of bodies of groundwater, or failure to prevent deterioration from high status to good status of a body of surface water is the result of new sustainable human development activities and all the following conditions are met: ... (d) the beneficial objectives served by those modifications or alterations of the water body cannot for reasons of technical feasibility or disproportionate cost be achieved by other means, which are a significantly better environmental option.'
Article 5	*Characteristics of the River Basin District, review of the environmental impact of human activity and the economic analysis of water use*	

Title	Specification	Provision
	Paragraph 5.1	‘Each Member State shall ensure that for each RBD or for the portion of an international RBD falling within its territory an analysis of its characteristics, a review of the impact of human activity on the status of surface waters and on ground water, and an economic analysis of water use is undertaken according to the technical specifications set out in Annexes II and III and that it is completed at the latest four years after the date of entry into force of this Directive.’
	Paragraph 5.2	‘The analyses and reviews mentioned under paragraph 1 shall be reviewed, and if necessary updated at the latest 13 years after the date of entry into force of this Directive [2013] and every six years thereafter.’
Article 6	*Register of Protected Areas*	
	Paragraph 6.1	‘Member States shall ensure the establishment of a register or registers of all areas lying within each RBD which have been designated as requiring special protection under specific Community legislation for the protection of their surface water and groundwater or for the conservation of habitats and species directly depending on water. They shall ensure that the register is completed the latest four years after the date of entry into force of this Directive.’
	Paragraph 6.2	‘The register or registers [of protected areas] shall include all bodies of water identified under Article 7(1) and all Protected Areas covered by Annex IV [i.e. ...areas designated for the protection of economically significant aquatic species...].’
Article 9	*Recovery of costs for water services*	
	Paragraph 9.1	‘Member States shall take account of the principle of recovery of costs of water services, including environmental and resource costs, having regard to the economic analysis conducted according to Annex III, and in accordance in particular with the polluter pays principle. Member States shall ensure by 2010: (i) that water pricing policies provide adequate incentives for users to use water resources efficiently, and thereby contribute to the environmental objectives of this Directive (ii) an adequate contribution of the different water uses, disaggregated into at least industry, households and agriculture, to the recovery of the costs of water services, based on the economic analysis conducted according to Annex III and taking account of the polluter pays principle. Member States may in do doing have regard to the social, environmental and economic effects of the recovery as well as the geographic and climatic conditions of the region or regions affected.’
	Paragraph 9.2	‘Member States shall report in the RBMPs [to be published at the latest 9 years after the date of entry into force of this Directive, 2009] on the planned steps towards implementing paragraph 1 [...] which will contribute to achieving the environmental objectives of this Directive and on the contribution made by the various water uses to the recovery of the costs of the water services.
	Paragraph 9.3	‘Nothing in this Article shall prevent the funding of particular preventative or remedial measures in order to achieve the objectives of this Directive.’
	Paragraph 9.4	‘[...] Member States shall report the reasons for not fully applying paragraph 1, second sentence, in the RBMPs.’
Article 11	*Programme of measures*	

Title	Specification	Provision
	Paragraph 11.1	'Each Member State shall ensure the establishment for each RBD, or for the part of an international RBD [IBRD] within its territory, of a programme of measures, taking account of the results of the analyses required under Art. in order to achieve the objectives established under Art. 4 [...]'
	Paragraph 11.2	'Each programme of measures shall include the "basic" measures specified in paragraph 3 and, where necessary, "supplementary" measures.'
	Paragraph 11.3	"Basic" measures are the minimum requirements to be complied with and shall consist of [...] (b) measures deemed appropriate for the purposes of Art. 9. (c) measures to promote an efficient and sustainable water use in order to avoid compromising the achievement of the objectives specified in Art. 4. [...] (i) for any other significant adverse impacts on the status of water identified under Art.. 5 and Annex II.'
	Paragraph 11.4	"Supplementary" measures are those measures designed and implemented in addition to the basic measures, with the aim of achieving the objectives established pursuant to Art. 4.'
	Paragraph 11.7	'The programmes of measures shall be established at the latest nine years after the date of entry into force of this Directive [2009] and all the measures shall be made operational at the latest 12 years after that date [2012].'
Article 13	*River basin management plans*	
	Paragraph 13.1	'Member States shall ensure that a RBMP is produced for each RBD lying entirely within their territory.'
	Paragraph 13.2	'In the case of international RBD falling entirely within the Community, Member States shall produce a single International RBMP. Where such a plan is not produced, a RBMP should be produced covering at least those parts of the IRBMP falling within its territory to achieve the objectives of this Directive.'
	Paragraph 13.4	'The RBMP shall include the information detailed in Annex VII.'
	Paragraph 13.5	'RBMPs may be supplemented by the production of more detailed programmes and management plans for sub-basin, sector, issue or water type, to deal with particular aspects of water management. Implementation of these measures shall not exempt Member States from any of their obligations under the rest of this Directive.'
	Paragraph 13.6	'RBMPs shall be published at the latest nine years after the date of entry into force of this Directive (2009).'
	Paragraph 13.7	'RBMPs shall be reviewed and updated at the latest 15 years after the date of entry into force of this Directive and every six years thereafter.'
Article 14	*Public Information and Consultation*	
	Paragraph 1	'Member States shall encourage the active involvement of all interested parties in the implementation of this Directive, in particular in the production, review and updating of the River Basin Management Plans. Member States shall ensure that, for each River Basin District, they publish and make available for comments to the public, including users: (a) a timetable and work programme for the production of the plan […] at least three years before the beginning of the period to which the plan refers; (b) an interim overview of the significant water management issues identified in the river basin at least two years before […]; (c) draft copies of the River Basin Management Plan, at least one year before […].
Article 15	*Reporting*	

Title	Specification	Provision
	Paragraph 15.2	'Member States shall submit summary reports of the Reporting of the analyses under Article 5 [...] undertaken for the purposes of the first RBMP within 3 months of their completion.'
Article 16	*Strategies against pollution of water*	
	Paragraph 16.6	'For the priority substances, the Commission shall submit proposals of controls for the progressive reduction of discharges, emissions and losses of the substances concerned and, in particular, the cessation or phasing out of discharges [...]. In doing so it shall identify the appropriate cost-effective and proportionate level and combination of product and process controls for both point and diffuse sources [...].'
Article 17	*Strategies to prevent and control pollution of groundwater*	
	Paragraph 17.2	'In proposing measures, the Commission shall have regard to the analysis carried out according to Article 5 and Annex II [due in at the latest 4 years after the implementation of this Directive, i.e. 2004].'
Article 23	*Penalties*	'Member States shall determine penalties applicable to breaches of the national provisions adopted pursuant to this Directive. The penalties thus provided for shall be effective, proportionate and dissuasive.'
Annex II	*Identification of pressures*	
	Paragraph 1.4	'Member States shall collect and maintain information on the type and magnitude of the significant anthropogenic pressures to which the surface water bodies in each RBD are liable to be subject, in particular: • estimation and identification of significant point [... and...] diffuse source pollution [...]; • estimation and identification of significant water abstraction for urban, industrial, agricultural and other uses, including seasonal variations and total annual demand, and loss of water in distribution systems; • estimation and identification of the impact of significant water flow regulation [...]; • identification of significant morphological alterations to water bodies; • estimation and identification of other significant anthropogenic impacts on the status of surface waters; and • estimation of land use patterns [...].'
Annex III	*Economic analysis*	'The economic analysis shall contain enough information in sufficient detail (taking into account the costs associated with collection of the relevant data) in order to: (a) make the relevant calculations necessary for taking into account under Art. 9 the principle of recovery of the costs of the water services, taking account of the long term forecasts of supply and demand for water in the RBD and, where necessary: • estimates of the volume, prices and costs associated with water services; and • estimates of relevant investment including forecasts of such investments (b) make judgements about the most cost effective combination of measures in respect of water uses to be included in the programme under Art. 11 based on estimates of the potential costs of such measures.'
Annex IV	*Protected areas*	
	Paragraph 1	'The register of Protected Areas required under Article 6 shall include the following types of protected areas: [...] areas designated for the protection of economically significant aquatic species [...].'

Title	Specification	Provision
Annex VI	*Lists of measures to be included within the programmes of measures*	‘The following is a non-exclusive list of supplementary measures which Member States within each RBD may choose to adopt as part of the Programme of Measures required under Art. 11(4) [...] (iii) economic or fiscal instruments [...].’
Annex VII	*River Basin Management Plans*	‘RBMPs shall cover the following elements:
	Paragraph 1	a general description of the characteristics of the RBD required under Article 5 and Annex II [...];
	Paragraph 2	a summary of significant pressures and impact of human activity on the status of surface water and groundwater, including: • estimation of point source pollution; • estimation of diffuse source pollution, including a summary of land use; • estimation of pressures on the quantitative status of water including abstractions; • analysis of other impacts of human activity on the status of water.
	Paragraph 6	a summary of the economic analysis of water use as required by Article 5 and Annex III;
	Paragraph 7	a summary of the programme or programmes of measures adopted under Art. 11, including the ways in which the objectives established under Art. 4 are thereby to be achieved:
	Paragraph 7.2	[...] a report on the practical steps and measures taken to apply the principle of recovery of the costs of water use in accordance to Art. 9;
	Paragraph 7.10	[...] details of the supplementary measures identified as necessary in order to meet the environmental objectives established;
	Paragraph 8	a register of any more detailed programmes and management plans for the RBD dealing with particular sub-basins, sectors, issues or water types, together with a summary of their contents [...].’

Abbreviations: RBMP- River Basin Management Plan, IRBMP - International River Basin Management Plan, RBD - River Basin District, IBRD - International River Basin District

ANNEX B2 Glossary

Source	Term	Definition
Information sheet – Estimating Costs (and Benefits)	Administrative costs	Administrative costs related to water resource management. Examples include costs of administering a charging system or monitoring costs.
	Affordability	The relative importance of water service costs in users' disposable income, either on average or for low-income users only.
Art. 2 (11)	Aquifer	A sub-surface layer or layers of rock or other geological strata of sufficient porosity and permeability to allow either a significant flow of groundwater or the abstraction of significant quantities of groundwater.* (2 definitions are given in the combined CIS glossary)
Art. 2 (8)	Artificial water body	A body of surface water created by human activity.* (2 definitions are given in the combined CIS glossary)
Art. 2 (27)	Available groundwater resource	The long-term annual average rate of overall recharge of the body of groundwater less the long-term annual rate of flow required to achieve the ecological quality objectives for associated surface waters specified under Article 4, to avoid any significant damage to associated terrestrial ecosystems.*
Information sheet – Baseline Scenario	Baseline Scenario	Projection of the development of a chosen set of factors in the absence of policy interventions. The definition in the combined CIS glossary is slightly different.
Art. 11 (3)	Basic measures	See Article 11(3) of the Directive.
Art 4 (7)	Benefits	See information sheet *Assessing Costs and Benefits*
Art. 2 (12)	Body of groundwater	A distinct volume of groundwater within an aquifer or aquifers.*
Art. 2 (10)	Body of surface water	A discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.*
Information sheet – Estimating Costs (and Benefits)	Capital costs	For the purpose of this Guidance Document divided into three categories: ➢ *New investments*. Cost of new investment expenditures and associated costs (e.g. site preparation costs, start-up costs, legal fees); ➢ *Depreciation*. Annualised cost of replacing existing assets in future. ➢ *Cost of capital*. Opportunity cost of capital, i.e. an estimate of the rate of return that can be earned on alternative investments.
Art. 2 (7)	Coastal water	Surface water on the landward side of a line, every point of which is at a distance of one nautical mile on the seaward side from the nearest point of the baseline from which the breadth of territorial waters is measured, extending where appropriate up to the outer limit of transitional waters.* 2 definitions are given in the combined CIS glossary, but one is for 'coastal water body'
Art. 2 (36)	Combined approach	The control of discharges and emissions into surface waters according to the approach set out in Article 10.*
Art. 2 (16)	Competent authority	An authority or authorities identified under Article 3(2) or 3(3).*

Source	Term	Definition
Information sheet – Assessing Costs and Benefits	Contingent valuation	Valuation of commodities not traded in markets, e.g. clean air, landscapes and wildlife. The valuation is based upon the responses of individuals to questions about what their actions would be if a particular hypothetical situation were to occur. When the average of responses has been calculated, with weighting if necessary, the valuation of a **public good** is ascertained.**
Information sheet – Assessing Costs and Benefits	Cost-benefit analysis	The evaluation of an investment project with a long-perspective from the viewpoint of the economy as a whole by comparing the effects of undertaking the project with not doing so.**
Information sheet – Cost-effectiveness analysis	Cost-effectiveness analysis	An analysis of the costs of alternative programmes designed to meet a single objective. The programme which costs least will be the most cost effective.**
Annex III	Cost-effective combination of measures	A combination of measures chosen subject to a cost-effectiveness analysis (see 'cost-effectiveness analysis')
Information sheet – Assessing Costs and Benefits	Damage function	A function of how pollution damage varies with the level of pollution emitted, giving a monetary value for that damage.***
Information sheet – Cost-effectiveness Analysis	Direct cost	A production cost directly attributable to the cost of producing one unit of a particular output.**
Art. 2 (32)	Direct discharge to groundwater	Discharge of pollutants into groundwater without percolation throughout the soil or subsoil.*
Information sheet – Estimating Costs (and Benefits)	Discounting	A method used to value at the same date economic flows and stocks which have originated at different dates.**
Information sheet – Estimating Costs (and Benefits)	Discount rate	The rate used for discounting future values to the present. In cost-benefit analysis, there is a distinction between a private and a social rate of discount. A private rate of discount reflects the time preference of private consumers; a social rate is based on the government's view, which can be more long-sighted as it attempts, in most cases, to take into account the welfare of future generations.**
Art. 4 (3, 5 & 7)	Disproportionate costs	See information sheet *Disproportionate Costs*
Art. 4 (5)	Disproportionately expensive	See information sheet *Disproportionate Costs*
Art. 2 (21)	Ecological status	An expression of the quality of the structure and functioning of aquatic ecosystems associated with surface waters, classified in accordance with Annex V.**
Art. 5 (1)	Economic analysis	See Annex III of the Directive
Information sheet – Estimating Costs (and Benefits)	Economic costs	See 'opportunity costs'**
Art. 2 (41)	Emission controls	Controls requiring a specific emission limitation, for instance an emission limit value, or otherwise specifying limits or conditions on the effects, nature or other characteristics of an emission or operating conditions which affect emissions. Use of the term 'emission control, in the Directive in respect of the provision of any other Directive shall not be held as reinterpreting those provisions in any respect.*
Art. 2 (40)	Emission limit values	The mass, expressed in terms of certain specific parameters, concentration and/or level of an emission, which may not be exceeded during any one or more periods of time. Emission limit values may also be laid down for certain groups, families or categories of substances, in particular for those identified under Article16.*
Information sheet – Estimating Costs (and Benefits)	Environmental costs	Represent the costs of damage that water uses impose on the environment and ecosystems and those who use the environment (e.g. a reduction in the ecological quality of aquatic ecosystems or the salinisation and degradation of productive soils).
Art. 2 (34)	Environmental objectives	The objectives set out in Article 4.*

Source	Term	Definition
Art. 2 (35)	Environmental quality standard	The concentration of a particular pollutant or group of pollutants in water, sediment or biota which should not be exceeded in order to protect human health and the environment.*
Section 2	Explicit economic function	Refers to the economic components that are specifically outlined in Annex III of the Directive.
Information sheet – Estimating Costs (and Benefits)	External cost	An external cost exists when the following two conditions prevail 1. An activity by one agent causes a loss of welfare to another agent; and 2. The loss of welfare is uncompensated.***
Information sheet – Cost Recovery	Financial costs of water services	Include the costs of providing and administering these services. They include all operation and maintenance costs, and capital costs (principal and interest payment), and return on equity where appropriate).
Art. 2 (23)	Good ecological potential	The status of a heavily modified or an artificial body of water, so classified in accordance with the relevant provisions of Annex V.*
Art. 2 (22)	Good ecological status	The status of a body of surface water, so classified in accordance with Annex V.*
Art. 2 (25)	Good groundwater chemical status	The chemical status of a body of groundwater, which meets all the conditions set out in Table 2.3.2 of Annex V.*
Art. 2 (28)	Good quantitative status	The status defined in Table 2.1.2 of Annex V.*
Art. 2 (18)	Good surface water status	The status achieved by a surface water body when both its ecological status and its chemical status are at least 'good'.*
Art. 2 (24)	Good surface water chemical status	The chemical status required to meet the environmental objectives for surface waters established in Article 4(1)(a), that is the chemical status achieved by a body of surface water in which concentrations of pollutants do not exceed the environmental quality standards established in #Annex IX and under Article 16(7), and under other relevant Community legislation setting environmental quality standards at Community level.*
Art. 2 (2)	Groundwater	All water which is below the surface of the ground in the saturation zone and in direct contact with the ground or subsoil.* 2 definitions are given in the combined CIS glossary
Art. 2 (19)	Groundwater status	The general expression of the status of a body of groundwater, determined by the poorer of its quantitative status and its chemical status.*
Art.2 (29)	Hazardous substances	Substances or groups of substances that are toxic, persistent and liable to bioaccumulate, and other substances or groups of substances which give rise to an equivalent level of concern.*
Art. 2 (9)	Heavily modified water body	A body of surface water which as a result of physical alterations by human activity is substantially changed in character, as designated by the Member State in accordance with the provisions of Annex II.*
Information sheet – Scale issues	Homogenous areas	Geographical areas that: ➢ Present homogeneous socio-economic characteristics today (a given economic sector or sub-sector localised in one geographical area of the river basin); and ➢ Are likely to react in a homogenous manner to measures or interventions.
Section 2	Implicit economic functions	Refers to references made to economic issues in other parts of the Directive text that will also require some economic analysis but which have not been mentioned nor made explicit in Annex III.
Information sheet – Estimating Costs (and Benefits)	Indirect cost	Overhead and other costs not directly attributable to the cost of producing one unit of output; a fixed cost.**

Source	Term	Definition
Art. 2 (3)	Inland water	All standing or flowing water on the surface of the land, and all groundwater on the landward side of the baseline from which the breadth of territorial waters is measured.*
Art. 2 (5)	Lake	A body of standing inland surface water*
Information sheet – Estimating Costs (and Benefits)	Maintenance costs	Costs for maintaining existing (or new) assets in good functioning order till the end of their useful life.
Information sheet – 'Disproportionate Costs' and 'Analysis of derogation for new modifications/ activities based on Article 4.7' (Annex D2a of this Guidance Document)	New modifications	All direct modifications to the physical characteristics of a surface or groundwater body, or alterations to the level of bodies of groundwater (e.g. straightening a river reach and alterations to the level of groundwater bodies). It does not deal with the chemical and ecological dimensions of good water status. *
Analysis of derogation for new modifications/ activities based on Article 4.7 (Annex D2a of this Guidance Document)	New sustainable human development activities	*New human development activities* are activities that relate to changes from high to good status in surface water. It includes all ecological, qualitative and quantitative elements in the definition of the water status. The focus is on the use that leads to the change in the water status. *Sustainable new human development activities* are activities described above that considers and integrates social, economic and environmental impacts with a temporal dimension (e.g. future generations) and potentially, a global dimension. See also *Annex D.2* of this Guidance Document.
Information sheet – Estimating Costs (and Benefits)	Operating costs	All costs incurred to keep an environmental facility running (e.g. material and staff costs).
Information sheet – Estimating Costs (and Benefits)	Opportunity costs	The value of the alternative foregone by choosing a particular activity.**
Art. 2 (31)	Pollutant	Any substance liable to cause pollution, in particular those listed in Annex VIII.*
Art. 2 (33)	Pollution	The direct or indirect introduction, as a result of human activity, of substances or heat into the air, water or land which may be harmful to human health or the quality of aquatic ecosystems or terrestrial ecosystems directly depending on aquatic ecosystems, which result in damage to material property, or which impair or interfere with amenities and other legitimate uses of the environment.*
	Price elasticity of demand	The responsiveness of quantity demanded of a good or service to a change in its price or in a consumer's income.**
Art. 2 (30)	Priority substances	Substances identified in accordance with Article 16 (2) and listed in Annex X. Among these substances there are 'priority hazardous substances' which means substances identified in accordance with Article 16 (3) and (6) for which measures have to be taken in accordance with Article 16(1) and 16(8).*
Art. 2 (26)	Quantitative status	An expression of the degree to which a body of groundwater is affected by direct and indirect abstractions.*
Art. 6 (2)	Register of protected areas	Shall include all bodies of water identified under Article 7 (1) and all protected areas covered by Annex IV.* The definition in the combined CIS glossary is longer.

Source	Term	Definition
Information sheet – Estimating Costs (and Benefits)	Resource costs	Represents the costs of foregone opportunities which other uses suffer due to the depletion of the resource beyond its natural rate of recharge or recovery (e.g. linked to the over-abstraction of groundwater).
Art. 2 (4)	River	Body of inland water flowing for the most part on the surface of the land but which may flow underground for part of its course.*
Art. 2 (13)	River basin	The area of land from which all surface run-off flows through a sequence of streams, rivers and, possibly, lakes into the sea at a single river mouth, estuary or delta.* There are 2 definitions in the combined CIS glossary
Art. 13 (4)	River basin management plan	Shall include the information detailed in Annex VII* The definition in the combined CIS glossary is longer
Art. 2 (14)	Sub-basin	The area of land from which all surface run-off flows through a series of streams, rivers and, possibly, lakes to a particular point in a water course (normally a lake or a river confluence).* There are 2 definitions in the combined CIS glossary.
Preamble (15)	Supply of water	A service of general interest as defined in the Commission communication on services of general interest in Europe.
Art. 2 (1)	Surface water	Inland waters, except groundwater; transitional waters and coastal waters, except in respect of chemical status for which it shall also include territorial waters.* There are 2 definitions in the combined CIS glossary.
Art. 2 (17)	Surface water status	The general expression of the status of a body of surface water, determined by the poorer of its ecological status and its chemical status.* The definition in the combined CIS glossary is slightly shorter.
Information sheet – Disproportionate Cost	Time derogation	A temporary extension of deadlines to achieve the environmental objectives set out in Article 4 of the Directive.
Information sheet – Estimating Costs (and Benefits)	Unit cost	The cost of producing one unit of a product.**
	Utility	The satisfaction derived from an activity, particularly consumption.**
Water Uses and Services (Annex B3 of this Guidance Document)	Water services	All services which provide, for households, public institutions or any economic activity: ➢ Abstraction, impoundment, storage, treatment and distribution of surface water or groundwater; ➢ Wastewater collection and treatment facilities which subsequently discharge into surface water.* See also information sheet *Water Uses and Services*
Water Uses and Services (Annex B3 of this Guidance Document)	Water uses	Water services together with any other activity identified under Article 5 and Annex II having significant impact on the status of water.* See also information sheet *Water Uses and Services*

ANNEX B3 Water Uses and Water Services

Directive references: *Article 1, Article 2 (paragraphs 38 & 39), Article 5* and *Article 9*

This Information Sheet helps you understand the definition of water services and water uses and how these categories are dealt with in the Directive.

What is the difference between water services and water uses?

A key objective of the Directive is to promote sustainable water use, based on a long-term protection of available water resources (Article 1). The Directive distinguishes human activities into 'water services' and 'water uses'. Those terms are defined in *Article 2* of the Directive (see *Box B3.1*) and are represented graphically in *Figure B3.1*. Water services are specifically referred to in the context of Article 9 and cost-recovery.

Box B3.1 – Water Uses and Services as Defined in Article 2

38) 'Water services' means all services, which provide, for households, public institutions or any economic activity:

(a) Abstraction, impoundment, storage, treatment and distribution of surface water or groundwater,
(b) Wastewater collection and treatment facilities, which subsequently discharge into surface water.

39) 'Water use' means water services together with any other activity identified under Article 5 and Annex II having a significant impact on the status of water. This concept applies for the purposes of Article 1 and of the economic analysis carried out according to Article 5 and Annex III, point (b).

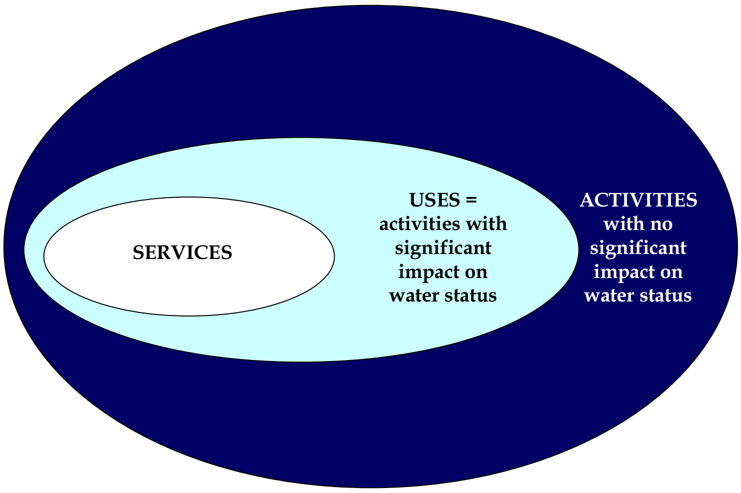
Overall, a water service represents an intermediary between the natural environment and the water use itself. The main purpose of the water service is to ensure that:

- Key characteristics of natural waters are modified (i.e. the service offered is this modification) so as to ensure it fits with the requirements of well-identified users (e.g. provision of drinking water); or
- Key characteristics of water 'discharged' by users are modified (i.e. the service offered is also this modification, e.g. waste water treatment) so that it can go back to the natural environment without damaging it.

Overall, a water service *per se* does not consume water nor produce pollution, although it can directly lead to morphological changes to the water ecosystem. Characteristics of waters that are modified through a water service include:

- Its **spatial distribution**, e.g. a water supply network for ensuring that water is reallocated spatially to every individual user;
- Its **temporal distribution**/flows, e.g. dams;
- Its **height**, e.g. weirs and dams;
- Its **chemical composition**, e.g. treatment of water, and wastewater;
- Its **temperature**, e.g. temperature impact on water.

Figure B3.1 – Water Uses and Services

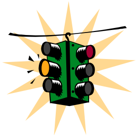


Key Points to Remember:

- ***Water Services*** include **all services** (public or private) of abstraction, impoundment, storage, treatment and distribution of surface water or groundwater, along with wastewater collection and treatment facilities. Member States shall account for the recovery of the costs of water services according to *Article 9*;

- ***Water Uses*** are all activities that have a significant impact on water status, according to the analysis of pressures and impacts developed in accordance to *Article 5 and its Annex II*. Economic analysis must be performed for all water uses *(Article 5 and Annex III).* Also, Member States shall ensure an adequate contribution of the different water uses, disaggregated into at least industry, households and agriculture, to the recovery of the costs of water services *(Article 9);*

- Some ***activities*** with no significant impact on water status are neither water services nor water uses. Clearly, this distinction can not be made systematic as it is based on the analysis undertaken in accordance to *Article 5 and Annex II*, e.g. in some cases, fishing will have no impact on water status, but over-fishing has a significant impact on the ecology of a river and water status.



Look out! Read Article 9 carefully.

Be careful when you read Article 9. Overall, this article states that Member States must ensure by 2010

- That water pricing policies provide adequate incentive for users to use water resource efficiently;
- An adequate contribution of the different water uses to the recovery of the costs of water services.

In complying with this obligation, Member States may take account of the social, environmental and economic effects of the recovery.

The first sentence introduces the principle of cost recovery for ***water services***. Later, it specifies that Member States shall ensure an adequate contribution of the different ***water uses*** to the recovery of the costs of ***water services***.... Thus, Article 9 combines both water services and water uses. For example, diffuse pollution to surface water or groundwater is not a water service as defined in Article 2. However, if it has a significant impact on the status of water, it is a water use. The water user will then be asked to contribute in an adequate manner to the costs of water services they have caused (e.g. costs of water treatment), based on the economic analysis undertaken according to Annex III and in accordance with the polluter pays principle.

More work lies ahead for the definition of Water Uses

By contrast to the approach taken for water services, the Directive does not specify a list of water uses to be considered. Basically, only the activities that cause significant impacts on water bodies and therefore pose a risk to achieving good status are covered by the definition of water uses. General experience shows that navigation, hydropower generation, domestic, agriculture and industrial activities are important water uses which may cause significant impacts and therefore have to be taken in consideration.

Thus, more work is needed…

- To determine a list of main water uses based on the assessment of significant human impact on water bodies (Article 5 and Annex II) before 2004. This is the same deadline as for the economic analysis of water uses required for the overall characterisation of river basins.

This work will be developed in the context of the review of the impact of human activity on the status of surface waters and on groundwater according to Article 5 and Annex II (see WFD CIS Guidance Document No. 3 on the assessment of 'Impacts and Pressures').

Recommendations for a practical approach to assessing cost-recovery

The proposed approach is based on the application of key principles for improving decision making and ultimately water status, i.e. **transparency** and **effectiveness,** and on pragmatism and best use of available resources for targeting the analysis to aid decision making where it is most required, i.e. **proportionality**.

For the purpose of reporting and cost-recovery assessment, the following elements should be considered.

1. **Proportionality** – cost recovery is assessed (i) when water services have a significant impact on water status, and (ii) when water uses have a significant impact on water status resulting in services developed for other water users for mitigating/reducing the observed negative damage. Thus, the cost-recovery assessment for 2004 should closely link to the analysis of pressures and impacts that needs to be undertaken by the same deadline.

2. **Effectiveness** – cost-recovery is assessed when cost-recovery and pricing is seen as effective for changing behaviour and are key elements in decision-making.

3. **Transparency -** for the areas or water bodies where water services have an impact on water status, should then systematically identified and the assessment of cost-recovery and pricing is performed. This ensures **transparency** as required by the Water Framework Directive. It also provides the basis for assessing the integration between water policy and other sector policies. To achieve maximum transparency, to ensure equitable and effective treatment *vis-à-vis* the internalisation of environmental and resource costs, and to preserve competition between economic sectors, water services should, where necessary, include both services provided by third parties and self services.

In the short term, for the first characterisation of the river basin district (Article 5):

- As little may be known on the effectiveness of cost-recovery and pricing for achieving the environmental objectives of the Directive, a more systematic cost-recovery assessment of all services should be performed as sound basis for follow-up effectiveness analyses as support to targeted policy intervention;
- Mainly available information will be used. This first identification will lead to the identification of missing data required for assessing cost-recovery coherently in accordance with the proportionality and effectiveness principles mentioned above.

In the longer term, for the river basin management plans, water services to be considered for assessing cost-recovery will build on the identification of water bodies at risk of failing good water status, along with input from the public consultation on the overview on significant water management issues in the river basin.

Whatever the outcome of the cost-recovery assessment, and as specified in Article 9.1, 9.3 and 9.4 of the Directive, it will not prevent Member States deciding on the level of cost recovery of the water services being identified, and on the contribution of water uses to the costs of water services, as long as it is duly reported on in the river basin management plans.

Annex C – Support to Implementation

ANNEX C1 Illustrative Terms of Reference for a Virtual Scoping Study on Cost-effectiveness Analysis

Aims and objectives

The aim of the study is to scope out how the cost-effectiveness analysis of measures to achieve good water status and related consultation could be carried out so as to aid decision-making on these measures and identify and investigate any issues and problems regarding such economic analysis. The scoping deals with both economic and technical issues and expertise as investigated in the cost-effectiveness analysis.

Issues

The specific issues to be examined include:

- Characterise and differentiate the various stretches of water bodies in the selected basin so as to identify bodies of water for which objectives must be set and measures identified and appraised;

- Characterise the various possible measures to achieve good water status in terms of the level (e.g. national or local) at which decisions have to be taken on them and the level at which these measures have to be implemented;

- Characterise the diverse parties affected positively or negatively by the impacts of these various possible measures to achieve good quality status, so as to help inform (in subsequent research) how their views could be input to decision-makers;

- How best to use the available information given by existing scientific, risk assessment and economic appraisal systems on the environmental, economic or social impacts of the possible measures, so as to aid decision-making on them. What are the key gaps in technical expertise and information that need to be addressed to undertake cost-effectiveness analysis?

- Identify outstanding staff resourcing and capability issues. For example, are there sufficient numbers of trained staff at regional level and centrally to co-ordinate data collection and economic analysis?

- Identify outstanding specific research issues that need to be addressed in subsequent studies.

Specific Tasks to be carried out

1. Characterise and differentiate the various stretches of water bodies in the selected basin so as to identify the appraisals needed for particular stretches of water for which objectives must be set and measures identified. These could form appropriate separate building block elements of the appraisal (and subsequent monitoring) of measures in the river basin management plans (RBMPs). This might characterise the main different types of water bodies in the basin in respect of, for example:

    - Their different water quality states and the extent to which individual water bodies now fail to achieve good status and will fail to achieve good status by 2015 and 2021;

    - The pressures on water quality now and in the future;

- The different types of options to achieve good status;
- The scale of costs and complexity involved in these measures (and hence the extent of the appraisals (of varying degrees of complexity/depth) that will be needed.

The study will need to extrapolate the findings for the selected basin to other river basins to give a qualitative and approximate assessment of the various depths of economic analysis that would be needed for all river basins in the country.

2. The consultants should devise a simple schematic way of presenting information from the appraisal of individual RBMPs in a way that can be aggregated to aid decision-making at the national level.

3. Characterise the various possible measures to achieve good water status in terms of the level (e.g. national or local) at which decisions have to be taken on them and the level at which these measures have to be implemented.

4. Characterise the parties affected positively or negatively by the environmental, economic or social impacts of the options, especially who benefits and who pays for the costs of the options? In particular specify whether they live within the basin. Investigate how this geographical characterisation of the parties affected could relate to the level at which the possible measures are decided upon and implemented (see above – state where above).

5. Identify what information is needed regarding consultation for the effective implementation of the WFD under Article 14. This should take account of the complex mix of local and national decisions and parties affected by them - see above– state where above - and the need for the consultation to input views rather than determine the decisions (especially at national level).

6. Review the availability of scientific, risk assessment and economic information on the environmental, economic or social impacts of the possible measures and options and show how these could best be used in the cost-effectiveness analysis and to present information on the impacts of options for the consultation. Show how to present clearly the findings and their assumptions and limitations? Identify what additional information, analysis and appraisal processes are needed and how could these best be provided?

7. Show how to present information on measures and combinations of measures to show costs, effectiveness and other factors (e.g. benefits) where appropriate and relevant.

8. Identify what information (in what form) is needed on the costs and economic impacts of the various types of measures (see (3) above) covering the different sectors (water industry, non-water industry, agriculture and other). Review the availability of this information.

9. Indicate how much time and resources would be available to carry out the cost-effectiveness analysis of measures in the selected river basin? Estimate how much time and resource would be required to carry out a similar analysis in various types of river basins (e.g. with different sizes, different pressures and impacts, different availability of information and research results). Identify or seek means of reconciling the likely imbalance between needs and available resources (e.g. streamline the cost-effectiveness analysis process while maintaining its key elements).

10. Identify specific research subjects and pilot RBMP studies that will then be needed to research in depth and clarify particular outstanding issues and problems regarding the practical application of the various elements of the cost-effectiveness analysis.

Outputs from the Study

The intended outputs from the study include:

- Show what information (in what form) is needed to inform decision-making (at which level and for which decisions) on the various types of options;

- Show how the various elements of the cost-effectiveness analysis could best generate this information and how this information could fit together well in practice;

- Identify key information gaps and specific research needs and priorities, especially regarding the development and application of economic appraisal and analysis tools and techniques. This would then form the basis and terms of reference for specific follow up work (e.g. to improve specific tailored economic appraisal techniques).

Study Form

This is essentially a scoping and ground clearing study anchored in a specific basin.

It will entail consultants reviewing the available material (e.g. on water quality states and reasons for failure, available economic information, reports on existing consultation procedures, planning documents with forecasts for key economic sectors/water users, etc).

They would then seek out and analyse the views and knowledge of experts (e.g. from government departments and key stakeholders) on **how** they could carry out **hypothetically (or virtually),** in a specific basin, a cost-effectiveness analysis of the measures for developing the RBMPs.

This virtual study will involve no original research and the consultants should not get bogged down in any detailed investigations. Thus, where data are not currently available, the consultants should use assumed illustrative dummy data and plausible information, that might be generated by the available sources and appraisal processes, to give a virtual illustration of how the cost-effectiveness analysis could be applied in practice – i.e. use assumptions and judgement to report the type of outputs from each element, rather than do any actual data collection as such.

The consultants would interview (probably by telephone) the appropriate experts and prepare a review and issues paper. They will organise a 2-day brainstorming workshop with key experts (mostly from relevant Government departments and devolved administrations, and also from key stakeholders) to work through and thrash out the issues concerned with carrying out the cost-effectiveness analysis.

There will be close links between this study and other scoping studies and research that the government departments are carrying out in the context of the implementation of the Water Framework Directive. For example, case studies on Heavily Modified Water Bodies or studies on scientific aspects, such as specification of water quality objectives and monitoring and characterisation of river basins.

The preliminary results and draft report will be discussed in a 2 day workshop with experts from government and key stakeholders. The main objectives of the workshop will be the discussion and evaluation of the preliminary results of the scoping study, the assessment of the relevance of the results to other river basins in the country, and a first discussion with stakeholders on the economic analysis carried out and its integration into the decision making process for developing RBMPs.

Expertise Required

The successful contractors' team will have to have the following expertise:

- Project management and managing a team of diverse experts so as to pull together their views;
- Economic appraisal and presentation of economic-related information for different audiences;
- Appraisal of the control measures covering the various sectors (households, industry, agriculture, etc.);
- Stakeholder consultation;
- Experts knowledgeable about scientific and risk assessment work relevant to the appraisals for the WFD and how this could effectively input into the cost-effectiveness analysis and consultation processes in this study;
- Organising and animating workshops with diversity of participants from government departments and key stakeholders.

The study period is 6 months. Experts' input to the study is estimated at 6 full man-months.

ANNEX C2 Stakeholder Analysis: Methodology and Key Issues

Introduction

When embarking on an interactive process it is of the utmost importance to consider who will be participating in the process. To get an overview of all the relevant stakeholders (or actors) in the field of interest, a so-called "stakeholder-analysis" can be performed. This analysis reduces the risk of forgetting an important actor and will give an idea about the different angles from which the subject can be viewed. The stakeholder-analysis itself is a relatively simple and a methodological exercise, and a possible methodology is presented in this Annex along with an illustration. However, it is left to the reader to assess how this can be adapted to her/his own situation and made relevant to the economic analysis process.

Background

A stakeholder can be any *relevant* person, group or organisation with an interest in the issue, either because he is going to be affected by the subject (victim, gainer) or because he has influence, knowledge or experience with the subject. The analysis will bring transparency in identifying what stakeholders already exist and which interests they represent. Types of stakeholders are: government, local authorities, non-governmental institutions, political organisations, research institutes, industries, agriculture, households or other businesses. A stakeholder-analysis is usually performed starting from the contents of a project using the "who?" question (for example: we want to build a house, who knows how to build it?). Be aware that the problem definition must be clear from the beginning and that the problem shall be viewed from as many different angles as possible.

Besides analysing the stakeholders it can be useful to map the environment of a project to identify external influences. The map could tell something about the interests, motives and relationships of the actors identified, the field of force they operate in, and risks. For example: which stakeholders have a positive or negative influence on the project, who has power, who has the biggest monetary interest? Similar mapping can be done for *factors* influencing the process, often expressed as threats (e.g. weather, financial or human capacities).

Generally, a process consists of several stages (as illustrated in Figure C2.1). For every single stage, it should be reviewed which stakeholders are relevant to involve in the process and if the stakeholders have the same "rights". The role and involvement of the stakeholder can differ from stage to stage, and the stakeholder-analysis will make this more transparent.

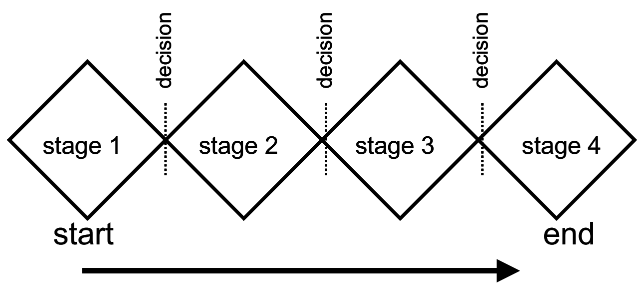


Figure C2.1: A process represented in diagram form

During the stakeholder-analysis the *degree of involvement* of every stakeholder (per stage) can be labelled as either (see Figure C2.2):

- *co-operating*: the stakeholder that will actually participate in and contribute actively to the process;
- *co-thinking*: the stakeholder of which you want input with respect to content, it is a source of knowledge like experts;
- *co-knowing*: the stakeholder which does not play an active role in the process but should be informed of its progress.

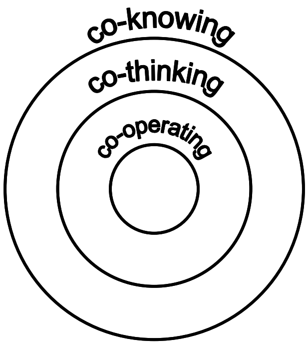

Figure C2.2: Target scheme to identify degree of involvement of stakeholder

If desired the identification approach can be refined by identifying the type of actor (see Figure C2.3):

- decision maker: stakeholders which decide about the project;
- user: stakeholders which use the result or are affected by it;
- implementer/executive: the stakeholders that have to implement the results or new policy;
- expert/supplier: stakeholders which put information, expertise or means at the disposal of the project.

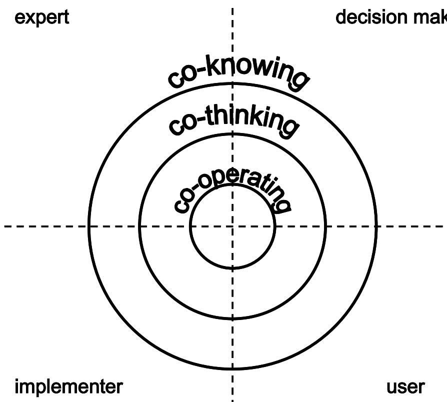

Figure C2.3: Refined target scheme to identify degree of involvement and type of stakeholder

Important! If the identified stakeholders are going to participate (actively or passively) in the project it is important to give feed-back to the stakeholder and specify clearly their role in order to avoid disappointments: management of expectations.

Stakeholder analysis: a simple methodology

Making the stakeholder analysis operational implies going through a series of steps of questioning and interaction. Although it needs to be adapted and refined to every situation, a simple methodology and series of steps is proposed below.

- Step 1 - Define the stage of the process that will be subject to a stakeholder analysis. Putting the subject in question-form makes it usually more accessible and facilitate the identification of key issues/stages. It appears rather wise to invite stakeholders (of which it is obvious that they are involved) to take part in a brainstorming session;
- Step 2 - A group, a maximum of 10 persons (the project team) including a chairman, performs a brainstorming session in which as many stakeholders and perspectives or angles linked to the selected stages are mentioned.
    - Keep it rather general, name groups or organisations, not yet concrete names or people;
    - Every suggestion is written down without judgement.
- Step 3 - Check if the main perspectives/angles can be split up into sub-units/organised in types;
- Step 4 – Allocate to the stakeholders identified a concrete name (and address/contact information);
- Step 5 - Check the result:
    - Did we check all the stages of the process?
    - Do we have the ones that benefit and the victims?
    - Is the own project organisation included?
    - Did we identify the people behind umbrella organisations?
- Step 6 - Once the stakeholders are identified, the long list can be ordered by identifying the degree of involvement of each actor in each stage:
    - Write down every actor on a Post-it notepaper;
    - Draw up the “target”-scheme with circles on a flip-over chart;
    - Be clear about the stage in the process that is effectively analysed.
- Step 7 - Put the notepapers in the right place in the “target”[9] (Figure C2.2 and if refinement is desired this can be repeated for Figure C2.3);
- Step 8 - Check if there are no big gaps;
- Step 9 - Use the result! e.g. for a communication plan to notify concerned stakeholders. Be very clear with each stakeholder about his expected role and involvement in the process (management of expectations);
- Step 10 - The brainstorming session can be continued to identify relationships between stakeholders, their interests and motives and factors that influence the process.

[9] Keep in mind that the degree of influence of the stakeholders is a factor to be considered. It might be useful more closely to involve “big” actors with much influence to ensure commitment and a supporting basis.

Illustration of the stakeholder-analysis

A small case is presented for the illustration of the methodology. The subject of the case is the pollution at the downstream part of the River Scheldt. The municipalities along the river recognise the problem and want to improve the water quality, they are initiating this case. The process is described in Figure C2.4:

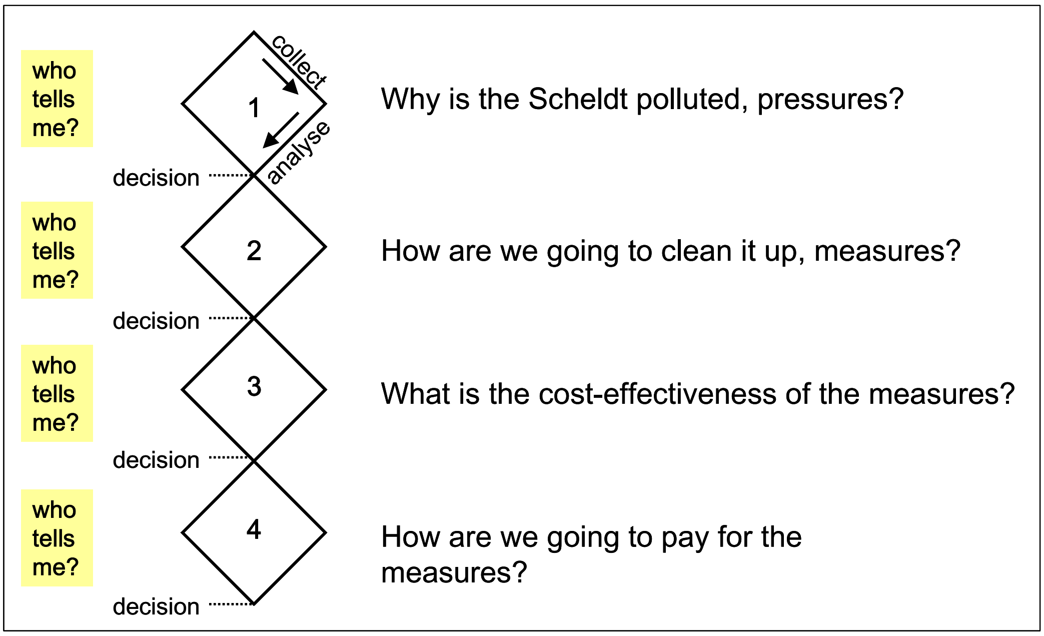

Figure C2.4: Different stages of a process concerning the pollution of the River Scheldt

Analogous to the presented methodology in the former sub-section, the possible results are presented below for the different steps of the stakeholder analysis and for the stage 1 of the process (i.e. why is the Scheldt polluted, pressures?).

- **Step 1** - Information is wanted about the pollution in the Scheldt, e.g. "Why is the Scheldt polluted?", who tells me that it is polluted?
- **Step 2** - The proposed project team will include the municipalities and they have decided to invite also representatives of the harbour of Antwerp and Vlissingen. As many different angles as possible are viewed during a brainstorming session. The output of this session is a (finite) list of stakeholders involved:

ICPS (Scheldt commission)	People in the neighbourhood
Agriculture	Harbours
Recreation	Municipalities
Dredging companies	Shipping traffic
Fisherman	Industries
Government	WWTP

- **Step 3** – More detailed discussions show that the type "Industries" can be split up into:
  - Industries with emission to the air (deposit);
  - Industries with discharge to the water.
- **Step 4** - The list is defined more precisely:

ICPS (Scheldt Commission)	**People in the neighbourhood**
Agriculture: - farmer A, B, C; - poultry farm D; - pig farm E, F.	**Harbours**: - Antwerp (B); - Ghent (B); - Terneuzen (NL); - Vlissingen (NL).
Recreation: - anglers; - canoeists; - cyclists.	**Municipalities** Antwerp, Ghent, Terneuzen, Vlissingen.
Dredging companies: - company X; - company Y.	**Shipping traffic:** EU umbrella organisation for shipping traffic.
Fisheries	**Industries:** - emissions to air: industry G; - discharge to water: industry H.
Government Belgium (Flandres, Wallonia, Brussels) The Netherlands	**WWTP** Antwerp, Ghent, Vlissingen, Terneuzen.

For all stakeholders the contact person/competent authority should be identified and the address/contact information identified.

- **Step 5** - Checking the result shows that it is unclear which shipping companies are represented by the “European umbrella organisation for shipping traffic”, as only shipping companies operating in the Scheldt area are seen as relevant. This will need further checks by the project team. It is also noticed that environmental NGO’s are missing from the list of stakeholders identified so far, and the union for the “Protection of the Scheldt landscape” is added to this list.
- **Step 6 & 7** - The degree of involvement of the stakeholders is expressed by allocating stakeholders into the target scheme (Figure C2.5). For the first stage of the process (why is the Schedlt polluted, what are pressures?), much information needs to be collected. Thus many stakeholders end up in the second circle (co-thinking) of the target scheme. Some stakeholders are known to have a great socio-economic influence and are asked to co-operate together with the project team (inner circle). The outer border of the figure show the organisations that will be informed about the project.
- **Step 8** - Check for gaps in Figure C2.5, refine it.
- **Step 9** - The results of the brainstorming session are incorporated into the project plan. Decision is taken that the harbours of Ghent and Terneuzen and Industry H, that are not yet part of the project team, will be approached for co-operation.
- **Step 10** - The brainstorming session can be continued to refine the target scheme according to Figure C2.3 and/or to map the environment. Simple questions such as: “What is the interest of Industry H?”; “What is the relationship between Municipality A or Harbour W?” will help in increasing the project teams understanding of the role and stakeholder relationships.

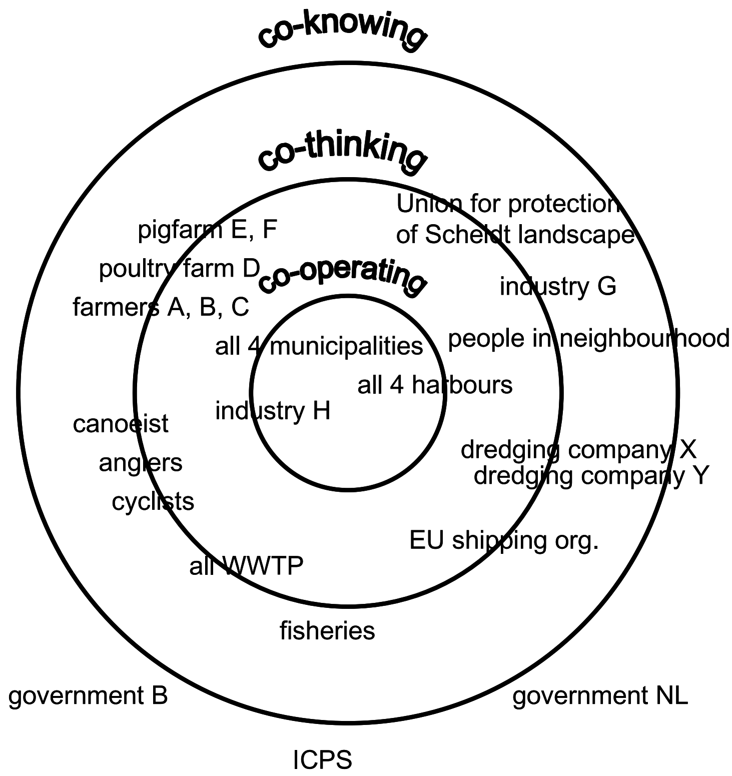

Figure C2.5: Target scheme with stakeholders who can tell about the pollution of the downstream part of the River Scheldt

ANNEX C3 Possible Reporting Tables

The tables presented below are by no means exhaustive and final. They have been developed as examples to support experts in different countries and river basins in developing their own templates. The tables do not mention the information on water uses, wastewater treatment, pollution emitted, changes in hydromorphology, changes in ecology, etc. that will come from the analysis of pressures and impacts as specified in Annex II of the Water Framework Directive. Clearly, similar tables can be draw for this biophysical information. Key is to ensure consistency and coherence (e.g. in selecting spatial scale of computation and reporting) between pressures and impacts and the economic analyses.

1. Economic analysis of water uses

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
Drinking water supply 1. Population connected to public water supply system 2. Population with self-supply 3. Number of water supply companies							
Wastewater treatment 1. Population connected to sewerage system 2. Population connected with wastewater treatment plant 3. Number of wastewater treatment companies							
Economic characteristics of key water uses 1. Agriculture ➢ Total cropped area ➢ Cropping pattern ➢ Livestock ➢ Gross production ➢ Income ➢ Total farm population 2. Industry ➢ Turn over for key sub-sectors ➢ Employment for key sub-sectors 3. Hydropower ➢ Installed power capacity ➢ Electricity production							

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
4. Navigation/transport							
➢ Number of boats through key points per year							
➢ Employment linked to navigation							
➢ Quantity and value of goods transported							
➢ Quantity and value of goods through key harbours							
➢ Employment linked to harbour activities							
5. Gravel extraction							
➢ Number of extracting companies							
➢ Total employment							
➢ Total turnover							
6. Fish farming							
➢ Number of fish farms							
➢ Total employment							
➢ Total turnover							
7. Leisure fishing							
➢ Number of person-days							
8. Boating and wind-surfing							
➢ Number of person-days							
9. Water-related tourism							
➢ Total number of tourist-day							
➢ Daily expense per tourist day							
➢ Total employment in the tourism sector							
➢ Total turnover of the tourism sector							
10. Flood control							

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
➢ Total population protected ➢ Total turn-over of protected economic activities							

2. Assessing trends and baseline scenario

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
Trends in macro-economic policies 1. Existing studies and reports on trends in agricultural policy 2. Existing studies and reports on trends in industrial policy 3. Existing studies and reports on trends in energy policy 4. Existing studies and reports on trends in transport policy 5. Existing studies and reports on trends in … policies							
Trends in exogenous variables 1. Population growth 2. Changes in economic development (DGP change) 3. Changes in water pricing policies 4. Technological changes ➢ Households water use ➢ Agriculture and irrigation ➢ Industry 5. Climate change 6. …							
Planned policies and investments 1. Proposed investments in water supply and wastewater treatment							

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
2. Proposed investment in pollution reduction programmes for agriculture							
3. Proposed investments in flood protection							
4. Proposed investments in wetland restoration							
5. Proposed investments in improved technology							
6. Proposed investment in water supply enhancement							
7. Other programmes and measures							
8. …							

3. Assessing cost-recovery (for each water service considered)

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
Prices for water services 1. Current water price ➢ Price level ➢ Price structure 2. Subsidies ➢ Government/regional authorities ➢ Cross-sectors							
Financial costs of water services 1. Capital costs ➢ Historical ➢ Replacement value 2. Operation and maintenance 3. Administrative costs							
Environmental costs 1. Internalised costs through charges/taxes 2. Direct assessment ➢ Changes in environmental quality ➢ Economic value/willingness to pay 3. Costs of preventive and mitigation measures ➢ Implemented ➢ Required for restoring good water status							

4. Basic economic information and indicators

Key variable	Source of data	Date	Spatial scale, lowest disaggregation level	Quality of data (good, medium, poor)	Availability of data	Cost	Comments
1. Discount rate							
2. …							

Reporting the economic elements of the characterisation of river basins – example of an executive summary

The format of the executive summary presented below is by no means exhaustive and final. It has been developed as an illustration to support experts in different countries and river basins in developing their own reporting templates and reports. The format and tables do not mention the indicators on water uses, wastewater treatment, pollution emitted, changes in hydromorphology, changes in ecology, etc. that will be computed as a result of the analysis of pressures and impacts as specified in Annex II of the Water Framework Directive. Clearly, similar tables or maps can be draw for this biophysical information. Key is to ensure consistency and coherence (e.g. in selecting spatial scale of computation and reporting) between reporting on pressures and impacts and the economic analyses.

Annex D – Methodological Tools for Undertaking the Economic Analysis

ANNEX D1 Information sheets

INTRODUCTION

This Annex contains a series of information sheets providing methodological Guidance for implementing the 3-step approach presented in the main part of this document. It is structured as follows:

- ***Scale issues***: This information sheet helps you understand at which geographical level you should carry out the economic analysis and report the results;
- ***Estimating costs (and benefits):*** This information sheet helps you understand how to estimate costs and benefits, which are seen as avoided costs;
- ***Reporting on cost recovery:*** This information sheet helps you understand what and how you should report on the recovery of costs of water services;
- ***Baseline scenario:*** This information sheet will help you develop one or several alternative baseline scenarios (or "business-as-usual" (BAU) scenarios). It proposes an optional approach to complement the forecasting analysis (to define the BAU scenarios) with prospective analysis;
- ***Cost-effectiveness analysis:*** This information sheet will help you carry out a Cost-effectiveness Analysis (CEA). The CEA is used for assessing the cost-effectiveness of potential measures for achieving the environmental objectives set out by the Directive and construct a cost-effective Programme of Measures;
- ***Pricing as an economic instrument:*** This information sheet helps you assess the effectiveness of pricing as a measure to achieve the environmental objectives of the Directive;
- ***Disproportionate costs:*** This information sheet will help you assess whether the costs of the Programme of Measures are disproportionate and whether derogation from the Directive's objectives could be justified following an assessment of costs and benefits.

SCALE ISSUES

Directive references: No specific reference in the Directive but many implicit references and key issues for making the economic analysis operational. This sheet underlies the overall (3-step) approach to the analysis.

This information sheet helps you understand at which geographical level you should carry out the economic analysis and report the results.

1. Objective

Scale issues are central to the development of integrated river basin management plans. They are key to the integration between different disciplines and expertise and to the development of activities aimed at informing, consulting and ensuring active participation of stakeholders and collecting information.

For the economic analysis, it is important to understand the level of efforts required in conducting the economic analysis in terms of:

- The type of information to be collected;
- The spatial and temporal scale at which the information needs to be collected (coverage);
- The type and the level of disaggregation of the analysis that should (or can) be performed.

Although mostly mentioned in the context of large river basins, identifying the ‘right’ scale for the analysis is relevant to all river basins.

2. What spatial scales and levels of disaggregation are mentioned in the Directive?

The Directive mentions a wide range of spatial or aggregation units (see *Table 1*). Overall, the Directive promotes the **river basin** as the basic hydrological system for characterising, analysing, defining and implementing programmes of measures. In some cases, however:

- Several river basins can be aggregated into **river basin districts** that are the basis for compliance checking and reporting by Member States. River basin districts combine hydrological and practical/administrative considerations (e.g. combining several small but similar river basins to limit planning and administrative burden). Hydrological considerations may be strengthened if river basins of a given district are inter-connected through water transfers;
- Large river basins can be sub-divided into smaller **sub-basins** to facilitate the process of developing management plans or when different countries share a river basin district that is then disaggregated into national sub-basins.

Table 1 – What does the Directive specify about data collection and analysis?

Building block	When is it a reference?
Hydrological/Ecological	
Water Body	➢ Characterisation of water status (*Annex II*); ➢ Further characterisation for those bodies at risk of failing environmental objectives (*Annex II*); ➢ Determination of environmental objectives (based on cost and benefit assessment) if derogation (*Article 4*); ➢ Justification of deadlines extension (*Article 4*).
Group of water bodies (grouping based on bio-physical & ecological criteria)	➢ Initial characterisation of River Basins (*Annex II*); ➢ Possible detailed programmes and management plans for water types (*Article 13.5).*
Protected Areas	➢ Designation of protected areas (*Article 6, Annex IV*).
River Basin	➢ Characterising, analysing, defining and implementing programmes of measures; ➢ Carrying out cost-effectiveness analysis (*Annex III*) for the identification of the programme of measures (*Article 11*).
River Basin District	➢ Carrying out and reporting economic analysis (*Article 5 and Annex III*); ➢ Evaluating pricing policies (*Article 9 and Annex III*).
Sub-basin	➢ Developing management plans (e.g. for national parts of international river basins, see below and *Article 13*).
Socio-Economic	
Water services	➢ Assessment of cost-recovery for water services (*Article 9*).
Economic sector	➢ Estimate the contribution to cost recovery by key water uses: household, industry and agriculture (*Article 9*); ➢ Possible detailed programmes and management plans for economic sectors (*Article 13.5).*
Water uses	➢ Economic analysis of water uses (*Article 5*); ➢ Adequate contribution of water uses to the costs of water services (*Article 9*).
Administrative	
State/Regional	➢ All activities linked to implementation (Member State's responsibility, e.g. reporting obligations); ➢ Plans for national portion of international river basins.
European	➢ Various reporting obligations from the Commission at the EU scale (*Article 18*); ➢ Cost-benefit assessment of the Directive at the EU scale (Commission's statement added to the Directive's text at the time of adoption).

3. At what scale should the economic analysis of water uses be conducted?

Reporting on the economic analysis of water uses (both the description of the existing situation and the analysis of the trends/baseline in key indicators and variables) has to be made at the river basin district scale (disaggregated into national portions of transboundary river basins whenever required).

However, lower spatial scales may be investigated according to:

- ➢ The scale at which **significant pressures and water uses** take place (e.g. a sub-region of the river basin or a specific sub-economic sector);

- The **decision making** scale, e.g. at which scales and for which decisions is the analysis used. For example, if some measures are applied at specific disaggregated scales (e.g. a specific watershed or a given economic sector), providing information on the economic importance of water uses at that scales may be appropriate; and
- The scale required for **information, consultation and participation**. It is important to ensure key indicators are computed at scales that are relevant to consultation and participation. Such scales are likely to be lower (e.g. a watershed or specific economic sector) than the river basin or river basin district.

Illustrations 1 to 3 of this information sheet (see below) provide some lessons on the definition of the adequate scale for analysis from testing and scoping exercises conducted during the preparation of this Guidance.

Illustration 1 – Defining the adequate scale of analysis by combining biophysical and economic information in the Scheldt river basin in Lille (France)

The WFD quantitative objective for groundwater is to balance abstraction and recharge. For the chalk aquifer around Lille, the relevant level of disaggregation for the economic analysis corresponds to a set of groundwater units for which:

- The recharge can be assessed for each individual unit;
- One abstraction is located in only one unit (no abstraction on boundaries);
- Abstractions in one unit have no (or limited) effect on the piezometry in other units.

If all these conditions are met, the physical system can be considered as a pool and economic information can be gathered for abstractions from this pool. With respect to pressures, it is important to consider both abstractions registered by national offices or water agencies and self-service abstractions. The second type of information will be more difficult to collect as it is rarely collected by water service operators or public agencies in charge of monitoring water services.

Source: G. Bouleau & A. Courtecuisse, Testing the WFD Guidance Document on groundwaters in the area of Lille. See Annex E.

Illustration 2 – Identifying coherent areas in the Rhône-Méditerranée-Corse basin (France)

A testing exercise in the Rhône-Méditerranée-Corse river basin in the South of France highlighted that defining the appropriate scale for the economic analysis has to take into account a variety of criteria:

- Economic activities (agriculture, industries, tourism);
- Hydrographic components;
- Social and land uses aspects;
- Availability of different data required.

As a result, the relevant scale for the socio-economic analysis, especially for large and heterogeneous river basins, is somewhere between the water body and the river basin levels. To subdivide the basin into coherent socio-economic areas, it was proposed to gather socio-economic, planning and land use information and adapt it from existing scales of analysis, such as hydrographic or administrative ones, to scales that meet the needs of the Water Framework Directive. One of the main interests of this approach is to integrate land planning and economic considerations into the analysis to facilitate information, consultation and participation of the public and stakeholders.

Source: P. Dupont & O. Gorin, Testing a pertinent scale for the economic analysis in the Rhône-Méditterrannée-Cors river basin. See Annex E.

Illustration 3 – Matching biophysical and economic information with administrative boundaries in the Vouga River Basin (Portugal)

The monitoring network in the Vouga River Basin in Portugal is not complete today for complying with the requirements of the Water Framework Directive. Thus, although it is possible to identify the existence of water quality problems and associated main pressures, the establishment of a clear link between pressures/discharges and water quality problems is not possible in most cases. The location of main polluting sources is known, but discharges are not fully characterized, and cause-effect relationships cannot be fully established. There is a need for the development and calibration of water quality models allowing for the establishment of such link, in the absence of a comprehensive monitoring network. This link is essential for the economic analysis, particularly for the cost effectiveness analysis of programmes of measures.

Different elements of economic information in Portugal are currently disaggregated into different administrative boundaries. At best, the scale is municipal, and in some cases it is regional (there are five regions in the mainland, which cut across river basins). Since regional and municipal boundaries do not coincide with river basin boundaries, the compatibility of scales is a relevant issue. As it is unlikely that all economic information will become available at a scale smaller than the municipal level, consistent criteria must be developed to partition municipal values between river basins (possibly using available GIS information to pinpoint clusters of users).

Source: P. Mendes. Scoping key elements of the economic analysis in the Vouga River Basin. See Annex E.

4. At which scale should we undertake the cost-effectiveness analysis?

From an economic point of view, and to account for the inter-connection between all water bodies of a given river basin, cost-effectiveness analysis is best performed at the scale of the **river basin**. But to undertake the analysis at lower scales is likely to be more manageable in cases of large numbers of water bodies, pressures and environmental problems within the river basin.

Identifying the scale at which environmental problems take place

The analysis of the pressures and impacts, along with the identification of significant water management issues, shows that specific scales can be attached to various environmental problems:

- Some pressures have an impact throughout the river basin, e.g. controlling flows in an upstream portion of a river basin will impact portions of downstream flows, while putting a dam downstream may stop migration of fish and thus impact the entire river’s ecology;
- Some pressures have a local impact, e.g. abstraction into a confined aquifer, or polluted discharge into a river that will then be naturally diluted; and
- Diffuse pressures often need to be accounted for at the river basin scale, as it is the addition of all pressures taking place within the river basin that is to be investigated.

Cost-effectiveness analysis should be performed at the scale at which environmental issues take place to ensure that the costs (especially other direct economic costs) and effectiveness of measures are fully accounted for in the analysis. In many river basins a range of environmental issues attached to different scales are likely be considered.

One pragmatic way to ensure some coherence between these analyses would be:

- **Step 1 -** To assess the scale at which environmental issues take place and classify these issues accordingly (from largest to lowest scale). This assessment is directly based on the analysis of pressures and impacts;
- **Step 2** – To undertake the cost-effectiveness analysis for the environmental issue that takes place at the river basin or largest scale considered, and select measures for solving this issue;
- **Step 3** – To assess the impact of these measures on other environmental issues, as it is likely that measures will impact on several issues. Identify the remaining environmental issues to be solved;
- **Step 4** – To undertake the cost-effectiveness analysis for the environmental issue that takes place at the next largest scale;
- The analysis continues as long as significant environmental issues remain. At the end of the process, add all the costs of the measures targeted to different environmental issues.

In some cases, cost-effectiveness analyses will be developed simultaneously for different environmental issues. It will be important then to ensure co-ordination and constant feedback between the different analyses undertaken.

Dealing with different sub-basins of the same river basin

For large river basins, sub-river basins may be proposed for undertaking the economic analysis. It is then recommended to adopt a stepped approach that follows the hydrological cycle/structure to ensure separate measures that are cost-effective for each sub-basin are also cost-effective at the river basin scale. A pragmatic approach is given below for a situation where pressures have a downstream impact on (surface) water status:

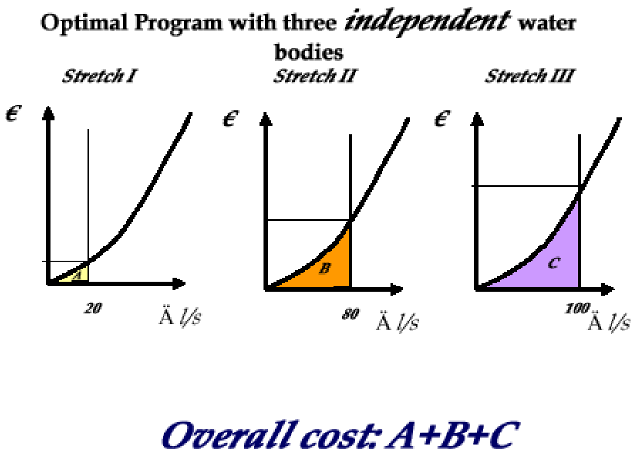
- **Step 1** – Start the analysis with the most upstream sub-basin. Identify cost-effective measures for this sub-basin along with their total costs and their impact on the status of water bodies;
- **Step 2** – Assess the impact (if any) of these measures on the status of water bodies of the next downstream sub-basin; and
- **Step 3 -** If the predicted water status for the downstream sub-basin is below good water status for some/all water bodies, cost effectiveness analysis is then performed at the scale of this downstream sub-basin to identify new measures, their impact, their costs.

The analysis continues then with these steps being systematically applied for all sub-basins while moving down to the most downstream sub-river basin. Clearly, there is a need to ensure the analysis moves regularly between different scales, i.e. the sub-basin, the basin, the country or group of countries, so measures that are relevant to different scales can be adequately considered and analysed (e.g. assessing the potential role of a tax on pollution discharges may require a direct analysis for all river basins of a given country if taxes are driven by national policies), as shown in *Illustration 4*. One may first investigate measures that apply at large scales to all sub-basins, and then move to measures that apply at lower scales and that can adjust/refine the broader effects of the large-scale measures. It may also be practical to develop separate cost-effectiveness analyses for individual environmental issues.

Illustration 4 – Cidacos (Spain): Investigating river basins and sub-basins

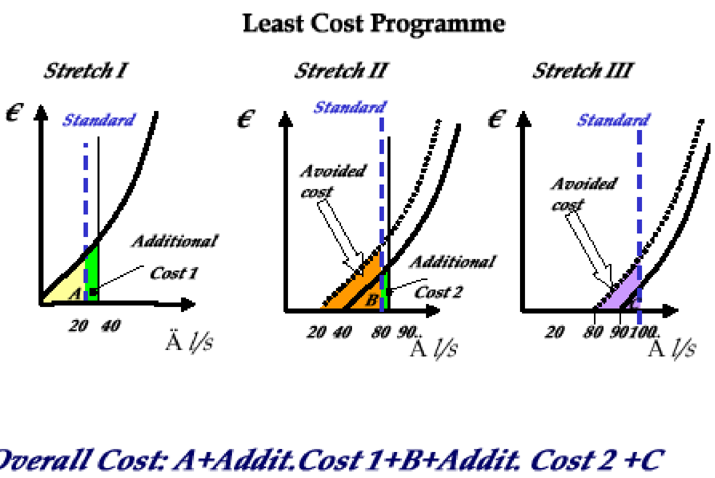
The Cidacos River is 44 km long, and drains a catchment of 500 km^2. Except for its initial part, the river runs through a plain, which is mainly agricultural (225 km^2). Animal farming is associated to farming with a total of 86 production facilities. Agricultural production is supplied with surface water and groundwater. The basin has 14 small population centres, with two small cities (Olite and Tafalla) and 17,000 domestic users. These are served by water from a small dam in the first stretch of the river, and also from two springs and some wells. These have water quality problems, from hard water and nitrates. The main industries are located in Olite and Tafalla, and industrial permits for water have been denied due to a shortage of good quality water supply.

The Cidacos scoping study distinguished between three water sub-basins or reaches: upstream, downstream and a middle stretch. In order to achieve good ecological quality (GEQ) an improvement to the water flow was considered, increasing flows by 20, 80 and 100 litres per second in the upper, middle and lower sub-basins respectively. The total costs of achieving the objective for each sub-basin *independently* can be obtained simply by aggregating the costs of the measures for the three areas (areas A, B and C in the diagram), i.e. the programme would cost € 1.2 million in total.



However, because the three sub-basins are connected, the cost of obtaining the GEQ in stretch II depends on the quantity of water it receives from the upstream basin (stretch I) and the cost of GEQ in the downstream basin (stretch III) depends on the ecological status of both stretches I and II. Therefore, the least cost programme of measures must take into account the externalities involved in the simultaneous improvement of the three interconnected sub-basins, as shown in the diagram below.

By improving the water flow above the minimum standard, it was shown that the marginal cost of achieving the required increase in the water flow in the middle and downstream sub-basins could be avoided. The (avoided) costs of the measures that would have been needed for stretches II and III were shown to be higher than the cost of increasing the water flow in stretch I. In Cidacos, the overall cost of the action plan obtained this way would be €0.56 million (or less than 50 per cent of the total cost of treating the three water bodies as independent).



Consequently, when considering the scale of the analysis the river basin as a whole must be used. The analysis cannot be done independently for each sub-basin, as it would exclude any shared benefits and costs of the programme of measures.

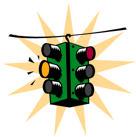
Source: Ministerio de Medio Ambiente, Gobierno de Navarra, 'Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River'. See Annex E.

5. Which basic units should be considered in the cost-effectiveness analysis?

The cost-effectiveness analysis will not be able to deal with all measures targeted to individual users and related environmental impact. Thus, a certain level of aggregation is required for the analysis to remain pragmatic, and also to account for the scale at which some measures apply.

However, one cannot aggregate all information and analysis at the river basin scale as it eliminates the hydrological structure of the river basin and the links between uses, pressures, and water status of specific water bodies. Assessing the basic unit that should be investigated into the cost-effectiveness analysis requires considering:

- The scale of water bodies themselves;
- The scale at which pressures and impacts take place (which areas need to be targeted by measures so as to restore good water status); and
- The scale at which measures will be implemented/will take place (see point below).



Look out!

Some measures for improving water status have an inherent scale of application/implementation that need to be considered for the cost-effectiveness analysis (e.g. environmental taxes are often national-based instruments). In other cases, the analysis of existing uses, pressures and impacts will lead to the identification of smaller geographical areas (e.g. a given watershed within a river basin), sub-sectors (e.g. a given chemical sector) or sub-uses (e.g. large users of water with swimming pools) that will be targeted by measures (e.g. the restoration of a specific wetland, or a change in water pricing for a specific urban area or irrigation scheme).

6. At which scale should we assess cost-recovery?

Assessing spatial relevance *vis-a-vis* cost recovery appears rather straightforward:

- Information on pollution, uses, financial costs and existing prices are usually collected for water service (or combined water service) areas. This information needs then to be aggregated at the river basin scale that appears as adequate for discussing overall financial flows and recovery issues;
- Environmental and resource costs may relate to the sub-basin or entire river basin (e.g. if a pollution created in the upstream part of a river basin has negative impact in the estuary of the same river). Assessing these costs requires a good assessment of the scale at which environmental impact of existing water services and uses take place. Costs can then be computed for each water service at the scale of the river basin; and
- The assessment of the relative contribution to these costs of key water uses combines both water uses and related services aimed at removing environmental damages caused by these uses. The Water Framework Directive requests a minimum disaggregation into agriculture, households and industry. According to local circumstances and key water uses identified in the analysis of pressures and impacts, this disaggregation may be further refined.

7. At which scale should reporting of information be carried out?

Different aspects need to be considered here:

- Firstly, it is important to identify the geographical scale at which relevant information and expertise is available. The scale at which information is available today is likely to lead to the use of proxies, (statistical) extrapolation or interpolation techniques to obtain robust estimates of key variables at the desired scale. It will be important to ensure assumptions and approximation are made transparent and reported along with results of the analysis;
- Secondly, the scale at which information and results are to be reported for effective information and consultation of the public; and
- Thirdly, the scale for reporting to the EU: in such case, the coverage is clearly the river basin district, with the analysis being presented for key spatial and socio-economic/water uses aggregates.

In addition to the River Basin Management Plans developed for each district, Member States may produce more detailed plans for specific sectors, issues or water types (*Article 13*), providing ample opportunities to focus on specific aggregation levels lower than the river basin. Such detailed plans may be identified in the context of consultation and participation of interested parties or directly result from the analysis of pressures, impacts and significant water management issues.

8. A checklist for a summary

Table 2 summarises spatial and disaggregation scales that can be investigated at the different steps of the economic analysis.

Table 2 - Checklist

Steps	Analysis	Reporting
Characterisation of the river basin	➢ **Economic analysis of water uses** 1. Assessment at the scale of significant water uses as identified by Annex II => assess economic indicators at the same scale 2. Possible further disaggregation if very high socio-economic variability for given uses that are likely to lead to choosing different measures/having different impacts on proposed measures ➢ **Trend analysis and baseline development** 1. Assessment of trends in key drivers/variables at a scale consistent with the economic analysis of water uses ➢ **Assessment of cost-recovery** 1. Identify the scale at which water services (or combined services) take place => assessment of cost-recovery at that scale 2. Identify uses that are damaging the environment and cause specific water services to other uses => compare their relative participation to the recovery of the costs of water services at the scale of the water use/services linked to damage caused by water uses	➢ **Economic analysis of water uses** 1. Reporting at the river basin scale 2. Possible reporting for specific water uses ➢ **Trend analysis and baseline development** 1. Reporting at the river basin scale 2. Possible reporting for specific water uses ➢ **Assessment of cost-recovery** 1. Assessment of cost-recovery at the river basin district scale or for national portion of transboundary river basins 2. Assessment of the contribution of water uses to the costs of these services at the river basin scale
Assessing the gap/risk of non-compliance	➢ **Costs of basic measures** 1. Assess total costs of basic measures at the river basin scale ➢ **Likely costs and qualitative impact of potential measures** 1. Assess tentative costs per type of measures considered 2. Assess the impact of potential measures at the scale of the likely-affected water use(s)	➢ **Costs of basic measures** 1. Total costs of basic measures at the river basin scale ➢ **Likely costs and qualitative impact of potential measures** 1. Tentative costs per type of measures 2. Impact of potential measures at the scale of the likely-affected water use
Undertaking the cost-effectiveness analysis	➢ **Costs of measures** 1. For each individual measure proposed – assess costs at the spatial or disaggregation scale at which the measure will apply ➢ **Effectiveness of measures** 1. Assess the effectiveness of measures at the scale at which the concerned environmental issues take place – this depends on the pressures and impacts concerned and the type of measure considered (at which scale is the measure applied, and which part of pressures will be affected) => compute one effectiveness indicator for each measure ➢ **Cost-effectiveness analysis** 1. Cost-effectiveness analysis undertaken at the river basin scale => identify cost-effective programme and total costs 2. If cost-effectiveness undertaken separately for different environmental issues and sub-basins, ensure a logical step-wise approach (from upstream to downstream, from general environmental issues to local environmental issues) and constant feedback loops between analyses 3. Further levels of disaggregation are possible in the analysis linked to the assessment of significant water uses and the potential measures investigated	➢ **Costs of measures** 1. For each individual measure proposed – linked to the spatial or disaggregation scale at which the measure will apply ➢ **Effectiveness of measures** 1. Effectiveness for each measure ➢ **Cost-effectiveness analysis** 1. Chosen measures and total costs of cost-effective programme reported at the river basin scale 2. If cost-effectiveness undertaken separately for environmental issues and sub-basins, report on the results (chosen measures, costs) of each individual analyses and assess qualitatively possible inter-relations between different analyses 3. Possible level of disaggregation linked to the assessment of significant water uses and potential measures investigated

ESTIMATING COSTS (AND BENEFITS)

Directive references: *Articles 4, 5* and *9* and *Annex III*
3-Step Approach: this information sheet underlies all key steps of the approach
See other information sheets: *Reporting on Cost Recovery, Cost-effectiveness Analysis* and *Disproportionate Costs*

This information sheet helps you understand how to estimate costs and benefits, which are seen as avoided costs.

1. When to Estimate Costs?

Estimating costs is important for several parts of the economic analysis:

- Taking into account the principle of **recovery of costs** of water services, including environmental and resource costs, in order to ensure that an adequate contribution to the recovery of the costs of water services is made by the different water uses, disaggregated into at least industry, households and agriculture (*Article 9, Annex III*);
- Conducting a **cost-effectiveness analysis** of alternative policy measures or projects (*Article 5, Annex III*);
- Assessing the costs of alternative options in the **designation of heavily modified water bodies** (*Article 4*);
- Assessing the need for a derogation based on an economic appraisal of disproportionate costs (such as for the setting of **less stringent objectives or time derogation** – *Article 4*).

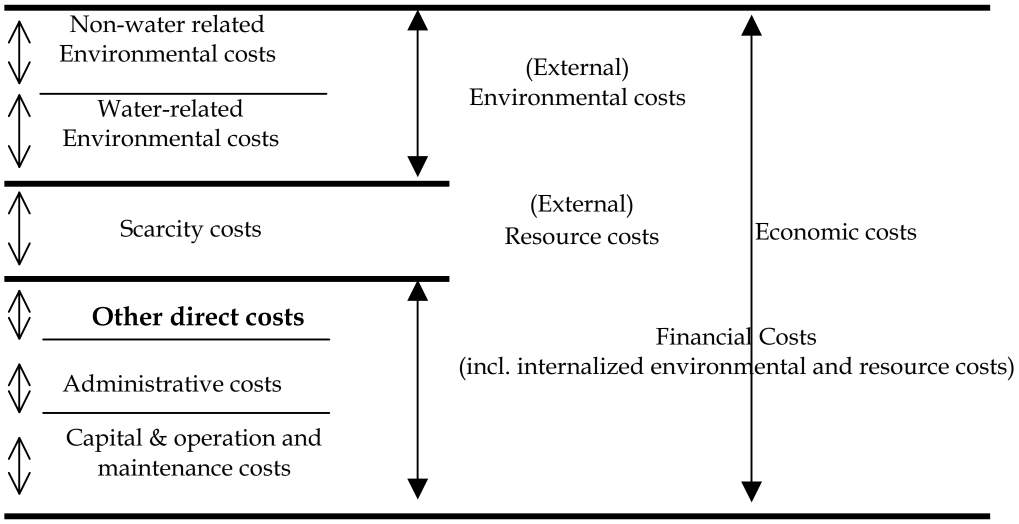
Note that the Directive defines costs as *economic costs*, which are the costs to society as a whole, as opposed to *financial costs*, which are the costs to particular economic agents. In the Directive (*Article 9*), economic costs are made up of three components (see also *Box 1*): financial costs, resource costs and environmental costs. This information sheet helps you analyse and estimate all of these cost categories.

2. Moving from Financial to Economic Costs

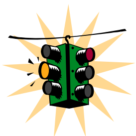
The Table below proposes an approach for moving from financial to economic costs.

Steps	Rationale
1. Estimate financial costs	Financial information is often more readily available than estimates of economic costs: as a result, they form a good basis for the analysis.
2. Make transfers (such as taxes and subsidies) explicit	Taxes only represent a transfer from society's point of view and should therefore be excluded from the economic analysis. However, environmentally related taxes might represent internalised environmental costs and should be accounted for as such.
3. In case of distorted markets and scarce resources: replace market prices by opportunity (or resource) costs	Because of distorted markets, market prices may not reflect the opportunity cost of the resource used, and therefore the benefits that could be achieved if the resource was assigned to its best available alternative use.
4. Include all non-priced environmental costs	For non-priced resources (and this is often the case for environmental resources), no price is paid as there is no market. To account for the total effect on welfare, these costs must be estimated and included.

Box 1 – What are the different types of costs mentioned in the Directive?



Source: Rogers *et al.* (1997)

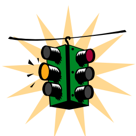


Look out! Treatment of indirect and induced costs

Direct costs (made up of mainly financial costs and administrative costs) are included in all components of the economic assessment for the purposes of the Directive. The treatment of indirect and induced costs is likely to vary according to the step of the economic assessment:

- *Indirect costs* are the economic costs for other sectors likely to result from the change in water status, such as a loss in productivity…;
- *Induced costs* are the costs resulting from second-order effects, such as the reduction in employment in the service sectors in rural areas resulting from a loss in employment in the agricultural sector due to water degradation.

Indirect costs may be considered when carrying out the cost-effectiveness analysis, but induced costs would only be taken into account (if possible) at the stage of the cost and benefit assessment for justifying derogation.



Look out! Focus on net costs

When estimating economic costs, you should focus on the *net costs*, including any savings or financial benefits, also known as 'negative costs'. An example of negative costs is income earned from selling sludge (fertiliser), which arises as a by-product of wastewater treatment. Since this activity brings in revenues, it should be subtracted from the costs of wastewater treatment.

Step 1 - Estimating Financial Costs

Financial costs in this context are the costs of providing and administering water services. They can be broken down in a number of cost elements, presented below. The Table gives the definition of each cost element and warns you about potential traps and difficulties.

Cost element	Definition	Look out!
Operating costs	All costs incurred to keep an environmental facility running (e.g. material and staff costs).	***When projecting operating costs, make sure to take into account additional costs linked to new capital investments.***
Maintenance costs	Costs for maintaining existing (or new) assets in good functioning order till the end of their useful life.	***As many water and wastewater assets are long-lived and buried under ground, it will be difficult to estimate the appropriate level of maintenance needed for exploiting the assets without leading to their deterioration.***
Capital costs: ➢ ***New investments***	Cost of new investment expenditures and associated costs (e.g. site preparation costs, start-up costs, legal fees).	➢ ***Associated costs can be substantial. In the absence of data, it is better to try and estimate them rather than neglect them;*** ➢ ***For projections, costs of new capital costs should be spread over a number of years. For this, the Annual Equivalent Cost Method is recommended*** *(see Box 2 and Illustration 1)*
➢ ***Depreciation***	The depreciation allowance represents an annualised cost of replacing existing assets in future. Estimating depreciation requires defining the value of existing assets and a depreciation methodology.	➢ ***Several methods can be used to estimate the value of existing assets, mainly the historical value, the current value and the replacement value methods*** *(see Box 3);* ➢ ***Applying existing accounting rules for calculating depreciation may not necessarily lead to the estimation of "economic" depreciation – they may need to be adjusted to reflect economic reality, i.e. that the value of assets declines faster towards the end of their life.***
➢ ***Cost of capital***	It is the opportunity cost of capital, i.e. an estimate of the rate of return that can be earned on alternative investments. The cost of capital applied to the asset base (new and existing) gives you the returns that investors are expecting to earn on their investments.	➢ ***The expected rate of return is likely to be different for public and private investors but no capital is ever "free", as there are always alternative investments;*** ➢ ***Estimating the cost of capital is likely to be difficult and contentious, as it depends on the return of alternative investments;*** ➢ ***Capital subsidies provided to private investors will need to be taken into account when calculating the amount of returns that they are allowed to earn.***
Administrative costs	Administrative costs related to water resource management.	➢ ***Examples include: costs of administering a charging system or monitoring costs.***
Other direct costs	This mainly consists of the costs of productivity losses dues to restrictive measures.	➢ ***Example: loss of agricultural production resulting from the creation of a retention area;*** ➢ ***Question: over which horizon should these costs be accounted for?***

Box 2 - The Annual Equivalent Cost (AEC) method

The Annual Equivalent Cost (AEC) method allows you to convert the Net Present Value (NPV) of a new capital expenditure into an annuity (or rental) which has the same value. This can be done as follows:

1. List all capital expenditures and when they are incurred;
2. Calculate the net present value of expenditures, using the chosen discount rate;
3. Convert this net present value into an "annual equivalent cost" (AEC) based on:

$$AEC = \frac{NPV * DiscountRate}{(1-(1+DiscountRate)^{-lifetime})}$$

AEC = annual equivalent cost
NPV = net present value of investment
Discount rate = chosen discount rate (the same as used to calculate the NPV)
Lifetime = lifetime of the capital equipment

Box 3 - Valuation of capital assets: Current vs. replacement value

Depending on the accounting system in use, it is possible to use various types of valuation methods for existing capital assets:

- The **historical value** is the value of the assets at the price they were originally purchased. Because of inflation, this value often bears no relation with what it would actually cost today to replace those assets – therefore, it is not the best measure for estimating economic costs;

- The **current value** is the historical value multiplied by an inflation index. Calculating this value raises a number of issues: 1. Estimating the inflation index may be open to interpretation (should the general inflation index or the construction (consumer?) price index be used?); 2. This method does not take account of technical progress: a water treatment plant that cost a given amount 10 years ago might cost half today thanks to technical progress. However, this method is relatively easy to apply and is more appropriate than the first one;

- The **replacement value** method estimates the present value of an asset from the current cost of replacing it for an identical service level. The advantage of this method is that it allows taking into account technical progress. However, it might be difficult, costly and time-consuming to apply to all the capital stock. In addition, the water sector being relatively less dynamic than, say, the telecommunications sector, the current value method may be sufficient for the purposes of estimating economic costs.

Illustration 1 - Deriving financial costs for the appraisal of measures in the Cidacos river basin

Cidacos is located in the region of Navarra, in Northern Spain, and is a tributary to the Aragon River. When conducting an economic analysis, deriving financial costs was necessary to determine the costs and benefits of achieving different objectives for water status (good vs. moderate), measures such as demand management, increased efficiency and water imports were considered.

The study calculated the annual equivalent costs (AEC) of each measure considered, assuming a discount rate of 2% and a time horizon of 30 years. This assumes that the costs of measures having a lifetime of more than 30 years have a lower effect on the AEC. The costs considered for the AEC calculation for each measure include:

- Investments costs
- Operation and Maintenance (O&M) costs
- Economic opportunity costs or benefits (when available)
- Environmental costs:
  - External avoided costs of measures (when available).
  - Other environmental benefits associated to the measure (apart from those deriving from the achievement of WFD objectives).

To derive financial costs, capital and O&M costs were expressed in relation to a physical measure, such as per Sq Km, per Ha, per Litre and per m3. This provided a uniform scale through which different costs and measures could be analysed and compared effectively. An issue that emerged in this exercise was the increasing marginal costs of some measures relative to others over time. As the cost analysis progressed, the increasing marginal costs of some measures emerged, through expanded service coverage or possible marginal efficiency gains, such as those aimed at improving efficiency in water use; or with the constant costs of other measures (e.g., water transfers). This point has important implications for ranking measures and choosing a cost-effective combination of measures. It should also be noted that the cost-effectiveness of a measure is not constant over time in some cases. Some measures have increasing marginal costs as technical efficiency improves (as we reach the maximum potential of the measure). This is relevant since assuming constant costs may lead to an inefficient programme of measures.

Source: Ministerio de Medio Ambiente, Gobierno de Navarra, 'Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River'. *See Annex E.*

Step 2 - Making Transfers Explicit

As mentioned above, taxes and subsidies should usually be treated as transfers within society and should therefore be excluded from the estimation of economic costs. However, it is important to distinguish between general taxes and environmental taxes and subsidies:

- General taxes need to be deducted from financial costs;
- Environmental taxes and subsidies may represent internalised environmental costs and, as such, should not be deducted from financial costs.

Step 3 - Taking Account of Resource Costs

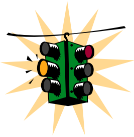
Resource costs represent the costs of foregone opportunities that other uses suffer due to the depletion of the resource beyond its natural rate of recharge or recovery (e.g. costs related to groundwater over-abstraction). These users can be either those of today, or those of tomorrow, who will also suffer if water resources are depleted in the future.

If markets function well, the opportunity costs of resources are reflected in the financial costs of resources. However, for environmental resources, these costs are often not included in market prices. Opportunity costs, the scarcity value of under-priced environmental resources like water, should therefore be included when estimating economic costs (see *Box 4*).

Step 4 - Including All Non-priced Environmental Costs

Environmental costs represent the costs of damage that water uses impose on the environment and ecosystems and those who use the environment (for example, a reduction in the ecological quality of aquatic ecosystems or the salinisation and degradation of productive soils). This loss in welfare may encompass lost production or consumption opportunities as well as non-use values (such as the value produced by contemplating a clean lake at dusk), which are harder to quantify. Environmental costs are not commonly estimated – steps and alternative methodologies for carrying out this estimation are therefore highlighted below.

In addition, as environmental costs can be seen as negative benefits and avoided costs (see *Illustration 2*), the following Section also discusses the estimation of environmental benefits, which will be useful for the cost and benefit assessment necessary to justifying derogation (see Information Sheet - *Disproportionate Costs*).



Look out! Before estimating environmental costs, it is necessary to know the environmental impacts of the measures used to reach the objectives.

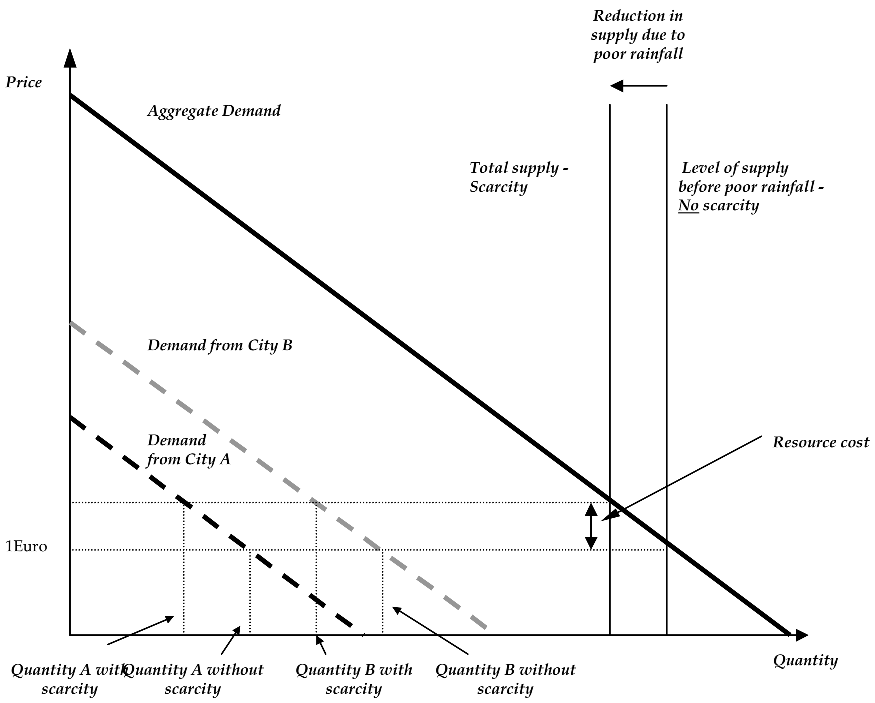
This information will be available from the work carried out by other technical experts (such as experts investigating impacts and pressures - see *Annex A* for contact details) – and environmental modelling might be required. When looking at environmental impacts, it is important to realise that measures taken to reach the objectives in one area will potentially have impacts downstream or on other parts of a river basin. In other words, linkages within a river basin district must be fully understood. Only once the magnitude of change in environmental quality has been measured, is it possible to link it to unitary costs and benefits estimated through different techniques or with the assessment of measures that would be required to prevent and mitigate etc.

Box 4 - Calculating resource costs

There are no well-established methods for estimating resource costs, although some attempts have been made at estimating them. As resource costs are seldom incorporated into market prices, it will be necessarily to rely on estimates of foregone demands and economic values.

The following example illustrates potential methods that would need to be developed:

- Two users (City A and City B) are competing for the use of the same water. It is possible to estimate the demand curve for each of them;
- If there is sufficient water available to satisfy both demands, there is no scarcity and the resource cost of water is zero;
- Suppose that due to poor rainfall in a given season, there is only a limited amount of water available (supply with scarcity). Due to this scarcity, there will be a resource cost, which can be calculated by finding the price for which total demand is exactly to the supply with scarcity. The difference between that price and the normal price is the resource cost, as shown in the Figure below.



What are environmental costs and benefits?

Society derives benefits (or costs, which are foregone benefits) from improved environmental quality in water bodies, which would arise from achieving the environmental objectives contained in the Directive. This value is made up of both 'use' and 'non-use' values (see *Box 5* for examples and below for an explanation). Other and broader benefits may need to be assessed in some instances, such as an assessment of the broader economic benefits for example, for conducting the required analysis for proposed new modifications. These are not explicitly dealt with here, however.

What are use and non-use values/benefits?

Use values/benefits. 'Use values' refers to the fact that economic agents currently use the environmental goods in question, either directly (by sailing on a lake for example) or indirectly (by watching a video of someone else sailing on that lake). Direct use values are the easiest ones to estimate, as they usually stem from products that can be traded in a market as entrants into a production process or final products (for example, water for food processing or fish).

Non-use values/benefits. Some benefits are not associated with any direct use, so called non-use values, but exist because individuals value an ecological resource without using or possibly even intending to use it, for example water quality and biodiversity in a lake.

Box 5 - Types of Environmental Benefits / Avoided costs

Benefit Class	Benefit Category	Types of benefits and examples
Use values	Direct use	Market (Commercial: fishing, navigation, tourism) Non-market (Recreational: water skiing, fishing, swimming, boating, photography)
	Indirect use	Amenity value derived from a nice environment Benefit extracted from someone else using the environmental good (e.g. Reading a fishing magazine) General ecosystem support (preserving the food chain to support fishing)
	Option value	Value derived from preserving potential direct or indirect use values in future, which depends on uncertainty over future demand and supply
Non-use values	Existence Bequest	Biodiversity, heritage and cultural values Preservation of water quality for family and future generations

Sources: *OECD (1999) and Timothy M. Swanson and Edward B. Barbier (1992).*

Illustration 2 - Benefits defined as avoided costs: *The Artois-Picardie basin*

Tourism is one of the main economic activities in the Artois-Picardie basin in the North of France. In particular, the 'Opal Coast' benefits from beach-oriented tourism, which provides 40 percent of the basin's turnover (around € 1 billion per year). Access to the region's beaches and the sea are critical factors for maintaining tourism. Hence, if the quality of water was 'sufficiently' bad, the beaches of this coastal stretch would have to be closed for bathing activities: users would either go elsewhere, or not take part in bathing activities at all.

Two studies were carried out by the Artois-Picardie Water Agency to assess the potential economic loss linked with such a scenario. The studies showed that between 30 to 50 percent of visitors to the area would cancel their trips, leading to economic losses ranging between € 300 million and € 500 million per year. These values can be seen as the benefits of providing bathing and other recreational facilities that are dependent on water quality. As a way of comparison, the money invested in sewage treatment for the basin totalled € 150 million over the last 10 last years. The magnitude of the benefits gained from good quality alone provides a compelling reason for continued investment in sewage treatment to avoid the potential cost of pollution.

Methodologies for Estimating Environmental Values

Various techniques exist for the valuation of environmental costs and benefits, which are more or less practical, time-consuming and have different cost implications. Below, we outline four possible methodologies for estimating those costs. A rough guide to choosing between these methodologies is presented in *Box 6* and an example of how stakeholders may be involved in the process is given in *Illustration 3*.

Method	Definition	Overall assessment
Market Methods	These methods use values from prevailing prices for goods and services traded in markets. Values of goods in direct markets are revealed by actual market transactions and reflect changes in environmental quality: for example, lower water quality affects the quality of shellfish negatively and hence its price in the market.	***Good method if market data exist but limited to direct use values for goods traded on a market. Since this is often not the case, other methods must be used.***
Cost-based valuation methods	This method is based on the assumption that the cost of maintaining an environmental benefit is a reasonable estimate of its value. References for this type of valuation include the costs of preventative and/or mitigation measures. This assumption is not necessarily correct: all mitigation may not be possible, in which case actual mitigation costs would be an underestimate of true environmental costs. By contrast, mitigation measures might not be cost-effective and those costs might be an over-estimate of the environmental costs. A distinction needs to be made between: ➢ The costs of measures already adopted, which are theoretically already included in financial costs. These costs should be reported as a distinct financial cost category. Counting them as environmental costs would be double counting; and ➢ The costs of measures that would need to be taken to prevent environmental damages up to a certain point, such as the Directive's objectives. These costs can be a good estimate of what society is willing to forego.	***Practical and relatively easy - a good starting point, although the costs of the environmental damage itself tends to be underestimated with this method.***

Method	Definition	Overall assessment
Revealed preference methods	The underlying assumption is that the value of goods in a market reflects a set of environmental costs and benefits and that it is possible to isolate the value of the relevant environmental values. These methods include recreational demand models, hedonic pricing models and averting behaviour models (see *Box 7* for a description).	***This set of techniques tends to be time-consuming and costly to use. The use of such techniques could be reserved to particular environmental issues that raise specific problems***
Stated preference methods	These methods are based on measures of willingness to pay through directly eliciting consumer preferences (i.e. asking them!) on either hypothetical or experimental markets. For hypothetical markets, data are drawn from surveys presenting a hypothetical scenario to the respondents. The respondent makes a hypothetical choice, used to derive consumer preferences and values. Methods include contingent valuation (see *Box 7*) and contingent ranking. It is also possible to construct experimental markets where money changes hand, e.g. using simulated market models. In the questionnaire, it is possible to ask respondents how much they would pay for avoiding an environmental cost or how much they value a given environmental benefit.	***As above***

Box 6 – A Rough Issues To Choosing a Methodology for Estimating Environmental Costs

Checkpoints	**Choice of method**			
	Direct market method	Cost-based valuation	Revealed preferences	Stated preferences
Are you measuring the value of the environmental cost before or after the environmental change?	After	Before or After	Before	Before
Is the market for the environmental value you want to estimate hypothetical or real?	Real	Real	Real	Hypothetical
Are markets directly or indirectly related to the environmental value you want to estimate?	Directly related	Directly Related	Indirectly related	Directly related
Is it important that you can estimate demand/supply elasticity?	Yes	No	Yes	Yes
Are (estimated) non-use values likely to be significant?	No	No	Yes	Yes
Does the method require significant time and financial resources?	No	No	Not necessarily	Yes

Some benefits will not be quantifiable, either because of technical reasons (e.g. all impacts of achieving the environmental objectives cannot be foreseen, it is not possible to quantify all the benefits of improved water quality in a river stretch etc.) or lacking resources (e.g. there is insufficient time to carry out quantitative studies before the RBMP in 2009 or it is too costly). In these situations, benefits should be assessed and described qualitatively.

The Use of Value Transfer

An alternative option to direct valuation of environmental costs is the use of *Value Transfer* (more commonly known as benefit transfer in the case of benefits). This method uses information on environmental costs or benefits from existing studies and uses this information for the analysis in the river basin under consideration. As a result, a data set that has been developed for a unique purpose is being used in an application for a different purpose, i.e. it transfers values from a *study site* to a *policy site,* i.e. from the site where the study has been conducted to the site where the results are used.
Above all, benefit transfer is suitable when technical, financial or time resources are scarce.

However, amongst other problems, it is important to note that since benefits have been estimated in a different context they are unlikely to be as accurate as primary research (see also *Look out!*). A step-wise approach should be developed in order to ensure that the transfer of values derived in other contexts can minimise the potential for estimation errors.

Box 7 – Examples of Revealed and Stated Preference Methods

Revealed Preference Methods

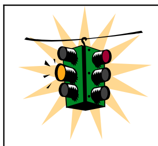
Hedonic Pricing. "Hedonic pricing methods explain variations in price [in the price of goods] using information on [qualitative and quantitative] attributes". They are used in the context of the water to value how environmental attributes and changes affect property prices. In addition to structural features of the property, determinants of property prices may include proximity to, for example, a river or lake. The change in property price corresponding to an environmental degradation, for example the pollution of a river or lake, is the cost of this degradation.

Averting Behaviour. This method derives values from observations of how people change defensive behaviour – adapt coping mechanisms - in response to changes in environmental quality. Defensive behaviour can be defined as measures taken to reduce the risk of suffering environmental damages and actions taken to mitigate the impact of environmental damages. An example of the former is the additional cost of having to filter or boil bad quality water before drinking it. The costs of mitigating the impact may entail expenditures on medical care needed as a consequence of drinking poor quality water. The expenditures produce a value of the risk associated with the environmental damage.

Recreation Demand Models (RDM). Improvements or deterioration in the water quality may enhance or reduce recreation opportunities, for example swimming, in one or more sites in a region. However, markets rarely exist to measure the value of these changes. RDM focus on the choice of trips or visits to sites for recreational purposes and look specifically at the level of satisfaction, time and money spent in relation to the activity. By assuming that the consumer weighs time and money as if he/she were purchasing access to the goods, for example a river stretch, patterns of travel to particular sites can be used to analyse how individuals value the site and, for example, the water quality of the river stretch. Reductions in trips to a river stretch due to a deterioration in water quality, and associated changes in expenditures, reveal the cost of this deterioration.

Stated Preference Methods

Contingent Valuation. Contingent Valuation is based on survey results. A scenario including the good that would be delivered and how it would be paid for (e.g. through an increase of the water bill) is presented to the respondent. Respondents are asked for their willingness to pay (WTP) for the specified good, e.g. improvements to the groundwater status. The mean willingness to pay is calculated to give an estimated value of the good, in this case improved groundwater status, and these means can then be aggregated to establish the value to the relevant population. However, note that one of the difficulties with this approach lies in ensuring that respondents adequately understand the environmental change that is being valued, for example going from poor to good water status.



Look out! When using Benefit Transfer, you must…

- Assess the quality studies to be used;
- Compare assumptions, baseline conditions, target population and policy measures etc. to ensure that the policy settings are similar; and
- Address uncertainty.

The methods used for transferring benefits include *Meta-analysis, Benefit function, Bayesian techniques* and *Point estimate*. To facilitate benefit transfers during the implementation of the Directive, it might be appropriate to build a trans-European database with references on benefits and costs.

Illustration 3 - Integrating stakeholder analysis in non-market valuation of environmental assets: estimating the value of a wetland area in Kalloni Bay on Lesvos island (Greece)

The study reviewed here sought to investigate the economic values placed on a wetland surrounding Kalloni Bay on the island of Lesvos and employed two types of methodology:

(1) Local people and visitors to the area were surveyed via a questionnaire: each respondent was asked to rate four possible development scenario for the wetland and were asked about their willingness to pay for their preferred scenario;

(2) Opinions from important local stakeholders such as fishermen, elected representatives, construction companies, and hotel owners about their priorities for both conservation and development were gathered through stakeholder focus groups. The stakeholder analysis was designed for: (i) identifying conflicting uses of environmental assets, (ii) conceptualising conflicts on the basis of property right allocations among social groups, regions and nations, and, last but not least, (iii) understanding the institutional mechanisms by which costs and benefits are appropriated.

Dynamics of the stakeholder focus groups
Individual based methods are often criticised for failing to account for institutional structures. As a result, it appeared important to reflect the institutional and social structure of the island through the focus group method. The focus groups revealed important differences in the social constructions made by different stakeholders about the wetlands and its place in the culture and economy of the Kalloni area. The issue of local people having rights over local resources was an important theme, and participants thought that problems and conflicts should be resolved locally. However, different stakeholders were reluctant to enter into discussions with each other. There was, in general, a belief that all of the different activities involving the wetlands such as tourism, agriculture and fishing could co-exist: many local people combine occupations (e.g. being simultaneously farmers and hotel owners). However, the links between the consequences of different activities were not always accepted. For example, farmers refused to make the connection between their use of fertilisers and pesticides and pollution of the bay. The uncertainty over property rights and responsibility was also a major area of concern, and inappropriate uses of land on one property were acknowledged as having detrimental effects on adjacent properties.

Economic valuation of the wetlands

The study yielded interesting results in terms of economic valuation of the wetlands. First, it made clear that the local population is capable of expressing a variety of preferences for extension or reduction of the wetland in terms of economic values, which can be captured by contingent valuation. Further, the stakeholder groups discussed different options for the future based on their needs, hopes and fears as particular interest groups, which informed the development of the scenarios and the choice of payment vehicle. By using these scenarios and from the focus group discussions with relevant stakeholders, a rich diversity in the motivations of different individuals and groups was encountered. For example, the local mayors valued the wetlands as a tourist potential that should be managed as a 'park', with strictly defined boundaries and distinct uses. On the other hand, for construction companies, the wetland was a nuisance that hindered their plans for development. However, the latter recognised that to some extent, they might benefit from an increase in tourism from the well-managed wetlands so their position was not so clear-cut. It resulted that because of the highly complex social constructs, stakeholder participation is essential to address conflicting interests, power-and-equity issues, and the tension between local and more global needs (e.g., tourism).

This study concluded that local people are quite capable of functioning as both citizens and consumers. As citizens, they feel responsible for their environment, though this is often expressed in very different ways, as the stakeholder focus groups demonstrated. However, they also feel responsible to themselves, as consumers of the wetland's economic potential. The conflicting issues that emerged through this study demonstrate the need for stakeholder communications in economic analysis, not only to characterize the social and political issues but also to establish a process through which participation by stakeholders creates ownership and self-determination for meeting environmental and economic objectives.

3. Reporting on Cost Issues

The calculation of full economic costs requires that assumptions be made about the lifetime of investments, about discount rates, depreciation methods, costing methods, valuation methods etc. Besides, in adjusting financial cost data for taxes and subsidies and in estimating the environmental and resource costs of ensuring sustainable water use, assumptions will need to be made as well.

To ensure the cost analyses of the member states are comparable, all assumptions and costing methods used should be made explicit, stating clearly how the presented cost information has been derived.

Though different Member States apply different standards for estimating economic costs it would be desirable to resemble as much as possible the methods and standards used in the international guidelines of for example the European Commission or the European Environmental Agency (see *Box 8)*, especially when international analyses are performed, for example in case of an international cost-effectiveness analysis. These guidelines may also help decide on issues such as which parameters and methods to include.

The general guideline is that when reporting on economic costs, all assumptions and costing methods should be clearly reported. Depending on the use of economic cost information, other requirements might apply. This is further elaborated in the information sheets *Cost-effectiveness Analysis*, *Reporting on Cost-recovery* and *Disproportionate Costs*.

Box 8 - Suggestions for Reporting on Cost Issues

Minimum requirements for the presentation of cost information according to EEA (1999)

1.It is essential that reported costs are properly defined. As a minimum, the total *investment expenditure* and total annual *operating/maintenance costs* should be reported separately.

2. As far as possible, it is recommended that all cost data should be documented in full in the year in which the actual expenditure is incurred, even if the data are subsequently adjusted to take account of time (such as by using *discount rate*s).

3. All costs in should be measured in relation to an alternative. The alternative most commonly employed is a projection of the existing situation, i.e. the situation in which the *environmental protection measure* has not been installed. Therefore, only *additional costs* actually incurred relative to the *'base cas*e' should be included in the reported cost data.

4. Where the costs associated with an *environmental protection measure* have been apportioned between two or more controlled pollutants, the method of apportionment should be described.

5. The reported cost data should only relate to *direct cost*s; *indirect costs* should be excluded from the cost data.

6. Where *environmental protection measures* produce non-environmental benefits, *revenues* or *avoided cost*s, these should be reported separately from *investment expenditures* and *operating and maintenance cost*s.

7. It should be remembered that costs and prices are not fixed forever. For example, the unit price of a measure often falls as it changes from an experimental measure to a mass-produced measure. Therefore it is recommended to use the most recent valid data available.

8. It should be remembered that old equipment can sometimes have a lower *efficiency* and higher maintenance costs than new equipment.

9. As a minimum, any *discount rate* used should be recorded.

10. If cost data are adjusted for inflation or changes in price through time, then the method used should be recorded and any index used should be recorded and referenced.

11. If determining annual cost data, the approach that has been used to derive the annual costs should be recorded, along with all underlying assumptions.

Note that this does not necessarily apply directly to the economic assessment required for the Directive – these are guidelines from the EEA only. For example, whereas the EEA recommends to only incorporate direct costs (and not indirect costs), the incorporation of indirect costs in the economic assessment for the Directive would depend on the stage of that assessment, as specified above.

REPORTING ON COST RECOVERY

Directive references: *Article 9* and *Annex III*
3-Step Approach: *Step 1.3* and *Step 3.3*
See other information sheets: *Estimating costs, Defining water services and uses, Baseline Scenarios, Pricing as an Economic Instrument*

This Information Sheet helps you understand what and how you should report on the recovery of costs of water services by types of water users.

1. Why is it necessary to report on cost recovery?

Article 9.1 of the Directive states that: "Member states shall take account of the principle of recovery of the costs of water services, including environmental and resource costs, having regard to the economic analysis according to Annex III, and in accordance with the Polluter pays principle".

This information sheet is a guide for reporting on cost recovery and is relevant for:

- Implementing the **recovery of costs of water services** and ensuring an **adequate contribution of the different water uses** to the recovery of costs of water services; (*Article 9*);
- Creating **water pricing policies** to provide adequate incentives for users to use the resources efficiently (*Article 9*); and
- Making the relevant calculations necessary for taking into account the principle of cost recovery in the **economic analysis** (*Annex III*) and making a first assessment of whether the cost-recovery objective of the Directive are currently met.

However; the information sheet focuses on the latter point (*Annex III*). A key objective of this initial analysis will be to improve **transparency** in order to understand which water services are actually paid for, to which extent, by whom and how. More specifically, this will entail identifying whether some external subsidies are provided to the water sector, or whether some cross-subsidies are paid between categories of water uses.

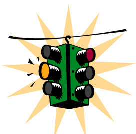
Finally, note that the objective of the Directive is not necessarily to move to "full cost recovery" but to move to a situation where the "polluter pays " principle is adequately applied. The Directive allows Member States to take into account the social, environmental and economic effects of cost recovery. But it is only with maximum transparency that the extent of these secondary effects of cost-recovery can be understood.

2. Approach to Analysing and Reporting on Cost Recovery

The approach that is proposed here for analysing and reporting on cost recovery and assessing the extent to which polluters pay can be broken down into a number of tasks, as shown in *Figure 1* of this information sheet. It is important to stress that this approach may need to be adapted to local and national situations and institutional setup for cost recovery.

Figure 1 – Tasks and Key Questions in Analysing and Reporting on Cost-Recovery

Key Tasks	…And Questions
1. Define the water services	What is the scale for the analysis? What are the differences in scale between water uses and water services? How can they be reconciled? What is the overall scope of the analysis
2. Identify providers, users and polluters	Who generates the costs of the water services? Do they receive a service or are they self-serviced?
3. Calculate financial costs of the water services	What are the financial costs of the water services?
4. Identify and estimate the environmental and resource costs of the water services	What are the environmental and resource costs? Can they be identified and estimated at least in qualitative terms?
5. Identify the cost –recovery mechanism	How are costs currently recovered: through prices, charges or through other institutional mechanisms of cost recovery?
6. Identify the cost –recovery mechanism	What level of costs do water users recover? What is the level of financial costs recovered? What is the amount of external subsidies to the sector? Where do these external subsidies come from and how are they financed?
6. Identify the cost –recovery mechanism	How can costs be allocated to water uses? What proportion of the total costs do water uses cover, and is that in accordance with their actual use?



Look out!

The suggested steps to report on cost recovery do not include investigating issues dealing with price incentives (Article 9). This is treated as a separate issue in a different information sheet (see *Pricing as an Economic Instrument*).

Task 1 - Define the Water Services

The first task is to define water services (see *Water Uses and Services* Information sheet) and to determine the scale of the analysis (see *Scale Issues* Information Sheet). Particular attention should be paid to the geographical scope of the analysis (local, regional, river basin, national, international). Subject to data availability, the definition of water services may have to be at the administrative rather than the geographical level. *Illustration 1* of this information sheet demonstrates how data were collated and adapted to RBD level in the Middle Rhine, however, in some cases, for lack of more disaggregated data, cost-recovery might need to be analysed at the national level (see *Illustration 2* for an example).

Illustration 1 – Cost recovery and data availability in the Middle Rhine, Germany

The principal water services in the Middle Rhine are public water supply and local authority sewage disposal, and both types are highly decentralised with a large number of companies. In general, the existence of consistent data may be a problem for the assessment of cost-recovery levels and, potentially, a decentralised structure could complicate data collection further. However, in the Middle Rhine, statistics is collated and categorised so that information based on administrative area definitions can be related to geographical definitions based on river basins. As a result, the Middle-Rhine scoping study shows that *existing secondary* data can provide enough information for a good first assessment of the level of cost recovery.

In order to assess the level of cost recovery of water services in the Middle Rhine, structural and output data were collated and processed. Essentially, the data collection was carried out in two stages (see Table 1):

Table 1

Type of data	Data sources
Stage 1. Collection and evaluation of generally available data: information on the structure of water uses and water services and related economic characteristics (e.g. charges, subsidies, financial costs of water supply and sewage disposal)	The Federal Statistical Office (censuses of all water supply companies, excluding publicly owned enterprises), regional statistical offices (environmental statistics form censuses of *all* water companies), and data and information from the technical and financial authorities of the Länder.
Stage 2. Collection and evaluation of third party data to supplement Stage 1.	The Federal Gas and Water Management Association, joint authorities/associations surveys on public sewage disposal, and evaluation of special surveys and expert reports.

Surveys to collect *primary* data were planned for a third stage but were not undertaken as *Stages 1* to *2* provided sufficient data to derive the current level of cost recovery. As an example, Table 3 contains a summary of data collected for *public water supply* in the region of Hessen. Table 2 (below) outlines the main results (financial statistics) for public water supply:

Table 2

Water service	Rate of cost recovery
Public water supply Cost recovery from revenue excluding allocations and subsidies Cost recovery from revenue including allocations and subsidies	 83% 90%
Internalised environmental and resource costs (groundwater charge) are approximately DM 52.6 million in total, which significantly exceeds the sum of total subsidies (DM 3.4 million) and the cost recovery shortfall (DM 19.7 million).	

It was found that the ability to adapt official statistics of the Federal Government and the Länder (administrative districts) to river basin district level (as required by the Directive) greatly improved the reliability of the estimates. In addition, to ensure the efficiency of supply, detection and evaluation of data, as well as comparability of the results, a central data pool will be set up to facilitate the availability and access to economic data.

Other expenditures	2,493,088	
Profits/Losses	**-22,005,022**	
Public investment allocations and subsidies	**10,702,090**	

Illustration 2 – Issue of Data Availability in the Netherlands

- In the Netherlands, data on the costs of wastewater treatment are available at the administrative level of the Regional Water Boards. The information supplied by the Water Boards includes other costs than those for wastewater treatment alone, and assumptions need to be made regarding their share of the total costs.
- Data are available both at the national and regional level. As the regional level does not yet correspond to the geographical level of the river basin, at this moment aggregated national data needs to be used for the analysis of the cost recovery.

In addition, the scale at which the costs of water services are incurred might be different from one category of costs to the other (financial costs would usually be collected at the water service level, whilst environmental and resource costs would be at the level of the river basin, the scale at which water uses can be analysed). Ways to reconcile these different scales and to combine data should therefore be sought during that first task. This might require co-ordination between different administrations (for example, the economic regulator of water services who would normally have access to data on the financial costs of water services and the environmental regulator, who may have data on the environmental and resource costs in general, although not necessarily allocated to water services).

Task 2 - Identify the Providers, Users and Polluters

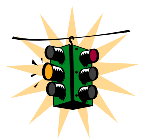
This task involves the identification of the actors involved in the generation of financial, resource and environmental costs. Water services are provided in different ways, e.g. on a communal or individual basis, by a public or a private company. The geographical scope of the analysis is determined by the level at which the responsible authority and the provider of the water service operate and the scale of the market served (see *Illustrations 1* and *2* of this information sheet).

Normally, little information is available for individually provided water services (agricultural groundwater abstraction, industrial waste water treatment, septic tanks of households etc.) - see the *Look out!* Box below. Should this be the case, an *estimation* of the extent to which water services are provided on an individual basis, for example the percentage of households with septic tanks or percentage of industry not connected to the sewerage system, can be attempted. It is only where there are significant environmental problems linked to self-services (such as mining of an underground aquifer due to too many private wells) that an appropriate estimate of all costs related to self-provided services is key to transparency and better decision-making.

A specific case is that of diffuse pollution, which can be created by agricultural pollution but also industrial or household uses (such as urban run-off). Even though diffuse pollution is not a water service, the costs resulting from diffuse pollution, in so far as they have an impact on the costs of water services (through an increase in water treatment costs for example), should be covered by those who have generated this pollution. With the Water Framework Directive (Article 9) requiring *an adequate contribution of the different water uses … to the recovery of the costs of water services*, it is important to ensure links can be made between water uses and related water services and costs.

Task 3 - Calculate the Financial Costs of the Water Service

To calculate the financial costs (see *Estimating Costs* Information Sheet), extensive information is needed regarding the various cost items involved in providing the water service. Typically, this type of information can be collected from the provider's annual production account or balance sheet or, if there is more than one provider, from their aggregated production accounts or balance sheets (see *Illustration 3* of this information sheet). Depending upon the relevant scale of analysis and the number of providers involved, this can be done at a local, regional, river basin or national level. *Illustration 4* of this information sheet presents an easy-to use methodology for estimating financial costs.



Look out! Cost-recovery of self-provided water services
Water services can be provided either by third parties (e.g. communal water services) or on an individual basis (e.g. water treatment facilities of industry, agricultural water abstraction, septic tanks of households etc.). For the latter, the financial costs of water services are covered as the user will usually have financed these investments. Nevertheless, they can be included in the analysis, in order to fully account for the polluter pays principle. In addition, the environmental and resource costs for these services should also be estimated.

Illustration 3 – Estimating cost-recovery in the Netherlands

Table 1 below shows the aggregated costs water quality (and quantity) management, including both financial, internalised environmental, and remaining environmental costs. This is the case because the costs of mitigation measures to compensate for water pollution (e.g. cleaning of polluted river beds and water soils, monitoring of the water quality) are included in the financial costs and paid for by the users through the wastewater treatment charge. Also, since the wastewater charge paid is related to the pollution caused, the polluter pays principle applies. In total, costs add up EURO 1,030 million.

Total revenues for water quality management amount to EURO 1,035 million. Revenues include financial returns on assets and the revenues received from the wastewater pollution charge. This charge is set to recover the costs of wastewater treatment and mitigation measures. From these revenues, the subsidies received for operating the wastewater treatment installation need to be subtracted, resulting in a total of 1,021 million.

The cost-recovery rate can therefore be estimated as:

$$\frac{\text{Total revenues-subsidies}}{\text{Total costs:}} = \frac{1021}{1030} = 99\%$$

Table 1 - Aggregated Balance Sheet of Water Boards in the Netherlands

Costs and revenues *(in million euro)*	**Water quantity management**	**Water quality management**
Total costs	668	1,030
Total revenues		
A received interest	37	85
B received waste water treatment charges		
C received apportionments for water quantity management	514	
D sales, rents and other taxes	14	17
E investment adjustments	9	5
F subsidies	46	14
G other income received from third parties	18	5
H internal adjustments	23	9
Total revenues	661	1,035
Net revenues -/-costs	-/-7	5

Illustration 4 – Estimating Financial Cost Recovery in the French West Indies

Two of the main features specific to water supply schemes are: (i) they incorporate assets with service lives of varying lengths, often extending beyond the life of the loans subscribed to finance them; and (ii) corresponding maintenance costs grow over time and are not easy to estimate.

In the French West Indies, a large, multi-purpose water scheme supplying raw water mainly for agriculture (52%) and domestic purposes (40%) provides the basis for a simplified case study on financial cost recovery to illustrate how these features should be taken into account. The scheme is publicly-owned (and as such, investments were funded by various local authorities from 1977 to 2000) but privately managed. From the scheme, 16.8 hm^3 of raw water are sold every year and nearly 10,000 ha are irrigated.

Given the asset lives and a discount rate estimated at 3%, the annual capital costs were calculated to estimate whether the scheme's financial costs are fully recovered. To calculate maintenance costs, an intermediate step in was made to estimate a maintenance rate for each type of asset, taking into account that these costs increase over time, and using lower and upper bound values derived from past experience (see Table 1 below).

Table 1: Capital and maintenance annual costs calculation (€ 2000)

Asset life	Maintenance rate	Total investment per type of asset	Annual capital cost	Total maintenance cost	Annual maintenance cost
100 years	1-2%	504,184	12,092	148,883	4,712
100 years	0.3-1%	11,588,767	298,198	1,311,909	41,518
75 years	0.3-1%	132,573,805	3,586,153	14,776,679	495,893
50 years	1.5-5%	1,640,445	58,292	193,798	7,532
50 years	1.5-5%	210,592	6,124	101,797	3,956
40 years	1.5-5%	7,495,407	244,879	3,264,663	141,237
30 years	1.5-5%	561,173	22,856	234,025	11,940
25 years	1.5-5%	274,366	12,811	105,158	6,039
20 years	1.5-5%	34,811	1,903	11,584	779
10 years	1.5-5%	58,533	4,871	10,111	1,185
Total		173,827,944	4,789,921	20,158,607	714,790

The total financial cost was then calculated by adding this table's intermediate (total) costs to operation costs. These were derived from existing data provided by the private operator.

Table 2: Total financial annual costs and its components per cubic meter (€ 2000)

Type of costs	Total value	Value per m^3
Capital costs	4,789,922	0.285
Maintenance costs	714,790	0.043
Operation costs	1,084,522	0.064
TOTAL	6,589,234	0.392

These total costs can be allocated between the different water users (irrigators and others) and compared with the price of water charged to those users. However, there are some clear limits to this approach: average costs calculated over a long period (75 years for some assets) are compared with fees charged in a given year. Thus, a comparison between average annual costs and current prices to estimate cost recovery only gives a rough estimate and should be interpreted with caution. In this case, water used for domestic purposes represented 40% of total volume used and 57% of total fees received, due to the lower price of irrigation water and to a different water pricing structure. For raw water, operation and maintenance costs were fully covered by users through tariffs but a large part of capital costs were covered through subsidies from the public authorities.

Based on several case studies conducted in France, this method for estimating financial costs appears relatively robust as it provides the means to estimate costs with assets of varying asset lifes. It can also be applied to external costs whenever it is possible to identify stakeholders who are affected by externalities and who have incurred expenses to avoid them or to remedy their effects. So far, however, this method has been applied solely to estimating financial costs.

Source: T. Rieu (2002, forthcoming).

Task 4 – Identify and Estimate the Environmental and Resource Costs of Water Services

According to the Directive's definition, environmental and resource costs should also be considered in order to take account of the principle of cost recovery. As mentioned in *Estimating Costs (and Benefits)*, the estimation of environmental costs and resources might be difficult, due to methodology issues. Some environmental and resource costs are already internalised and as such, are included in the financial costs (see *Illustration 5*). Non-internalised environmental costs will prove most difficult to quantify and incorporate in the cost-recovery equation. For those, and for the sake of improving transparency, it might be sufficient to identify the costs and estimate them in a first instance.

Illustration 5 – Introducing a Natural Resource Tax (NRT) in Latvia

The Natural Resource Tax (NRT) was introduced in Latvia in September 1995 as a means to incorporate environmental externalities into the cost of water and wastewater services. Groundwater and surface water abstractions are charged, together with discharges.

The NRT rates vary according to the type of water abstracted and the type of pollutants. The following table shows the NRT rates for both water extraction (ground or surface) and water pollution:

	Unit	NRT-rate
Ground water extraction	€ / 1000 m^3	17.7
Surface water extraction	€ / 1000 m^3	3.5
Water pollution with SS	€ / tonne	17.7
Water pollution with COD, P and N	€ / tonne	53.1

Source: Latvian Law on Natural Resource Tax adopted on 14 September 1995.

In the following table, the Latvian NRT rates for groundwater extraction and pollution with P and N are compared with NRT rates in other Central and Eastern European Countries and some EU Member States.

	Ground water extraction (€ /1000 m3)	Water pollution (P) (€ / tonne)	Water pollution (N) (€ / tonne)
Latvia	**17.7**	**53.6**	**53.6**
Lithuania	10 – 24	404.3	118.9
Romania	7.3 – 8.4	43.6	43.6
Slovenia	30	5783	694
Estonia	16 – 48	216.6	130.3
Czech Republic	56	1960	1120
Poland	92.3		
The Netherlands	150 (1998)		
Denmark	670 (1998)	14,620	2,660
Germany		46,000	1,900

Source: REC (October, 2001)

This table shows that the NRT rate for groundwater extraction is generally lower in Latvia compared to other Central and Eastern Europe countries, and substantially lower than in EU Member States (it should be noted that GDP per capita in Latvia is only 29% of the average in the EU).

In addition to this relatively low NRT rate, it appears that the tax on water extraction and water pollution does not achieve its intended goal to achieve full cost-recovery while protecting the environment. The rates are relatively low and have remained unchanged since 1996, whilst the inflation between 1996-2001 was 43%. As such, the NRT rates probably do not cover environmental costs, at least from pollution (with respect to abstraction, given abundant groundwater resources and relatively low extraction rates, resource costs are close to zero). In order to prevent social problems, however, and given that water and sewerage tariffs are already relatively high, the NRT rates could only be increased in line with the expected economic growth in Latvia. Many small businesses have difficulties paying even the relatively small NRT and have little incentive to do so given that the monitoring mechanisms are deficient. From this case, it transpires that the NRT currently in place in Latvia largely represents a compromise between social, economic and environmental goals rather than a fully-blown economic instrument for recovering environmental costs.

Source: I. Kirhensteine (2000, forthcoming).

Task 5 - Identify the Cost Recovery Mechanism

This task involves identifying the mechanism currently used for recovering the costs of water services by water users. This would generally involve payment by users (through prices, charges, taxes) or alternative institutional mechanisms for recovering costs. This task should pay specific attention to the institutional mechanisms that are used in order to recover costs going beyond the mere pricing mechanisms. As shown in *Illustration 6* below, water users may sign a specific agreement between themselves in order to share the costs of an improvement in water status, which might reflect more closely the way in which they are sharing the benefits than through relying on an administrative pricing mechanism.

If prices and charges are the main cost-recovery mechanism, it would be important to collect data on the tariff structure, including the price per unit of water service used (for instance, EURO per m^3 or fixed charge per household etc.). If more than one user group is involved, the unit price may be aggregated and averaged across one or more user groups.

Illustration 6 – Institutional mechanisms for cost recovery in Tarragona (Spain)

In Spain, as in other semi-arid regions around the Mediterranean, increasing pressures on available water resources requires improving the efficiency of existing water uses. A water user association in Tarragona came up with an innovative negotiated arrangement in order to increase its available water resources by financing improvements in irrigation water uses.

Background. In Spain, irrigation is a key factor for agricultural production and the Government has played an important role in irrigation development. As a result, irrigated agriculture is by far the largest water consumer. Many irrigators have historical water rights and enjoy large water allotments, but they are faced with low guarantee levels, as allocation rules in times of scarcity give priority to urban uses. To regulate highly variable rainfall patterns, the Government invested in water system regulation infrastructure, with the construction of large water storage reservoirs. Growing water demand together with declining responsibilities for further reservoir building has resulted in increased resource scarcity and mounting competition amongst water users, focusing the debate in the water sector on conservation and reform.

Financing the modernisation of irrigation systems. In some old irrigation districts, technological improvements on the irrigation networks could allow for water savings, especially in areas where possibilities for further reservoir building are limited. Irrigation modernisation programmes can be beneficial for farmers but also for domestic users and the environment, through the resulting water savings. In the region of Tarragona in the Ebro river basin in Spain, where beneficiaries were well defined and third party effects insignificant, private negotiation led to the implementation of irrigation modernisation programmes. A water user society (municipal and urban water users) agreed to pay for modernisation investment in two irrigation districts in the Ebro river basin. In turn, these irrigation districts agreed to reduce their water entitlements (by the amount of water saved through distribution system modernisation) in favour of the water user society. This direct negotiation between water users appears as an alternative to the use of pricing mechanisms for reaching the cost-recovery objectives. In practice, urban users agreed to pay the costs of additional supplies through the financing of irrigation improvements. However, the circumstances in which this kind of institutional solution can be used are relatively limited. In most cases beneficiaries include a large number of downstream users including the environment and public price setting and subsidy transfer would play a key role to give incentives for the adoption of water conservation measures in irrigation districts.

Source: M. Blanco (2002, forthcoming).

Task 6 - Calculate the Recovery Rate of the Economic Costs of Water Services

The next task involves calculating whether, at an aggregated level, the cost of water services is globally recovered via revenues from users of this water service. This will need to be carried out water service by water service. In order to do so, it will be important to assess the revenues received by the water service and to assess whether any external subsidies are paid in order to finance the costs of this water service.

As highlighted in *Box 1* below, subsidies can be paid either directly or indirectly. In addition, they can be paid continuously or have been paid in the past (for example, a capital grant paid in the past to finance investments, or a write-off of capital asset value when transferring some assets in the private sector, as it was done in the United Kingdom at the time of privatisation). Therefore, it will be important to define clearly what is considered to be an external subsidy and when it was granted. An example of cost recovery and identification of subsidies in Hungary is given in *Illustration 7*.

Box 1 – Cost recovery: The issue of subsidies

The polluter pays principle (PPP) requires that users pay according to the costs they generate. However, subsidies reduce users' contribution to the full cost of water services and disable price incentives to use resources in a sustainable manner – both important objectives of Article 9.

Subsidies are allocated to either providers, users or polluters in different ways. They can be paid **directly** by the (central or local) government:

- to the provider of water services in the form of investment subsidies. *(capital subsidies, lowering fixed costs)*;
- to the provider of water services in order to co-finance the operation of the infrastructure *(operational subsidies, lowering variable costs);*
- to water users *(income transfers, lowering the price/charges paid by the user).*

In addition, subsidies can be paid **indirectly** by:

- users/polluters paying the costs of other users/polluters. ross subsidisation may arise between different users (households, agriculture, industry), different regions (dry and wet, populated or less populated) and/or different types of users (rich or poor, small or large users etc.).

When user groups pay only part of the costs of a water service, the rest of the costs will have to be paid or subsidised by others. These others can be the public at large contributing through general taxation (tax revenues being used by the central government to subsidise the supply of water services in ways described above) or other user groups that pay a larger fraction of the total costs (including resource and environmental costs) than they generate.

Once the external subsidies have been identified, the general formula for calculating the cost recovery rate for water services can be calculated as follows:

$$CRR = \frac{TR - Subsidy}{TC} * 100\% ,$$

where CRR is the Cost Recovery Rate, TR the total revenues (depending on the cost recovery mechanism this figure could be based on either fixed or variable charges in EURO/year), Subsidy the total amount of subsidies paid to the water service, and TC the economic costs (in EURO/year) of the water service provided.

If the water service is provided free of charge, the CRR equals zero. The problem with assessing the full extent to which the PPP holds is that external resource and environmental costs must be calculated and added to the financial cost. This may be difficult due to data availability (e.g. cause and effect are not always clear and environmental costs are often incurred at a scale that is larger than the scale of analysis). In such a case, to make an estimation of the extent to which environmental and resource costs are recovered, aggregated data on the quantity of water used by the different sectors and the amount of pollution caused by water services may at least be sufficient to inform a general assessment of the most important pressures and pollutants. In combination with information on environmental charges and levies, they can provide sufficient information to give a qualitative estimation of the extent to which the polluter pays principle has been applied.

In addition, due to the difficulties of identifying and allocating environmental and resource costs, it is important to distinguish between financial cost-recovery and overall cost-recovery. Financial cost-recovery should be analysed in the first instance as a minimum, and then overall cost-recovery could be estimated on top of this, bearing in mind the difficulties of doing so.

Illustration 7 - Cost recovery in Hungary and the need to identify subsidies

To meet EU accession requirements, Hungary must comply with EU regulations concerning wastewater collection and treatment by 2015. As a result of accession negotiations, total wastewater collected must be 79.5%, and the level of treated sewage must be 90% (from 38.5% in 2002). The investment costs for this undertaking will total € 820 millions. Most of the necessary investments will be financed by State and EU subsidies, although the present level of these subsidies is already high with over 1/3 of the water services companies having negative earnings.

An assessment of cost-recovery in Hungary remains difficult: the water services sector is highly fragmented with companies using different accounting systems; data gathering and processing is costly, due to the number of companies and claims of data confidentiality; economic valuation of environmental costs is lacking.

An overhaul of the water services sector in 1990 led to increased decentralisation, with local control transferred to local and regional companies (with public ownership of assets), and the establishment of 5 regional, fully state-owned companies that handle bulk production and some supply. Regulatory responsibilities and ability to set prices for water and sewage were also transferred to local water authorities (except for the regional companies, whose prices are set by the Ministry of Transport, Telecommunication and Water Management – MoTTW). Local control over pricing means varied costs relative to production costs – areas with higher production costs must charge more for water than areas with lower production costs. Along with the transfer and loss of centralized control, the central government also decided to reduce subsidies for operation costs in the water sector, claiming that local water charges should recover the water sector operating costs. However, as illustrated in the following table, this is a difficult task.

Table 1: Characterisation of the Water Services Sector in Hungary

Agriculture	Industry	Household Use
"Free price" system, where control over pricing is exerted via the tender process.	Systematic economic change since 1988 led to declines in industrial production and use of less polluting production.	Water/sewerage pricing a political decision, with responsibility in the hands of local officials.
Prices vary based on use of gravity or pump, distance to carry water, required pressure, economies of scale, whether there is infrastructure to be maintained, etc.	Decrease in demand due to price increases and bankruptcy of production companies.	High prices relative to disposable income, along with unwillingness (or ability) to pay has led to 10% consumer debt to companies. Even if the charges per unit of consumption = the costs per unit, actual revenues from charges will still not fully recover costs.
Prices usually cover operation and maintenance costs only	Revenues (industry and households combined) cover only operating costs, not depreciation or development. Amortisation isn't used as a practice, so future costs are undervalued.	Revenues (households and industry combined) only cover operating costs, not depreciation or development. Amortisation isn't used as a practice, so future costs are undervalued.
Water use rights by application and last for 3 years, except for a large regional water supply company that also operates irrigation objects in a 25-year concession.	Large industrial users mostly extract water individually. The prices of water purchased are not centrally regulated, which means diverse pricing structures.	Due to legal/technical constraints, it is impossible to shut down water services for non-payment to households.
Prices not available to the public. No official requirement to collect price data; data that is collected is generally considered confidential.	Revenues from industry are used to cross-subsidise household use.	Benefits from cross-subsidy from industrial sector.

The subsidies that are provided by the central government are the responsibility of the MoTTW. Each year, the MoTTW sets threshold values for water and sewage unit costs and municipalities (local governments) with higher costs receive the difference as a subsidy. The charges paid by the household consumers in the subsidised settlements are then equal to the threshold level of costs.

In practice, the Ministry first decides on the aggregate amount of transfers in each year, and then determines threshold values. In 1998, 1999 and 2000, total subsidies amounted t to CHF 3.4, 3.8 and 4.1 billion (at current price) respectively. For 1998, this is less than 0,5% of the total costs of water and sewage services provided for households in the country. More than one third of the settlements in Hungary (usually smaller villages) receive this kind of subsidy.

With a relatively low level of forecasted household incomes, simply raising the water charges will not result in an improved water sector. Further, increased investments from the EU and the state alone will also not result in an improved water sector. Given the state of the sector, and the need for further investments and reform to meet the EU accession goals, a closer look at how the subsidy system operates, how these are implemented, and how they are measured to meet overall policy goals may be necessary. The situation in Hungary may also be relevant to accession countries facing similar challenges, and to some Member States.
Source: P. Krajner (2002, forthcoming).

Task 7 - Identify the Allocation of Costs to Users and Polluters

The allocation of costs to water users will require determining a number of cost drivers, which are proxy indicators for estimating the amount of costs that they generate. These cost drivers are likely to differ according to the type of costs that are at stake. For example, in the case of the provision of a water distribution service, "volume of water used" might be an adequate driver for allocating operating costs whereas "required pipe capacity" may be a more appropriate driver for allocating investment costs. Cost drivers for environmental costs might be linked to the quality of the water discharged into the environment or into the sewer.

Specific attention should be paid to the potential existence of cross-subsidies between users of the water services (see *Box 1* of this information sheet). The availability of data will largely determine to what extend those cross-subsidies can be made explicit. Typically, the allocation of costs to different categories of water users can be a difficult exercise.

3. Reporting on Cost Recovery

It follows from the tasks outlined above that information is needed on the specific water services involved, their costs (including possible environmental and resource costs) and the way they are paid for (or not), providers, users/polluters and possible subsidies/transfers is required to estimate the rate of cost recovery (see *Illustration 8* of this information sheet for an example on how this may be achieved).

This information can usefully be compiled in a matrix, as shown in *Table 1* of this information sheet. This structure makes the interactions between the economic system and the water basin explicit and combines all the necessary information in one general accounting matrix. In this structure, a distinction is made between the different water users (households, industry and agriculture) and providers of water services (communal and individual). A similar structure is currently used by the National Accounting Matrices, Water Accounts (NAMWA)[10].

[10] This structure has been elaborated in the NAMEA (National Accounting Matrices-Environmental Accounts) and NAMWA (National Accounting Matrices- Water Accounts) by the Netherlands Statistical Bureau (CBS), and is now being reproduced in most EU member states and further elaborated by Eurostat.

Illustration 8 – Observatory for household water pricing (France)

Since the middle of the 1990s, increased attention has been paid to water pricing for households in France, with the launching of observatories in different Ministries and within the river basin water agencies. Originally, these observatories were developed to determine the average price per cubic meter of water (including water supply and waste water treatment). Already from the beginning, some attempts were made to identify the different components of the price (investment, maintenance, subsidies, etc.). However, the results of these studies were highly variable from one region to the other. In 1999, the Ministry of Environment and the water agencies decided to create a national observatory of domestic water prices at the National Institute for Environmental Statistics (IFEN). This observatory is based on information collected from 5000 municipalities, which are interviewed every three years. A great deal of technical and economic information is collected, such as:

- Price per cubic meter;
- Status of infrastructures;
- Forecasted investments;
- Information on subsidies…

While still in its start-up phase, it is expected that the data from this new national observatory will stimulate more work in the field of cost-recovery for household-related water services that will be of direct use for implementing the economic-related articles of the Water Framework Directive.

http://www.ifen.fr/pages/4eaulit.htm#65

Table 1 - General structure of information requirements with respect to reporting on cost recovery

Water service	Provider	User/Polluter	Financial costs	Resource costs	Environmental costs	Possible cost recover mechanisms	subsidies/transfers involved
Supply of (drinking) water	communal/ individual (agriculture, industry, household)	Households Agriculture Industry	Annual costs of water infrastructure, maintenance and operation costs	Opportunity costs of alternative water uses	Environmental damages due to abstraction, storage, impoundment etc.	Utility charges, market prices, abstraction taxes/charges paid by households, industry and agriculture etc.	Subsidies to low-income households, capital subsidies on investments in water supply infrastructure
Irrigation	communal/ individual (agriculture)	Agriculture	Annual costs of irrigation system, maintenance and operation costs	Opportunity costs of alternative water uses	Environmental damages due to abstraction, storage, impoundment etc.	Abstraction charges and/or charges paid for the use of the irrigation system by agriculture etc.	Subsidies on agricultural water use, capital subsidies on investments in irrigation system.
Hydro power	communal	Industry Households	Annual costs of investment, maintenance and operation costs	Opportunity costs of alternative water uses	Environmental damages of impoundment, dehydration of nature		Subsidies on industrial electricity use, capital subsidies on hydropower dam construction.
Drainage	communal/ individual (agriculture)	Households Agriculture	Annual costs of investment, maintenance and operation costs	Opportunity costs of loss of wetlands	Environmental damage to wetlands, dehydration of nature	Water management charges paid by households, agriculture, industry	Financing of large scale drainage out of general means, other subsidies
Sewerage	communal/ individual (industry)	Households Agriculture Industry	Annual costs of sewerage system, maintenance and operation costs		Environmental damage of (residual) water pollution	Sewerage and pollution charges paid by households, industry, agriculture	Capital subsidies on investments in the sewerage system, financing of sewerage out of general means
Waste water treatment	communal/ individual	Households Agriculture Industry	Annual costs of waste water treatment, operation and maintenance costs		Environmental damage of (residual) water pollution	Waste water treatment and pollution charges paid for by households, industry, agriculture	Capital subsidies on investments in waste water treatment, subsidies to users of waste water treatment.

BASELINE SCENARIO

Directive references: Article 5, *Article 9* and *Annex III*, also implicit in *Annex II*
3-Step Approach: *Task 1.2*, *Task 2, Task 1.3 and 3.3*.
Information sheets: *Recovery of Costs* and *Cost-effectiveness Analysis*

This information sheet will help you develop one or several alternative baseline scenarios (or "business-as-usual" (BAU) scenarios), and proposes an optional approach to complement the forecasting analysis (to define the BAU scenarios) with prospective analysis.

1. Objective

Article 5 requires that each Member State shall ensure that "an economic analysis of water use is undertaken for each River Basin District" and Annex III further specifies that this analysis should "take account of the long term forecasts of supply and demand for water in the RBD and where necessary: estimates of the volume, prices and costs associated with water services and estimates of relevant investment including forecasts of such investments".

The construction of long-term forecasts (what is referred to as *business-as-usual* scenarios) during *Step 1.2* of the 3-step economic approach is needed for:

- Identifying whether there is a gap in water status between the projected situation and the Directive's objectives by 2015 (*Step 2* – as illustrated in Figure 1 of this information sheet);
- Identifying potential measures to bridge that gap (if there is one) and construct a cost-effective programme of measures (*Step 3.1 and 3.2*);
- Making the relevant calculations necessary for taking into account the principle of cost recovery of water services, taking into account long-term forecasts of supply and demand for water in the River Basin District (*Step 1.3 and 3.3*).

Note that the *business as usual* scenario will only integrate what would happen in a given river basin district without the Water Framework Directive, due to changes in population, technologies, the implementation of water policies resulting from previous European directives, other sector policies, climate change, etc. During *Step 1.2* of the economic assessment, it will be important to focus on the forecasting of pressures and of key socio-economic drivers that are likely to affect those pressures. It is only during *Step 2* of the overall approach that these forecasts are translated into an assessment of their impact on water status.

2. Key Issues

Given the use of the baseline scenario, it is important to broaden the scope of the forecasting analysis suggested in Annex III in order to:

- Forecast not only investments but other key parameters and drivers influencing water supply and demand (or more generally all significant pressures), since a failure to do so would undermine the definition of the programme of measures;
- Not rely too much on a mere projection of past trends, as such forecasting method tends to produce misleading results: forecasts need to integrate predictable changes in

past trends based on a series of assumptions concerning these changes;

- Identify (and distinguish) variables that can be derived with a high degree of confidence and those that are uncertain. This distinction should be made for 'physical' parameters as well as for economic and policy-based drivers; and
- Build a series of alternative scenarios using alternative assumptions, particularly with respect to policy options. This will allow stressing the main (significant water management) issues in the river basin district, and discussing policy options by simulating their consistency and their long-term significance (e.g. it can be useful to compare two distinct scenarios, one where water prices and charges are kept stable and one where they increase: both assumptions are realistic, but stem from different policy options).

In order to build the baseline scenario, it will be necessary to forecast a set of variables before assessing the impact that these changes will have in terms of pressures and water status. It will be important to distinguish between three types of variables as presented in Table 1 below.

1. Trend variables: underlying (exogenous) trends, on which water policy has no direct influence;
2. Critical uncertainties: variables which are particularly difficult to predict, and might have a significant impact on the final result;
3. Water policy variables (see *Table 1* below): variables linked to the underlying water policies, independently from the implementation of the Water Framework Directive (as the focus is on building a "business as usual scenario")

Table 1 – Categories of variables to be examined for the business as usual scenario

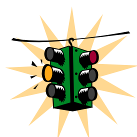
Categories of variables	**Examples**
Trend variables	• Changes in demographic factors, e.g. population growth in specific urban areas; • Economic growth and changes in economic activity composition, e.g. growth of the relative importance of services; • Changes in land planning, e.g. new areas dedicated to specific economic activities, land management in the catchment for reducing erosion.
Critical uncertainties	• Changes in social values and policy drivers (e.g. globalisation / regionalisation; policies relying on economics, technology vs. on values and lifestyles); • Changes in natural conditions, e.g. climate change; • Changes in non-water sector policies, e.g. changes in agricultural policy or industrial policy that will affect economic sectors.
Water policy variables	• Planned investments in the water sector, e.g. for developing water services or for restoring the natural environment/mitigating for damaging caused by given water uses; • Development of new technologies likely to impact on water use for industrial production and related pressures.

3. Practical Tasks for deriving the Baseline (*Business-as-Usual*) Scenario

The proposed approach for developing the Baseline Scenario is outlined in three tasks, as shown in *Box 1* of this information sheet. This box serves as a visual aid throughout the process outlined below.

Box 1 – Illustration of the General Method

Task	Output	Visual illustration
1. Assess current trends in *trend* variables, including physical parameters and socio-economic drivers	Short-term projections of trend variables based on existing trends	 *Variables are projected based on current trends over a short-term horizon*
2. Project certain changes in water policy variables	Longer-term projections of variables incorporating changes in current trends	 *Variables are projected over a longer-term horizon, incorporating certain changes in water policies*
3. Integrate changes in "critical uncertainties" and derive one or several realistic business-as-usual scenarios	Build several baseline or *Business-as-usual* scenarios	 *Alternative BAU scenarios are constructed, out of several combinations of assumptions on trend variables, water policy variables and critical uncertainties*



Look out! Developing the baseline is an iterative process

The first baseline scenarios developed for supporting the development of river basin management plans are likely to build on existing knowledge of trends in key variables and lack robustness and to incorporate many uncertainties. As the assessment of significant water management issues evolves, it will be possible to identify areas where further work is needed to improve the baseline scenarios. To enable revisions, it would be important to keep a log of:

- The overall reasoning process: assumptions, choices of variables, range of variation, priorities in analysis;
- Calculations made with respect to key variables, physical parameters and formulas (and ideally provide a schematic description of calculations);
- Databases used for calculations; and
- Perceived limitations in the analysis and suggested future work.

Task 1 - Assess current trends in "trend" variables (including physical parameters and socio-economic drivers)

The output of this task is a survey of past observations, historical data and a forecast of ongoing trends over a relatively short-term horizon. This work will be partly based on physical and ecological characterisation of the river basin and will build on technical and data handling/statistical expertise. The analysis of past evolution of water resources and physical parameters will mostly rely on technical expertise and on the analysis of trends in pressures, water uses, water services and impacts. The data to be gathered are summarised in Table 2 below.

The methodology for this task will be based on a comparison between the past and present status of *trend* variables in the river basin (including water uses, water services and physical parameters -as per Annex V of the Directive). This should enable:

- *Pointing to significant changes in the river basin district*: e.g. major degradations and improvements: what quality and quantity parameters have deteriorated or conversely improved, and what were the most apparent causes?
- *Gathering knowledge on the evolution of the human and technical context*: population and its location, economic activity components, equipment and water works;
- *Assessing the rate of policy implementation* and especially, the pace of water investments over the recent period;
- *Evaluating the likelihood of the above trends to be prolonged over the mid-term future*: are there good any reasons for assuming that the worsening /improving parameters will stop worsening / improving?
- *Compiling a first identification of the main pressures likely to cause a future gap* between the Directive's objectives and the possible future situations, and thus help identifying key driving forces and drivers linked to these pressures.

Table 2 - Data to be gathered in Task 1

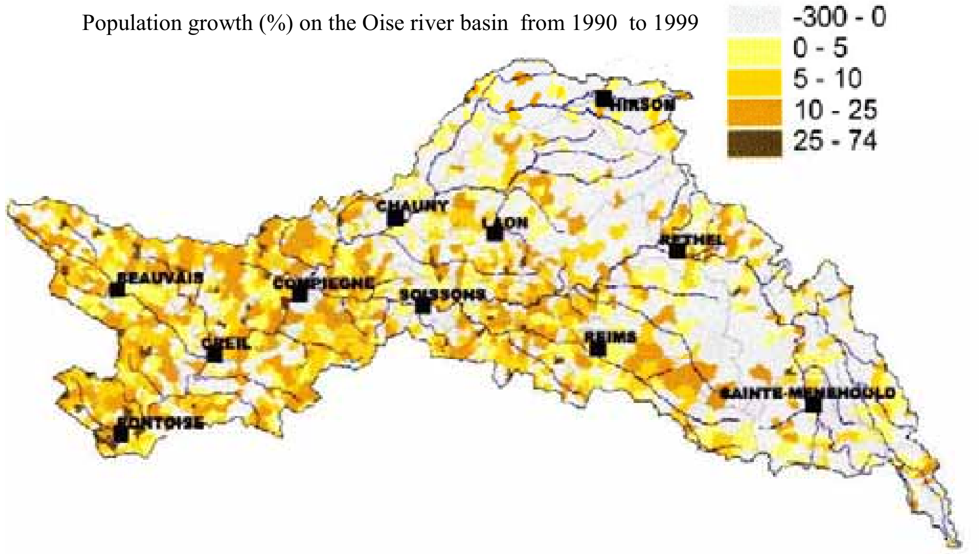
TASK 1	Key points	Output
Identify Trends in Physical parameters	Map evolution of: • Trends in water status over the past relevant period (e.g. evolution of pollution and ecological quality)	Overview of general trends in the hydrological system in the RBD.
Identify Trends in socio-economic drivers influencing water uses and, water services and impacts	Map evolution of: • Equipment (e.g. water distribution and sewage, rates of households and industries connected to public network) • Pricing (e.g. pricing policies, average prices) • Uses (e.g. hydropower, navigation, angling, etc.) and related impacts (e.g. power produced, transportation volumes, number of angling people, etc.)	Overview of general trends in water uses and services in the RBD.
Identify Trends in Water Policies and Regulations	• List past and existing national water policies • State the level of compliance with water-related environmental directives (e.g. habitats directive) and describe past investments and efforts • Describe trends in rates of a. Equipment in water distribution treatment and in sewage treatment capacities; b. Agri-environmental policies implementation; c. Industrial compliance.	Overview of general trends in the implementation of present water policies and regulations.

Illustration 1 - Oise river basin (France): case study of deriving a baseline scenario

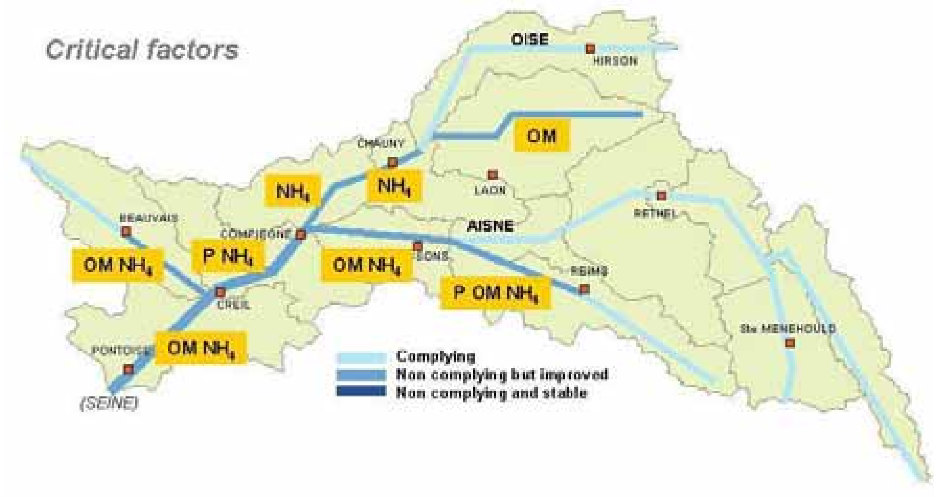
As part of the Seine River District in France, the Oise River Basin suffers from high diffuse pollution from agricultural runoff, high urban water intensity, dense industrial concentration on main and smaller rivers, and overall poor water quality in the main river and some of its smaller tributaries. By identifying past trends and the present state of water policy, surface water quality and pollution (including sewage equipment and discharges), a baseline scenario was formulated to provide insight to policy makers for addressing present and future water resources management. The following maps highlight some of the study's results:

Task 1 - Evaluation of major past trends
Evolution of polluting activities 1990-1999:
+2.7% population increase (+0.3%/year)
+11% industry production growth (+1.3%/year)

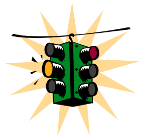
Population growth (%) on the Oise river basin from 1990 to 1999



Task 2 - Baseline projections
In a second phase, the effects of the development of future activities and planned policies and programmes (sewage works) in the Oise river basin were simulated and critical factors that limit compliance with good quality (chemical) status were identified. The baseline scenario highlighted major difficulties for achieving surface water quality objectives, including durable nitrate pollution involving groundwater and incompatibility between the "good" status definition and some natural processes (e.g., suspended matter standards versus erosion). While the baseline scenario has a useful purpose, there is an extreme uncertainty about the future level of economic activities in the region, particularly for industry and agriculture. The availability of data for this study was a great asset that allowed for scenario building, and the study provided useful results about the risk of non-compliance with the good status objectives of 2015, and allowed for a wider vision than recent planning preparation (up to 2006).



Source: Agence de l'Eau Seine-Normandie, 2002 (provisional assessment).



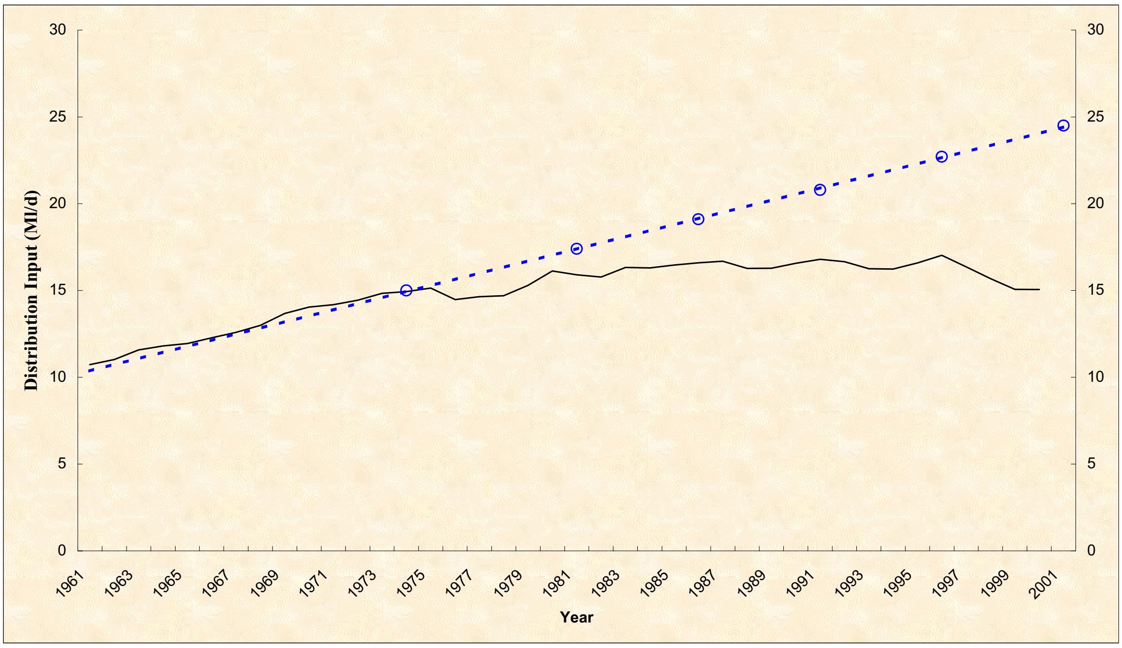
Look out! Do not rely too much on past projections and examine alternative scenarios, rather than an unique one

Reviews of existing past projections have shown that long-term projections in the water sector usually proved false when evaluated afterwards. Accordingly, it would be dangerous to suggest that an adequate image of the future can be the result of a mere projection of past trends. In addition, it will be important to avoid presenting one "image of the future" as a baseline scenario. A plurality of images, from a series of combination of variables, will be preferred.

Illustration 2 – Issues with trend extrapolation: "The past is not necessarily a good indicator of the future" (England and Wales)

In England and Wales, water demand rose steadily from 1960 to 1975. Applying an assumption that "the past is a good indicator of the future", it would have been logical to apply a simple linear relationship to demand from 1975 onwards. However, a simple non-causal relationship ignores the real drivers affecting water use. It is therefore not surprising that this extrapolation technique often fails, as it would have done in this hypothetical example (see Figure 1).

Figure 1 Water supply in England and Wales, 1961-2000



For short-term forecasting a more refined approach using a multiple linear regression form of extrapolation of trends might be suitable. This might be dependent on variables such as temperature and rainfall but it is likely to be more effective if applied to specific elements of water demand rather than *total* water demand. Indeed, the problem with overall trend forecasting is that it fails to analyse causal relationships and as a result, lacks transparency. Therefore, a more disaggregated approach to demand forecasting might be preferable (see *Illustration 3* of this information sheet).

Using simple trend projections might have benefits, as it is a low cost method and that it is quick and simple to derive a trend line. However such method has also many disadvantages, in the sense that it produces low quality forecasts and that it is reliant on good quality time series from which to derive statistical relationships. In sum, the past is not a reliable indicator of the future for anything other than possibly short-term forecasting.

Illustration 3 – A disaggregated approach to demand forecasting (England and Wales)

A preferred approach to trend projection and an important building block of any demand forecasting exercise requires adopting a disaggregated approach to demand forecasting, in order to identify the key drivers of demand and in particular, the key sectors having an impact on demand. This illustration draws on water demand forecasting activity undertaken to develop a water resources strategy for England and Wales. Its purpose is to demonstrate the level of detail necessary to reasonably apply assumptions about future water use brought about by changes to the key drivers of demand. The approach is valid for different sized areas although in small river basins there may be local issues relating to robustness of sample sizes and data availability.

The causalities of short-term changes in water demand are likely to be different to those affecting the longer-term. In the case of the former, it may be sufficient to examine recent history to establish how existing pressures are likely to translate into total water demand. Since water demand within a river basin will fluctuate over the longer-term (+5 years) as individual water uses grow and/or decline, it is logical to estimate how total water demand may change by examining the drivers of demand and the consequences for *each use*. Table 1 summarises the breakdown of total water demand used in the case study referred to above.

Table 1 Elements of water use by sector

Sector of demand	Component of demand	Micro-components of demand
4 no. sectors:		
• Household	8 no. components eg Toilet use, personal washing, clothes and dish washing, garden watering.	14 no. micro-components eg various WC, bath, shower, hand basin, washing machine, washing by hand, garden sprinkler.
• Industrial and commercial	18 no. components eg Chemicals, food & drink, textiles, retail, hotels.	Not applicable.
• Agricultural spray irrigation	23 no. crop types relating to three different soil types and seven agro-climatic zones.	Not applicable.
• Leakage	Reported and unreported leakage on trunk / distribution mains and on service connections to customers.	Not applicable.

A similar level of disaggregation to that described is recommended as good practice in order to introduce sufficient confidence into the supply-demand balance assessments that are key to establishing a baseline water use estimation.

The benefits of such detailed disaggregation include:
- Improved robustness of forecasts by reducing the uncertainty inherent in use of generic assumptions;
- Transparent forecasts of total water demand where the key sectors for growth / decline can be described explicitly – provides a clear platform on which to engage stakeholder debate;
- Application of specific assumptions can be restricted to just the relevant sectors;
- Facilitates development of sector-based scenarios of political, economic, social and environmental futures; Facilitates application of "*what if …?*" tests to forecasts, such as impacts of water management policies, technology etc.

The disadvantages of such disaggregation include:
- Availability and costs of obtaining econometric and water use data at such a detailed level;
- Cost effectiveness may be questionable for very short-term forecasting (year on year) particularly in regions where there are considerable surplus resources and robustness of forecast is less critical.

• Personal water use preferences/behaviour, eg washing and garden watering	✓			
• Resource stress				
• Rate of uptake of water-use minimisation measures by industry and commerce			✓	

Task 2 – Project certain changes in water policy variables and derive longer-term projections

Based on the previous task, key driving forces and drivers related to water and water policy (be they hydrological, socio-economic or policy/regulatory related) should be identified and analysed. In this task, it is proposed to concentrate on changes that are more certain and for these certain changes:

- To make reasonable assumptions about the future dynamics of the analysed drivers;
- To assess the impact of changes in these drivers on pressures; and
- To estimate the resulting impacts and thus water status.

Above all, this task is intended to assess the outcomes that can be awaited from the implementation of other water and environmental Directives, and notably their results in terms of water pollution abatement investments, taking into account the future capacities that are effectively planned for the next years.

Task 1 will have given an estimation of the future increase in raw pollution from human activities (pressures analysis). This task will try to answer the following questions:

- What additional quantities of pollution will be abated in the future (e.g. following the construction of additional sewage treatment works)?
- What will be the effects of planned policies on water availability for the water services and uses (e.g. regulation policies, storage equipment policies…)?

This task is central to the Water Framework Directive process and thus has to be steered by the district authority at high decision-making level. A "strategic co-ordination group" will probably be needed to incorporate all expertise and interdisciplinary inputs in the process. Again, on these matters, it is recommended not to strive for describing one unique image of the future if not possible. When choices among different values are necessary for some variables (e.g. activities growth rates, technological changes, policy implementation rates…), a series of alternative baseline scenarios can be prepared. The table below summarises the approach in Task 2.

TASK 2	**Key Points**	**Output**
Make assumptions about the future dynamics of trend variables identified in Task 1	• Determine whether parameters have stabilised (e.g. household connections to public networks, tax levels); • Determine the supposed effect of proposed future policy measures on the water status (e.g. new investment programmes, new national regulations, already planned institutional changes and public equipment policies such as energy, transportation, etc.: what possible effect on water quality and availability?).	Assumptions on the future dynamics of trends
Make projections based on certain trends	• Derive the projected values of the different parameters for 2015; • Check the general consistency of the different trends, explain the apparent inconsistencies (e.g. how can we explain a forecast of growing investments along with a supposed decrease in river quality? Because of a rise in general pollution flows out from economic growth). Propose one or several combinations of assumptions on trends	Baseline or Business-as-usual projections of the RBD in 2015

Illustration 4 - A methodology for scenario building developed for the region of Sfax (Tunisia)

Relevant experiences of scenario-building used in the policy debate are few and far between, which is why it is interesting to introduce an approach developed in Tunisia, in the context of acute water pressures. While Tunisia may not be representative of European contexts at large, the approach taken was usefully applied despite the lack of means and data, and it proposed some simple tools to build scenarios, based on "re-using" the technical forecasts that generally exist in water planning institutions.

In Tunisia, the scenario-building exercise was conducted to feed the debate on strategies related to water demand management, as the approach still tends to focus on supply-side solutions without examining the links between water resource management, land use planning and economic development. For instance, irrigation demands are often considered as an input into the projections rather than something that can be acted upon independently.

As such, the scenario-building exercise followed a four-step process:

Step 1: Use technical planning forecasts as a foundation, and analyse the underlying assumptions in detail;
Step 2: Build scenarios using basic assumptions combined into contrasted scenarios, and make an explicit representation of the water uses/resource system to quantify the water balance with the assumptions;
Step 3: Choose a range of combinations for the assumptions (e.g., one combination is the backbone of one scenario), and then calculate the water balance over time that corresponds to the combination;
Step 4: Based on these elements, imagine a plot that tells the story of the system from now until 2030, giving consistency to the assumptions and water balance curves.

The region of Sfax's demographic projections demonstrates this four-step process.

For **Step 1**, three alternative choices were considered to forecast the region's demography:
- The first considered three possibilities of evolution for the agglomeration of Sfax's population;
- The second concerned two possibilities of evolution for the demography of other cities in the region;
- The third considered two possible evolutions of the rural population.

Data was technical and derived use per use. For every use, more or less simple trends analyses of past evolutions were used to derive projections of, for example, population, unitary domestic consumption, or irrigated area (see Fig.1). This simple framework was used as a basic representation of the water uses/water resources system.

Figure 1: Example of assumptions formulation on the demographic evolution of the Sfax region

	2000	2005	2010	2015	2020	2025	2030	
Population du Grand Sfax								
x 1000 hab								
- hypothèse de désaffection D1a	492,0	548,6	611,6	675,3	745,5	823,1	908,8	(+2,2% jusqu'à 2010, et +2% après)
- hypothèse de mise en valeur progressive D1b	492	543,2	599,7	678,6	767,7	868,6	982,8	(+2% jusqu'à 2010, puis +2,5% après)
- hypothèse de non migration D1c	492	556,7	629,8	712,6	806,2	912,1	1032,0	(+2,5% sur toute la période)
								Hypothèses du PAC de Sfax
Population Communale hors Grand Sfax								
Taux de croissance annuel de 1984 à 1994 : 10,65 %/an								Incertitude sur ces données indirectes
Taux de croissance annuel de 1994 à 2000 : 16,58 %/an								Incertitude sur ces données indirectes
- hypothèse de développement d'autres centres urbains D2a : +5%/an								
x 1000 hab	58,0	74,0	94,5	120,6	153,9	196,4	250,7	
- hypothèse de non développement des autres villes D2b: +4%/an jusqu'à 2010, +2% après								
x 1000 hab	58	70,6	85,9	94,8	104,7	115,5	127,6	
Population rurale du gouvernorat								
Taux de croissance annuel de 1984 à 1994 : 1,58 %/an								Incertitude sur ces données indirectes
Taux de croissance annuel de 1994 à 2000 : 2,06 %/an								Incertitude sur ces données indirectes
- hypothèse de maintien de l'activité rurale D3a : +2%/an	315,4	348,2	384,5	424,5	468,7	517,4	571,3	
- hypothèse d'exode rural D3b: +1%/an jusqu'à 2010, puis +0,5%/an après	315,4	331,5	348,4	357,2	366,2	375,5	384,9	

Step 2 requires a check on the global consistency of a combination of assumptions. In the Sfax region, the following critical queries were posed: (i) what are the underlying assumptions for each growth curve (population, leakages)? Is it an exponential, linear or logistic curve? What is the growth rate?; and (ii) What is the statute of the variable: is this a trend that can be extrapolated, a critical uncertainty (depending on external uncertainties) or is it a project variable (which is subject to decisions by stakeholders)? (iii) What is the anticipated water resources supply/demand balance and is the sum of water uses below the maximum available resources? Also, the political and social context of the scenarios must be considered in conjunction with the technical assumptions that form their foundation.

Step 3 requires combining basic assumptions to develop alternative scenarios by reducing a set of basic assumptions, explaining qualitatively the process of evolution and quantifying the assumptions on future evolutions. In Sfax, the alternatives developed were land use planning, spontaneous development, and the baseline scenario. To represent the scenarios, it was important that they were consistent in format with a structured list of assumptions to ensure transparency (for discussion with stakeholders); a quantitative evaluation of the resources/demand balance; a narrative illustrating the causal paths, major issues, and transitions that could occur; and, if possible, a geographic representation of the spatial distribution of resources and uses. It is important to stress that *transparency of the scenario construction*, methods and use of the data sources is *as important as the reliability of the data* underlying the assumptions.

The water resource/uses water balance, modeled in Step 2, combined with the set of assumptions for the land use planning scenario resulted in a situation where the forecasted solicitation of the deep aquifer from planned development became greater than the threshold for aquifer renewal. It was therefore necessary to imagine other ways to generate water supply, particularly concerning agricultural use of groundwater.

Step 4 requires imagining a plot and a narrative. The following was imagined for the land-use planning scenario:

"A very dynamic land use planning policy is being implemented. Local development stakeholders are negotiating subsidies and some autonomy from the state in a way that natural water resources limitation cannot be taken into account. Finally, the development model for which a lot of money has been invested is put into question because of excessive water use."

Then, this scenario was imagined for the spontaneous development scenario:

"*The city of Sfax continues growing without implementation of land use planning policies. Because of water scarcity and of the Euro Mediterranean free trade zone, agricultural employment in the region decreases drastically. Sfax must incorporate this new population and labour force, which accelerates water supply problems in the city. Thanks to its political weight, the city manages to have a bigger allocation from the national water resources network, but national solidarity and water resources sharing becomes a problematic national political issue."*

This last example shows why social and political elements must be added to the technical forms of the baseline scenario. While the techical plans indicate a growing and intensifying irrigation sector, the sector's future is in fact more uncertain. Both for regional and national policies, the impact of external factors on water scarcity are important to at least acknowledge, even if they are not quantifiable.

The scenario approach presented here is possible to implement without important efforts and even with little data. It exemplifies that the baseline scenario necessitated by the Water Framework Directive can be built as one particular combination of assumptions, for instance the one based on land use planning and other existing plans. The other possible combinations are also plausible and are necessary counter examples to the baseline scenario. It is therefore necessary to put into discussion the scenarios that are built, and to ensure that the construction method is transparent enough for any stakeholder to be able to participate in the discussion.

Illustration 5 - Example output from a scenario building exercise in the Ribble (England)

The case study identified seven pressures on the water status of the Ribble basin, of which water industry discharges (STW), the presence of dangerous substances, agricultural and diffuse pollution and abstraction were found to be significant. The Table below illustrates how the outputs of a characterisation and risk assessment can be presented, drawing on experience in the Ribble river basin. Though the Ribble case study analysed pressures quantitatively and qualitatively, the results below are presented in a qualitative form: the arrows denote whether the pressures are likely to fall, rise or remain at current levels whilst H, M and L describe the likely magnitude of risk of failure to achieve a given water status (good, moderate or poor). The Table shows that there is a high risk of failing to achieve good status in 2015, 2021 and 2027 on account of STW discharges and diffuse pollution from agriculture and that abstraction could contribute significantly to the risks of failing to achieve good water status in 2027.

		Likely Development in Pressure			**Likelihood of limiting achievement of quality states in future plan periods**								
Ribble	Significant?	2000 to 2015	2015 to 2021	2021 to 2027	2015			2021			2027		
					G	M	B	G	M	B	G	M	B

Task 3 - Integrate Changes in Uncertain Parameters (integration of critical uncertainties)

In this task, more uncertain changes that are likely to have significant impacts on the pressures and water status are integrated into the analysis for developing the final business-as-usual scenarios to be used for identifying the gap in water status.

At this stage, the possibility of uncertain events or "what-if scenarios" will therefore be integrated into the "business-as-usual" scenario with questions such as:

- What if the river basin district goes through a technology or water consumption shift?
- What if a series of severe droughts or flooding events occur during the next 10 years?
- What if agriculture common policy is radically changed? etc.

Of course, possibilities for such variations are infinite. However the first two tasks will have helped designating the key parameters on which uncertainty analysis is necessary (e.g. if diffuse pollution appear as a major issue in a district, analysis of uncertainty in that field is worthwhile, through the analysis of alternative agricultural policies for example). The Table below summarises the key issues that could be examined during that Task. Taking into account such changes will produce the Baseline scenarios for the district.

Task 3	Key points	Output
Identify changes to the parameters that are uncertain and could have significant impacts on the water policy	Pay special attention to: • Increase in magnitude and frequency of uncertain events (policy and technological shifts, meteorological events such as floods and droughts occurrence) • Possible reactions and feedbacks from the environment: acceleration of water quality improvement due to enhancing of auto-purification by the water environment; apparition of new quality parameters previously hidden (again recommended use of modelling) • Possible social changes having significant impacts on the water system: consumption habits (housing, land planning, …), institutional design of water policy • Possible economic changes having significant impacts on the water system: economic growth cycles, investment flows, employment, economic policy, taxing system, etc. • Associate and merge analyses of "demand" and of "supply" of water. Baseline scenarios are particularly necessary for preventing the dissociation of supply policies and demand-side management, "putting offer and demand in the same image".	Alternative baseline scenarios

Illustration 6 – The incorporation of critical uncertainties in the development of a Water Resources Strategy (England and Wales)

The only certainty surrounding long-term forecasts is that they are likely to be wrong! Any best estimate forecast contains uncertainties. One way of dealing with some of these uncertainties is to define scenarios, or story lines, within which the key drivers of demand evolve on a justified basis. The use of scenarios enables us to test not only "*what if…?*" scenarios but it also provides an indication of the sensitivity of components to particular assumptions.

The Agency's case study referred to above (see *Illustration 3* of this information sheet) used a demand-forecasting approach based on the projection of disaggregated demands. In order to assess the key uncertainties related to these forecasts, the possible impacts of different socio-economic and political pressures on the key drivers of demand were examined using the *Foresight* tool, developed by the UK Government to project alternative Environmental Futures scenarios over a period of several years. Note that the process used in developing this Foresight generic tool involved drawing on national and global future scenarios for the state of the environment as a whole (without focusing particularly on water), which were then developed and reviewed by business, government and academia. This produced a tool that others can use to explore possible futures.

Scenario development

In the study, four future scenarios for water use were developed for the period 2010 and 2025, which reflected different permutations of regionalisation versus globalisation and communitarian versus individualistic traits.

Key lessons

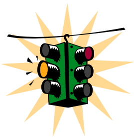
The areas of greatest residual uncertainty in this process were in relation to the pace at which policies might be applied and their relative success. Expert advice drawn from stakeholders in business, trade associations, economists, government and the water industry helped to minimise such concerns. Wherever possible these judgements were reinforced by practical examples and real experiences. One weakness that emerged from the use of scenarios, however, is if the forecast relies on unsubstantiated key judgements about demand changes.

The benefit of this approach is to acknowledge that the future cannot be reliably predicted, however, it is possible to identify the circumstances under which significant demand changes might realistically occur. As well as facilitating a means of testing combinations of assumptions and their relative effects / sensitivity, this method permits an examination of the robustness of management options to a range of demands. Also it facilitates debate on the potential acceptability of various options under certain socio-economic conditions.

Source: Environment Agency for England and Wales (August, 2001).

4. The role of public participation in scenario-building

The choice of assumptions made while developing a *business as usual* scenario will require discussions with the public and stakeholders, and input from economists and technical experts.



Look out! Participation in scenario building can take many forms

Participation in scenario building can take many forms. Most past experiences demonstrate that public participation should be placed as much "upstream" in the process as possible. At least 3 modes of participation are possible:

- *Participation by collective building of scenarios*: involve the public in the process in the choice of assumptions and their values;
- *Participation by checking coherence of the proposed scenarios*: check consistency of assumptions and of scenarios with the various visions that are shared or distributed among social groups;
- *Participation by asking the public to question the main "statements" in water policy*: scenarios illustrate and somehow caricaturise the most common policy statements, helping the public to input into decision-making and fostering transparency in the process.

The use of scenario building for public participation

One particular method of involving the public is to use scenario building (or foresight methodologies). This may usefully complement forecasting (i.e. the derivation of the business-as-usual scenarios) in order to structure policy discussion and public participation, and identifying key water management issues. Scenario building as an exercise is not so much carried out to produce one single image of the future, but it intends to foster the debate on present and immediate future policy options by exploring their possible future consequences. Prospective scenarios can provide colourful illustrations of the main issues for water management, give extended view of the ongoing policy debate on water (e.g. supply- or demand- management), illustrate the *pros* and *cons* of the possible solutions, reveal possible factors of change, and offer a possibility of a wide but formalised interdisciplinary discussion. Prospective scenario building is proved to be much less "data-demanding" than forecasting a baseline.

Optional additional task	Key points	Output
Combine various combinations of possible changes in parameters, using futures studies methodology	Design several contrasted scenarios in order to allow for uncertainties surrounding the key parameters Organise and give effective result of stakeholders and public participation	Exploratory scenarios

Methods and practical tasks in this field are very diverse, with respect to:

- The spatial scale: world perspective, river basin / regional scale, local scale.
- The time horizon: preferably long-term horizons (25 to 100 years);
- The type of "input variables": either in qualitative or quantitative terms;
- The type of output: contrasted "visions", possible statements on water status, qualitative and/or quantitative scenarios, …

The role of public participation in scenario building at river basin district level: A summary

Task	Role of public participation	
Task 1	System analysis and choice of determinant assumptions In-depth interviews with main stakeholders, experts and institutions of the district, aimed at: • Defining the key variables that determinate the water system in the district according to the interlocutors; • Proposing a hierarchy for these variables (more or less determinant); • Describing their range of variation	Overview of general trends in key variables – Short-term projections
Task 2	Scenario building based on task 1 inputs and participation from stakeholders, experts, representatives, scientists through working groups, thematic workshops, etc …	Baseline scenario without uncertainty
Task 3	Large-scale debate on the proposed scenarios: presentation at various policy levels, large communication, and collection of opinions from the public. The list of assumptions that underlie the scenarios should be delivered as clearly as possible to allow transparency and possibilities for criticism and reformulating, etc.	Alternative baseline scenarios incorporating uncertainty
Task 4 (optional)	Amendment of scenarios, and quantification refinement: based on previous tasks, derive and calculate the precise significance of scenarios for their systems and instruments: investment and subsidising system, pricing, technical actions, policy organisation, etc. Organisation of large scale publication and participative discussions.	Exploratory scenarios

5. Summary

The development of baseline or *business-as-usual* scenarios require a range of economic and technical expertise to account for, and investigate, trends and evolutions of a wide range of hydrological, technical, socio-economic and regulatory parameters. Methods that need to be mobilised include:

- Statistical analysis of past data;
- Economic and environmental modelling, e.g. to asses the impact of changes in sectoral policy drivers on key pressures;
- Review of existing planning documents that develop scenarios for key socio-economic sectors; and
- Interaction with, or participation of, key stakeholders.

The development of the baseline scenarios investigates drivers and parameters at different scales:

- For parameters and drivers linked to **local changes**, input into the analysis of potential changes in these parameters and validation of key assumptions with stakeholders and the public is likely to enhance acceptance of results of the analysis and the selected baseline; and

- For **global changes** (e.g. climate change) and EU/national sector policies, interaction and feedback will be required between river basins and between countries to ensure coherent assumptions are made for foreseen changes in key drivers.

COST-EFFECTIVENESS ANALYSIS

Directive references: *Articles 4* & *5* and *Annex III*
3-Step Approach: *Step 3.2*
See other information sheets: *Baseline Scenario*, *Estimating Costs* and *Disproportionate Costs*

This information sheet will help you carrying out a Cost-effectiveness Analysis (CEA). The CEA is used for assessing the cost-effectiveness of potential measures for achieving the environmental objectives set out by the Directive and construct a cost-effective Programme of Measures.

1. Objective

Cost-effectiveness analysis (CEA) is an appraisal technique that provides a ranking of alternative measures on the basis of their costs and effectiveness, where the most cost-effective has the highest ranking. The CEA proposed here takes an *economic* view of cost-effectiveness (see *Estimating Costs* Information Sheet for a definition of the term).

The CEA is used for assessing the cost-effectiveness of potential measures for achieving the environmental objectives set out in the Directive, and in particular for:

- Making judgements about the most cost effective **programme of measures** which could be implemented in order to bridge a potential gap in water status between the baseline scenario and the Directive's objectives (*Annex III*) (see also *Baseline Scenario* Information Sheet); and

- Assessing the cost-effectiveness of **alternative measures** in order to estimate whether those programmes of measures are disproportionately costly or expensive (*Article 4*) (see also *Disproportionate Costs* Information Sheet).

The focus of this information sheet is on the first component of this analysis. The sheet outlines issues relevant to estimating the effectiveness, costs and economic impacts of water improvement measures as well as the key tasks of the CEA.

2. What are the Key Issues?

Key issues to look out for when conducting the cost-effectiveness analysis include:

- Provide value added information to aid decision-makers;
- Be practical and proportionate, allowing for the costs of carrying out the analysis and the availability of data and the importance of the effects and costs in question;
- Cover fully the costs and economic impacts of measures for the different sectors, whilst avoiding double counting;
- Be applicable to a wide range of measures in a RBMP (see *Box 1* of this information sheet), including specific control and abatement measures for both water quality and water resources (e.g. abstractions);
- Be able to cover measures that incur costs and achieve effectiveness in different periods;
- Be readily applicable in practice and capable of generating summary cost estimates in and across basins, sectors and measures in order to aid decision-making on measures that could be taken at national level and subsequently included in the RBMPs.

Box 1 - Possible measures for implementing the Water Framework Directive

Possible Measure/sector	**Decision-making body**	**Level of decision**	**Level of Implementation**
1. Requirements for water industry to implement measures to reduce abstraction	National Relevant Ministry	National	River Basin District
2. Controls on other Direct dischargers	Environment Agency National ministries re control measures for other sectors	RBMP & also In line with National/Agency policy on sector	River Basin District
3. Controls on other abstractors	Environment Agency	RBMP	River Basin District
4 Best practice controls on pollution and abstraction at farms	Agency in charge of environment (but, in a clear national policy context)	RBMP & also In line with National/Agency policy on sector	River Basin District
5. Controls on other indirect dischargers (e.g. run off from traffic on roads)	National Ministry	Highways Agency, Local Authorities	Highways Agency, Local Authorities/basins
6. Agri-Environment programmes (financial and technical assistance and advice to go beyond good practice)	National agriculture + finance ministries in response to Ministry submissions	National	Regional/basins
7. Economic instruments	National agriculture + finance ministries In response to Ministry submissions	National	National taxes (but pollution charges and tradable permits are local)
8. Morphological measures	River Basin Agency	RBMP	River Basin District

3. What are the Practical Tasks?

The key components of the CEA are the costs and effects on water of the measures. These and other tasks are outlined below. At times, this will save you doing the job twice, since most of the cost analysis for the cost and benefit assessment will have already been performed for the cost-effectiveness analysis. Some other key points to consider throughout the process include:

- The cost-effectiveness analysis should be used to refine the programme of measures by focusing on the largest cost components and the major determinants of the effectiveness of measures. The analysis should then be used to develop packages of the most cost-effective measures for achieving alternative water status;
- Some measures have differing uncertainties concerning their effectiveness and costs. To allow for this, it would be desirable to use ranges of costs instead of point estimates;
- It is costly to undertake a CEA. Therefore, the focus of the analysis should be on the limited number of water bodies requiring actions to achieve good status. Consider only those measures that are likely to be worthwhile for achieving this aim.

The analysis of cost-effectiveness can be broken down in five basic tasks and one optional (see *Figure 1* of this information sheet).

Figure 1 – Tasks and Key Questions in Analysing and Reporting on Cost-Recovery

Key Tasks	…And Questions
1. Define Scale of the Analysis	Where are the most significant pressures causing the failures located? At which scale do the measures under consideration for addressing the gap have an impact?
2. Define Time Horizons	What measures can be implemented in the first RBMP (2009-2015) period? If the objectives cannot be met by 2015, which measures can be implemented in later periods? What are the major cost elements that could be reduced by an extended deadline?
3. Determine the Effects of Measures on Water	What is the technical feasibility and applicability of specific control measures? How should the effectiveness of measures be assessed and on the basis of which parameters? How do the measures affect the risk of an incident taking place?
4. Estimate the Costs of Proposed Measures	What are the direct costs of measures and environmental costs (or benefits) non linked to water? How are these costs allocated between different sectors and who pay for the measures? Are any of these costs likely to be disproportionate for a particular group?
5. Assess Cost Effectiveness	What is the cost-effectiveness of each measure? How can the most cost-effective programme of measure be constructed? How can alternative programmes of measures to meet an objective be compared?
6. Optional – Assess wider economic impacts	What is the overall cost impact of the programme of measures particularly on the Exchequer costs? What are the wider economic impacts of the cost-effective programme of measures?

Task 1 - Define the Scale of the Analysis

Sub-task	Key points	Look out! Define the spatial scale	• Define the spatial scale according to the level identified by the IMPRESS Working Group for the location of the significant pressures that cause the failures (see *Illustration 1* of this information sheet). • Extend the scope of the cost-effectiveness analysis depending on the scope of the environmental and economic impacts of the main measures under consideration.	Data can be aggregated to identify key environmental and sectoral problems and appraise the cost-effectiveness of measures at RBD level.

Illustration 1 – Determination of scale based on information in Cidacos (Spain)

The analysis of pressures in the Cidacos river has played three roles for the cost-effectiveness analysis:

1. To define water bodies for the analysis on the basis of homogeneity of pressures/human activities;
2. To design programmes of measures that help to reduce key pressures;
3. To understand factors behind existing pressures and their likely evolution in order to make projections about the likely status of water quality in 2009 and 2015.

In Cidacos, information about emissions exists (for point pollution) or in some cases it is possible to rely on estimates (for diffuse pollution). For example, estimates of leachate of nutrients from farms are based on estimates empirically tested elsewhere (elaborated by the National Plan of Irrigation) applied to the existing information for Cidacos. This depends on the types of soil, types of crops and productivity, irrigated areas, use of water and monthly distribution, irrigation techniques and efficiency of irrigation systems. This information exists in the Cidacos river ordered by irrigation co-operative and by total number of hectares.

The identification of the water bodies for the analysis was done on the basis of types of pressures and in such a way that it would be possible to monitor improvements of water status resulting from the programme of measures. Control stations helped defining the limits of the water bodies used for the Cidacos study.

Source: Ministerio de Medio Ambiente, Gobierno de Navarra, 'Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River'. See ***Annex E.***

Task 2 - Define Time Horizons

Sub-task	**Key points**	**Look out!** Identify the relevant time periods for the analysis	• Focus, firstly, on measures to be implemented in the first RBMP period 2009 – 2015; • Look at later RBMP periods (2015 – 2021 and 2021 – 2027) if the measures cannot achieve cost-effectively good status by 2015; • Look at later RBMP periods if there are uncertainties about the costs and effectiveness of the measures applicable in the first RBMP and scope for increasing effectiveness and reducing costs. • Identify the major cost elements that could be reduced by an extended deadline and an actual start in developing and applying more efficient control measures (started in the period 2009 - 2015 although the measures would come into effect in a later period). This will require a clear signal to the sectors concerned so as to prompt such an actual start to the development and application of more efficient control measures. In addition, it is necessary to examine scope for this increasing the effectiveness of measures (especially in respect of development and application of technological changes).	Distinguish between: • Long run ongoing costs in 2027. (opportunity costs of the resources used for achieving good status instead of alternative uses); • Short run dislocation costs and economic impacts of measures to achieve good water status by 2015 and 2021.

Task 3 - Determine the Effects of Measures on Water

CEA requires comparable and if possible, quantitative information on the effects of measures.

Sub-tasks	**Key points**	**Look out!** Assess technical feasibility and applicability of specific control measures for each RBD	Base the analysis on: • Analysis of the current and future pressures on water in the basin, which should characterise these pressures into main segments of the key sectors that cause most of the problems to identify and develop measures effectively targeted at them; • Views of stakeholders involved in the practical implementation of the measures to address the specific pressures (e.g. water industry, non-water industry, agriculture). • Studies and reviews of available technologies (e.g. BREF notes, BAT reviews) and prospects for the development and application of technical changes.	
Assess effectiveness (see Illustration 2 for an example).	• Clarify how (risks of) failure to achieve the good status target will be defined and interpreted in practice; • Effectiveness needs to be assessed in terms of reductions in the risks of pollution incidents arising (e.g. slurry run off, leaks) as well as reductions in continuous discharges and abstractions; • How to assess the likely effects on discharges and abstractions and correspondingly the effects on biological water quality of specific measures, especially where measures focus on achieving behavioural and more qualitative changes (e.g. changes in farm practices); • How to assess and allow for any time lags before a measure could become fully effective? Would this extend over a number of planning periods? The problem of time lags may be addressed by setting interim targets and periodic reviews of their achievement; • How to allow for the complex synergistic effects of policy measures that may have a nation or region-wide scope and serve multiple objectives or have multiple effects. • Prospects for the development and application of technical changes that could increase the effectiveness of measures for achieving good quality if such changes were embarked upon over an extended deadline.	Multi Criteria Analysis based on scientific advice may serve to combines these various effects into a weighted composite index so that the relative effectiveness of the measure can be assessed on a consistent basis. Consider how long before a measure can be • in place and operational; • fully effective; • will impact on the water body so that it recovers to a higher status

Key issues to address include:

- ➢ How to choose and combine criteria for determining the relevant effects? Effects on water are diverse (e.g. effects on emissions of dangerous substances; water flows; water pollution levels, biological quality of the water body; and groundwater etc); and
- ➢ Should failing one criteria mean failing to meet the objective (fail one fail all) or should the fact that different measures may have different effects on different metrics be taken into account?

To make it easier, it would be important to identify the effect of the measures on each parameter as clearly as possible (see *Illustration 3* of this information sheet).

Illustration 2 (below) demonstrates how the effectiveness of measures was assessed for the Ribble basin.

Illustration 2 – Assessing the effectiveness of measures in the Ribble (UK)

This example illustrates how effectiveness of measures was assessed in the Ribble basin. It is assumed that an aggregate 50 percent reduction in nutrient levels would be needed to achieve the necessary reduction in the risks of not achieving good water status. However, it should be noted that, depending on the outcome of other research on the appropriate compliance assessment model, different formats for presenting risk reduction information might be more appropriate. In addition, precise estimates of the risk reduction may not be the most appropriate format for presentation. Broader categories of risk reduction (High-Medium-Low, or ranges) may be better. However, in order to make the analysis tractable, point estimates are used here.

The table presents estimates of the effectiveness of number of measures for the River Ribble. For example, STW optimisation may be judged to deliver a 20% risk reduction (+/- 5%, i.e. 15% to 25%). The measure can become operational immediately (i.e. no specific time lag). This might be contrasted to the agricultural general binding rule measure, which might deliver the risk reduction, but entails considerable uncertainty about its effectiveness and would require a significant lead time. Full effectiveness of this measure would not be expected until the 2021 planning date. In addition, this measure is not currently available, as it would need to be negotiated at a national level.

Aggregate risk reduction required			Risk reduction delivered			Feasibility	Expected km delivered in 2015		
2021	2027	Measures	2015	2021	2027	Uncertainty range	2015	2021	2027
Elevated Nutrient Levels									
50%	50%	STW Management optimisation	20%	20%	20%	5%	5	5	5
		STW Opex scheme	50%	50%	50%	10%	14	14	14
		STW Capex scheme	50%	50%	50%	10%	14	14	14
		Agri surveillance/enforcement	2%	2%	2%	1%	1	1	1
		Agri General binding rule	10%	50%	70%	25%	3	14	19
		Agri Nutrient surplus charge	15%	30%	50%	25%	4	8	14
Land drainage									
0%	0%	Risk acceptable, do nothing	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.
Dangerous substances									
25%	25%	Monitor + R&D	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.
Abstraction									
0%	50%	Monitor + R&D	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.

Illustration 3 – Issues in conducting the cost-effectiveness analysis in Cidacos (Spain)

In Cidacos, information for determining water quality status was drawn from the control stations in the river that measure a number of quality parameters and other stations that measure quantity of water, pluviometry and estimate runoff. There are also two stations that monitor biological indexes along the river all year long, allowing for the identification of the current status of key parameters in winter and in summer.

Selecting quality parameters
From an initial assessment, a few key parameters were selected for the Cost Effectiveness Analysis, including water quality and hydromorphological parameters that need to improve to achieve the objectives (as defined in the existing quality plan).

The criteria for selecting those parameters were the following:

- Those parameters where there is a gap or which are closer to thresholds;
- Those parameters that may be sensitive to further expected pressures;
- Those parameters that may be sensitive to the introduction of measures aimed at improving other parameters.

The hydromorphological parameters chosen were: water flow, and improvements of river borders and river vegetation. Others such as the existence of barriers, bridges, etc., were not considered for the purpose of this study since it was difficult to assess the effectiveness of the measures when the inter-relations between physico-chemical and hydromorphological parameters with the biological parameters have not been characterized.

Examining the effects of measures on combined sets of parameters
From the study, it became clear that it is important to identify and characterize the inter-relations between the different “selected” parameters in order to assess with some accuracy the effectiveness of measures. Some simple examples are: an improvement of water flow affects dilution of pollutants and hence has a positive effect on physico-chemical parameters. However the objective of water flow is not affected by the water quality parameters. By contrast, water flow would be negatively affected by the improvements of river border vegetation (that demands water). It is important also because it helps identify those parameters (often those with key synergies) on which it could be most effective to intervene.

Analysing the effectiveness of measures
The analysis of the effectiveness of the measures for the Cidacos river were based on:

- Empirical information on the impact of measures on pollution emissions;
- Empirical information about the water saving potential of measures and how this translates into increased water flow;
- Expert judgement about how these will lead to an improvement in the specific parameters.

The effectiveness of the measures was estimated on the basis of actual data for the Cidacos River. For example, the estimation of the effectiveness of measures aimed at improving water flow (such as improvement of irrigation, canals, substitution of pipes, or changes to low pressure water distribution systems) varies according to water use and density of irrigation networks. This information applied to the real data on the Cidacos (on density and number of hectares with different water applications) leading to estimates of ***total maximum water saving potential for each individual measure***.

In the case of agriculture, 27 measures were analysed in terms of their maximum potential for water savings or reduction of Nitrites, Nitrates, and BOD5. These have been expressed in absolute numbers or expressed either as a percentage reduction of pollution or percentage increases in water savings in relation to the base line indicators. The main problem was how to measure the improvement of water quality resulting from a certain reduction in pollution. Another problem was to identify how much each user contributes to the water status of the river.

This information used in relation to agriculture had been collected to prepare the National Irrigation Plan. The available information for urban areas came from empirical evidence of demand management programmes, management of urban water, inspection reports to companies and commercial water uses and the reports on measurements on pollution from wastewater treatment plant outlets.

Source: Ministerio de Medio Ambiente, Gobierno de Navarra, ‘Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River’. *See Annex E.*

Task 4 - Estimate the Costs of Proposed Measures

Analysing the costs and economic impacts consistently for distinctly different sectors is a major challenge. All costs should be measured in comparison with the business as usual situation that would arise in the absence of the option. Also, who pays for measures that have significant effects on particular parties (e.g. water customers in respect of water bills) and the scale of any such payments should be identified. Therefore the allocation of costs of the proposed measures is a key element of the analysis.

Sub-tasks	**Key points**	**Look out!** Determine costs of measures	• Estimate costs of measures (including direct costs, financial and administrative) and environmental costs not linked to water (see below). *Illustration 5* and *Annex I* of this information sheet give an example of such costs from the Ribble basin; • Examine how to review and validate the cost estimates (and note that costs are dynamic – they change as a result of developments in sectors); • The links between costs and the business-as-usual case need to be considered as implementation of current legislation will affect additional measures needed and also change the prevailing prices and incentives structures for agriculture; • Allocate the costs of measures to water users (see *Illustration 4* of this information sheet), and identify winners and losers, in order to potentially feed into the analysis of disproportionate costs to justify derogation – This would also determine the institutional viability of proposed measures.	Formats should be developed for different types of sectors and measures. These need to build on the existing costing conventions currently used in each sector (see *Annex I* of this information sheet).
Determine costs of other policy measures	• Estimate the costs of control measures such as economic instruments, water pricing measures, cost recovery charging levels and technical and financial assistance measures (e.g. agri-environment measures, waste minimisation programmes) to encourage behavioural changes (e.g. changes in farm practices).	
Estimate non-water environmental impacts from the control measures	• Focus only on the external elements and determine the scale and significance of such external impacts (materiality) as any direct costs of measures are included in the financial costs, e.g. impacts on natural habitats of particular measures; environmental impacts from combustion and extraction of the energy and raw materials used in some control measures, nuisance from sewage treatment works and impacts from transport of sewage sludge.	The CEA does not value the water related benefits of measures. Benefits are included in the appraisal of derogations, see *Disproportionate Costs* Information Sheet.

Illustration 4 – Allocating costs of measures to water users in Cidacos (Spain)

In the Cidacos case study, the most cost-effective measures require many actions in the irrigation communities located upstream of the river and no action in those located downstream. The cost reduction gains that result from this approach far outweigh other more symmetric alternatives. However, the drawback is that measures must be funded and the target farmers' cannot finance the programmes of measures by themselves. Therefore, they must rely on other farmers' contributions, especially those whose irrigation districts will not be modernised or rehabilitated**.**

The consideration of institutional issues means that the costs and benefits for the six irrigation communities of the Cidacos River would have the following effects:

Stretch Irrigation community	Net margins variation (in % with respect to the present situation)
Stretch I	
▪ **CR Barasoain**	27.4
▪ **CR Pueyo**	11.5
Stretch II	
▪ **CR Olite**	-18.8
▪ **CR Tafalla**	-12.4

The numbers in the Table gives an idea of the winners and losers from the proposed programme of measures, which may stir conflicts amongst usually quite united stakeholders. Thus, measures will need to be taken to enhance the persuasiveness to gain the support for a cost- effective set of measures. While in the Cidacos project, it is assumed that all irrigators will be charged equal water rates, the net margins variation found in the study might support the option to implement differential rate schemes.

Source: Ministerio de Medio Ambiente, Gobierno de Navarra, 'Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River'. See Annex E.

Task 5 – Assess Cost-effectiveness

The unit-cost effectiveness estimates from above analyses should form the main element of the appraisal of costs of measures. Cost-effectiveness can be presented in two ways: (i) costs divided by the effect, or (ii) effect divided by costs. For the selection of measures in the framework of the Directive, the former is used:

Costs per effect:

KEm = Km/BEm

KEm - cost-effectiveness of measure m (Euro/m3)
Km - economic costs of measure m (Euro)
BEm - the water quality improvement (= the effect) of the measure (say in km or m3 of improved water body)

The cost-effectiveness analysis itself can be broken down into a number of tasks:

- Analyse the costs of individual measures;
- Produce ranking of measures based on their cost-effectiveness (see *Illustration 5* of this information sheet);
- Produce proposed programme of measures to achieve given objective; and
- Rank alternative programme of measures to achieve a given objective based on their overall effectiveness.

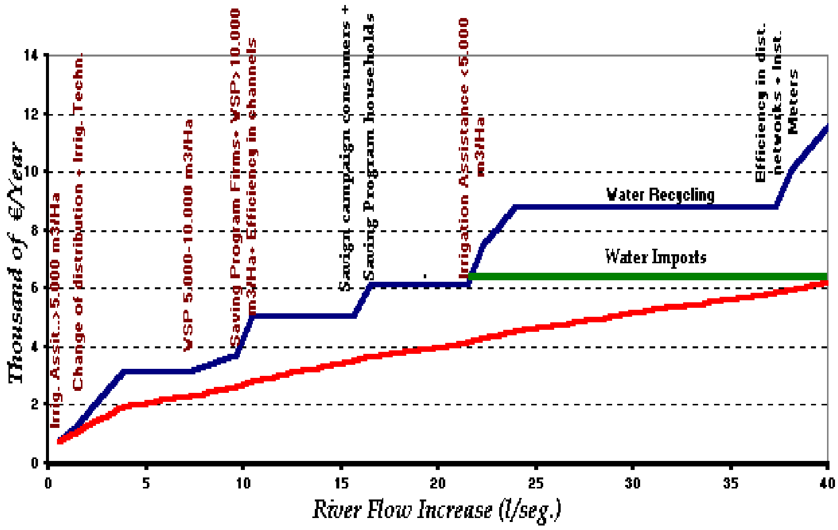
A summary of the cost-effectiveness analysis in the Ribble is given in *Illustration 6* of this information sheet.

Illustration 5 – Ranking measures based on their cost-effectiveness

Different measures can be implemented to achieve an improvement in the water status for a specific parameter. In order to select an appropriate set of measures, these can be ranked according to technical efficiency (ability to obtain an X reduction of pollutants or increase in river flow) and associated costs.

In the Cidacos scoping study, a total of 26 policy measures for improving the water flow were identified initially. These measures involved reducing pressures on water abstraction by reducing the water demand, increasing the efficiency of the water distribution networks in urban and the rural areas, and importing water from another basin through existing infrastructure, and each of them was appraised according to effectiveness and cost. As shown in the diagram below, the cost and efficiency of each measure can be represented by marginal cost curves (see blue and green curves), indicating the cost in euro per unit of achieved flow increase (litre per second) and so provide a ranking. (The red curve shows the average cost of the resulting policy package.)

In the Cidacos river, an increase in the water flow of 50 litres per second is required to meet the objectives of the Directive. Following the ranking of measures (as shown in the diagram), it was shown that the most effective measure (i.e. the measure that could achieve the greatest increase in water flow at the lowest cost) was the implementation of a water saving programmes (WSP) in the agricultural sector (achieving 20% of the requirement, or 10 litres per second), mainly by reducing the demand and changing irrigation techniques for farms using more than 6.000 m3 per Ha, followed by WSP designed to reduce the demand in households and firms (urban uses), which achieved another 15 percent (or 7.5 litres per second) of the required flow increase.



However, note that the cost effectiveness (and ranking) of a measure is not always constant. For some measures, the marginal cost increases with the level of efficiency (see water recycling, blue curve). It is therefore important to carefully look into the behaviour of costs: assuming that costs are constant may lead to an inefficient selection of measures.

Illustration 6 – Estimating the cost-effectiveness of proposed measures in the Ribble (UK)

This illustration demonstrates how costs of measures were reported and used to calculate the cost-effectiveness of measures in the Ribble river basin.

Annex I (to this information sheet) illustrates a worked example of proformas for recording and presenting the ranges of costs of individual measures. The example used is that of the Ribble STW Capex scheme. Capital and operating costs were recorded separately. In capital costs, a distinction is made between the costs of the pollution control equipment and installation. In operating costs, a distinction was made between changes in operating costs and changes in revenues or receivables. These were then used with information on the economic life of the investment (30 years in this example) and the discount rate (6%) to estimate the present value of costs and the equivalent annual value of costs. Recorded costs were reported in a common unit – Annual Equivalent Cost (AEC).

The reported (financial) costs (see Annex I to this information sheet) were used together with the appraisal of the other impacts and the assessment of the effectiveness of the option to calculate cost-effectiveness. Table 1 below presents an illustrative assessment of the costs and effectiveness of options for the Ribble. Cost-effectiveness is measured here in terms of the annual equivalent costs of the measures divided by the km of river delivered to good status. This is a fairly simplistic statistic, which may not be appropriate in all circumstances. It is of great importance that the calculated CE variable should show explicitly the uncertainties, regarding both the costs as well as the effectiveness of some measures. This can only be resolved through the judicious use of ranges of cost and CE calculations.

The key points in Table 1 are highlighted in bold. This shows that Sewage Treatment Works (STW) optimisation is most cost-effective (EAV= Euros1,852/km/yr) but is insufficient alone to achieve the target status. It would achieve 20% of the required 50% risk reduction.

For 2015, the STW Capex scheme is the next most cost-effective measure, followed by the General Binding Rule (GBR) with agriculture and the STW opex scheme. The GBR measure, however, is more cost-effective in the long run because of the long time-to-effect lag due to the lags in implementation of the measure and the slow environmental response to this measure.

Once the cost effectiveness is assessed, strategies involving packages of options can be defined on the basis of meeting the different targets at different points in time. If the objective is G2015, the best strategy would be STW optimisation, GBR + opex scheme; then monitor to see how effective the GBR is and turn off the op ex scheme, if/once the full effect is felt. This flexibility would not be possible if the initially cheaper Capex solution was chosen. If target is moderate status in 2015, followed by achieving good status in 2021, however, the op ex scheme would not be necessary and this would reduce significantly the costs.

0%	0%	50%	Monitor + R&D	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.	

A key element will be to take into account uncertainty in all elements of the analysis, as it can significantly affect the results (see *Illustration 7*).

Illustration 7 - Addressing uncertainty in cost-effectiveness analysis: an example from the Scheldt estuary

A cost-effective analysis of the Scheldt estuary's morphological measures involved three different types of uncertainty: The effectiveness of the measures; the costs of the measures; and the assumptions made in the baseline scenario.

To address the first uncertainty, experts were asked to estimate the probability of measures reaching their ecological objective. If the probability was below 100%, additional measures were defined until the ecological objectives were reached. This means to address the measures' effectiveness within the CEA was then formulated by summing the probability of reaching the ecological objective times the costs of the additional measures to reach the objective.

The cost of the measures was accounted for by including ranges of costs instead of point estimates. The uncertainty surrounding the loss of added value through reduced navigation in the Scheldt estuary was considered especially large, and for the calculation of these costs large assumptions were made. This uncertainty was expressed in the CEA by including the probability of the actual costs being lower, and using expected cost figures instead of point estimates in the analysis.

To address the uncertainty surrounding assumptions made in the baseline scenario, experts were asked to judge the probability that the assumptions were correct. This involved asking experts whether they thought the baseline would succeed in maintaining the natural dynamics of the estuary. Experts judged the probability of this being true as 80%, leaving a 20% change that additional measures would be required. As this finding revealed major savings for the first alternative and major costs for the second, including the uncertainty of assumptions in the baseline scenario made quite a difference.

In average annual costs (million EUR/YR)	Option 1 De-poldering	Option 2 No further deepening
Uncertainty not included	7.3	38
Most extreme, with uncertainty	11	- 45.4
Expected outcome, with uncertainty	8.4	11.9

By including uncertainty into the expected costs of measures in the cost-effectiveness analysis, the outcome of the assessment changed considerably. Besides, it made the range of costs explicit, a range that turned out to be much larger for the one option then it was for the other. As this is important information for decision makers, uncertainty should always be included when performing a cost-effectiveness analysis.

Task 6 (Optional) – Estimate the Economic Impact of Measures

In addition to this process, it may be useful to estimate the economic impact of the proposed measures, although this would go strictly outside of the cost-effectiveness exercise. In addition to direct costs, such an analysis would account for induced costs (i.e. the costs on other economic sectors) and the environmental costs not linked to water (see *Illustration 8* for an example).

Sub-tasks	**Key points**	**Look out!** Estimate the exchequer (net) costs	The net impacts on public expenditures and revenues may be important because of the impacts on the economy of a change in net exchequer costs. This primarily includes the impacts of expenditures for agri-environment schemes and net impacts on revenues of economic instruments and, in countries with publicly owned water services, the impacts of changes in the prices charged for water services.	Includes primarily the impacts on expenditures for agri-environment schemes, revenues of economic instruments and impacts of changes in the prices charged for publicly owned water services.
Estimating wider economic and social impacts	• Include, for example, significant changes in patterns of employment, economic impacts on upstream suppliers or downstream customer industries and impacts on local economic development from changes in the price of water supply and discharges and changes in water quality; • Include effects of changes in water bills on the retail price index (RPI) and inflation.	Consider these only where there are particular concerns about economic and social impacts, e.g. dislocation costs and frictional unemployment impacts in a sector.

Illustration 8 – Impact of the incorporation of the economic impact of measures on the ranking of measures in Cidacos river basin (Spain)

Any change in the economic conditions affecting irrigated farms can potentially have other direct costs and also indirect costs. Costs that would need to be taken into account are those that affect land dedicated to agriculture and water consumption. "Other direct costs" are likely to be small if farmers keep the same practices or cropping patterns that they used prior to the implementation of a given measure. But if farmers' consumption is expected to fall, their output will change and their labour demand will also fall.

The Cidacos study considered (as in the Spanish Ministry Agriculture National Irrigation Plan) that 1 € of output produces 0.319 € of further added value. This is one measure of other direct costs (or benefits). The other is the impact in the labour market. The Cidacos case study makes the assumption that the loss of one hectare of irrigated land eliminates about 40 € of wages in addition to the losses of farmers' income.

An application is shown for the measure "restoration of the riverine forest".

	Net margin (including subsidies, €)	Subsidies €	Lost wages €	Indirect economic effects, €	Flow increases in litres/s
1 Ha in CR – A	775	189	26	255	0.06
1 Ha in CR- B	1096	153	54	360	0.07
Average	935	171	40	308	0.06
15 Ha	14,029	2,567	593	4,616	0.96

In addition, wider costs in the irrigation sector may be associated with those costs that are borne by stakeholders beyond the gates of the farms. In the Cidacos case study, it was assumed that attention should be given to those sectors linked to the agricultural sector, such as farm input suppliers and food processors. In addition, irrigated agriculture hires workers to perform various tasks, generating labour rents that are important in many agricultural areas. Impacts on the rural economy are thus integrated to the study, evaluating the other direct costs and labour market effects.

The Table below reports the selected programme of measures' costs in terms of Euros per increased unit of river flow. The reported evaluations indicate that incorporating wider costs in the analyses provides a different picture than excluding them. These differences are amplified when the costs reported in the table are brought to the basin-wide analysis, where other sectors and the spatial dimensions of the measures are fully integrated. For instance, if a measure applied in a non-agricultural sector has a cost of 5000 Euros for each litre/second of additional flow, many measures will not be desirable if all costs are included, and others would be more cost-effective if those costs are not included.

Measures' costs (expressed in Euros per increased flow of 1 litre per second)

	Indirect and labour effects included			Only direct effects included		
Measures	Water Body I	Water Body II	Water Body III	Water Body I	Water Body II	Water Body III
A	672	2846	2522	672	2356	2522
B	2576	6466	5892	2103	4865	4433
C	3567	6366	7652	2684	4790	5758
D	4301	6845	9667	3236	5151	7274
E	5552	12624	12320	4177	9499	9270
F	6440	12887	15828	4846	9697	11910

Water body I = upstream; Water body II = middle stream; Water body III = downstream

As a general rule, if cost differences are not very significant, an evaluation focused on direct costs may provide a valid starting point. However, if wider costs are thought to be important and sensitive to the regional or local economies, then they should be taken into account at least in the sensitivity analysis.

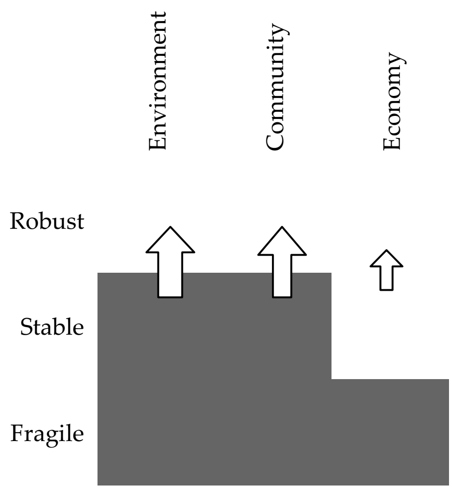
Illustration 9 – Analysis of Alternative Agricultural Measures: the Wise Use of Floodplains Project in the Erne Catchment (Ireland)

In order to engage stakeholders in thinking about local sustainability and the effectiveness of alternative measures to reach quality objectives, the Wise Use of Floodplains project in the Erne Catchment in Ireland used a simple model for public participation entitled the Local Sustainability Model (LSM).

The basic model can be supported with more detailed analysis or sub-models on specific issues. The participative process of establishing the baseline and discussing predicted impacts is as valuable as the result itself. The model is a simple three by three matrix. The columns represent three aspects of local sustainability: the natural environment, the community and its culture, and the economy. These are ranked as being Robust, Stable or Fragile. Communities can use this framework to assess how their area performs, shading in the model to provide a "picture" that local people can recognise.

THE LOCAL SUSTAINABILITY MODEL



Example of the local sustainability models use. Newtonbutler, Erne Catchment, February 2001.

1. Baseline conditions in the Catchment are represented by the shaded boxes.
2. Arrows show the predicted impacts of the measure being considered: a proposal to establish a single integrated cross-border Erne catchment management body.

The process of establishing the model leads a community through discussions on these three aspects using local knowledge and professional expertise. The example on the right shows an area which has a stable natural environment and community, but where the local economy is fragile. For potential catchment management options, or measures, arrows are drawn on the matrix reflecting the expected impacts. The model allows locals and professionals to share this qualitative impact assessment without the domination of one or the other.

Based on participatory work using tools such as the LSM, the Erne Wise Use of Floodplains Project developed options to restore water quality in the Erne catchment. An impact assessment study enabled comparison of their cost-effectiveness. Participatory work by the Erne project identified land management options and environmental impact criteria that were key to water quality in the catchment. These options included co-ordinated catchment-level changes to agricultural practices in the Erne, such as:

- Whole-scale buy-in to agri-environment schemes;
- Whole-scale adoption of mixed/organic farming methods; and
- Introduction of buffer strips on the most polluted rivers.

The economic, social and environmental impacts of these measures where analysed in a consultant's study that used a set of financial indicators, and ten weighted environmental and social criteria. The effectiveness scores were inevitably subjective, and encountered problems of double counting. Practitioners can be wary of these issues, and should develop and verify effectiveness scores with as wide a range of stakeholders as possible.

The management option's socio-environmental scores were compared to their predicted additional costs to taxpayers. The study revealed the current financial support for agriculture in the Erne catchment, and could be used to design more cost-effective policy modifications. The methodology developed in this project is interesting in the sense that it allows identification of cost-effective policies in relation to social and environmental objectives.

4. What are the Requirements for the Cost-effectiveness Analysis?

A broad-brush qualitative assessment provides a good foundation for the CEA. It can be used to identify the relevant costs, economic impacts and non-water environmental impacts of measures (see *Tasks 4* and *5* – see also the illustration on the methodology used in the Erne catchment in Ireland). However, a quantitative analysis is necessary on top of this, looking at (ranges of) estimates for the effects on water quality, and the financial costs of the main measures.

Where relevant, there should be a qualitative description of impacts over and above the direct costs already estimated. They may include:

- The nature, scale and significance of other considerations such as any wider economic and social impacts;
- Any distributional issues regarding who pays the costs;
- The ability of the sector to pay (or likelihood to pass on) the costs;
- Non-water environmental impacts of the measures; and
- The (administrative) costs of designing and implementing the measures.

As an option, the analysis can be taken further through the inclusion of the following actions:

- ***Developing nation-wide guidelines to assess cost-effectiveness.*** These guidelines should be developed in collaboration with the other regulators and representatives of the major stakeholders;

- ***Developing Guidance, drawing on practical experiences of the effectiveness of main measures.*** This would again probably be at national level and based on commonly applicable measures;

- ***Developing tailored formats for the estimation and presentation of cost estimates for the main types of measures for the major sectors.*** Costs should be presented in terms of changes in the cost elements arising from the proposed measures as compared with a business as usual baseline scenario. The appropriate expert and regulatory bodies should review carefully the estimates in relation to (ranges for) benchmark cost estimates for standard cost items. These benchmark estimates could be based on expert review of available estimates for each standard cost item. Ranges for the cost estimates should be presented, clearly and explicitly so that these can form the basis for discussions with the main stakeholders concerned. The segments of the sector to which the estimates relate, and key assumptions and factors behind uncertainties surrounding the estimates should be set out. This would allow subsequent improvements, as better information is obtained through increasing experience in applying the control measures;

- ***In the middle of the following RBMP period (i.e. around 2013), there should be an evaluation to check the costs and effectiveness of the measures in the first agreed RBMP.*** This will provide a better basis for assessing the cost effectiveness of measures for the next RBMP. It will also offer opportunities for increased feedback and system learning.

Annex I (of this Information Sheet) – Illustration of Format for Presenting Costs

1. CAPITAL COSTS			
Cost component	Cost (euro)		
	Low estimate	Medium estimate	High estimate
Pollution control equipment costs			
Primary pollution control equipment	450,000	600,000	750,000
Auxiliary equipment	112,500	150,000	187,500
Instrumentation	150,000	200,000	250,000
Modifications to existing equipment	157,500	210,000	262,500
Other (please specify)			
Total pollution control equipment costs	870,000	1,160,000	1,450,000
Installation costs			
Land costs	37,500	50,000	62,500
General site preparation	15,000	20,000	25,000
Buildings and civil works (eg foundations/ supports, electrical, piping, insulation etc)	225,000	300,000	375,000
Labour and materials (engineering, construction and field expenses)	157,500	210,000	262,500
Other (please specify)			
Total Installation costs	435,000	580,000	725,000
Other capital costs			
Project definition, design and planning	75,000	100,000	125,000
Testing and start-up costs	15,000	20,000	25,000
Contingency	22,500	30,000	37,500
Working capital	15,000	20,000	25,000
End of life clean up costs	30,000	40,000	50,000
Miscellaneous	37,500	50,000	62,500
Total other capital costs	195,000	260,000	325,000
Total capital costs	1,500,000	2,000,000	2,500,000

***Note:** Present Value of costs =Capex + (opex * discount multiplier). Equivalent annual cost = NPV/discount rate multiplier. Discount multiplier = 14.59 for a 30 year investment at 6%.*

2. CHANGE IN OPERATING COSTS (INC. REVENUE CHANGES)			
Cost component	Annual costs (Euro p.a.)		
	Low estimate	Medium estimate	High estimate
Change in operating costs			
Additional labour for operation and maintenance	15,000	20,000	25,000
Water/sewerage			
Fuel/energy costs	12,000	12,000	12,000
(specify energy/fuel type)	Grid	Grid	Grid
Reagent costs			
Waste treatment and disposal	22,190	32,920	43,650
Other materials and parts			
Change in operating costs of any additional pollution abatement equipment operation			
Insurance			
Taxes on property			
Environmental tax/charge			
Other general overheads (please specify)			
Total additional operating costs	49,190	64,920	80,650
Change in revenues			
By-products recovered/sold	2,000	2,000	2,000
Other (please specify)			
Total revenues			
Net change in operating costs	47,190	62,920	78,650

3. TOTAL COSTS – PRESENT VALUE or EQUIVALENT ANNUAL COST (Euro)			
Cost component	Low estimate	Medium estimate	High estimate
Total capital costs	1,500,000	2,000,000	2,500,000
Net change in operating costs	47,190	62,920	78,650
Economic assumptions			
Economic life of equipment		3	
Discount rate			
Net present value	2,188,500	2,918,000	3,647,500
Equivalent annual cost	150,000	200,000	250,000

PRICING AS AN ECONOMIC INSTRUMENT

Directive references: *Article 9*
3-Step Approach: *Step 1.3 and 3.1*, and potentially *Step 3.2*
See other information sheets: *Estimating Costs, Reporting on Cost Recovery*

This information sheet helps you assess the effectiveness of pricing as a measure to achieve the environmental objectives of the Directive.

1. Objective

The Directive recognises water charges and prices as basic measures for achieving its environmental objectives. This information sheet proposes and illustrates a range of methods for assessing whether pricing policies (actual or proposed) provide appropriate incentives for users to reduce their water uses and pollution. This is particularly relevant for two main purposes:

- Assessing the incentive properties of current pricing policies (*Step 1.3*) and preparing the basis for the introduction of pricing policies that provide adequate incentives for users to use water resources efficiently (*Step 3.4* and *Article 9*);
- Reporting on the tasks and measures proposed for ensuring that pricing plays its due role in enhancing the protection of water resources (*Articles 9 & 13 and Annex VII*).

2. How does pricing impact water consumption and discharge?

The price of water is an important variable that influences the amount of water used by users or the amount of pollution they discharge. As such, it can be a useful measure to introduce (amongst others) in order to meet the objectives of the Directive:

- Pricing policies can help make users more efficient in their use of water resources by giving them financial incentives to shift to technologies and practices that ensure a better use of available resources or act to reduce leakage; and
- Similarly, on the dirty water side, pricing can incentivise users to shift to less polluting input or processes, eliminate highly polluting production lines and practices, or install treatment facilities to treat polluted water before discharging it into the environment.

To yield such effects, however, pricing policies must be designed so that a reduction in the quantity of water used or pollution discharged would lead to a simultaneous reduction in the total bill for the particular user. ***This means that the price of water should be proportional to the quantity of water used or the pollution generated*** (see *Box 1* of this Information Sheet).

Incentive-based pricing can be more or less effective depending on its design…

- **Seasonal tariff variations** can be very effective to provide higher incentives for saving water in periods with high scarcity only (e.g. increase *a* - see *Box 1* - in the summer);
- **Increasing-block tariffs,** with dissuasive charges above a certain level, can be an effective way of reducing demand from users with very high demands;
- **High fixed charges** (F in *Box 1*) and low volumetric charges might reduce tariffs' incentive properties on demand.

Box 1 – Tariffs with a volumetric element are key to introducing incentives

To introduce incentives, tariffs should incorporate a volumetric element, such as:

$P = F + a.Q + b.Y$, *where,*

P = total price for water services (e.g. supply of water, treatment);
F = a component of the price related to fixed costs (e.g. overheads);
a = the charge per unit of water extracted from the environment and used, linked to variable costs (e.g. pumping costs);
Q = the total quantity of water used;
b = the charge per unit of pollution produced and emitted to the environment, linked to variable costs (e.g. variables costs of treatment, emission charges etc; and
Y = the total volume of pollution emitted.

… and on user demand characteristics – for example, the impact of volumetric tariffs on demand might be negligible:

- If the total bill represents a small portion of a user's production costs or income;
- If the water user has no alternative (due to technical, social or economic constraints).

An important measure of whether or not pricing policies are likely to have an impact on water demand is the price elasticity of demand (see *Box 2* of this Information Sheet).

Box 2 – Estimating the Price Elasticity of Demand

How responsive the demand for water is to a change in price is usually captured by the notion of "price elasticity of demand". This parameter is defined as the percentage change in quantity demanded when the price changes, divided by the percentage change in price (see Box 3 for an illustration). For example, suppose that a 10 percent increase in price reduces the water demand by 5 percent, then the price elasticity of demand is -5/10 = -0.5. The higher the price elasticity in absolute terms, the more responsive the demand will be to changes in prices. The price elasticity of pollution discharge can be computed in a similar way.

- ***It is important to note that elasticity can vary through time as well as across different levels of consumption along the demand curve.***

To develop efficient incentive pricing policies and to assess the impact of these policies on water uses and pollution and on the state of the environment, it is important to answer the following questions:

1. Are prices paid proportional to water used or amount of pollution discharged (see *Illustration 1* of this Information Sheet for an example of water pricing structures)?
2. How do changes in prices (for different starting points) lead to changes in the demand for water or the pollution discharged, i.e. depending on the price elasticity of demand?
3. How do changes in demand affect water status, in order to understand the effectiveness of pricing as a measure for reaching the environmental objectives of the Directive?

In addition, it is important to take into account other policies than those strictly related to water might affect demand (see *Illustration 3* of this Information Sheet). The second point represents the main challenge from an economic point of view and is illustrated in *Box 3* of this Information Sheet.

Illustration 1 – Current water pricing in the Vouga river basin (Portugal)

In the Vouga River Basin, information on water pricing was sought during a scoping exercise for the implementation of the WFD. It was found that this information was available for only 18 out of 32 municipalities and for the two existing public irrigation facilities. The outstanding feature of the data was the wide disparity both in tariff structures and in actual tariff levels.

For the irrigation facilities, the users' payments are unrelated to actual water consumption (in one case there are per ha charges and in another case per hour) so pricing has no incentive impact whatsoever.

As with municipal systems, all require a monthly fixed payment (which varies with the requested capacity) as well as a variable (per m^3) charge. However, there are great disparities in the rates and in the structure of the variable part.

- For similar capacity, the monthly fixed payment can be very different; for instance, for 30 mm it varies between 1.05€ and 9.5€;
- Only three municipalities have seasonal rates (higher in the summer, mainly for larger consumption);
- The majority of municipalities charge different rates for domestic, industrial, agricultural, and other users; only two apply the same rates to all users;
- Some municipalities charge a constant price per m^3 for the industrial and commercial sectors. Otherwise, increasing block rates are applied but in two distinctive ways: for one group (e.g Mira) the price charged on all water consumed is defined by the block where total consumption falls (average price equals the block rate), whereas in the other group (e.g. Castro Daire) the price charged for each m^3 is the price of the block where that m^3 is (average price equals a weighted average of block rates). The first scheme is meant to discourage excessive consumption, although it implies highly irregular marginal prices as shown below:

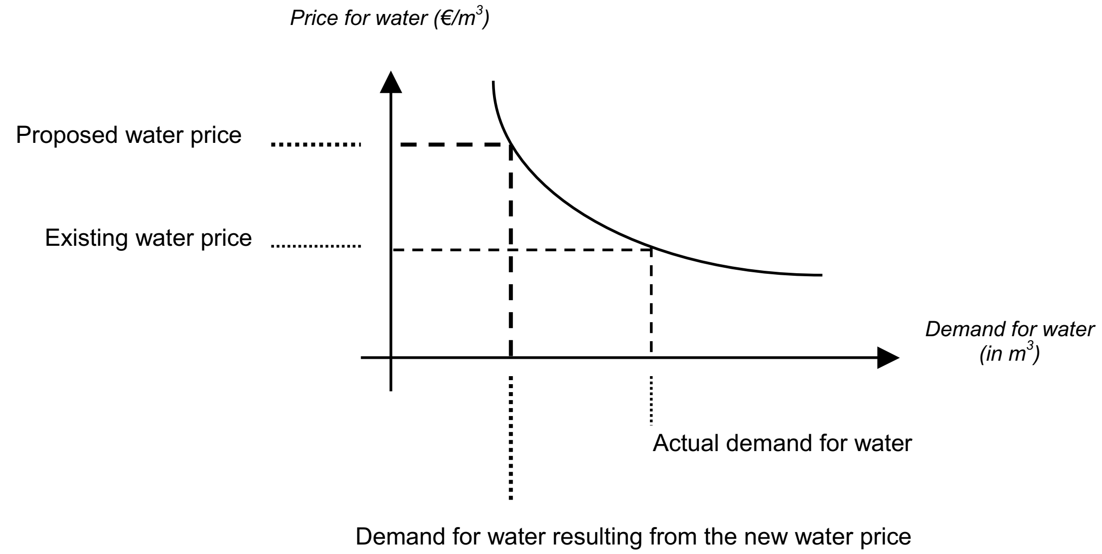
Municipality	**Block structure and prices**				**Marginal Price for 5th m³**	**Marginal Price for 6th m³**	**Marginal Price for 7th m³**
Mira	**Block**	**0-5 m³**	**0-10 m³**	**0-15 m³**			
	€/m³	0.22	0.30	0.37	0.22	0.70	0.30
Castro Daire	**Block**	**0-5 m³**	**6-10 m³**	**11-20m³**			
	€/m³	0.17	0.30	0.55	0.17	0.30	0.30

Such disparity is especially odd considering that many municipalities are connected to the same bulk supplier, who charges all municipalities the same price per m^3. Moreover, there are a few cases where the rates charged by municipalities are lower than this bulk rate.

Source: P. Mendes. Scoping key elements of the economic analysis in the Vouga River Basin. See Annex E.

Box 3 – The impact of price on demand

The approach promoted by the Directive in the use of pricing as an instrument (or as a measure) consists of defining an environmental goal and calculating the total amount to be paid by users (the tariff), by category of user, in order to achieve this goal. However, given that pricing is only one measure amongst a package of measures, this might be difficult.



3. Possible Approaches for Assessing the Relation Water Prices/Water Demands

Several approaches can be used to assess the relation between water prices and water demand/pollution discharged, as follows:

Interviewing key experts/stakeholders: ask people "what if?" questions in order to assess how they would react to a proposed change in the tariff structure or level.

Reviewing existing literature. Several types of literature reviews can be performed:

- Review of analysis already carried out in the river basin of interest. If this analysis is not out-dated and no significant changes in key variables and policies have taken place since it was carried out, then it can potentially provide useful information;
- Review of analysis carried out for the same uses under the same hydrological and socio-economic conditions;
- General literature review, although this is likely to yield only very general results (such as agriculture is more responsive to price changes than households) that have no direct practical use in performing economic analysis for the Directive.

Developing statistical models for specific sectors. Two types of statistical models can be developed:

- *Cross-sectional models* can be developed for comparing responses to price changes of user groups that face different price regimes at a given point in time; and
- *Time-series models* can be developed for comparing responses to price changes of a user group across a period of time.

The simplest statistical approach may consist of comparing two (or more) groups of users that face two (or more) different price regimes (e.g. an irrigation district paying a flat rate for its water versus an irrigation district where volumetric charges are applied). However, extrapolating the results of such comparisons to other situations is very delicate.

Such models have mostly been developed for analysing price incentive issues for the household sector, as information on the volumes used and prices tends to be more readily available (see *Illustration 2* of this Information sheet).

Developing behavioural models for specific sectors. Optimisation models can be developed for the various economic sectors to estimate the relationship between the price for water and the water demand/pollution discharged. Such models are formed by combinations of mathematical equations that attempt to reproduce real decision-making processes that aim at achieving given objectives (e.g. maximising the total income of a firm) taking account of key technical, legal and economic constraints faced by given economic sectors. Key tasks for carrying out behavioural modelling are outlined in *Box 4*, and an application is shown in *Illustration 4* of this Information sheet.

Behavioural models can be built for an entire sector, i.e. accounting for all farmers of a given irrigation scheme, if the different users of this sector are homogeneous in terms of objectives, constraints, conditions. However, if different users in the sector face a wide variety of strategies and constraints, it is more appropriate to identify key types of users and develop models for each user type.

Illustration 2 – An application of time series modelling: Did water pricing play a role in reducing household water consumption in Athens, Greece?

Severe droughts at the end of the 1980s and beginning of the 1990s have resulted in significant changes in the price of water in the region of Athens. Such price changes have taken place in a policy context where the need for demand management beside efforts to discover and tap additional water resources is increasingly recognised.

To assess the role water pricing can play to reduce the water consumption in the domestic and small commercial sector supplied by the Athens Water Utility Company (EYDAP), a statistical analysis of past price and water consumption information was undertaken to estimate the price elasticity of water demand. The information used for this statistical analysis included (i) the quarterly water consumption (in m^3) for an eleven-year period (1989 to 1999) for a sample of 1000 consumers, and (ii) price levels for the same period.

It is to be expected that consumers with different levels of water consumption will react differently to water price changes. Therefore, a statistical cluster analysis has been performed to identify five groups of consumers based on their quarterly consumption levels: (i) lower than 15 m^3; (ii) between 15 and 30 m^3; (iii) between 30 and 45 m^3; (iv) between 45 and 60 m^3; (v) above 60 m^3.

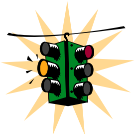
The analysis of the consumption information showed that the dramatic price increase that took place in the third quarter of 1992 led to a significant reduction in the demand for water. This was the case for all the groups of consumers except for the group with the lowest water consumption (lower than 15 m^3), which did not alter its consumption.

On the basis of the quarterly water consumption and (deflated/constant) price levels, a statistical time series model was developed to estimate the long-term price elasticity of the water consumption for each consumer group. To validate the model, all variables were tested and found to be statistically significant.

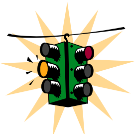
The results show that the long-term price elasticity of demand for the different consumer groups range from -0.58 for the low consumption group (i.e. quarterly consumption lower than 15 m^3) to -0.87 for the very large consumption group (i.e. quarterly consumption above 60 m^3). These elasticity values show that water pricing (combined with active information and awareness campaign) can be used as a major measure for controlling water consumption in the Athens area, and that price changes are likely to have a greater impact on the water consumption of large water consumers as compared to small water consumers.

Box 4 - Key Tasks for developing behavioural models

1. Define key relationships between input and output variables and basic assumptions. Make sure you characterise the relationships between price and demand for water;
2. Using a first set of information from a real-life situation, estimate the parameters of these relationships through calibration of the model to ensure that the model adequately reproduces the conditions of this real life situation;
3. Using a second set of information from a real-life a situation (e.g. a different year), validate the model by ensuring that it can also predict adequately the second situation;
4. Run simulations with the validated model, e.g. change the parameter 'water price' in the model and run the model so that it estimates the related demand for water, and repeat this operation as many times as required;
5. Use the results from several simulations, to build the water demand curve and estimate the price elasticity of demand for different price levels.



Look out! Models can be useful tools to organise participation
Models can be very useful tools to support discussion between experts and stakeholders about various water pricing measures. This element of assistance to the discussion is sometimes more important than its exact predictions.



Look out! Reality is often more complicated than simple models

Many countries in Central and Eastern Europe have witnessed significant changes in water consumptions since the early 1990s. Such changes were as much related to changes in water prices (following a cut in subsidies to the water sector) than to overall economic changes, which resulted in a drop in economic activity. Therefore, to account for changes in non-water related variables in time series models would be particularly important when analysing changes in water demand and tariffs in Central & Eastern Europe.

Illustration 3 – Taking account of broader policies to estimate the incentive properties of pricing policies: the impact of the CAP in Cidacos (Spain)

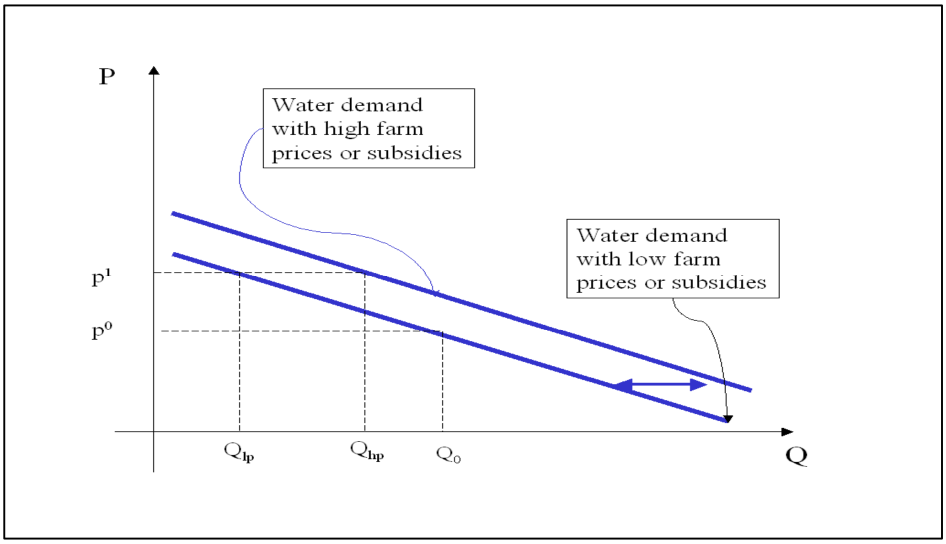
That the Common Agricultural Policy (CAP) programmes affect farmers' water demand has been thoroughly documented across many European countries and regions. This implies that water-pricing policies will, in principle, have different effects depending on the Agricultural policy scenario considered.

In general, those CAP programmes that provide measures of income support decoupled from production would not affect irrigators' water demand. By contrast, those other programmes based on production subsidies will have a significant impact on farmers' water demand. In the latter case, farmers' responses to pricing policies will be sensitive to the agricultural policy scenario. The way to ascertain the effects of a change of policy in farmers' water demand is to simulate farmers' behaviour. In the absence of calibrated models, relevant to the area of study, one can formulate several policy scenarios and carry out simple sensitivity analysis.

In the Cidacos case study, the following scenarios were proposed:

A key implication of assuming one or another CAP scenario is that irrigation water demand will shift as the economic conditions improve or get worse. This implies that farmers' demand response to water pricing will change as agricultural prices or product subsidies change. This is reflected in the following graph:

		Correcting factors	
Scenario	*Costs*	*Prices*	*CAP - subsidies*
Business-as-usual	1	1	1
Agrarian	0.9	1.2	1
WTO - liberalisation	1	0.8	0.7



Source: Ministerio de Medio Ambiente, Gobierno de Navarra, 'Virtual Scoping Study of the Cost Effectiveness Analysis in the Cidacos River'. See Annex E.

Illustration 4 – An application of behavioural modelling: Demand for irrigation water in Tarquinia (Lazio, Italy)

Water uses in the Marta River are characterised by a high number of users and a high degree of pollution. Keeping the river water flow above a minimum vital level is seen as a key target for both water management and sanitary authorities. However, this requires lower demand from some economic sectors during periods of significant water shortages. Therefore, to assess the role water pricing could play to reduce water demand from agriculture, an economic linear programming model was developed for the entire irrigation system.

Following a detailed analysis of the irrigation and farming systems, the model was developed as an aggregation of sub-models representative of the conditions faced by different farm types (facing a variety of land, labour, financial constraints) and for different districts of the irrigation systems with different water availability and distribution systems. The objective of the linear programming model was to maximise the gross income from agricultural activities, taking account of the key constraints faced by farmers in terms of labour availability, access to hired labour, land constraints, crop rotation constraints, and water availability. Built with a series of equations (equalities or inequalities) that link input (fertiliser, labour, water) and output (yield, gross margin) variables, and for a variety of crops, the model identifies the combination of crops that yields the highest farm income within the limits of the constraints set. By comparing the cropping pattern estimated by the model with real cropping pattern information for two different years, the model was calibrated and validated.

The model was then used to assess the changes in cropping patterns, farm income and water consumption that would result from changes in the price of irrigation water. The model was run several times with different price levels, and the water consumption resulting from each price level and computed by the model were recorded.

The results obtained from different model simulations, i.e. the water demand and the price elasticity of the water demand for different price levels, are presented in the table.

	Actual water demand	**Proposed water price increase**			
		+5%	**+15%**	**+25%**	**+50%**
Water demand (1000 m^3)	9,212	8,851	8,733	8,479	8,116
Price elasticity of demand		-0.78	-0.35	-0.32	-0.24

Note that the estimated values of water demand and elasticity are valid for conditions close to actual agricultural policies. Significant changes in these policies, for example a change in subsidies and agricultural product price support, would change the opportunities and constraints faced by farmers, and therefore also their responses to changes in the price level.

4. What is the most appropriate approach, depending on circumstances?

Each approach set out above has its strengths and weaknesses and is more or less suitable according to circumstances, as presented in the Table below.

Approach	***Strengths***	***Weaknesses***	***When is it suited?***
Interviewing experts and key stakeholders	➢ Fits participatory approaches to water management	➢ Rough estimates ➢ Difficult to evaluate robustness of the information	➢ Local level with a limited number of users (e.g. one specific industrial plant in a sub-basin) ➢ Comparing limited number of very significant tariff changes
Reviewing existing literature	➢ Can be useful as a first proxy ➢ Potentially less costly than other approaches	➢ Limited amounts of literature available (mostly on household uses – little on pollution)	➢ Analysis in the first instance to define the type of measures
Developing statistical models	➢ Can have strong predictive powers in a given area	➢ Difficult to extrapolate the results	➢ More complex, multi-variate models might sometimes be needed
Developing behavioural models	➢ Attempts to reproduce real-decision making processes on the part of users	➢ Mostly accurate for ranges of parameters not too far from real life conditions	➢ To model behaviour for an entire sector, particularly if users are rather homogeneous in terms of strategies and constraints

The approach chosen to assess the relationship between the price and water use will also depend on the information, human and time resources available. For example, undertaking a literature review and discussing pricing policy changes with key stakeholders may be the only short-term possibility. However, in the long run, it is important to ensure that more robust and accurate results are achieved. It is also important to ensure that the analysis and level of details are appropriate for the issues of the river basin considered.

Clearly, the incentive dimension of pricing policies is key, but not the only measure to achieve the WFD objectives. The definition of new pricing policies also needs to consider cost recovery issues, as specified in Article 9 (see *Reporting on Cost Recovery* Information Sheet). In addition, other social, environmental and economic effects of proposed changes in water pricing policies must be taken into account when designing these new policies.

DISPROPORTIONATE COSTS

Directive references: *Article 4* (Paragraphs 3-5 and 7)
3-Step Approach: *Step 3.3*
See other information sheets: *Estimating Costs*, *Cost-effectiveness Analysis*

This information sheet will help you assess whether the costs of the Programme of Measures are disproportionate and whether derogation from the Directive's objectives could be justified following an assessment of costs and benefits.

1. When is it Necessary to Assess Disproportionate Costs?

This information sheet presents an approach for determining whether the total costs of the programme of measures are disproportionately costly or expensive and is relevant for justifying derogation. In particular, this approach is relevant for:

- **Designating heavily modified water bodies (HMWB)** when the beneficial objectives served by the artificial or modified characteristics of the water body cannot, for reasons including **disproportionate costs**, reasonably be achieved by other means, which are a significantly better environmental option (*Article 4.3*, see *Illustration 1* of this information sheet for further explanation);

- **Time derogation** when completing the improvements in the status of water bodies within the time scale would be **disproportionately expensive** (*Article 4.4*, see *Illustration 2* of this information sheet for further explanation);

- **Less stringent environmental objectives** when the achievement of these objectives would be infeasible or **disproportionately expensive** and the environmental and socio-economic needs served by such human activity cannot be achieved by other means, which are a significantly better environmental option not entailing **disproportionate costs** (*Article 4.5*); and

- Failure to achieve good status or failure to prevent deterioration as a result of **new modifications** to the water body when the beneficial objectives served by those modifications or alterations of the water body cannot for reasons including **disproportionate costs** be achieved by other means, which are a significantly better environmental option (*Article 4.7*).

The analysis of whether costs are disproportionate or not will need to be initiated relatively early in the process, around 2006, in order to ensure that the public can be consulted on such a key element of the economic assessment (by 2008) and that work can be co-ordinated with other expertise, as this process will require a combination of technical and economic expertise. The precise tasks of the analysis are described in *Box 5* at the end of this information sheet. If achievement of good quality status is only possible after 2015, an interim lower objective can be set for 2015 and a time derogation be registered in the RBMP. If in 2009 it is considered that good status cannot be achieved by 2027, less stringent objectives should be registered in the plan.

Illustration 1 - Disproportionate costs in the designation of Heavily Modified Water Bodies: An example from the Netherlands

For the designation of Heavily Modified Water Bodies (according to *Article 4.3*), alternatives for the beneficial objectives of a water body must be presented. These alternatives must be: 1) technically feasible, 2) a better environmental option and 3) not cause disproportionate costs. In the EU Heavily Modified Waters working group, four typical Dutch water bodies* were tested for designation as HMWB. A summary of the alternatives to maintain the beneficial objectives and the costs involved is presented in the table below.

This table shows that although the absolute costs (A) may seem high for the 1st case (1000 millions €), the relative costs as expressed per km^2 of restored water body (B) show a different picture. There, the costs are still the highest for the first case (6000 €/km^2), but they are much more of a similar order of magnitude than in the other cases. Another criteria presented is to scale the costs to the size of the catchment (C), which in this example reverses the conclusion drawn from approach A: now the costs for case 1 are the lowest (5 €/km^2). The exercise presented illustrates how such 'benchmarking' can present a framework to assess the disproportionality of costs. It should be kept in mind that in the final conclusion, issues such as the ability to pay and the (intrinsic) value of the type of ecosystem restored should also be considered.

Designation task	**Dammed estuary (1)**	**Lowland brook (2)**	**Shallow lakes (3)**
Measures to achieve GES	Destruction of dam	Land reclamation for restoration of stream morphology	Land reclamation for restoration lake hydrology
Define beneficial objectives?	Safety, fresh water supply	Safety, agriculture	Safety, fresh water supply, recreation
Define alternative for beneficial objective?	Higher dikes to maintain safety and relocate fresh water intake points	Create retention areas; buy alternative land for agriculture; mitigate costs of yield losses	Displace the present habitation (no cost estimate); use surface water for drinking water
A: Costs of alternative	1000 millions €	1.5 million € + 2.5 million € /y	PM + 9.24 million €/year
B: Costs per km^2 (restored) water body	6000 K€/km^2	3600 K€/km^2	PM+3900 K€/km^2
C: Costs per km^2 catchment	5 K€/km^2	500 K€/km^2	PM+2000 K€/km^2

* *The waterbodies studied were: The Haringvliet Estuary (Dammed estuary; 1); the Hagmolenbeek (Lowland brook ; 2) and the Veluwerandmeren & Loosdrechtse Plassen (Shallow lakes; 3)*

Source: M. van Wijngaarden (2002, forthcoming).

Illustration 2 - Considerations for time derogation in the Alsace (France)

In the Southwestern part of the Alsace region (France), the potash mining activity has generated an intense pollution of the Rhine valley alluvial aquifer. The pollution originates from huge waste dumps containing salt (sodium chloride) that have accumulated since the early 1900s and have been leached by rainfall. The polluted water has progressively extended over time following the aquifer's flow lines. Different measures aimed at reducing the salt emission, increasing salt elimination and accelerating dilution through artificial aquifer recharge have been implemented, resulting in a significant reduction of pressure over the last 10 years. However, these measures are unlikely to be sufficient to restore the quality of the aquifer by 2015.

A hydrodynamic model was used to test current measures' effectiveness. The results indicate that if the measures already implemented are maintained from 2002-2027, the salt concentration of water will fall below 250 mg/l in the whole aquifer (to drinking standard) and approximately 96% of the salt present in the aquifer in 2002 will be removed. From this model it can be concluded that the current measures are sufficient to achieve the objective of good status in 2027, and that a time derogation can be defined if the more intensive, alternative programs of measures are disproportionately expensive. This scenario corresponds to the "third best" option in the Figures 1 and 2 below.

Two more intensive alternatives were defined to meet the 2015 objective. The first (or "second best") option consists of constructing more lines of pumping wells to prevent migration of the pollution plume, to meet the environmental objective in 2021. The "first best" option consists of constructing hydraulic barriers plus a line of pumping wells and a pipeline to evacuate the pumped water, and will meet the environmental objectives by 2015. Costs for these options are still being studied. The following charts show the three options according to their ability to meet the quality and time objectives.

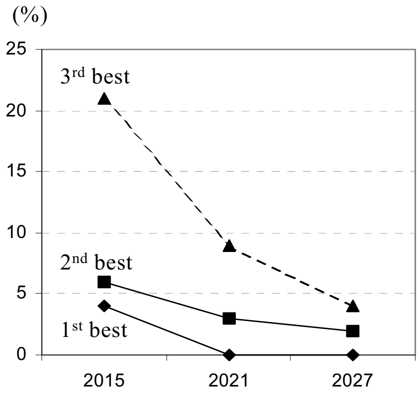


Figure 1: Quantity of salt remaining in the aquifer as a percentage of the initial stock (2002) for the three scenarios

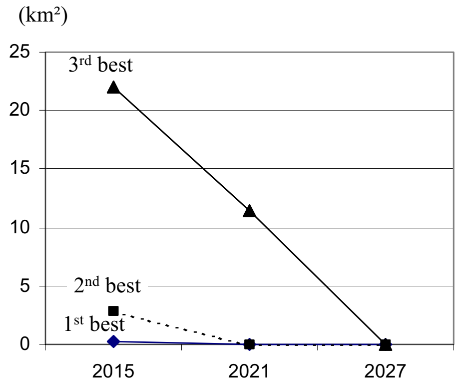

Figure 2: Area where the salt concentration is higher than 250 mg/l for the three scenario (in km²)

A preliminary analysis shows that the benefits of the first best option likely to accrue to direct uses (agriculture, industry, drinking water) are not likely to be significant in either monetary value or through employment or economic development. However, the benefits for *future* uses (avoided costs of treating polluted drinking water; gains from future industrial/economic development; etc.) may be more significant.

The work presented is ongoing and does not yet answer the question of the type of derogation needed for the Alsace aquifer. Part of the discussion concerns the choice of simulation model to determine the effectiveness of the alternative programmes of measures. In this case, the comparison of technical effectiveness of various programmes of measures has been undertaken using a simple hydrodynamic model. The major difficulty here was choosing the level of detail for the model, which determines the accuracy of results and the confidence stakeholders may have in the analysis. The choice of model also raises the question about how uncertainty should be considered in the logical argument to justify a derogation. Should the Member State petition for a derogation when the models say that the gap between the simulated quality of water and the objectives is expected to be close to 20% with a possible error of plus or minus 25%? Or should the error be expressed in number of years (the objective will be reached in 2015 plus or minus 5 years)?

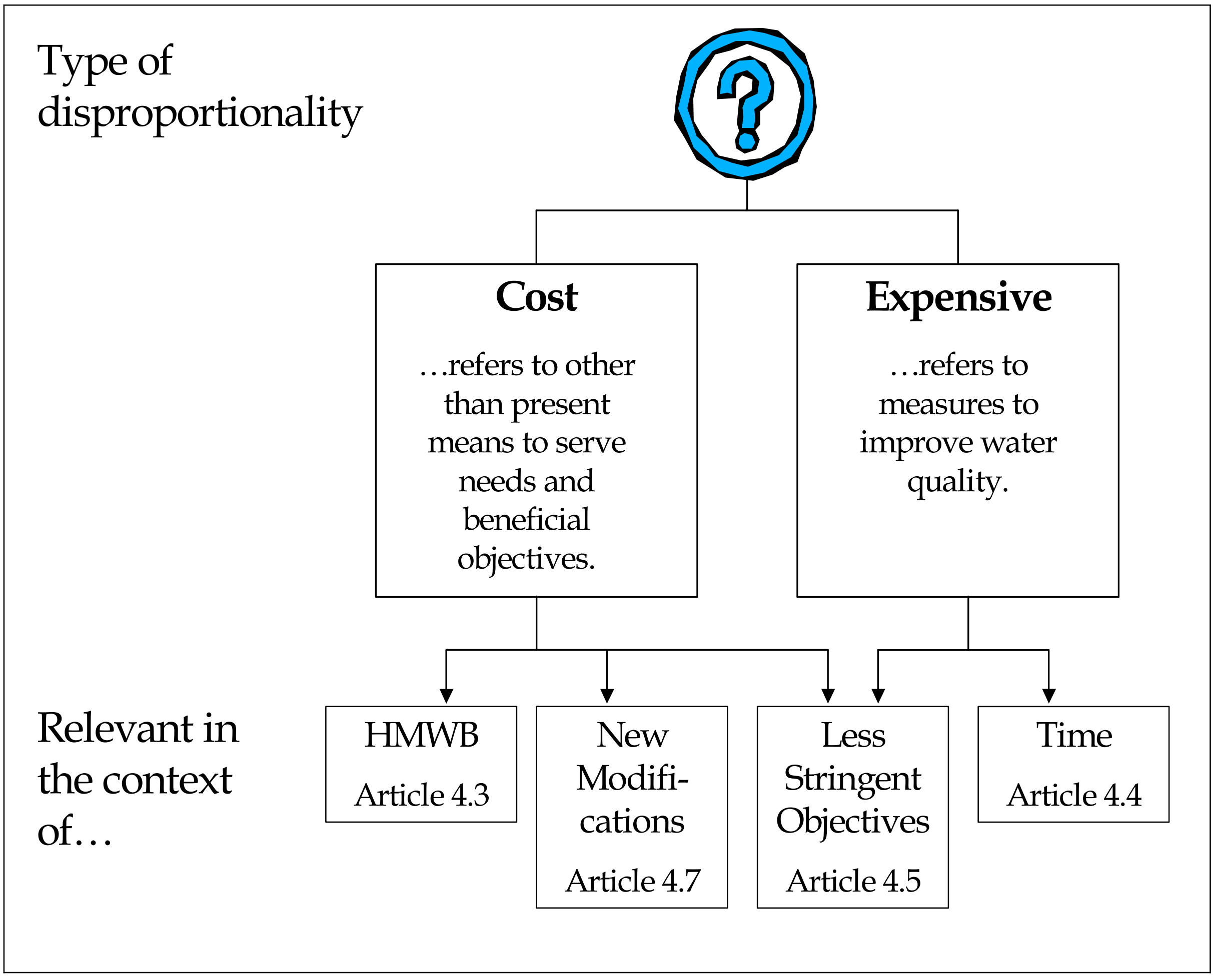
Source: J.D. Rinaudo and C. Pelouin. Assessing disproportionate costs in the Alscae aquifer. See Annex E.

2. What are the Key Issues?

'Disproportionate cost' refers to 'beneficial objectives being achieved by other means' in the context of designations, derogations and new modifications. 'Disproportionately expensive' refers to measures for improving water quality (see *Box 1* of this information sheet). This has two implications:

- Extended time or less stringent objectives can be justified on the grounds of **disproportionately expensive** measures (Articles 4.4 and 4.5); and
- Designation of heavily modified water bodies, new modifications and (again) less stringent objectives can be justified when the current needs and socio-economic benefits accruing from this activity cannot be achieved by other means not entailing **disproportionate costs**.

Box 1 – Disproportionality and Derogation



Note that Annex D.2b of this Guidance Document goes into more details for explaining the procedure to follow for designating Heavily Modified Water Bodies (Article 4.3) and justifying a derogation based on Article 4.7 following new modification/activity.

Look out! Estimating all benefits to society…
One source of identification of impacts of qualitative benefits is the consultation required under *Article 14.1* of the Directive. However, note that benefits that may accrue to 'interested parties' are not the only source of benefits. The analysis should attempt to fully incorporate all possible impacts so that the total economic value to society as a whole is established.

How Should Alternatives be Compared?

When derogation relates to heavily modified water bodies, new modifications or less stringent environmental objectives, it must be ensured that the human activity affecting these waters, and the environmental and socio-economic benefits accruing from this activity cannot be achieved by other means not entailing disproportionate costs. If there is an alternative option to achieving the objectives, its costs must be assessed so that they are not disproportionate. Importantly, alternative means should be a significantly better environmental option, not restricted simply to water quality. 'Significant' implies that the benefits from the alternative means should be appreciable compared to the original means.

What is Disproportionate?

Illustration 3 of this information sheet demonstrates in a simplified way what 'disproportionate cost' means. Whether an improvement is found to be disproportionately expensive or 'other means' disproportionately costly will be decided by individual Member States on a case-by-case basis (see *Illustration 4* of this information sheet for an example on decision making). Ultimately, disproportionality is a political judgement informed by economic information. Given the uncertainty around estimates of costs and benefits, bear in mind that:

- Disproportionality should not begin at the point where measured costs simply exceed quantifiable benefits;
- The assessment of costs and benefits will have to include qualitative costs and benefits as well as quantitative;
- The margin by which costs exceed benefits should be appreciable and have a high level of confidence;
- In the context of disproportionality the decision-maker may also want to take into consideration the ability to pay of those affected by the measures and some information on this may be required. This analysis might need to be disaggregated to the level of separate socio-economic groups and sectors, especially if ability-to-pay is an issue for a particular group within the basin. Whether and where this information is available depends on the scale or geographical area for which costs and benefits are considered (see *Box 2* of this information sheet).

Illustration 3 – The interpretation of the Directive on disproportionate costs

A sewage treatment works is discharging effluents into a watercourse (a small stream), which is a tributary and flows 1km down from the discharge into a much larger water body (a large river). The water quality of the tributary is of moderate status whilst the river is of good status. The tributary runs under roads and through an industrial estate.

The costs of possible measures, modifications to the works and a higher level of treatment for the effluent are high. The quantifiable benefits of improving the water quality on the tributary are appraised using benefits transfer techniques and a check is made to see if there would be any regeneration benefits. The measured benefits are low; in addition there are qualitative benefits from improving the ecology but there is little possibility of improved recreational use or angling. It is decided for the 2009-2015 River Basin Management Plan that the costs of reaching the environmental objectives of the tributary significantly exceed the benefits and the measures are judged to be disproportionately expensive. A lower quality objective, moderate, is recorded in the RBMP for this particular water body.

For the less stringent objectives to be set, the 'environmental and socio-economic needs served by such human activity cannot be achieved by other means which are a significantly better environmental option not entailing *disproportionate costs*'. The need served by the human activity is the disposal of sewage effluent.

In accordance with the Directive, an alternative option to higher levels of treatment, which meets the need, is explored with the water company. It is possible to build a pipeline from the treatment plant directly to the river and thus bypassing the tributary. Due to large dilution factors, this measure would have no negative impact on the water quality status of the river and is a better environmental option because the tributary is cleaner than under the first option.

The cost and benefits of each of each option are compared but it is found that the pipeline option would be disproportionately costly, as it would entail much higher costs but only a slight increase in benefits. Having explored other means of meeting the needs of achieving the human activity and rejected them, the less stringent objective for the water body is set.

Illustration 4 - Using an expert panel to assess disproportionate costs in the Scheldt estuary

The Scheldt estuary, located in part in the Netherlands and Belgium, is an important source of economic land use and navigation. However, increased socio-economic pressure has directly affected the estuary's morphology, and resulted in a reduction of the system's natural dynamics. After developing a base case scenario and trend line to project future impacts, an expert panel representing both countries was convened to assess whether the costs of measures to reach the desired ecological objectives were disproportionate.

The panel first assessed the broader socio-economic effects of two alternative scenarios: either reducing the navigation channel by not allowing further deepening, or to reduce economic land use by de-poldering agricultural land. For these, a distinction was made between significant effects with associated costs, non-significant effects and effects that were significant but not quantifiable. The first category of effects was introduced to the cost-effectiveness analysis, and included increased salinity, yielding extra drinking water costs; increased scarcity of land, impacting land prices; and effects on recreation in the region, yielding either a loss or gain of added value. Because these broader effects were included, the outcome of the original cost-effectiveness analysis changed, and the option for no further deepening became the most cost-effective.

Non-significant effects were then disregarded, while the third category of effects was left for the final stage of preparing the river basin management plan, the assessment of the financial implication, organisation and instrumentation of the plan. These included the effect of the chosen option on political relations between the Netherlands and Belgium, societal support for the option, and the effect on regional employment.

To judge whether the no further deepening option posed disproportionate costs, the panel used the following criteria:

- Ability to pay;
- Cost comparison;
- Cost-benefit assessment.

Because public funds are sufficient to finance the proposed measures and the relative costs for private sector are relatively low (maximum 38 million Eur/yr, with an added value of 16 billion Eur/yr), ability to pay was not deemed disproportionate. A more extensive analysis would include the use of indicators, the effect on the sector's competitiveness, or on the financial solvability of the private sector company.

Cost comparison was also not considered disproportionate. A similar project in the Netherlands was sited as having relatively higher costs to reach comparable ecological gains. For a more extensive cost comparison, the panel proposed to use the indicator of costs per ha of comparable nature quality created in another domestic project.

An analysis of functional impacts demonstrated a difficulty in quantifying ecological objectives and societal benefits for the purposes of a cost-benefit assessment. As the other criteria showed that the costs of reaching ecological objectives in the Scheldt estuary were not disproportionate, the panel decided not to assess the relative value of costs and benefits.

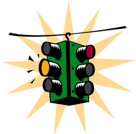
Source: Beckers et al., Scheldt International River Basin: Testing elements of the 3-step approach. See Annex E.

Box 2 – Issues to consider when assessing ability to pay

- Do we consider ability to pay of certain sectors separately, i.e. households, agriculture and industry? Are cross subsidies possible for the financing of measures, say between agriculture and industry?
- At what administrative level do we consider ability to pay? At the level of the river basin, at regional or national levels?
- Are state subsidies possible?
- How do ability to pay and cost recovery levels interact?
- How far do we look for costs and benefits accruing from a measure? Only within the river basin?
- How do we treat costs and benefits of a measure that occur upstream or downstream and affect other water bodies?

3. What are the Practical Tasks for Assessing Disproportionality?

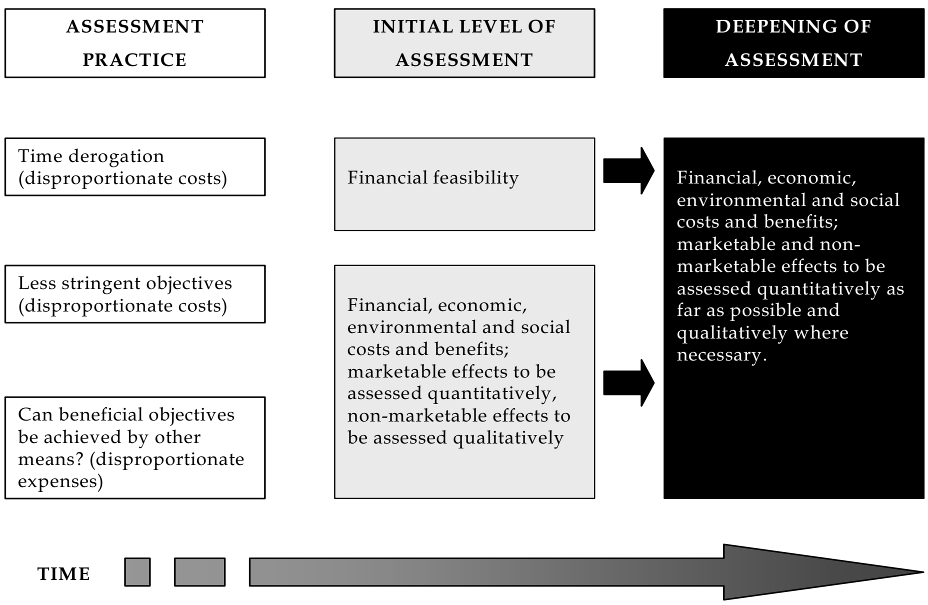
The analysis required for justifying derogation from the environmental objectives of the Directive is directly related to methodologies used for carrying out cost and benefit assessments. However, the approach proposed here is substantially different and reflects the requirements of the Directive.



Look out! Traditional cost-benefit analysis
The traditional Cost Benefit *Analysis* (CBA) estimates the *net benefit* (or cost) of an activity, policy or project in monetary terms (often for a country). The valuations are based on "the willingness to pay of the potential gainers for the benefits they will receive as a result of the [activities], and on the willingness of potential losers to accept compensation for the losses they will incur[11]. In layman terms, this means comparing variations of quantifiable costs and benefits, caused by the activities, for people affected by the policy under consideration.

The overall process for assessing disproportionality is presented in Box 3 below, showing a gradual deepening in the level of assessment.

Box 3 – Assessing Disproportionality



[11] The Department for Transport, Local Government and the Regions (DTLR) in the UK (2001), 'Multi Criteria Analysis: A Manual'

Assessing disproportionality

As shown in *Box 3*, the assessment may be largely qualitative at the initial stages. Costs and benefits of the alternative programmes of measures for achieving different water quality states should be identified and listed, though not necessarily fully valued. The extent to which costs and benefits are valued will depend on the type of derogation:

- For derogation on the basis of less stringent objectives and for the assessment of 'other means' (HMWB and new modifications), a fully quantified valuation may be undertaken for market costs and benefits and described in qualitative terms for non-market cost and benefit items (see *Box 4* for an example of a checklist);

- For time derogations, simple financial criteria may suffice to prove disproportionality as this is only a temporary measure. Over time, and as more robust quantitative data are collected, a deepening of the assessment could include a more extensive identification and quantification of costs and benefits, including financial, economic, environmental and social costs and benefits.

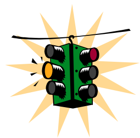
Box 4 – Example of AST Checklist

Option Definition and description

Option / BUC		Option Description	Problem	EAV of costs £/yr
Option	**Ribble nutrient strategy**	Undertake STW optimization, operational P removal and negotiated agreement with Dairy farmers	Excessive input of nutrient which limits the achievement of good status	370,000
BUC:	B2015-->M2021-->M2027			
Option	G2015-->G2021-->G2027			

Objectives, criteria and impacts		Qualitative measure	Quantitative measure	Assessment
Environment				
Ecology of waterbody				
Diverse Ecology	a	Adequate reduction in the risk of meeting good status so that good status should be achieved by 2015	Risk of not meeting good status reduced from 55% to 5% delivering 27km of water to good status	+ve
River bank habitat	a	Factors not limiting at present, but improved structure of riparian zone	No quantitative measure	*[BT value = £8,000/yr]*
Water quality	a	Water quality (nutrient status limiting) this limit is removed.	Reduction in nutrient loading from 150% of capacity to 80%	+ve
Local Air Quality	b	No impact	No quantitative measure	n.a.
Regional Air Quality	c	No impact	No quantitative measure	n.a.
Global Air Quality	d	Reduced methane emissions from dairy farming	Reduction of approximately 300 tonnes of CO_2 equivalents	BT value = £1,500/yr
Landscape	e	No impact	No quantitative measure	n.a.
Townscape	e	No impact	No quantitative measure	n.a.
Heritage of historic resources	e	No impact	No quantitative measure	n.a.
Economic value of water (priced) uses	f			
Public water supply		No impact	No quantitative measure	n.a.
Industrial water use		No impact	No quantitative measure	n.a.
Agricultural water use		No impact	No quantitative measure	n.a.
Commercial fisheries/shellfisheries		No impact	No quantitative measure	n.a.
Economic value of water (unpriced) uses	g			
Informal recreation		Improved recreation opportunities from moderate to good	15km of improved bankside habitat involving 1000 visits per year	BT value = 25,000/yr
Angling		Improved fishery quality from T2 to T1	Delivers 8km of improved fishery involving 250 angling visits per year	BT value = 40,000/yr
Other in-stream uses		None	No quantitative measure	n.a.
Residential amenity		No impact	No quantitative measure	n.a.
Commercial amenity		No impact	No quantitative measure	n.a.
Wider economic impacts	h			
Employment		No impact	No quantitative measure	n.a.
Regeneration		Rural economic diversification	No quantitative measure	+ve
Competitiveness		No impact	No quantitative measure	n.a.
Social	I			
Social inclusion/cohesion		No impact	No quantitative measure	n.a.
Distribution of costs and benefits		Improvement	Index of cost recovery improves from 0.90 to 0.95	+ve
Policy Integration	j			
Land-use policy		Consistent with land use policies	No quantitative measure	+ve
Other government policies		Generally supportive of other government policies	No quantitative measure	+ve

However, it is often very difficult to obtain (reliable) quantitative estimates for all costs and benefits, which are necessary for conducting a CBA. Therefore, the proposed disproportionality assessment should use quantified costs and benefits where possible, **but it strongly emphasises the need to incorporate qualitative measures where quantitative ones are unavailable.** The final output should look at developing a table where qualitative, quantitative and monetary information is presented so that trade-offs are transparent, e.g. when justifying derogation for a specific water body (see *Illustration 5* of this information sheet).



Look out! There is a link between the disproportionate cost analysis and the cost-effectiveness analysis: don't do it twice!
In terms of process, it is important to bear in mind that the evaluation of costs and benefits for the purpose of the disproportionality assessment will take place after having conducted a cost-effectiveness analysis for the construction of a programme of measures. As a result, it will not be necessary to estimate again the costs (and potentially, benefits) that will have been estimated for the cost-effectiveness analysis. For the measures that are part of the programme of measures, the cost-effectiveness analysis will have estimated:

- The direct or financial costs (including administrative costs);
- The non-water related environmental costs;
- The resource costs;
- The indirect costs (i.e. related losses in economic production).

In addition to this, and for the measures in the Programme, the disproportionality assessment will require estimating the induced costs (i.e. costs for other sectors of the economy) and the water-related environmental costs. However, in some cases, the induced costs might have been estimated as part as a follow-up to the cost. For measures outside of the programme, all these cost categories will need to be estimated. A fully quantified cost benefit analysis is not required for each assessment, however costs and benefits should be quantified wherever possible – in particular where markets exist.

Illustration 5 – Assessing disproportionate costs in the Ribble (United Kingdom)

This illustration outlines the procedure carried out for assessing disproportionate costs of measures in the Ribble basin. Drawing on potential impacts (identified by the stakeholder consultation processes at the earlier Objective specification stage), a matrix of costs and benefits for two identified measures was developed (see tables). The first (high cost) Option 1 achieves good status by 2015. The second (lower cost) Option 2 achieves good status by 2021. An important prior consideration here is the extent to which costs can be reduced by extending the time scales for the measures.

Given the potentially large number of water bodies for which more detailed assessments may be needed, it will not be possible to carry out original research and surveys in each and every case. Consequently, some form of 'benefits transfer' (BT) analysis may be needed, which would apply valuations derived from other studies of similar cases.

The results of the application of the BT exercise are shown in the tables, where monetarised benefits of £74,500/yr (Option 1) and £51,000/yr (Option 2) are estimated.

Given the high incremental cost of Option 1 (£300,000/yr), the results of the benefits transfer exercise are taken as evidence that a timing derogation, allowing good status in 2021 (Option 2) to be the objective, may be an appropriate strategy. In this case, however, it is assumed that there is sufficient uncertainty about whether the BT exercise fully captures the important differences between the options – particularly in terms of the incremental ecological improvements, which are not measured well in the existing benefits transfer information, and the rural economic diversification benefits. It is decided, therefore, that this water body should be passed on for further stakeholder consultation.

However, in-depth stakeholder consultation can only cover a small number of people. In addition, the consultation raises the issue of how to value some types of benefits – those that accrue to relatively affluent sections of the population, who may not reside within the basin but may bring in tourist revenues. These are issues that require a more broad-based assessment, using a more representative sample of affected people. Consequently, the conclusion of the assessment is, that this water body should be one of those, on which further stated preference analysis would be undertaken.

Analysis of the data (through modelling) reveals an implicit valuation of the benefits of Option 1 at £40,000/yr.

This information would then be incorporated into the revised AST to facilitate the overall decision making by DEFRA (Department of Environment, Food and Rural Affairs). This final decision-making would be done on the basis of all the evidence – quantitative, qualitative and indicator (monetary and non-monetary). In this case, the implication would be that the goal of good water status in 2015 would involve disproportionate costs.

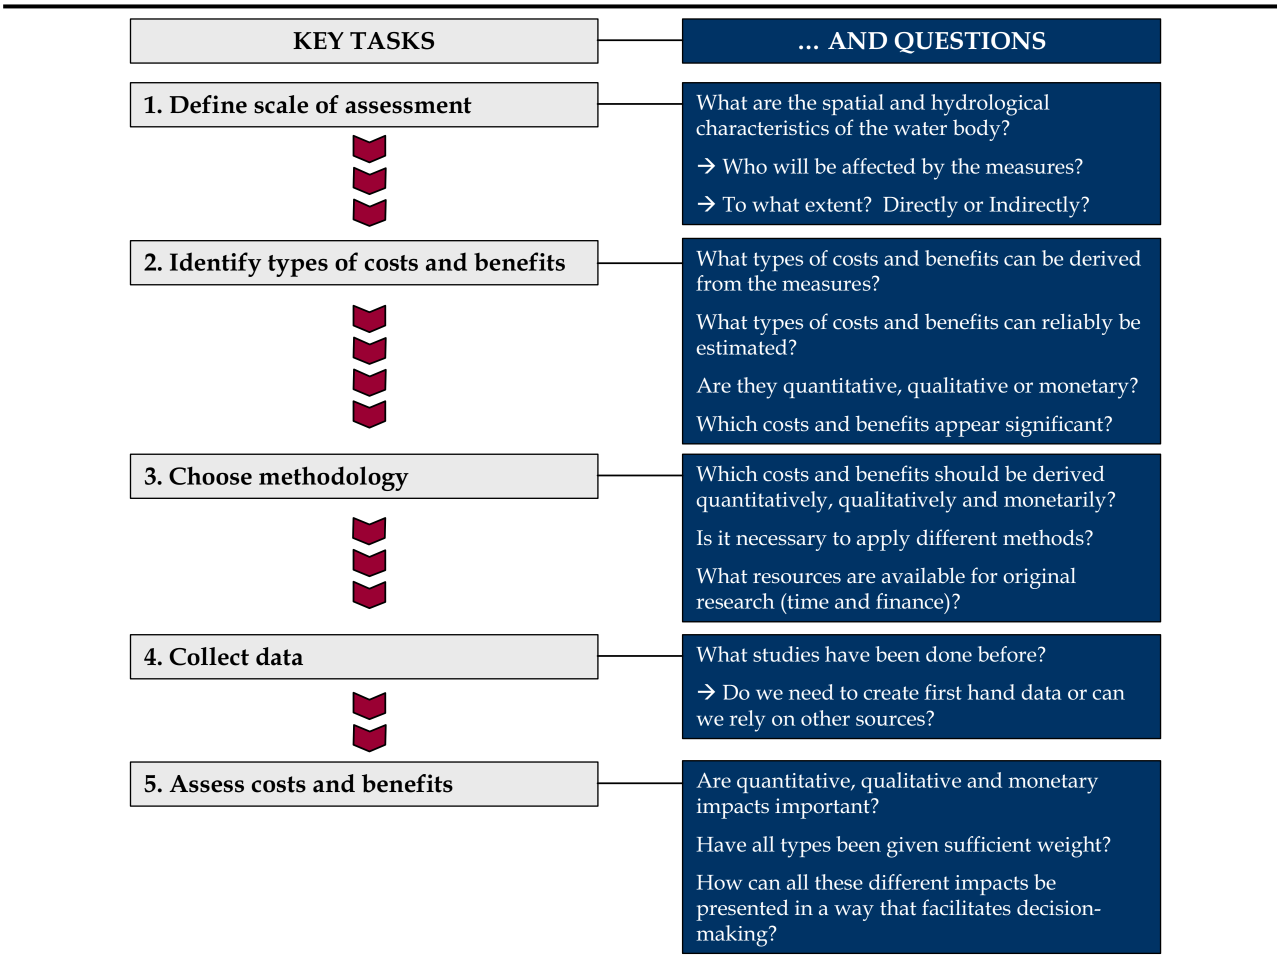
3. What are Practical Tasks for Comparing Costs and Benefits?

The rest of this information sheet deals in more details with the process for carrying out the estimation of costs and benefits. Attempting to measure the net benefits for the whole economy would often prove impossible. For the assessment of costs and benefits, the assessment would therefore need to be limited to the parties *directly* concerned with the policy measures.

In fact, a derogation would often be sought for failing to meet the Directive's objectives at the level of a particular water body and the definition of the appropriate scale of analysis would also have to do with the spatial and hydrological characteristics of the water body. For example, in order to reach the environmental objectives for a small, acidified lake, you may consider implementing a liming scheme. When looking at the costs and benefits you may want to restrict the impact assessment to the population of the one village immediately adjacent to that lake. However, if you are dealing with pollution of a complex groundwater system, the scale of impacts may necessitate the inclusion of neighbouring villages.

Tasks for assessing costs and benefits of reaching the environmental objectives of the Directive are presented in *Figure 1* below and explained in the following Sections.

Figure 1 – A Process for Assessing Costs and Benefits



Task 1 - Define the Key Groups Potentially Affected by the Measures Aimed at Achieving Good Water Status

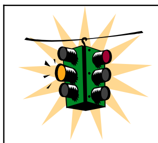
Achieving the environmental objectives set out in the Directive will have varying impact on a large number of parties. However, all these groups will not be affected directly and, as mentioned above, it might be difficult to assess the induced costs and benefits and unnecessary or too difficult to assess the tertiary impacts. Remember that every assessment has finite resources. It is therefore important to concentrate on groups that are most affected.

Task 2 – Identify the Types of Costs and Benefits Arising from the Measures and Focus on the Significant Ones

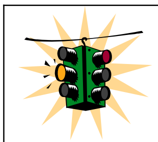
Once the user groups have been identified, the types of costs and benefits that are likely to arise must be determined. In *Task 3.2* of the Guidance, the most cost-effective measures will need to be identified (see *Estimating Costs* Information Sheet and Task 4 of the *Cost Effectiveness Analysis* Information Sheet). Following this task, the direct and non-water related environmental costs of the programme of measures will be known.

It is important to evaluate and focus on the costs and benefits likely to have an important impact, for example those that appear to have a significant effect compared with the baseline (see *Baseline Scenario* Information Sheet) and, within them, identify the different types of benefits (requiring different methods of measurements).

As an option, a matrix can usefully be created to map and rank the different types and significance of benefits arising from achieving the objectives. This matrix/list should include both qualitative and quantitative benefits and address issues such as magnitude of benefits, importance in relation to decision-making and other criteria for selecting or deselecting different benefits.



Look out! …for double counting when estimating costs and benefits!
The use of multiple methods may be important to compare different measures of costs and benefits, however it is important to avoid *double counting*. Double counting may arise because the same benefits have been 'picked up' several times (either as benefits or avoided costs) within the same study or separate studies when adding values across and will overstate the expected benefits.



… and don't forget to take into account uncertainty of the estimates!
It is important to describe the sources of estimates and confidence for all sources of cost and benefit estimates. This is important since all estimations of benefits, whether qualitative or quantitative, can be more or less certain. In particular, when using benefits transfer, using estimates in a context that they were not derived in may induce a high degree of uncertainty.

Task 3 – Choose Methodology for Estimating Costs and Benefits and Collect Data

Estimating Costs Information Sheet outlines the many ways of measuring environmental costs and benefits. Different methods can be used to estimate different types of benefits and are appropriate in different contexts. For example, direct market methods are applicable when environmental goods are factor inputs and changes in availability or quality affects production costs and a qualitative description is useful under some circumstances. *Box 6* in *Estimating Costs* Information Sheet, which gives some guidance on when to choose what methodology.

Task 4 - Carry Out the Assessment of Costs and Benefits

It is important to assess *all* costs and benefits, including qualitative and quantitative (biophysical and monetary) items. By now, you will have estimated the cost of the measures (see *Task 3.1* of the Guidance). Similarly, you will have assessed environmental impacts of the programmes of measures. You should describe these clearly.

If unit costs have been derived and will be applied to the environmental impacts, the number of units and cost or benefit per unit must be presented. This will facilitate the estimation of total effects: for unitary measures the unit environmental cost or benefits should be multiplied by the quantified biophysical impact.

- ***Note that technical expertise (e.g. from experts working on the analysis of pressures and impacts) is necessary for producing such estimates. There is a need to integrate economic and biophysical impacts in the Cost Benefit Assessment.***

Where qualitative values are minor, these shall at least be listed alongside the quantitative estimates of net benefits to support/contradict them. However, it is likely that qualitative values will play an important role. Look at each sector for costs and benefits, and present these in a way that aids decision-making. A tool could usefully be developed to achieve an efficient presentation. A rough example of such a presentation for reducing anthropogenic pressures (mainly nitrates) in agriculture is given in *Illustration 6* of this information sheet.

Like the Cost Effectiveness Analysis, the Cost Benefit Assessment may be incremental. In initial stages, a large part of the assessment may be qualitative, this will help single out the key issues. Quantitative estimates (both monetary and biophysical) may be added over time and as more research is complete and data are available.

Neither point estimates nor simple qualitative descriptions will alone give the decision maker information on how changes to different variables may affect the results of the assessment. It is therefore important to address uncertainty in the information presented, whether quantitative or qualitative (see *Illustration 6 - Figure 1* of this information sheet), to guard for different outcomes. Focus on the variables that are likely to have the greatest impact, and define how much these may change and would have to change in order to change the outcome of the whole assessment.

Illustration 6 - Improving the quality of water by reducing pressures from intensive agriculture by application of the proposed cost and benefit assessment methodology: An example

Objective: to improve the quality of water by reducing pressures from intensive agriculture. The assessment looks at the costs of investments and measures needed to improve water quality (and reduce the level of nitrates) and the expected benefits from these measures.

Task 1 – Define the Key Groups for the Assessment. Intensive agriculture over a limited area gives rise to a high anthropogenic pressure on the natural environment. This pressure may manifest itself in a deteriorating quality of surface waters, and may have negative economic impacts on a wide range of users, the most significant impacts being on the immediate geographical area on agriculture, industry, households, shellfish fishery and some recreational activities.

Task 2 – Identify the Types of Costs and Benefits. The programme of measures to restore water quality will affect users in the following ways:

Types of Costs

Agriculture	Restoring water quality entails investments and preventive measures and charging (a tax) on pollutants (an internalised environmental cost that can be treated as a financial cost). For curative measures, the storage and application of slurry have to be improved. This has different cost implications depending on animals. Preventive measures mainly involve the creation of grass strips, on 1 to 3 percent of the useful agricultural area. There is also a tax on every kilo of excess nitrogen.
Local Authorities and Households	To improve water quality, there has to be investment in municipal wastewater disposal systems. This involves investment and operating costs.
Industry	Industry has to invest in wastewater disposal to preserve water quality and will also increase the operating costs. Costs will have a negative effect on the unit production cost of businesses.

Types of Benefits

Local Authorities and Households	In effect, local authorities are choosing between investing in measures to protect the drinking water supply, or to bear greater health risks. An improvement in water quality makes it possible to avoid these costs (generate benefits).
Recreational Activities	Households use surface and coastal water resources for recreational activities (bathing, sport, walks, fishing). Deterioration in the quality will lead to either less use or greater health risks, all of which entail a cost.
Effect on Shellfish Culture	Water quality has a significant effect on the selling price of shellfish and the volume produced: where quality is good, it permits direct sales, giving bigger margins and a higher value added (packaging, dispatch, sale).

Task 3 - Choose Methodology and Collect Data. Once the types of benefits and costs have been identified, it is possible to select the appropriate methodologies for collecting data on benefits. Note that the costs will need to be assessed in the cost-effectiveness analysis required by *Task 3.2*. In this particular case, different methodologies are chosen for different benefit components.

Task 4 – Assess Costs and Benefits. Quantitative estimates of costs and benefits are aggregated and qualitative estimates are listed alongside.

Choice of Methods

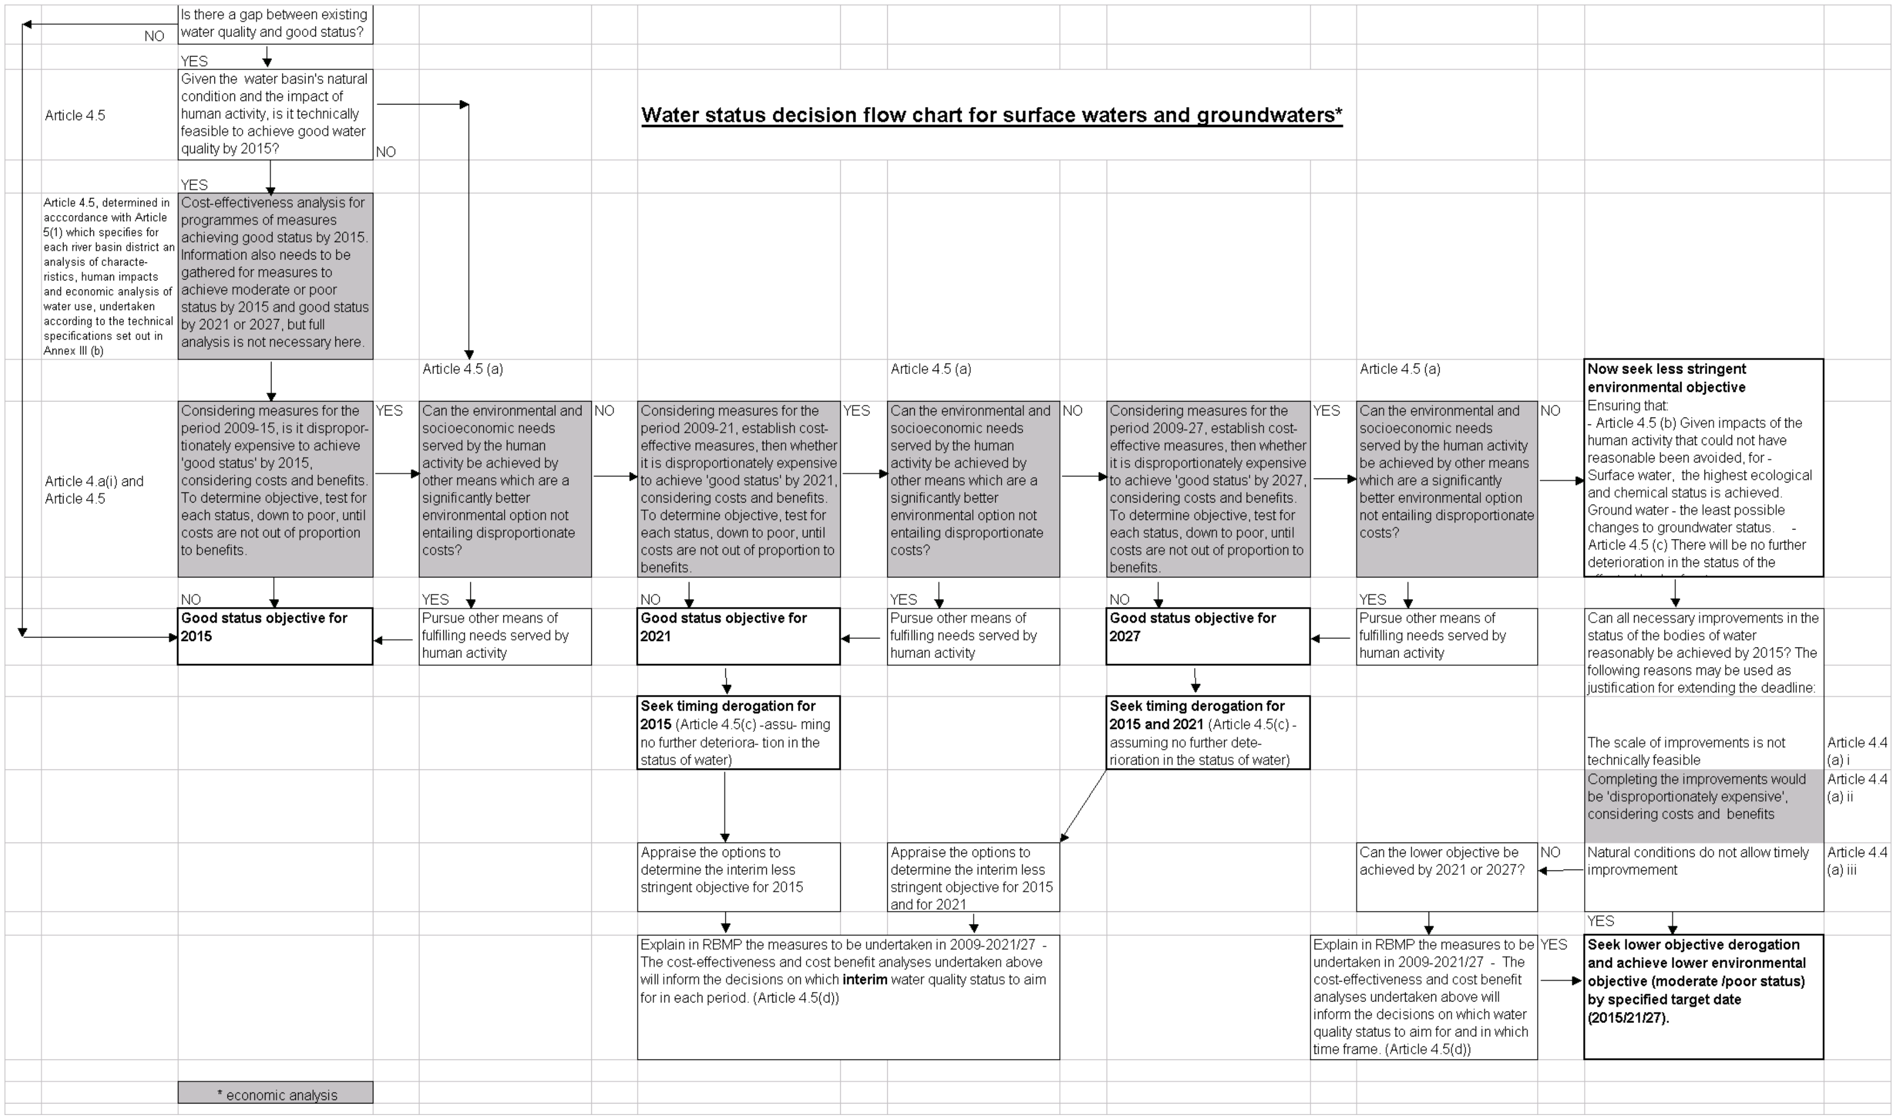
Local Authorities and Households	The costs of protection stem from the setting up of de-nitration or de-nitrification plants, changes in agricultural practices and the search for alternative sources of supply. Benefits are measured through the costs of mitigation.
Recreational Activities	Contingent valuations have been used to show households' willingness to pay to preserve these recreational uses (on top of their current water bills). These figures correspond to the user gain linked to bathing and to the value attributed to catching certain species of fish.
Effect on Shellfish Culture.	The economic loss for shellfish culture is reflected in the loss of production and profits for businesses located in the polluted area. Direct market methods were therefore used to elicit the values.

(Illustration 6 continued)

Figure 1- Assessing Costs and Benefits: ***Reducing the Anthropogenic Pressures (Mainly Nitrates) of Agriculture***

SECTOR	ITEMS	ASSESSMENT TYPE		
		Qualitative	**Quantitative** (Biophysical impacts)	**Quantitative** (Monetary impacts)
	Costs	-	-	(€)
Agriculture	Pollution control (slurry) of stock farming			
	Changing farming practices			
	Grass strips creation (preventative measure)			
Industry	*All industry* Wastewater disposal improvements: Investment costs Operating cost			
	Shellfish industry Investments in purification system			
Households	Effects of more costly wastewater disposal			
	Benefits	-	-	(€)
Agriculture	-			
Households	Avoided health costs from improved drinking water			
	Costs avoided for treatment of drinking water (de-nitration and de-nitrification plants)			
Industry	*Agri-business* Costs avoided for de-nitrification			
Recreation	Improved recreational quality			

Box 5 – Decision Flowchart



Annex D2 Analysis of derogation for New Modifications/Activities (Article 4.7) and for Designating Heavily Modified Water Bodies (Article 4.3)

INTRODUCTION

This Annex (separated into Annex D2a and Annex D2b) presents two methodological notes dealing with issues and options for integrating economics into:

- The justification for derogation that may be obtained for new modifications and activities that lead to a deterioration in water body status, following the provisions of Article 4.7 of the Water Framework Directive;
- The designation process for heavily modified water bodies as specified in Article 4.3 of the Water Framework Directive.

Both elements of the Directive have been combined in this Annex because of similarities between the role economics can play in both processes. As they stand, these notes intend to provide *food for thought* for experts that will be involved in such processes.

The note on the designation of heavily modified water bodies has been developed by the working group dealing specifically with heavily modified water bodies in the Common Implementation Strategy (see Annex A1), with input from the WATECO working group. It will be further modified, refined and integrated into the final guidance that will be developed by the heavily modified water bodies working group.

ANNEX D2a Economic Assessment of New Modifications/Activities Entailing a Deterioration in Water Status

The Directive recognises the need for integrating economic, social and operational concerns in the development of a programme of measures and integrated river basin management plans. Consequently, it allows Member States to derogate from the Directive's environmental objectives, either through the setting of a longer time frame or lower environmental objectives.

This Annex focuses on derogation that may be obtained for new modifications and activities that lead to a deterioration in water body status, following the provisions of *Article 4.7* of the Directive. It suggests a possible approach in seven steps for carrying out the analysis aimed at supporting decisions on derogation, based on a close analysis of the text of the Directive. **Figure D2a.1** summarises this approach and suggests that a number of conditions must be fulfilled in order to justify obtaining a derogation on the basis of Article 4.7.

Box D2a.1 – Summary provisions of Articles 4.7 and 4.8 of the Directive

Member States will not be in breach of the Directive when:

- Failure to achieve good groundwater status, good ecological status or, where relevant, good ecological potential or to prevent deterioration in the status of a body of surface water or groundwater is the result of **new modifications** to the physical characteristics of a surface water body or **alterations** to the level of bodies of groundwater, or
- Failure to prevent deterioration from high status to good status of a body of surface water is the result of **new sustainable development activities**.

The conditions in which such derogation can be obtained are restricted in the following sections of Article 4.7, which provides that Member States have to ensure that:

(a) **All practical steps** are taken to **mitigate** the adverse impact on the status of the water body;

(c) The reasons for those modifications or alterations are of **overriding public interest and/or the benefits to the environment and to society** of achieving the objectives [of the Directive] are outweighed by the benefits of the new modifications or alterations to human health, to the maintenance of human safety or to sustainable development;

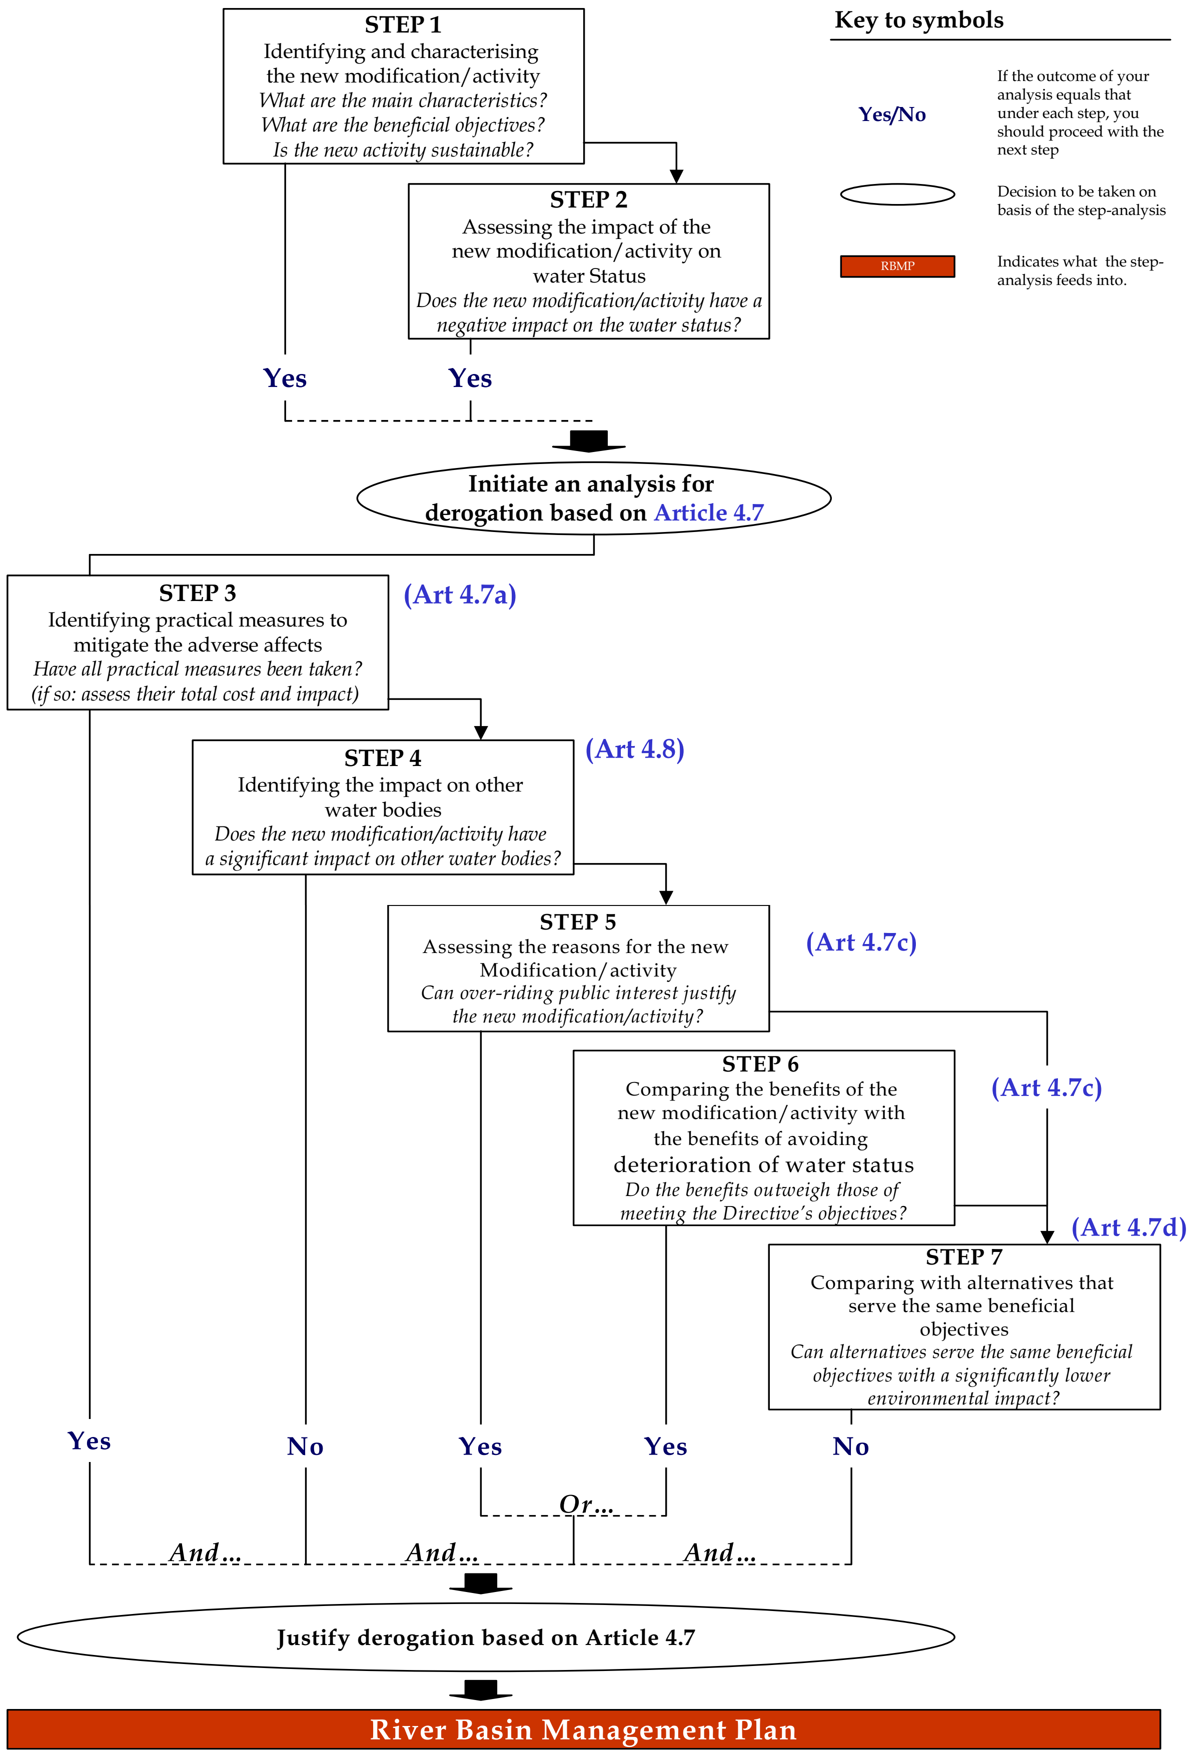
(d) The **beneficial objectives** served by those modifications or alterations of the water body **cannot for reasons of technical feasibility or disproportionate costs be achieved by other means**, which are a significantly better environmental option.

Finally, Article 4.8 sets some conditions for the use of Article 4.7 by stating:

- When applying paragraph… 7 [of Article 4], a Member State shall ensure that the application **does not permanently exclude or compromise the achievement of the objectives of this Directive in other bodies of water** within the same river basin district and is consistent with the implementation of other Community environmental legislation.

The rest of this document sets out a possible approach for making Article 4.7 operational. Note that this analysis could either take place in isolation when a new modification/activity emerges (for example, a new cropping pattern or a new industrial activity) or within the context of the application of the 3-Step Approach used for implementing the economic aspects of the Directive as a whole. In fact, many of the steps described below closely resemble some of the steps of the 3-Step Approach.

Figure D2a.1 – Economic Assessment of New Modifications and Activities



The analysis below will be used as a tool for estimating the need for derogation, which ultimately, is likely to be a political decision. Key decisions will follow from the following steps of the analysis:

1. *Step 1 – Identifying and characterising the new modification/activity;*
2. *Step 2 – Assessing the impact of the new modification/activity on water status:*
   - ***Decide whether to initiate the analysis for obtaining an Article 4.7 derogation.***

3. *Step 3 – Identifying practical measures to mitigate the adverse effects;*
4. *Step 4 – Identifying the broader impact on other water bodies;*
5. *Step 5 – Assessing the reasons for the new modification/activity;*
6. *Step 6 – Comparing the benefits of the new modification/activity with the benefits of avoiding deterioration;*
7. *Step 7 – Comparing the benefits of the new modification/activity with alternatives that serve the same beneficial objectives:*
   - ***Assess whether a derogation based on Article 4.7 can be justified. This can only be justified if all of the conditions for each Step 3 to 7 are fulfilled, as per Figure D2a.1.***

Step 1 – Identifying and characterising the new modification/activity

What defines a new modification or new activity?
There are two categories of "modifications" that may give rise to a derogation:

- ***A modification to the physical characteristics of the water body***, such as straightening a river or modifying the level of groundwater bodies, but without modifying the chemical and ecological dimensions of good water status (below: **new modification)**;
- ***A modification resulting from new sustainable development activities,*** although this can only be used for obtaining a derogation when surface waters go from high to good status (below: **new activity**).

The most complex issue here will be how to define *new sustainable development activity,* which mirrors the difficulties in defining the concept of *sustainability*, which integrates:

- Economic, social and environmental aspects;
- A temporal dimension (e.g. future generations) and potentially, a global dimension.

As a result, discussing the sustainability of a single economic activity or physical alteration must be put into the context of wide society objectives and goals. Box D2a.2 gives a summary of the issues linked to the definition of sustainable development and sustainability.

Practical implementation will need to be done by answering key questions:

1. What are the main characteristics of the modification or new activity?

First, it is required to identify the issue. This will be done through collecting information on the modification or activity such as:
Dimension and capacity of a dam, length of river modified, production capacity of a new industrial plant, employment linked to the development of this new industrial plant, total turnover, discharge and total volume of water potentially abstracted by a pump, total irrigated area and cropping pattern and number and type of water users involved.

Box D2a.2 – Sustainable Development and Sustainability - Selected References and Issues

The profile of sustainability and sustainable development issues has constantly increased since the early Brundtland Commission report. Along with this increasing interest, a wide number of definitions have been proposed for this highly complex issue. For example:

- Looking at sustainability from a very global point of view like the World Commission on Environment and Development (1987): *Sustainable development is the development that meets the needs of the present without compromising the ability of future generations to meet their own needs.* The minimalist interpretation of this definition implies that future generations should not be left worse off than current generations;

- In 1992, the UNCED (United Nations Conference on Environment and Development) "Earth Summit" meeting in Rio De Janeiro, agreed prescriptions for achieving sustainable development. These prescriptions recognised that the "integration of environment and development concerns and greater attention to them will lead to the fulfilment of basic needs, improved living standards for all, better protected and managed ecosystems and a safer, more prosperous future.";

- Looking at sustainability with an increased environmental focus like the European Environment Agency (1995): … *Linked to this is the concept of the 'carrying capacity' understood as the maximum impact that a given ecosystem can sustain without permanently impairing the integrity and productivity of the ecosystem.* This clearly does not mean natural resources cannot be used; it is possible to use resources (even depletable ones) as long as the interest of future generations can be protected. The question remains on the sharing of natural resources between present and future generations and what form should this sharing take;

Thus, alternative interpretations of sustainability include (T. Tietenberg, 1996*):

- Sustainability as non-declining well-being: resources used by previous generations would not exceed a level which would prevent future generations from achieving a level of well being just as great. Thus, the value of individual components of capital stock (human, social and natural) can decline as long as the remaining elements increase to compensate this decline. This definition assumes a good substitution between natural capital and human and social capital;

- Sustainability as non-declining value of natural capital stock: the total value of natural capital should not decrease. Key to this definition is the recognition of the limited substitution between natural capital and man made capital. One form of natural capital could be decreased if it can be compensated by the increase of another natural capital (e.g. reduction of the value of fisheries compensated by an increase in the value of forests);

- Sustainability as non-declining physical service flows from selected resources. This definition stresses the physical dimension of the natural resources as opposed to their value as in the previous definitions. In the presence of critical thresholds for some resources, the cost of further degradation may escalate rapidly, calling for policies that maintain the quality and resilience of these resources. In the case of resources where critical thresholds can be defined, sustainability constraints are likely to be more binding.

The types of capital that sustain well-being including man-made, natural, human and social capital and their "adequacy" to support well-being depends on the interaction among them, as well as on the size of the population, its characteristics and preferences. The different types of capital also provide one of the main mechanisms through which generations are connected to each other – as the stocks are influenced by current investment decisions, but human lives span several generations.

To assess the sustainability of patterns of economic development, the level of demand of natural resources and the transformation processes required by human activities should then be considered. The trade-offs between different types of capital may need to be evaluated empirically for their substitutability (a rather controversial and difficult issue), describing the acceptable trade-offs. The social components and impact of policies has to be simultaneously considered. As summarised in the recent European Union strategy for sustainable development (2001), *in the long term, economic growth, social cohesion and environmental protection must go hand in hand*.

In the context of Europe, the recognition of the importance of sustainable development has led to the promotion of new instruments of analysis and planning. This includes the preparation of sustainable strategies at national, regional and local level, the preparation of Local Agenda 21 after the Aalborg Charter. At the European Union level, key policy elements include the preparation of the new Spatial Development Perspective, the Vienna Framework for Action for sustainable development, and the above-mentioned recent European Union Strategy for Sustainable Development. Regions across the European Union are currently preparing and proposing strategies and measures towards a more sustainable future.

**Source: T. Tietenberg (1996), 'Environmental and Resource Economics', 4th edition, Harper Collins*

2. ***What are the beneficial objectives served by the modification or new activity?***

   Second, it is necessary to understand the beneficial objectives of this new activity or modification. This will be based on a comparative analysis whereby the proposed activity should be compared with alternative options from an environmental and economic point of view. Examples of beneficial objectives include:
   - *Supply of specific water services to consumers or specific users, power generation and supply of electricity, employment or rural development.*

3. ***Is the new activity sustainable?***

   As mentioned above, the issue of sustainability is a complex one. To determine whether the activity is sustainable, a comprehensive assessment of its implications from an economic, social and environmental perspective will be required, such as:
   - *Economic impact: turnover, income and production patterns;*
   - *Environmental impact: water, air, soil, biodiversity, landscape, overall resource use, waste arising and renewability of resources;*
   - *Social impact: employment at both the local and the regional or national level of unemployment, social exclusion, etc.*

4. ***What is the coherence between the proposed modification/activity and existing sustainable plans and strategies?***

   Assessing the coherence between proposed modification or activity and existing local, regional, national and European sustainable development plans and strategies will ensure that the modification or activity is put into a more long-term sustainability perspective and that its contribution to broader objectives are assessed. Also, this will ensure that the interpretation of "sustainable development" is in coherence with the environmental impact assessment or strategic environmental assessment criteria that will be used prior to authorising this new activity or modification to go ahead.

Step 2 – Assessing the impact of the new modification/activity on water status

Why is it important to assess the impact on water status?
- To determine whether you need to carry out the analysis in the first place: it is only if the new modification/activity has an impact on water status that a derogation is needed;

Practical implementation can be done in two stages:

- Assess the new pressures related to the new modification/activity, especially the impact on water abstraction and pollution;
- Assess impact of these pressures in terms of likely changes in the ecological quality or quantity of water (e.g. when looking at alterations to the level of groundwater bodies).

➢ ***As mentioned above, the analysis carried out as part of Steps 1 and 2 will enable decision makers to assess whether the procedure for obtaining derogation based on Article 4.7 should be initiated. A procedure should be initiated if the proposed new modification/activity has a negative impact on water status and if the new activity is sustainable. The steps that follow include all the tests that will need to be carried out in order to justify a derogation based on Article 4.7.***

Step 3 – Identifying practical measures to mitigate the adverse effects

Why consider whether practical measures can be taken to mitigate the adverse effects?
Article 4 (a) specifies that Member States should ensure that all practical steps are taken to mitigate the adverse impact on water body status. Whether those steps (or measures) are practical or not will depend on them being both technically and financially feasible.

Practical implementation of this step will include:

- Define a range of practical mitigation measures based on their:
    - Technical feasibility within the timeframe considered (e.g. 6 years or 12 years if one time derogation is used);
    - Financial feasibility, based on their costs vs. available financial resources.
- Analyse the likely impact of these mitigation measures on the status of the concerned water body (quantity, quality, ecology);
- Assess the total costs of mitigation measures.

➢ ***An Article 4.7 derogation can only be justified if all practical mitigation measures have been taken. In addition, this Step will contribute to predicting the water status of the water body following the introduction of practical mitigation measures and assessing their total costs, so that they can be incorporated into the river basin management plan.***

Step 4 – Identifying the broader impacts on other water bodies

Why identify the impact on other water bodies?
Article 4.8 requires Member States to ensure that the new modification/activity does not permanently exclude or compromise the achievements of the Directive's objectives in other water bodies. Analysing the likely impact on other water bodies may be more difficult than analysing the impact on the local water body (as per ***Step 2***), as it requires a good understanding of the functioning of the hydrological cycle within the river basins and the biophysical relationships between water bodies. For example, it will require understanding the impact of installing a dam supplying water to an urban area in the upstream part of a river on the water status of the river's estuary, 50 kilometres downstream.

Practical implementation of this step will require:

- Assessing the likely impact of the new modification/alteration/activity on the status of other water bodies within the same river basin district before mitigation measures;
- Assessing the likely impact of the new modification/activity with mitigation measures.

➢ ***If the new modification/activity is likely to have a significant impact on other water bodies even if mitigation measures are implemented, then Article 4.7 cannot apply and the modification or new activity cannot be implemented. The contrary leads to continuing the analysis and applying the following tests.***

Step 5 – Assessing the reasons for the new modification/activity

Can over-riding public interest be invoked as a reason for the new modification/activity?
Article 4.7(c)) refers to modifications that are of over-riding public interest. However, this concept is not defined in the Directive. Similarly to what is specified in the Habitats Directive, it may cover issues of human health and human safety or other imperative reasons of social or economic nature. Making the concept of over-riding public interest practical is difficult. Key elements that may be considered for doing so include:

- Ensuring that the new modification/activity is primarily to fulfil public interests, i.e. not solely in the interest of private companies or individuals;
- The interest must be over-riding, i.e. not all types of public interest can apply. In this context, it is reasonable to assume that it must be a long-term interest. This time issue is coherent with Article 4(8) that stresses the need to ensure that improvements in the status of other water bodies cannot be permanently compromised.
- The proposed new modification/activity aims at protecting fundamental values for citizens' lives and society (e.g. health, safety), within the framework of fundamental policies for the State and society.

Practical implementation of this step will require analysing the following:

- Assessing whether the new modification/activity fulfils a public service obligation;
- Assessing whether the new modification/activity is in society's long-term interest;
- Assessing whether it aims at protecting fundamental values for citizens and society.

Note that for the analysis of the long-term interest, prospective analysis similar to what is performed for the development of the base line scenario may be undertaken. Clearly, the analysis will need to be in proportion with the importance of the new modification/activity in terms of its economic impact, its impact on the quality of waters and of the environment and on sustainable development.

➢ ***If the new modification/activity is not justified by over-riding public interest, then Article 4.7 cannot applied except if the benefits of achieving the Directive's objectives are outweighed by the benefits of the new modification/activity to human health, human safety or sustainable development (as per analysis in Step 6 below).***

Step 6 – Comparing the benefits of the new modification/activity with the benefits of avoiding deterioration of water status

Do the benefits of the new modification/ activity outweigh those of meeting the water quality objectives of the Directive?
Article 4.7(c) specifies that even if the new modification/activity is not of over-riding public interest, a derogation based on Article 4.7 could still be obtained if the benefits of the new modification/activity in terms of human health, human safety or sustainable development outweigh the benefits of achieving the objectives of the Directive in terms of water status.

Practical implementation of this step will require:

- *Investigating issues similar to those considered in analysing the "sustainability status" of new activities* as per ***Step 1*** of this analysis. These include: improvement in human health, improvements in human safety (e.g. in the case of flood protection projects), increase in economic activity or production.

- *Assessing the foregone benefits resulting from the failure to achieve the environmental objectives of the Directive*, based on the evaluation of the environmental, economic and social water-related benefits. In both cases, it should be attempted to quantify and express benefits or foregone benefits in monetary terms so as to make both parts of the analysis comparable. In many cases, however, it will be difficult to express all benefits or foregone benefits in monetary terms. Thus, the different benefits and impacts should be presented, whether in monetary terms, quantified or assessed qualitatively, in a multi-dimensional table.

  - ***If the benefits of the new modification/activity outweigh the foregone benefits from improved water status, then an Article 4.7 derogation can be invoked.***

Step 7 – Comparing with alternatives that serve the same beneficial objectives

Can alternatives serve the same beneficial objectives with a significantly lower environmental impact?
Article 4.7(d) sets as a condition that a derogation can only be obtained if the beneficial objectives to be obtained by the new modification cannot be achieved by other means with a significantly lower environmental impact, due to reasons of technical feasibility or disproportionate costs. This analysis will be similar to that carried out for designating heavily modified water bodies.

Practical implementation of this step will require:

- *Identifying the alternative options that provide the same beneficial objectives.* These may include local alternatives (e.g. pumping groundwater from an adjacent aquifer instead of building a dam on a river for supplying water to an urban area), or regional and national options (e.g. supplying electricity from a wind power station in other parts of the country instead of building an hydro-power plant on a river). A wide range of cost-effective options should be considered, and not only infrastructure development that may be easier to analyse;
- *Comparing the environmental impact of the new modification with that of alternatives.* As a first step, a qualitative assessment of the main environmental issues is required. A simple table may be prepared comparing the new modification and the proposed alternatives from the point of view of their environmental impact on water, air, soils, biodiversity, landscape, etc. In some cases, it may be possible to quantify the physical impacts on specific media, and to transform them into monetary (thus comparable) values;
- *Estimating the costs of the new modification versus that of alternative options.* These costs include investment costs, operation and maintenance costs, and any foregone benefit that may result from changes in economic activities linked to the alternatives or proposed modification. As the lifetime of the activity and proposed alternatives are likely to vary, all costs need to be annualised and computed in net present values.

  - ***If the new modification has no alternative with significantly lower environmental impact, then a derogation based on Article 4.7 can be sought.***

Information and Approaches to Undertaking the Steps

The different steps presented above require a wide range of information, expertise and knowledge on the biophysical (e.g. assessing the impact of the new activity on the status of the concerned water body), economic (e.g. assessing costs and impact on economic sectors) and social issues. Although one may attempt to quantify as much as possible the different elements to be investigated, this will often not be possible and most of the tests and questions presented above therefore needs to aggregate a wide range of quantitative and qualitative information. Approaches that can be used to gather this information include:

- *Qualitative description of the situation or impact*. In cases where it is difficult to quantify specific variables (e.g. a change in landscape), a qualitative description of a change is adequate;
- *Assessment of functional impacts (changes in services provided or functions linked to water bodies)*. Changes in services provided or functions linked to water bodies can serve as good proxy to changes in benefits or foregone benefits linked to a modification or new activity;
- *Consultative Forum*. Involving stakeholders for providing information and their assessment of various alternatives and options. This approach, that takes account of social issues and cultural/local perceptions, is clearly in line with the encouragement to involve all interested parties as spelled out in Article 14 of the Water Framework Directive;
- *Expert Group Panels*. Involving a (subjective but well-justified and transparent) technical assessment of alternative options by a multi-disciplinary team of experts; and
- *Economic assessments*. Good for comparing the costs of different alternatives for delivering the beneficial objectives considered, for comparing the benefits and foregone environmental benefits linked to new activities, for comparing (when monetary valuation possible) the environmental impact of different options.

The involvement of stakeholders and of experts panel groups is particularly important to assess issues that are multi-dimensional and that cannot be summarised into a single variable or figure. This is particularly true for assessing:

- Existing trade-offs between social, economic and environmental issues and deciding whether a new activity is sustainable (***Step 1***);
- Whether the modification or new activity can be justified on over-riding public interest grounds (***Step 5***);
- Whether the benefits from the proposed modification or activity are higher (or better valued) than the degradation to water bodies (***Step 6***); and
- Whether the proposed modification or new activity is indeed better than possible alternatives (***Step 7***), i.e. how to interpret the notions of *significantly better environmental option* and *disproportionate* costs.

Table D2a.2 summarises the general types of information required for the different steps of the analysis supporting the use of Article 4.7 and Article 4.8. The table stresses the multi-disciplinary approach required for assessing whether the use of derogation under these articles is indeed justified.

Table D2a.2 – Information Needed for Undertaking the Steps

Steps in the assessment		**Type of information**			
		Environment	Economic	Social	Technical
Describe the modification or new activity and its impact	Describe modification or activity				
	Assess sustainability				
	Assess impact on water status				
Identify mitigation measures and their impact	Define mitigation measures				
	Assess impact of mitigation measures on water status				
Assess impact on inter-connected water bodies					
Justify the modification or new activity	Assess overriding public interest				
	Benefits of activity versus foregone benefits				
Compare the modification or new activity with alternative options for providing beneficial objectives	Identify technically feasible alternatives		instruments		
	Compare environmental impact		When monetary values available		
	Compare costs				

ANNEX D2b Consideration of the Possible Appraisal Techniques Involved in the Designation Process for Heavily Modified Water Bodies

1.0 Purpose

1.1 This paper is intended as guidance for the case studies being undertaken on Heavily Modified Waterbodies (HMW) (WFD CIS Guidance Document No. 4). It is anticipated that the experience gained from the case studies will inform the development of Common Implementation Strategy Guidance.

1.2 The designation of water bodies as heavily modified involves the use of tests specified in Article 4(3) of the Water Framework Directive. This paper considers some of the options available to inform this decision making process.

1.3 The paper has been produced by the representatives from the HMW and Economics working group. It has been discussed and approved by the HMW Working Group.

2.0 Introduction

2.1 The designation process of heavily modified water bodies starts with the identification of those water bodies, which are substantially changed in character as a result of physical alterations by human activity (see HMW paper 3 (strategy)). This identification step does not require the use of economic assessment.

2.2 Following this initial identification step, two tests are proposed in Article 4(3) for the designation of heavily modified water bodies.

- Firstly, it is necessary to assess whether there are significant adverse effects on specified uses, which would result from the necessary mitigation measures required to achieve good ecological status for the water bodies considered;

- Secondly, if uses are significantly affected, then a review of other better options for providing the specified use should be undertaken by investigating issues of technical feasibility, environmental impact (better environmental options) and costs (disproportionate costs) of these options.

2.3 In practical terms, a very large number of water bodies will have to be assessed for possible designation as HMW over the period until 2009[12]. It will therefore be important to ensure that the methods used for the designation process are simple and pragmatic. Moreover, it is important to develop appropriate options so that the complexity of the assessment methodology can be made proportionate to the circumstances.

2.4 There are different appraisal techniques, which could help in the designation process by providing a systematic way of analysing and reporting designation decisions. Examples of techniques that may be chosen (independently or combined) include:

- **Qualitative description of the situation** - appropriate for circumstances where the situation is clear cut (refer to HMW paper 5 "pressures and physical alterations", No 11 negative list;

[12] How to identify water bodies (based on which criteria, which scale, etc) still needs to be discussed and agreed in the context of the Common Implementation Strategy activities. The chosen approach is likely to influence the total number of water bodies within a river basin, and thus the total number of heavily modified water bodies to be designated.

- **Consultative forum** - involving a participatory approach to identifying whether foreseen impact on uses is indeed considered as significant. This approach, that takes account of social issues and cultural/local perceptions, is clearly in line with the encouragement to involve all interested parties spelled out in Article 14 of the Directive;

- **Expert group panels -** involving a (subjective but well-justified and transparent) technical assessment of the options by a multi-disciplinary team of experts;

- **Assessment of the functional impacts** - providing an assessment of the impact upon the "use(s)" in terms of changes in services provided or functions linked to the water body;

- **Economic assessments** - by comparing costs of different alternatives for delivering the beneficial objectives considered, or by comparing costs and benefits of options.

3.0 HMW Designation test "Significant Adverse effects upon specified uses" - Article 4(3)(a) (ii - v)

> ***Article 4(3)(a)***
> *the changes to the hydromorphological characteristics of that body which would be necessary for achieving good ecological status would have significant adverse effects on: …….[specified uses]*

3.1 This test requires consideration of the context and scale of the effects on the listed activities (uses) which would result from necessary changes to achieve good status. There is no obvious way in which a single value could be considered significant. The assessment of significance will, by necessity, be based on the context and scale of the modification to the water body.

3.2 Simple qualitative descriptive methods would be appropriate where:

- The adverse effects on uses are relatively small in relation to the specified use (clearly not significant); or

- The adverse effects on uses are large and clearly prejudice their viability (clearly significant). This is particularly relevant when necessary changes to achieve good status imply the cessation of specific uses, functions and related human activities.

3.3 There may be a number of circumstances where the scale of adverse effect is more finely balanced. Under these circumstances, it is appropriate to undertake a quantitative assessment of the impacts to the use to justify their significance. Simple and consistent tools and approaches may therefore be required to assess the significance of impacts upon uses. This could include the following approaches.

- An assessment can be carried out of the change in use and function (e.g. the reduction in the quantity of hydro-power that can be generated from a hydro-power scheme). This can provide a first and robust quantification of the resulting change in use;

- It may be possible to assess the economic impact resulting from necessary changes to achieve good status. Thus, the economic benefits (in €) linked to the use of water under the present situation are compared with the economic benefits (in €) that would be obtained from the required change in use.

3.4 In both cases, relative values are preferred to absolute values for discussing the issue of significance. For example, a reduction of an irrigated area by 100 ha can be considered as significant as compared to a total irrigated area of 105 ha, but not significant as compared to a total area of 120,000 ha. This clearly makes the choice of the denominator of the relative value of particular importance (i.e. to identify the scale of the use to be considered). The information obtained can be fed to a consultative forum or group of experts for deciding whether changes are indeed considered as significant.

4.0 HMW designation test "Significant Adverse effects upon the wider environment" - Article 4(3)(a)(i)

> ***Article 4(3)(a)***
> *the changes to the hydromorphological characteristics of that body which would be necessary for achieving good ecological status would have significant adverse effects on: …….*
> *(i) the wider environment*

4.1 Changes in the hydro-morphological characteristics of a given water body may have significant impact on the wider environment, for example:

- The restoration of flood plains may threaten a specific landscape and biodiversity that has developed over the years as a result of the elimination of the floods in the riparian zones and former floodplains;

- The removal of a dam that may lead to the elimination of wetlands that have developed in connection to the water storage.

4.2 Where the modified waterbody could be designated under another Directive such as the Habitats Directive, it is assumed that the Directive with the highest standards will apply. If a HMW was designated under the Habitat and Species Directive, it would not be appropriate to consider mitigation measures required to achieve good status, if this compromised the reason for designation.

4.3 As for the previous test on the significance of adverse effects on uses, there may be a need to quantify such changes. However, to provide meaningful quantification of changes in values of landscape or biodiversity is likely to be difficult and a source of controversy (e.g. a reduction by 20% of the hedge rows of a given landscape clearly does not reduce the value of the landscape by 20%). Consequently, the qualitative assessment of changes is the preferred option. The information obtained could also be fed to a consultative forum or group of experts for deciding whether changes are indeed considered as significant.

5.0 Designation test: "Beneficial Objects" Article 4(3)(b)

the beneficial objectives served by the artificial or modified characteristics of the water body cannot, for reasons of technical feasibility or disproportionate costs, reasonably be achieved by other means, which are a significantly better environmental option.

5.1 This part of the article requires consideration of whether there are better environmental options for delivering the beneficial objectives served by the artificial/modified characteristics. However, identification of better environmental options is constrained by consideration of reasonableness that is made operational through two elements: technical feasibility and level of costs.

5.2 Thus, there are three aspects to this test. Alternative means to achieve the existing "water use" (or uses) must:

- be technically feasible;[13]
- achieve significantly better environmental option;
- not be disproportionately costly.

Significantly better environmental option

5.3 Reaching an agreed understanding of the meaning of significantly better environmental options has proved difficult. Two interpretations of the Directive's requirements have been proposed.

- The assessment should only consider local alternatives associated with the water environment. This may be consistent with the Water Framework Directive *per se*, but not with the overall issues of sustainability as promoted in EU and national sustainable development strategies;

- A wider interpretation requires consideration of local alternatives and regional/national alternatives that may provide the same service/function (e.g. replacing navigation with road or rail transport, replacing hydropower with nuclear or wind energy) and investigating the impact of these options on a wide range of environmental concerns.

5.4 The wider interpretation involves looking at not only water, but also air, soils, bio-diversity or landscape issues. This ensures alternative options are not better options from a purely water point of view leading to replacing water problems by other environmental problems (this may be the case for example if navigation is replaced by road transport). In the case of water, options have to account for the improvement in water quality resulting from the restoration to good ecological status in the heavily modified water body considered.

5.5 As a first approach, a qualitative assessment of the main environmental issues is required. A simple table may be prepared comparing the existing use and the proposed alternatives from the point of view of their environmental impact.

5.6 In some cases, the quantification of the physical impacts of the existing use and alternatives may be possible. Such impacts may be transformed into monetary (and thus comparable) values.

Disproportionate costs

5.7 Three possible approaches to assessing whether costs are disproportionate are described:

[13] Technical feasibility is put here as the first check, as assessing the environmental impact of options that are not technically feasible is clearly of no use.

- comparison of costs of alternatives;
- comparison of overall costs and benefits of modifications and alternatives; and
- costs versus ability to pay.

All three approaches could be considered in the case studies.

Comparison of cost alternative

5.8 The concept of disproportionate costs can be assessed by comparing the existing costs of delivering the use, service or beneficial objective, with the costs of alternative options. The main cost elements that are to be considered include:

- For the existing situation***:*** operation and maintenance costs, but also replacement costs (principal and interest payment);

- For each option/alternative**:** capital costs (principal and interest payment), operation and maintenance costs, and possible foregone benefits from changes in economic activities resulting from the option (e.g. reduction in agricultural production resulting from the development of a retention area as an alternative to dykes for preventing floods)

Costs versus ability to pay

5.9 Assessing costs of alternatives with ability to pay. Although ability to pay is not directly a designation process issue, it can be a useful way to assess different alternatives serving the same beneficial objectives.

Comparison of overall costs and benefits

5.10 Comparing the overall costs and benefits of the existing modification. This assessment ensures that the modification provides an overall net benefit to society, and is more consistent from an economic perspective than the two tests (comparing environmental impacts and the costs of alternatives separately) proposed above.

General considerations

5.11 The economic appraisal of the alternative modifications will need to consider in priority:

- The best practice techniques customarily used for each type of modification (e.g. flood defence, navigation etc.) to ensure environmental impacts of alternatives are properly compared;

- The most cost-effective alternatives, i.e. those that provide the same service at the lower costs.

5.12 In some situations, local cost information may be collected for comparing alternatives. In other situations (e.g. when comparing the costs of hydropower as compared to other energy sources), or as a first step/proxy, benchmark information available at regional, national or European scales can be used.

5.13 To ensure cost information between existing modifications and options can be compared, and because of the likely different life times and temporal distributions of costs, all costs have to be annualised using standard discounted cash flow analysis and appropriate discount rates.

Descriptive or quantitative methods

5.14 It is considered that in many circumstances the Article 4(3)(b) test can be addressed by describing the modification, its use and the consequences of its removal. Where such a descriptive analysis is insufficient to reach a determination, further quantification and assessment of economic variables analysis should be undertaken until a determination is possible.

5.15 It is clear that it will not be possible to define clearly where the boundaries between qualitative and quantitative assessment should be drawn. The application of the designation test to the case studies will provide a better understanding of the situations and conditions under which general and qualitative descriptions are considered sufficient. These decisions will also be a matter of local expert judgement. Consequently, it will be important to ensure that the decisions are made in a transparent and objective manner. The process of designation will be part of the River Basin Management Planning process. Designation decisions will consequently be subject to the Article 14 requirements for active involvement of all interested parties as well as the formal consultation requirements.

5.16 The information obtained on the environmental impact and costs of alternatives could be fed to a consultative forum or group of experts for deciding whether costs of alternatives are indeed considered as disproportionately high as compared to the costs of the existing means.

6.0 Timetable and River Basin Planning

6.1 HMW should be provisionally identified by 2004 as part of the characterisation of river basin districts required by Article 5. As specified above, this only requires the identification of those water bodies, which are substantially changed in character as a result of physical alterations by human activity. The identification step does not include any economic assessment and the designation tests should not be considered at this stage.

6.2 The designation tests should be considered as part of the River Basin Management Planning process to be completed by 2009. However, the logistics of the plan will require the consideration of the designation tests early during the planning process. Indeed, the designation tests must be complete in time to allow for the identification of the programmes of measures required to deliver good ecological potential in the most cost-effective way. The recommended date for the completion of the designation tests will build on the work of the *Economics* and the *Good Practice in River Basin Planning* working groups.

6.3 In the context of the preparation of the River Basin Management Plan, it is important to ensure compliance with Article 4.8. This requires Member States to ensure that the designation of specific water bodies as heavily modified *does not permanently exclude or compromise the achievement of the objectives of the Directive in other bodies of water within the same river basin district, and is consistent with the implementation of other Community environmental legislation*. Where failure to comply with Article 4.8 is predicted, then the body of water cannot be classified as heavily modified and should reach good ecological status.

7.0 Conclusions

7.1 A common appraisal framework for designating heavily modified water bodies across Europe is presented in Figure 1. Although the different steps of this framework are valid for all situations, the level of analysis and the need for quantification and economic assessment is likely to be variable, to take account of differences of the modification examined and its importance at the local and national scale.

7.2 The case studies within the HMW project offer the opportunity for Member States to test in a consistent manner the different steps of the designation process and to assess the level of quantification and economic assessment that may be required under specific situations. This will provide valuable examples of how the process of addressing the designation tests can be undertaken, and may allow the identification of types of analysis adapted to types of situations.

The following issues should be considered:

- Identification of methods and procedures to make decisions;
- Consideration and testing of relevant methods for evaluating the impact of changes to natural conditions in terms of changes in uses, functions, economic benefits;
- Assessment of disproportionate costs in terms of: (a) comparison of costs of alternatives; (b) comparison of overall costs and benefits of modifications and alternatives; (iii) costs versus ability to pay;
- Consideration of who should be involved (e.g. consultation forum, experts groups) during the designation process.

7.3 In many cases full scale economic assessment will not be necessary and descriptive methodologies may be sufficient for sound judgements to be made. The use of economic appraisal methodologies should themselves be proportionate, and used where such economic assessment is likely to improve decision-making. It will then be important to ensure adequate economic information is collected at the right spatial scale (i.e. linked to the beneficial objective and use) so the economic assessment can be performed in a timely manner.

7.4 Table 1 attempts to provide preliminary Guidance for the type of approach that may be required under different situations. However, Table 1 is to be taken cautiously for two reasons:

(i) the content of the table is to be refined and validated through the process of designating water bodies in the different case studies developed by the HWM group;

(ii) the designation of heavily modified water bodies can be part of an iterative process that alternate discussion with stakeholders and further analysis if required/no consensus is obtained on the answer to the specific tests that are part of the designation process.

7.5 To assist in the reporting of the case studies a standard format is provided (Table 2). This table lists the range of issues and information that may be considered through the designation process. Clearly, not every cell of the table needs to be completed. This is particularly the case for comparing the environmental impact of the modification with alternatives: some environmental impacts will be described qualitatively, while others will be quantified in terms of physical changes or in monetary terms.

Figure 1 - Flow chart summarising the steps required to address the Article 4.3 designation tests

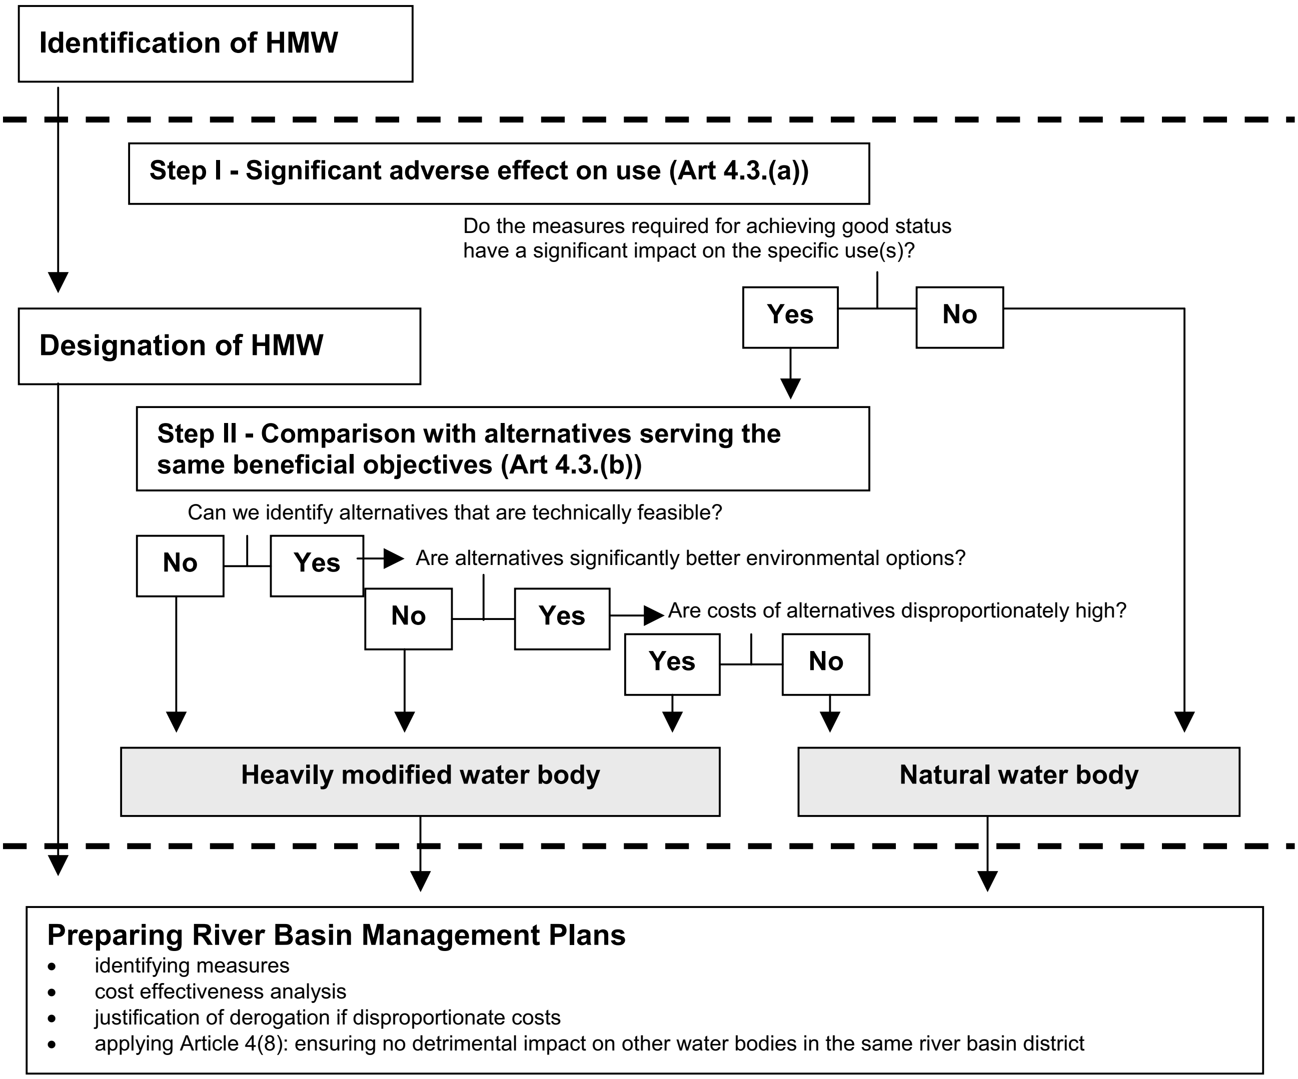


Table 1 - Preliminary Guidance on the use of descriptive and quantitative methods

Test	Qualitative assessment	Quantification of impact on use, function	Assessment of economic variables using benchmark information (costs, benefits)	Assessment of economic variables requiring specific methodology
Significant adverse effect	If abandonment of, or major change in, use/function/activity, or If very limited change in use	When partial change in use, function		Where significance of change in use uncertain
Better environmental options	Qualitative assessment for impact on different media as basis for analysis	If uncertain about which option is best		
Disproportionate costs	Description of scale of costs and also benefits if judgement / conclusion is clear	N.A.	National / Local scale benchmarking may provide sufficient clarity for good judgement	Where local situation significantly different from benchmark case or where other reasons for uncertainty exist

Table 2 - Reporting template for appraisal methods

Annex E – Results of Scoping and Testing in Pilot River Basins

INTRODUCTION

This Annex presents the activities and projects undertaken by experts from different river basins and countries for testing specific elements of the economic approach proposed in the WFD CIS Guidance Document No. 1. These activities have been key in assessing the feasibility and practicality of this approach. Furthermore, they have provided opportunities in many countries for launching discussions between technical and economic experts, stakeholders and policy makers on the key elements of the economic analysis and more generally of integrated river basin planning.

The Annex provides:

- A summary table of the activities in terms of location and key issues investigated;
- An individual summary for each activity, presenting: (i) the key water management issues at stake in the river basin or sub-basin considered; (ii) the objectives of the study and activities undertaken; (iii) expertise, stakeholders and information mobilised; and (iv) results, lessons for success, problems and outstanding issues.

The case studies included, with their specific area of focus are:

1. **Alsace Plain Aquifer (France):** Estimating disproportionate costs;
2. **Bordeaux Aquifer (France):** Testing the cost-effectiveness analysis;
3. **CIDACOS River Basin (Spain):** Undertaking the cost effectiveness analysis;
4. **Corfu Island (Greece):** Carrying out the economic analysis of water uses;
5. **Middle-Rhine River Basin (Germany):** Assessing the recovery of the costs of water services;
6. **Motala River Basin (Sweden):** Scoping an integrated appraisal for river basin management plans;
7. **Oise River Basin (France):** Testing the development of baseline scenario;
8. **Ribble River Basin (England):** Integrated appraisal for river basin management plans;
9. **Rhone-Méditerranée-Corse River Basin (France):** Assessing the pertinent spatial scale for the economic analysis;
10. **Scheldt International River Basin (The Netherlands, France, three Belgium regions):** Testing elements of the three-step approach;
11. **Sèvre Nantaise River Basin (France):** Testing the chronological feasibility of the three step approach;
12. **Vouga River Basin (Portugal):** Scoping key elements of the economic analysis;

More information on the individual summaries can be obtained:

- On the Web site www.eaufrance.tm.fr, where the final reports of the different case studies are stored and are accessible to all; and

- Directly from the contact person(s) identified at the end of each individual summary. This contact person(s) will be able to further explain the activities developed and results obtained, and to provide you with the names of other experts that have undertaken the projects and the analyses.

River Basin (country)	Issues addressed	Key lessons learnt	Part of the 3-Step Analysis
Alsace plain aquifer (France)	Assessing disproportionate costs	Use of simulation models for baseline/effectiveness analysis/disproportionate cost analysis - Difficulty to find benefits in an aquifer (except drinking water)	Step 3 – Identifying measures and economic impact ➢ Assessing disproportionate costs (Costs Benefit Assessment)
Bordeaux aquifer (France)	Analysing the cost-effectiveness of measures	Importance of the scale of analysis in the results of cost effectiveness analysis	Step 3 – Identifying measures and economic impact ➢ Analysing the cost-effectiveness of measures, scale of analysis
Cidacos river basin (Spain)	Carrying out the full economic analysis, including the involvement of stakeholders – Specific focus on agriculture	Importance of linking water pricing/price elasticity with changes in sector policies – Key methodological issues for the cost-effectiveness analysis (scale, which costs, looking at impacts) – Importance of the financial feasibility of proposed measures	Main parts of the full 3-Step analysis ➢ Water uses and services, costs, cost-effectiveness ➢ Disproportionate cost analysis
Corfu Island (Greece)	Initial assessment of water uses, test of data availability and organisations	Low data availability	Step 1 – Characterising RBs ➢ Mainly water uses and services
Middle Rhine river basin (Germany)	Carrying out an economic audit of water uses - Assessing the recovery of costs for water services	Importance of data collection for the initial status – Role of existing statistics in assessing cost-recovery	Most of Step 1 – Characterising RBs ➢ Water uses and services ➢ Cost recovery
Motala river basin (Sweden)	Identifying information needs and gaps for the economic assessment and decision-making	Importance of data collection, link with stakeholders (public participation) and economics as a decision making tool – need to find coherence between data from wide range of organisations	Most of Step 1 – Characterising RBs
Oise river basin (France)	Building baseline and prospective scenarios	Need for building alternative scenarios	➢ Step 1 & 2 – Identifying significant water management issues - Baseline scenario
Ribble river basin (England)	Carrying out appraisal to construct efficient programme of measures to reach set objectives – integration between appraisal and consultation/participation – linking river basin planning and agriculture policy	Importance of common understanding and training process – Proposed approach considered feasible and applicable to other river basins	Main parts of the full 3-Step analysis ➢ Identifying water uses & services, estimating costs, analysing the cost-effectiveness of measures, disproportionate cost analysis
Rhône Méditerannée Corse river basin (France)	Identifying/Assessing criteria for the definition of the scale of the analysis	General approach linking economic, biophysical and planning/land use information for investigating scale issues, no specific economic methodology tested	Step 1 – Characterising RBs ➢ Defining the scale of the analysis

River Basin (country)	Issues addressed	Key lessons learnt	Part of the 3-Step Analysis
Scheldt International river basin (The Netherlands, France, Belgium regions)	Analysing water uses, initial identification of measures, cost-effectiveness analysis – Looking at water quality, groundwater abstraction and morphology	Importance of physical parameters (hydro morphology), in economic analysis (links with experts on pressures & impacts) – Use of expert panel for assessing disproportionate costs – Lack of coherence between different parts of an international river basin	Main parts of the full 3-Step analysis ➢ Water uses and services, costs, cost-effectiveness
Sèvre Nantaise river basin (France)	Testing of the feasibility of the 3-Step approach	Need to check data availability – Need to involve stakeholders Difficulty to find data on environmental benefits	Main parts of the full 3-Step analysis ➢ water uses and services, costs, cost-effectiveness
Vouga river basin (Portugal)	Identifying gaps in available data and creating links with stakeholders and other working groups	Low data availability Link with stakeholders (public participation) and other technical groups (e.g. dealing with Heavily Modified Water Bodies)	Most of Step 1 – Characterising River Basins

Alsace Plain Aquifer (France): Estimating disproportionate costs

Keywords	Cost effectiveness analysis, disproportionate costs, derogation, groundwater, pollution, hydrodynamic model, simulation
Location (river basin, country)	Alluvial aquifer of the upper Rhine valley, Alsace region, France
Key water management issues	• Groundwater pollution: since the 1910s, the potash mining industry has generated huge waste dumps with high salt contents (NaCl). These dumps have been leached by rainfall, resulting in significant contamination of one of the largest European aquifers; • Significant pollution control measures have already been implemented, leading to a progressive restoration of the aquifer. However, these measures might not be sufficient to reach the objective of "good status" by 2015. Additional measures may be needed to reach the objective but their cost is likely to be disproportionate with regard to the benefits and the financial capacity of actors.
Objective and the study's function in the overall analysis	• Estimate the risk of non-compliance using hydrodynamic simulation models; • Compare alternative programmes of measures through cost effectiveness analysis; • Define "disproportionate costs" using different approaches and implications. Develop a method to justify derogation on the basis of the disproportionate cost argument. Test this method on the case study; • Identification and evaluation of benefits (in case of groundwater quality restoration).
Planned activities and overall structure of the study	• Step 1: Development of a simple hydrodynamic model to simulate the impact of various programmes of measures. Key issue: choosing a model (trade-off between accuracy and cost); • Step 2: Simulation of the baseline scenario & identification of additional measures needed to reach the objective in 2015. Key issue: addressing uncertainties; • Step 3: Cost-effectiveness analysis of the alternative measures; • Step 4: Defining what is a disproportionate cost: (i) costs versus ability to pay; (ii) cost versus benefits; (iii) costs versus best alternative use of public finance; • Step 5: Identifying and assessing the value of benefits related to groundwater restoration.
Disciplines and expertise mobilised	• Economist & hydrologist from BRGM; • Consultative group (Rhine Meuse Water Agency, government administrations & regional authority): discussion of the method, assumptions and results; • Stakeholders (mining company, municipal water suppliers, farmers organisations, industrial water user association, scientists).
Key information source mobilised (reports, books, statistics…)	• Pollution monitoring data & geological information (to develop the model): annual pollution monitoring reports; • Interviews with stakeholders to identify and quantify benefits; • Scientific reports to cross check information from experts.

Alsace Plain Aquifer (France): Estimating disproportionate costs

<u>Stakeholders</u> involvement	• Experts of the consultative group involved in: (i) the definition of "disproportionate"; (ii) the identification of the programmes of measures; • Stakeholders consulted through interviews on: (i) the definition of benefits for current water users and (ii) the prospects of future water demand and potential benefits for future generations of aquifer restoration.
Highlights/Results/Successes	• Pointing at: ⇨ The need to use simple hydrodynamic models to simulate the baseline scenario and to assess the effectiveness of alternative programmes of measures; ⇨ The need to involve stakeholders in the identification of costs and benefits, and to cross check this information with experts/scientists/secondary data.
Key problems and potential solutions	• All costs and benefits cannot be assessed in monetary value. How can they be aggregated when expressed in different units (Euros, number of jobs, etc)? How can this difficulty be solved to calculate a cost-effectiveness ratio? To compare costs with benefits? • Some benefits, in particular those accruing to future generations, are uncertain. We suggest that the estimate of these benefits should be associated with a probability of occurrence. The total benefits should be expressed as the sum of the benefits weighted by their probability of occurrence.
Outstanding issues	• Three very different approaches can be used to define what is a "disproportionate cost". This choice determines the methodology to be adopted to justify a derogation: ⇨ Costs are reputed to be disproportionate if costs to be born by actors exceeds their financial ability to pay; or ⇨ If the overall costs exceed the overall benefits for the society as a whole (the State should only implement measures which lead to an improvement of the social welfare); or ⇨ If the rate of return over public investment needed to finance the measures (given the maximum amount that can be reasonably paid by other actors) is lower than any other water restoration programme in the river basin district that can be financed given the limited financial resources. It is important that one of these approaches be selected as a reference.

Bordeaux Aquifer (France): Testing the cost effectiveness analysis

Keywords	Cost effectiveness analysis, scale issues, groundwater, economics and decision making.
Location (river basin, country)	Deep aquifers of Gironde (Bordeaux) department: Adour-Garonne district (southwest of France). A local master plan (SAGE) was adopted on the coastal zone of this geographic area.
Key water management issues	• Over-exploitation of these aquifers with 150 Mm^3 abstracted per year; • Important catchment for domestic uses mainly for the Bordeaux municipality and tourism along the coast; • Abstraction for irrigation (corn and vegetables); • Abstraction for industry and geothermics; • Risk of saline intrusion to the aquifer, and of decreased piezometric water levels.
Objective and the study's function in the overall analysis	• Testing the feasibility of the cost effectiveness analysis: ⇨ Determine the type and availability of needed data? ⇨ Determine the coherent scale of analysis; ⇨ Determine the analysis' level of certainty: which type of costs should be taken into account?
Planned activities and overall structure of the study	• Step 1: Comparison between baseline scenario and 2015 objectives; • Step 2: Defining technical and economic adjustment variables; • Step 3: Crossing these variables and using them to model the aquifer and define alternative scenarios; • Step 4: Identification and calculation of cost needs to be taken into account (using models for non-market costs); • Step 5: Comparison of alternative scenarios by actualisation of costs.
Disciplines and expertise mobilized	• Technical expertise: agency experts, BRGM for building the models of the aquifers, and a local co-ordinator for the master plan; • Economic expertise: economist from the university; support from the agency.
Key information source mobilised (reports, books, statistics…)	• Data collected for the master plan: data on abstraction (agency) and model of the aquifer (BRGM); • University studies on economic losses for users; • Estimation of experts on "water saving policies".
Stakeholders involvement	• The experts of the agency were involved in the technical analysis, but it was more difficult to involve them in the economic part; • The local co-ordinator of the master plan represented local decision makers.
Highlights/Results/Successes	• Pointing at the reliability and the interest of the cost effectiveness analysis at a local scale, particularly when the master plan only contained small elements of economic analysis.
Key problems and potential solutions	• Difficulties linked to data: insufficient data on water uses, water pricing, and "water saving policies"; • Difficulties linked to economic tools, particularly when transferring results from one or two other cases, or in making methods understandable to non-economists.

Bordeaux Aquifer (France): Testing the cost effectiveness analysis	
Outstanding issues	• Need to set precise limits for cost effectiveness analysis: it is impossible to compare the results of a global cost effectiveness analysis (at the scale of the whole aquifer) with the sum of cost effectiveness on separate, homogeneous part of the aquifer; • Need to develop a socio-economic database for water issues and water uses; • Need to develop links and common understanding between economists and decision makers.
Contact person(s)	Stéphane ROBICHON Agence de l'Eau Adour-Garonne 90 rue du férétra F-31078 Toulouse Tel. +33 5 61 36 37 88 Fax. +33 5 61 36 37 38 Email Stéphane.robichon@eau-adour-garonne.fr

Cidacos River Basin (Spain): Undertaking the cost effectiveness analysis

Keywords	Cost-effectiveness, integration between economics and biophysical expertise.
Location (river basin, country)	Ebro River Basin (Spain)
Key water management issues	• High variability in water supply; • Water abstraction pressures; • Diffuse pollution from farms; • Water emergencies for domestic water supply; • Flooding problems during specific times of the year; • One of the main axis of economic development for the Navarra region; • Existence of plans in the region to conserve biodiversity, using rivers as ecological corridors.
Objective and the study's function in the overall analysis	• The study developed a step-by-step implementation of the cost effectiveness analysis proposed in the Guidance with special emphasis on measures affecting water flow. It addresses the implications of conducting the analysis at a river basin level (inter-related water bodies) versus water body by water body. Implications of analysing the inter-relation between measures affecting water quality and water quantity are detailed. The study also draws lessons for the planning processes.
Planned activities and overall structure of the study	• Step 1: Initial information collection on natural water regime, regime of abstractions in the river, water quality and information on biotic indexes; location of control stations and regularity and reliability of information of parameters. Assessment of additional information required by the Directive (mainly related to hydro-morphological indicators). Site visit. Preparation of characterisation initial report; • Step 2: Interview key stakeholders in the river basin for a first overview of significant water issues in the basin (key pressures today and for the future), for interpreting existing information; for defining objectives for the basin for each parameter and for establishing a first catalogue of measures. Analysis of gap. Selection of parameters where there is gap and control parameters; • Step 3: Collection of additional information on key pressures, cost of measures and effectiveness of measures for improving water status (focus on water flow and physico-chemical parameters). Calculation of cost effectiveness indicators (focus on agricultural measures and urban measures). Ranking of measures for improving water status as they affect individual parameters and considering reassessment of gap in linked water bodies and interrelations between parameters. Development of an ad-hoc model; • Step 4: Analysis of the economic impacts of the programmes of measures and the distributional implications of different financing plans. Analysis of environmental costs of programmes of measures (non water or in other basins). Analysis of sensitivity of changes in ranking of measures when incorporating environmental and economic impacts. • Step 5: Refinement of the analysis incorporating feedback in Workshops with EC experts; • Step 6: Workshop with key stakeholders for discussing and validating the preliminary results and comparing costs and benefits of achieving different levels of objectives. Stated preference survey; • Step 7: Write conclusions for a protocol for the economic analysis in RBP to facilitate implementation in the country;

Cidacos River Basin (Spain): Undertaking the cost effectiveness analysis	
Disciplines and expertise mobilised	• Combination of economic expertise, hydrologist, engineers, biologist, chemical engineers; • Input from water managers, agricultural organisations, local organisations, academics, regional and basin authority administrators, environmental concerns.
Key information source mobilised (reports, books, statistics…)	• Existing Planning documents and information from the ministries of agriculture, environment, from the river basin authority, the regional government, specialised water organisations (irrigation, domestic water supply and WWT); • Statistics from national organisations; • Monitoring information from monitoring stations; • Previous research on effectiveness of measures, elasticity of demand and behavioural models of water use behaviour when confronted with uncertainty.
Stakeholders involvement	• Key stakeholders from the river basin (environmental authorities and experts, water service suppliers, irrigation authorities, river basin authority and regional authorities, water users, beneficiaries of water improvements, majors of urban areas, local environmental groups, water supply companies); • Two workshops organised to share/discuss the results of the study, to take key decisions/collect information, evaluate environmental benefits and analyse disproportionate costs issues.
Highlights/Results/Successes	• Cost effectiveness analysis completed resulting in measures being ranked according to their cost effectiveness (including economic impacts and environmental costs). Preparation of river basin plans including a variety of measures affecting agricultural and urban users. Analysis of final costs of river basin plan when considering the linked effects of improvement in inter-related water bodies. Analysis dealing with uncertainty of quantitative value of environmental costs; • Analysis of the different financing alternatives of RBP and their impacts on prices paid by different users (and upstream and downstream). Analysis of institutional viability of measures and distributional effects of measures. Disproportionate costs analysis structure. Stated Preference survey for analysing environmental benefits; • The study used real information on the basin as much as possible.
Key problems and potential solutions	• Information for assessing environmental costs and benefits was not available. Different hypotheses on environmental costs were considered to analyse their impact on the relative desirability of different measures; • The effectiveness of measures was difficult to assess. Consequently, some assumptions were made; • Data on unit costs of measures exists in many cases but needed to be analysed in detail to ensure proper calculation of Annual Equivalent Cost.
Outstanding issues	• The contribution of different pressures to the actual status of water bodies remains a key priority to perform cost effectiveness analysis and to choose programmes of measures; • Analysis of effectiveness of measures and incorporating considerations of institutional viability of measures; • The analysis had concentrated on measures affecting water flow and physico-chemical parameters. Further analysis is required to analyse how these measures improve habitats and hence biological parameters. Measures affecting any one parameter will have “knock on” effects and this needs to be known; • Need to carry out further analysis of social impacts of implementing programmes of measures.

Corfu Island (Greece): Carrying out the economic analysis of water uses

Keywords	Integration between economics and biophysical expertise.
Location (river basin, country)	Island of Corfu (NW Greece). The island was considered as a River Basin on a pragmatic basis, given that Greece has a large amount of islands, each with many small river basins.
Key water management issues	• Water reserves are subject to very high pressures since a significant water deficit exists on the island. This leads to conflicts between water uses. Note that water for all uses on the island is of groundwater origin and that apart from the deficit, groundwater deterioration problems exist (presence of gypsum and saltwater intrusion due to over-exploitation). To highlight the magnitude of pressure on water resources, we have to take into account the high seasonal variability of water demand, which inevitably follows the tourism peak, condensed in the summer period. To illustrate the high priority of tourism and the magnitude of conflict among uses, it is interesting to observe that in the Ropa Valley where the main land use is agriculture, the only irrigated area is a golf course.
Objective and the study's function in the overall analysis	• The study aims at investigating the link between biophysical information and the economic analysis process; • It has been designed as a "non-virtual" exercise, to test the feasibility of the process of data collection/analysis and not to undertake the overall economic approach proposed in the Guidance Document. • A specific approach has been adopted based on the use of a GIS system to facilitate data storage, retrieval, processing/analysis and final data visualisation and map output; • This is considered necessary due to spatial (temporal) variability of water resources/demand characteristics, of water uses, economic activities, and pricing policies.
Planned activities and overall structure of the study	• Step 1: Initial literature review for assessing the information base; • Step 2: Interview key local water administrators (Region, Prefecture, Municipalities) for developing main assumptions for the analysis; • Step 3: Analysis of data collected and preparation of synthesis report; • Step 4: Refining the results, further elaboration; • Step 5: A Workshop with all target groups for discussing the results and raising awareness in all river basins in the country about the role of economics in the WFD is scheduled for late Summer 2002.
Disciplines and expertise mobilized	• Combination of economic expertise, hydrogeology (water quantity and quality characteristics), climatic data, land use.
Key information source mobilised (reports, books, statistics…)	• Planning documents from the Ministries of Agriculture and Interior; • Statistics on demographic data and activities by socio-economic sector; • Information collected by I.G.M.E. on water quality and quantity; • Information collected on costs of water services and water demand.
Stakeholders involvement	• Local water administrators, harbour authority, and water service suppliers were interviewed during the initial phase of the study.

Corfu Island (Greece): Carrying out the economic analysis of water uses	
Highlights/Results/Successes	• Some issues were not investigated due to the specifics of the pilot area. Thus, not all aspects of the Guidance Document were assessed; • Overall, readily available statistical information provided most of the information included in the study; • Lack of time hindered the development of a strategy for raising proper awareness, resulting in poor reporting from local authorities on data they are responsible to collect; • Data from more centralized sources were better organized and more easily obtained.
Key problems and potential solutions	• Information for assessing environmental costs was not available; • Difficulties with project financing; • The establishment of a "Water Agency" to operate as the sole organization for water management and to serve as the advisory and co-ordinating office for regional competent authorities may bring solutions for more coherent information collection and storage. Such establishment is currently being discussed in Greece.
Outstanding issues	• The allocation of costs to different uses was not performed, and the analysis remained at a very aggregated level. Further analysis will be required for assessing cost-recovery at the sectoral level; • The feasibility of applying the approach chosen in this study to all river basins in Greece remains to be assessed. Due to a potential lack of funding and time constraints, the collection of new data as performed in this study may pose significant problems. These issues need to be faced in a pragmatic way.
Contact person	Georgia Gioni Institute of Geology and Mineral Exploration 70 Messoghion st., 115 27 Athens, Greece Tel. +3010 77 08 410 Fax. +3010 77 71 589 Email: mdmwat@otenet.gr

Middle Rhine River Basin (Germany): Assessing the recovery of the costs of Water Services

Keywords	Cost recovery, economic assessment, data access
Location (river basin, country)	Middle Rhine, located in Germany
Key water management issues	• Cost recovery in the water services sector. •
Objective and the study's function in the overall analysis	• The study addresses the methodological and empirical issues associated with the collection and evaluation of economic characteristics relating to water services (water supply & sewage disposal). It was carried out to prepare for implementation of the provisions of the European Water Framework Directive (reporting; preparation of a Middle Rhine management plan); to consolidate the methodological concept for an economic analysis of water use (recovery of costs for water services, with due regard for economic and resource costs); and to develop an appropriate empirical concept to obtain necessary economic data and information to complete the analysis.
Planned activities and overall structure of the study	• Conduct a three-stage survey in the Lander of Hesse and Rhineland-Palatinate concerning economic characteristics of water services; • Stage 1: Collect and evaluate generally available, primary data from federal and regional statistical offices concerning manufacturing data and environmental, manufacturing, employment and investment costs, and financial data for water and energy companies. Local data included information on population, and environmental statistics, financial data on local water supply companies and sewage plants. Data and information from the technical and financial authorities of the Lander provided information about information systems on water services, land survey data, water and shipping authorities, various charges for water services, and on subsidies, measures for water protection, and sustainable use of resources. Any gaps in the data may be supplemented with third party data; • Stage 2: Collect and evaluate third party data and information, such as water statistics and water rates from the Federal Gas and Water Management Association (BGW), ATV-DVGW/BGW's joint survey on public sewage disposal, and also evaluate special surveys and expert reports; • Stage 3: Primary surveys within the context of implementing the Water Framework Directive. No primary surveys were implemented within the context of this pilot project, as the data available was enough to complete the analysis. Primary surveys should only be implemented in isolated cases where there are decisive information gaps. When carrying out primary surveys, collaboration with the relevant specialist organizations is advisable.
Disciplines and expertise mobilized	• Economics for the Hessian Ministry for the Environment, Agriculture and Forestry.

Middle Rhine River Basin (Germany): Assessing the recovery of the costs of Water

Key information source mobilised (reports, books, statistics…)

- Primary data was used from the Federal Statistical Office, regional statistical offices for local authority data, research from water authorities and environmental agencies. Other primary data from the technical and financial authorities of the Lander was used regarding information systems about water supply and sewage disposal, land survey information, data about water and shipping authorities, on subsidies for water management plants and measures for water protection, and on charges (wastewater, groundwater, etc.);
- This includes an evaluation and full census of all companies in the State of Hesse for 1998. These evaluations are annual and comparable in form by all Lander, constituting a comprehensive, reliable information base;
- Secondary data and information came from the Federal Gas and Water Management Association, ATV-DVGW/BGW's joint survey on public sewage disposal, and evaluation of special surveys and expert reports;
- Primary surveys in collaboration with specialist organizations.

Stakeholders involvement

- None.

Highlights/Results/Successes

- Principal findings of an analysis of the public water supply reveals that cost recovery from revenue (excluding allocations and subsidies) in Hesse is approximately 90%. Internalised environmental and resource costs (groundwater charges) significantly exceed the sum of total subsidies and the cost recovery shortfall;
- For sewage disposal in the Hesse, cost recovery from revenue (excluding allocations and subsidies) is approximately 80%. Cost recovery from revenue including allocations and subsidies is approximately 92%. Internalised environmental and resource costs (sewage charge) was significantly lower than the sum of total subsidies and the cost recovery shortfall.

Key problems and potential solutions

- Not all of the sources for third party information are generally available. The availability of results from special surveys and the requirements governing the adoption of such data should be reviewed in each individual case. Where data is adopted, agreements must be signed with the respective institutions and fees may be payable. It would appear expedient to aim for centralized solutions in this context;
- The abundance of data contributes to substantial time and efforts to provide an analysis, as it was necessary to combine fundamental data and information from various sources that were not necessarily compatible. Adapting the official statistics of the Federal Government and the Lander to the data requirements of the WFD may significantly improve overall reliability when determining economic characteristics;
- Further, the area-wide implementation of the proposed survey and requisite constant updating necessitate a suitable form of data processing and the supply of information to the specialist authorities, as well as advance clarification of accessibility for the various parties involved in sub-regional management plans. Setting up a central data pool from which the required data about river basins could be extracted would be beneficial for this purpose.

Outstanding issues

- Decentralised nature of the water services sector in the Middle Rhine River Basin (with 275 water supply companies and 562 sewage treatment plants) has major significance to the potential impacts of water use on the environment and for determining economic characteristics of the water supply;
- There are a number of small impoundments used for energy extraction that are of local significance and were not considered for this report.

Middle Rhine River Basin (Germany): Assessing the recovery of the costs of Water

Contact person	Dr Arnold Quadflieg, Ministry for the Environment, Agriculture and Forestry. Tel: + 49 611 815 13 50/Fax: + 49 611 815 19 41/Email: a.quadflieg@mulf.hessen.de

Motala River Basin (Sweden): Scoping an integrated appraisal for river basin management plans

Keywords	Water quality control and management, economic appraisal, river basin characterisation, staff resources, information gathering
Location (river basin, country)	Motala River Basin, Sweden.
Key water management issues	• Intensive agricultural pressure (cereal crops, meat production); • Diversified farming and forestry; • Coastal areas face decline in fisheries and increased tourism, leading to eutrophication in some water bodies; • Acidification on the fringes of lakes in the central plains; • Diversified economic sector in urban areas with IT industry and small metal industries; • Surface water used for drinking in urban areas; • Hydropower fully exploited between 1890-1918; energy production still important.
Objective and the study's function in the overall analysis	• This study aims to show what type of information is needed to inform decision-makers (at which level and for what decisions) on the various types of options available to meet the requirements of the WFD. Additionally, the study shows how different elements of the appraisal system could best generate this information, and how the information could be implemented into decision-making. Finally, key information gaps and specific research needs and priorities are identified.
Planned activities and overall structure of the study	• Step 1: Characterise and differentiate (parts of) water bodies to identify bodies of water where objectives must be set and measures both identified and appraised; • Step 2: Characterise various possible measures to achieve good quality status and the level at which these measures have to be implemented; • Step 3: Characterise the diverse parties affected positively or negatively by the impacts of these possible measures; • Step 4: Determine the best use of information provided by the existing appraisal system on the environmental, economic or social impacts of the possible measures, and identify key gaps in expertise and information to be addressed to undertake cost-effectiveness and cost-benefit analysis; • Step 5: Identify staff resources; • Step 6: Identify outstanding research issues.
Disciplines and expertise mobilized	• Environmental issues, economics; • Agencies involved in (general) river basin management: Municipal governments, Motala River Association for Water Care, the Lake Vätten Association for Water Care.
Key information source mobilised (reports, books, statistics…)	• Statistics Sweden (collects data for 119 main river basin); • Swedish Meteorological and Hydrological Institute (has a register where all Swedish river basins larger than 50 km^2 and all lakes larger than 1 ha are being mapped); • Swedish Waste and Wastewater Association (for data on costs for water use and wastewater disposal); • Regional and municipal government information; • Water-related associations (e.g., Swedish Board of Agriculture, Farmers Association, National Board of Fisheries, Swedish Environmental Protection Board).

Motala River Basin (Sweden): Scoping an integrated appraisal for river basin	
Stakeholders involvement	• None.
Highlights/Results/Successes	• Because of a long history of attention towards environmental quality issues, national and regional environmental strategy programmes are in place to address sustainable water management, to protect endemic marine species populations, to limit pollution in lakes and rivers, and to reduce water-borne emissions of nitrogen from human activities to the Baltic and its archipelago by half (between 1985-1995); • Scaling for basin-wide and sub-basin levels to achieve specific targets for phosphorus and nitrogen reduction was accomplished, and specific sectors were assigned the responsibility to meet each measure's objectives.
Key problems and potential solutions	• Despite ongoing programmes to meet targets, some sub-basins are not meeting the established environmental targets. Starting from an existing source apportionment that shows the contribution of polluters in the sub-basin, a cost-effective pollution abatement scheme should be made for the whole river basin and including the whole River Basin District, to achieve good quality status. Ideally, such a scheme would be based on marginal costs for pollution control, although required economic information is difficult to obtain and the criteria for the trade-off between sectoral needs and wants are not yet well developed; • The abatement level of point source emissions in Sweden is already high, particularly regarding phosphorus, due to the implementation of tertiary wastewater treatment in the 1970s and 1980s, and regulation of industrial emissions. This increases the marginal costs for further treatments, and may influence a cost-effectiveness analysis. In other sectors, for example in farming, where these are fewer technical fixes, reliable data on marginal pollution control costs are less distinct. Instead, actual data for selecting among measures are (i) efficiency (achievement of effects with little regard to costs), and (ii) the degree of acceptance from stakeholders.
Outstanding issues	• Need for further information about the link between pollution abatement costs in the most polluted water bodies, to investigate cost-effective solutions, including improvements such as wastewater treatment plants, costs of constructing wetlands and buffer zones, restore old industrial sites and waste deposit for heavy metals and other harmful substances; • Need to assess the costs/reduced profits for farmers that change their land use practices; • Need to research subject of valuing environmental public goods, possibly through contingent valuation methods adapted to include social learning and public participation in decision-making; • Need to research the extent to which environmental changes, in particular regarding water quality in Sweden, will be a consequence of endogenous socio-economic factors over the next 25 years.

Motala River Basin (Sweden): Scoping an integrated appraisal for river basin

Oise River Basin (France): Testing the development of Baseline Scenario

Keywords

Baseline projection, baseline scenarios, surface water, ground water, integration between economics and biophysical expertise, cost recovery

Location (river basin, country)

Oise river basin, part of the Seine river district (France)

Key water management issues

- High diffuse pollution from agriculture (mainly intensive cropping, high livestock density);
- Important urban areas, mainly downstream but also on some upstream areas;
- Dense industrial concentration on main and smaller rivers;
- Poor quality of Oise river and very poor quality of some smaller rivers;
- Existence of a master plan for the Seine river district.

Objective and the study's function in the overall analysis

- Assessment of data availability;
- Simple technical and socio-economic previsions testing: population, activity growth, population growth; pollution abatement equipment programmes and their effects on future discharge;
- Methodology testing and improvement for baseline projection and scenarios, focusing on surface water quality;
- Illustration of potential benefits of baseline scenarios for water policy settings.

Planned activities and overall structure of the study

- Step 1: Identify past trends and present state of water policy, surface water quality and pollution (including sewage equipment and discharges);
- Step 2: Establish baseline projection; assessment of the confidence of key data, methods and results (water quality, investment estimation); water quality evolution estimated by expert knowledge;
- Step 3: Baseline scenarios including cost recovery examination; water quality evolution estimated by model;
- Step 4: Insights for water policy-making: evaluation of the relevance of present policy, cost recovery issues, knowledge needs;
- Step 5: Insights on methodology: feasibility of global approach and of specific tools (e.g. environment response modelling), along with needed improvements.

Disciplines and expertise mobilised

- Biophysical expertise, engineering (sewage techniques and efficiency) and economics;
- Multi-disciplinary co-ordination and synthesis;
- Communication expertise for effective dissemination of study output.

Key information source mobilised (reports, books, statistics…)

- Detailed data on water pollution sources (raw pollution, treatment, discharge, main investment programme or needs proceeding from present water policy), water intakes and water quality;
- Expert knowledge on mean pollution ratios;
- Demographic data (past, present and future provisions);
- Regional planning documents.

Stakeholders involvement

- Main stakeholders involved in the study: water agency bureau for Oise river basin (manager, planning expert, investment support manager, water quality expert), water agency experts (economics, engineering and water quality), independent scientists (modelling environment response) and private consultancy (co-ordination and synthesis, communication);
- Associated stakeholders include regional representatives of Environment Ministry.

Oise River Basin (France): Testing the development of Baseline Scenario	
Highlights/Results/Successes	• Proved feasibility of methodology on Oise river basin scale; • Good confidence can be reached on assessment of pollution sources, discharges and equipment needs for industry and households; • Baseline scenario highlights major difficulties for achieving surface water quality objectives: durable nitrate pollution involving ground water, long improvement process for very poor quality sectors, incompatibility between good status definition and some natural processes (suspended matter standards towards erosion).
Key problems and potential solutions	• Main problems are related to groundwater: distribution of discharges (non connected households, breeding farms) between surface and ground water, magnitude and speed of contaminating and decontaminating mechanisms in soils and groundwater, pollution transfer from ground to surface water. There is a need for specific knowledge and for integrating surface and ground water; • Drastic uncertainty about future level of economic activities (industry and agriculture): scenarios are needed but not sufficient, perspective has to be used.
Outstanding issues	• Specific key expertise involved is not economics, but “economic approach”, i.e., multi-disciplinary co-ordination and synthesis plus uncertainty management; • Existing data allow baseline projection on surface water pollution and quality, highlighting needs for scenarios and for environment response models; • Methodology feasible at Oise river basin scale, projection relevant for 5 to 7 years (anticipated), scenarios and probably perspective necessary for a projection up to 15 years; • Study provides useful results about compliance defaults of present policy towards good status objective for 2015, allowing a wider vision than recent planning preparation (up to 2006).

Ribble River Basin (England): Integrated appraisal for river basin management plans

Keywords System of measures; risk-based assessment, cost-effectiveness

Location (river basin, country) Ribble River basin, located in the Northwest of England.

Key water management issues

- Water abstraction pressures;
- Diffuse pollution from agricultural land, compounded with somewhat impermeable clay soils;
- Varied water quality in urban and rural reaches;
- Lack of wastewater treatment facilities;
- Pressures from tourism and economic development and regeneration.

Objective and the study's function in the overall analysis

- This hypothetical study uses existing data and assumptions for missing data. It charts the whole process of carrying out an integrated appraisal of measures – from choosing a system of measures and conducting a cost-effectiveness analysis to determining options for disproportionate costs - for achieving good water quality in the basin through a six-step process, rather than the three-step process suggested by the Guidance Document. Specific emphasis is paid to the Cost Effectiveness Analysis. The case also identifies and investigates the issues and problems that arose throughout this "virtual" process, and looks ahead to future requirements beyond the 2004 deadline.

Planned activities

- Use of expert interviews (both telephone and face-to-face) with key decision makers, stakeholders and experts, to gain perspectives on the appropriate processes for developing an integrated study, developing tools and information to perform the "virtual" study;
- Develop a background review and issue report that presented an illustrative, outline an approach for integrated assessment in six steps (detailed below), along with a range of worked examples to indicate how this assessment process could address some of the issues raised by stakeholders and decision makers;
- Host a two-day workshop to discuss findings and issues regarding practical implementation of this approach; identify strengths of the approach and prioritise future research needs.

Overall structure of the study

- Step 1: Objective specification, to produce an agreed and consistent programme of measures, which incorporates national, regional and local objectives related to water and other quality issues. Interview key decision-makers, stakeholders and experts to seek their views regarding the appraisal system, determine the information needed to aid decision-making and on the availability of data for this;
- Step 2: Assessment of pressures and risks of non-compliance under a business as usual case. This risk-based assessment maps the likelihood that water bodies will fail to achieve good water status in future planning periods without any additional policy measures;
- Step 3: Option screening. Identify feasible and cost-effective measures aimed at reducing the risk of not achieving good water status in different plan periods;
- Step 4: Option appraisal. Identify and appraise cost-effective measures for achieving various classes of water quality status, and an assessment of the costs and ancillary impacts of these measures. This aims to cover in an even-handed way all of the effective measures for the main sectors (e.g., water industry, non-water industry, agriculture, and other diffuse sources of water pollution).

Ribble River Basin (England): Integrated appraisal for river basin management	
	• Step 5: Objective refinement. To assess the most appropriate measures for particular water bodies given the feasibility of identified measures in achieving different classes of water status and their costs. This process focuses on examining whether the system of measures selected is disproportionately expensive, so as to inform the decision of whether derogations may be needed; • Step 6: Plan agreement. Develop an agreed set of actions for the Agency, its partners, sectors and specific geographic areas and involving national, regional and local stakeholder consultation.
Disciplines and expertise mobilized	• A range of experts with backgrounds including economics, policy, environmental data assessment, water quality, water resources, HMWB, agricultural specialists, local and regional authorities; • Experts in public consultation/participation; • Functional experience included the strategic, policy, and operational levels.
Key information source mobilised (reports, books, statistics…)	• Expert interviews with key decision-makers, stakeholders and experts; • Available data assisted with assumptions where data is unavailable; • The appraisal is a virtual study; no new empirical research was used, nor do the findings have any empirical status.
Stakeholders involvement	• Study was developed by the Environment Agency with WRc and Environment & Society Research Unit (ESRU, University College London); • Two-day workshop hosted 55 delegates, about half were from the Environment Agency, and the rest representing a wide range of organizations including the Department for Environment, Food and Rural Affairs (DEFRA) in England and Wales, European experts including EC DG Environment officials, OFWAT, academics, NGOs and expert stakeholders from the water industry, National Farmers Union, and the Royal Society for English Nature.
Highlights/Results/Successes	• Uses a six-step approach rather than the three-step approach suggested by the WFD. The study stresses that the six steps identified are not linear; there are numerous links and feedbacks required and inputs regarding consultation, the framework (Guidance) and tools that feed into all stages at different points; • Process-oriented study addresses how the different steps required to implement an integrated system of measures system might be considered, with clearly detailed responsibilities, inputs, outputs, relationship to the WFD deadlines, and relationship to WFD requirements, while identifying further issues for discussion; • Identifies the need to undertake a risk assessment of water bodies that may fail to achieve a good quality water state in future plan periods when developing the business as usual case. Addresses issues with developing the proper tools and methods to conduct a risk analysis where lack of data with different levels of certainty, and where qualitative data may; • Discuss the integration between sector policy (namely agricultural policy) and the process of developing integrated river basin management plans.
Key problems and potential solutions	• Simplistic worked examples demonstrate the need for more complicated analysis, modelling multiple outputs and indirect impacts of measures; • Use of “fail one fail all” for indicators projecting water quality status fails to capture the degrees of impact each indicator may have; • Study proposes using a weighting system to differentiate between levels of indicator.

Ribble River Basin (England): Integrated appraisal for river basin management	
Outstanding issues	• The overall process for integrated appraisal for RBMPs in the context of the direct needs of the WFD, and the capabilities of the Environment Agency to meet these needs; • Whether to assess impacts measure by measure, or strategy by strategy; • With the large number of water bodies and lack of resources to study each, developing a form of benefits transfer will be necessary to apply valuations derived from other studies of similar cases.

Rhône Méditerranée Corse River Basin (France) : Assessing the pertinent scale for the economic analysis

Keywords Scale, agriculture, industry, tourism, local water management plans, redefining perimeters, detailed data on water use, public consultation.

Location (river basin, country) Rhône-Méditerranée-Corse Basin (France).

Key water management issues

- Population density with diversified spatial distribution;
- Heterogeneity of population with high demand and discharges in vulnerable zones;
- Desertification of mountainous zones;
- Importance of tourism with accompanying pressures on water supply;
- Intense agricultural region with cattle breeding;
- High industrial activity concentrated in five areas.

Objective and the study's function in the overall analysis The Rhône-Méditerranée-Corse (RMC) Agency investigated the basic territorial scale that could be used for an economic analysis. The main objective was to define operational ways (choice of criteria, indicators, cartographies) that would allow competent district authorities to define criteria suited to their river basin for identifying coherent and relevant geographic territories to undertake the economic analysis and to address the constraints raised by an analysis strictly limited to a water body scale.

Planned activities and overall structure of the study A preliminary study was carried out at the end of 2001. The objective of the study is not to give a "recipe" for all districts, every case being specific and presenting a specificity due to the natural environment and the socio-economic context. Rather, the aim is to propose a methodological approach based on an exhaustive research of criteria describing economic activities, while keeping in mind the need to adapt data, tools and geographic zones (hydrography or management entities) in each district.

Disciplines and expertise mobilised

- The study was undertaken by the RMC water agency;
- Multi-disciplinary consultation.

Key information source mobilised (reports, books, statistics…)

- Detailed data on water use sources (agriculture, tourism, industry, natural parks, population, etc.);
- Expert knowledge.

Stakeholders involvement No stakeholder involvement in the study.

Highlights/Results/Successes It was necessary to stay within a reasonable budget for data collection to define territorial scales for economic analysis. Consequently, comments relative to indicators and cartographies demonstrate that most of the time and for most basins, hydrographic territories close to the socio-economic areas can be defined based on the criteria for the study. In the RMC basin case, the "SDAGE territories" seem most relevant for adaptation to the model. In other basins, territories can be defined with assistance from geographic commissions, local water development and management plans (SAGE), or other local management areas.

The following stage consisted in redefining perimeters of SDAGE territories (in the case of RMC basin). As a result, the basin was cut in 18 large zones. The final division will be defined taking into account the water bodies' perimeters while taking care, if possible, not to divide the entities of local management (local water development and management plan, parks, etc.).

Rhône Méditerranée Corse River Basin (France) :	
Key problems and potential solutions	It is necessary to avoid as much as possible dividing a territory such as natural reserves, parks, or other entities and divide it between two entities. However, it is sometimes difficult to conciliate all of the existing divisions with the information brought by a study of socio economic criteria and hydrographic logics. The methodology used tried to identify successively relevant criteria and, if possible, to discriminate between economic activities. It was then a question of identifying all the hydrographic partitions to identify one that had closer information brought by the interpretation of the previously identified criteria. This method limits costs and offers a necessary qualitative approach that accounts for local and concrete characteristics. The methodology is based on a compromise between socio economic, hydrographic, territorial criteria, etc., and so contains some degree of interpretation.
Outstanding issues	The study began with significant efforts in terms of data collection and information research with data suppliers or with competent entities in the main economic fields of economic activities (agriculture, industry, tourism, etc). In the French case, it has to be underlined that the majority of information is available easily (at low cost) on the municipal scale even if certain sectors for confidentiality purposes provide their data only for larger scales, as is the case with the agricultural sector. It is thus a question of refining the initial division by including each local community in a single economic zone, and each water body in a single economic zone, following the text of the framework directive, which specifies that the economic analysis can be made by grouping water bodies.

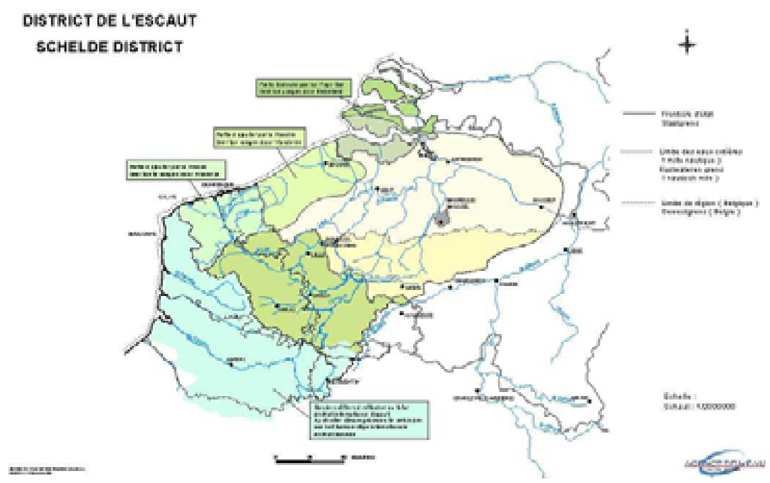
Scheldt International River Basin (The Netherlands, France, three Belgium regions): Testing elements of the three step-approach

Keywords

Characterisation, cost-effectiveness, integration between economics and biophysical expertise (Impact & Pressure), groundwater abstraction, surface water quality, morphology, International district, data availability

Location (river basin, country)

Scheldt International River Basin (France, Belgium[14] and The Netherlands)



Key water management issues

- **International context;**
- **High density of population and industry;**
- Rather bad quality of surface waters and Heavily Modified Water Bodies;
- Diffuse pollution from agriculture;
- Local stress on water resources (groundwater);
- Existence of master plans for some parts of the river basin and an international commission for the protection of the Scheldt.

Objective and the study's function in the overall analysis

- The study aims at applying the approach and some elements of the draft Guidance Document (baseline scenario, cost-effectiveness analysis) on three individual case studies: surface water quality, groundwater abstraction and morphology. The purpose of this work was to test the feasibility of the process and methods rather than to provide specific results, and to assess the availability and comparability of data between the five parties involved in the Scheldt International River Basin.

Planned activities and overall structure of the study

- Step 1 - initial literature review phase for assessing the information base in the five parties involved in the river basin considered;
- Step 2 – workshop in Amsterdam involving WATECO and IMPRESS working group experts (November 2001) – analytical process based on the Ribble scoping – identification of 3 sub-case studies (water quality, groundwater abstraction, morphology);
- Step 3 – Workshop in Brugges (February 2002) – report from each of the three case studies team;
- Step 4 – Presentation of the preliminary results at the "Lille 3" conference – March 2002;
- Step 5 – Writing of a synthesis and possible follow-up of the work started through the "Scaldit" project.

[14] including the 3 Belgian regions : Brussels, Flanders and Wallonia

Scheldt International River Basin (The Netherlands, France, three Belgium regions):

Disciplines and expertise mobilised	• Combination of economic expertise, impact and pressure, soil scientists; • Input from River 21 project for the characterisation and baseline scenario; • Support from the EC DG Environment, consultants (ERM) and academics (ENGREF) for the case study on groundwater abstraction; • Access to the data collected by the Secretariat of the International Commission for the Protection of the Scheldt.
Key information source mobilised (reports, books, statistics…)	• Planning documents and indicators from the water bodies and administration from the fives parties (mainly from the RIZA, VMM, Artois-Picardie Water Agency, IBGE and Ministry of Environment from Wallonia); • Data on water quality, groundwater abstraction.
Stakeholders involvement	• The involvement of stakeholders was limited (initially a workshop with stakeholders was proposed but had to be cancelled due to time constraint). However, the need for stakeholder' input has been clearly identified (data, expertise, discussion on potential measures...).
Highlights/Results/Successes	• The test of the process has allowed the clear identification of the working links required for integrating the economic analysis in the whole process of developing an integrated river basin management plan in an international river basin district; • All the steps of the economic approach (characterisation, risk assessment, cost-effectiveness analysis) performed for the morphology case; • Elaboration of a rough method to assess the impact of main water uses on water quality; • Analysis of the aquifer system of the entire river basin district and proposal of a simple model for applying the economic approach.
Key problems and potential solutions	• The monitoring system differs between countries/parties. A solution could be to harmonise these systems; this could be developed along activities aimed at modelling the entire district integrating sub-catchments to tackle upstream/downstream interdependencies; • The need to find the "right" scale to undertake the analysis. This generates preliminary work in order to understand the functioning of the district (e.g. relations between the different aquifers).
Outstanding issues	• The baseline scenario and the cost-effectiveness analysis were skimmed over as the data or the expertise were lacking or difficult to collect for a test in an international context; • Set up of an informal network of experts (mixing disciplines and countries) that could be a resource for the implementation of the WFD

Sevres-Nantaise River Basin (France): Testing the chronological feasibility of the three step approach

Keywords	Cost effectiveness, cost benefits, baseline scenario, scenarios of investment, costs of programme of measures, cost recovery.
Location (river basin, country)	Sèvre Nantaise river basin – Loire Brittany district (centre of France). A local water master plan (SAGE) was adopted over this geographic area.
Key water management issues	• Lack of own water resources: 50% of the drinking water comes from other river basins; • Important tourism in the river basin; • Abstraction for irrigation (corn and vegetables); • Abstraction for industry (96 large industries in the river basin); • Important diffuse pollution (pig farming).
Objective and the study's function in the overall analysis	• Testing the chronological feasibility of the three-step approach; • Availability of data required (mainly for cost recovery); • Building of prospective scenarios; • Elaborating and evaluating programmes of measures based on cost effectiveness and cost benefit analysis; • Estimating the current level of cost recovery for the three main sectors (household, agriculture, industry).
Planned activities and overall structure of the study	• Collection of existing data and "proxy" to assess initial status; • Build a baseline scenario; • Build an alternative programme of measures, estimating costs and benefits; • Compare the alternative scenarios on the basis of cost effectiveness and cost benefit analysis; • Estimate the current level of cost recovery per sector.
Disciplines and expertise mobilised	• Technical expertise: agency experts and consultant. • Economic expertise: consultant with support from the agency and the Ministry.
Key information source mobilised (reports, books, statistics…)	• Data collected for the master plan: data on abstraction, water quality and economic activities, along with modelling of the impact of alternative investment programmes; • University studies on environmental benefits; • Estimation of experts on: investment costs, level of cost recovery.
Stakeholders involvement	• Agency experts were involved in the technical and economic aspects of the study; • No involvement of the actors of the master plan (local decision makers) was required, because they did not have to validate the proposed scenarios due to the short duration of the study, and the earlier stage of development of the master plan (initial status).
Highlights/Results/Successes	• Pointing at the reliability of the chronological link of each step of the 3-step process provided in the Guidance Document.

Sevres-Nantaise River Basin (France):	
Key problems and potential solutions	• Difficulties linked to the data: there is an important need for data (physical, economic, etc.), for each step. The availability has not been tested with this study, as data was collected or constructed from other, former studies; • Difficulties linked to economic tools: environmental costs and benefits are hard to quantify, and they are hard to transfer easily; • Difficulties linked to reporting cost recovery: it is possible to have data on cost recovery for households. For industry and agriculture, little data exists at each scale (local, regional, district, national).
Outstanding issues	• Need to involve stakeholders in future studies; • Need to develop an economic database in the field of environmental cost and benefits; • Need to develop knowledge about cost recovery in industry and agriculture.
Contact person(s)	Yves Mérillon Agence de l'Eau Loire Bretagne Avenue de buffon BP6339 45063 Orléans cedex France Tel. +33 2 38 51 73 15 Fax. +33 2 38 51 74 74 Email yves.merillon@eau-loire-bretagne.fr

Vouga River Basin (Portugal): Scoping key elements of the economic analysis

Keywords	Linkage between economic and biophysical analysis, sources of information, stakeholder participation, cost recovery, current price structures.
Location (river basin, country)	Vouga river basin (Portugal).
Key water management issues	• Urban, industrial and agricultural pollution; • Institutional arrangement complexity; • Inappropriate management resources; • Implementation of the existing River Basin Plan and National Water Plan.
Objective and the study's function in the overall analysis	• The main goal was to perform a virtual economic analysis, along the lines of what will be required for 2004 (Art. 5 of the WFD).
Planned activities and overall structure of the study	• Step 1: Identification and characterisation of the main users; • Step 2: Collection and organisation of the existing information; identification of information gaps; • Step 3: Interviewing stakeholders; • Step 4: Analysis of price and cost structures; • Step 5: Analysis of cost recovery and incentive properties of pricing schemes; • Step 6: Initial analysis of gaps in water status in co-operation with other national working groups.
Disciplines and expertise mobilised	• Direct involvement of economists and environmental and water resource engineers; • Work developed by the economic group of INAG, the institution responsible for the WFD implementation in Portugal; • Universities and research centres were involved though protocols with INAG (UNL and ISCTE).
Key information source mobilised (reports, books, statistics…)	• Vouga River Basin Plan and National Water Plan; • Stakeholder interviews; • Other official statistics (INE).
Stakeholder involvement	• Development of specific questionnaires to fill the main economic information gaps; • Group visits to the river basin with direct stakeholder contact.

Vouga River Basin (Portugal): Scoping key elements of the economic analysis

Highlights/Results/Successes	• There is considerable variability in municipalities' price structures and there are no clear criteria in the definition of price schedules. The revenues of supply and wastewater systems are not usually enough to cover investment and operation costs. The only case where data was sufficient yielded estimates between 85% and 115% of operation cost recovery for water supply; • For agriculture, data is very poor. Infrastructure values are outdated, there are no organised records of exploration costs, and water volumes are not metered. Prices in public irrigation facilities are low and unrelated to actual water consumption. The managers of those facilities expressed a common opinion that no one would use the water if prices increased. For other types of irrigation systems, no information is available; • For industry, there is some data on consumption and costs for large industrial facilities, but information is missing for many plants, especially those that have self-services for water abstraction, treatment and wastewater discharges.
Key problems and potential solutions	• Available economic information is incomplete, piecemeal, unevenly spread in space and time and not always comparable. Existing information is not readily available since it is not organised in a way that would make it straightforward to use; • The situation should improve with the recent approval of a mandatory set of accounting standards for local authorities, and with the carrying out of planned national surveys of supply and wastewater systems as well as water uses in general; • Information on water quality is not complete, as the national monitoring network is in the process of being set up; • The group was unable to go very far into the identification of gaps in water status and subsequent selection of programmes of measures because the other working groups were just starting their activities; • Some information is, at most, disaggregated into municipalities. As municipal boundaries do not coincide with river basin boundaries, the compatibility of scales will be a relevant issue.
Outstanding issues	• Co-operation with the other working groups did not go as far as would be desired to perform the complete economic analysis; • Very limited approach to baseline scenario development; • Available information was insufficient for cost-effectiveness analysis.

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (hereafter referred to as Common Implementation Strategy (CIS) for the Water Framework Directive (WFD)). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, the European Commission (Directorate General for Environment, Unit B.1) was invited to set up an informal process for drafting a horizontal Guidance on the application of the term "water body" which is defined in the Directive. This term is essential for several aspects of implementation, such as the typology, the reference conditions, the classification of the status and the monitoring.

A drafting group was established in March 2002 and a first draft was discussed on the Strategic Co-ordination Group meeting in April 2002 and the meeting of the Water Directors in June 2002. Following this meeting in Valencia, the members of the Strategic Co-ordination Group were invited to comment the draft paper in two rounds and revised versions were presented in each meeting of the group. In addition, the Expert Advisory Forum (EAF) on Groundwater discussed and contributed twice to the refinement of the groundwater Section in this document.

Due to the active and constructive contribution of all experts in the drafting group, the EAF Groundwater and the Strategic Co-ordination Group, it was possible to present the final draft of the horizontal Guidance Document on "water bodies" to the meeting in Copenhagen, where the Water Directors reached the following conclusions:

"We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders of the Directorate General for Environment of the European Commission for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation."

1 Introduction

1.1 Background to Guidance

The Water Framework Directive (2000/60/EC) is a comprehensive piece of legislation that sets out, *inter alia*, clear quality objectives for all waters in Europe. In order to make the implementation of the Directive, and the compliance checking of its quality objectives, operational, the concept of "water bodies" has been introduced as the key units to which a number of the Directive's requirements are related.

Several of the working groups of the Common Implementation Strategy for the Water Framework Directive (2000/60/EC) have requested horizontal Guidance from the European Commission on the interpretation and application of the term water body. The working groups have asked for such Guidance in order to assist them in the preparation of their own Guidance on issues such as reference conditions (WFD CIS Guidance Document No. 10) and intercalibration (WFD CIS Guidance Document No. 6).

In addition, several Member States have contributed to discussions on the application of the term water body, and a number of documents have been produced. These are listed in the Annex to this paper, and are available on the WFD CIRCA system where electronic formats are available. These discussions have revealed that there are different views among Member States on the interpretation, and consequently practical application, of the term water body.

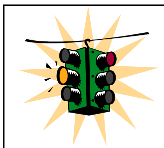
1.2 Purpose of Guidance

The purpose of this Guidance Document is to build on these discussions to develop a common understanding of the definition of water bodies and specific practical suggestions for the identification of water bodies under the Water Framework Directive.

1.3 Structure of Guidance

The following Section on the background includes general considerations applicable to surface and groundwater. However, the Directive's requirements for characterising, and its objectives for surface water bodies and bodies of groundwater are different. These differences affect the way the respective water bodies should be identified. Hence, the Guidance paper is therefore divided into two main sections. Section 3 provides guidance on the application of the term surface water body. Section 4 provides guidance on the application of the term body of groundwater.

Each Section is structured so that it describes the **principles** involved in, and a **hierarchical process** for, sub-dividing river basin districts into water bodies. The main steps in the proposed hierarchies are summarised in **Figure 7** and **Figure 11**.



Look out! The methodology from this Guidance Document must be adapted to regional and national circumstances
The Guidance Document proposes an overall pragmatic approach. Because of the diversity of circumstances within the European Union, Member States may apply this guidance in a flexible way in answer to problems that will vary from one river basin to the next. This proposed Guidance will therefore need to be tailored to specific circumstances.

Having said that, it should be clear that the identification of water bodies must be consistent and co-ordinated within a river basin district. In particular, international river basin districts need to develop common approaches for the whole river basin.

2 Background

2.1 Purpose of identifying "water bodies"

The Water Framework Directive covers **all** waters, including inland waters (surface water and groundwater) and transitional and coastal waters up to one sea mile (and for the chemical status also territorial waters which may extend up to 12 sea miles) from the territorial baseline of a Member State, independent of the size and the characteristics[1].

This totality of waters is, for the purpose of the implementation of the directive, attributed to geographical or administrative units, in particular the **river basin**, the **river basin district**, and the "**water body**"[2]. In addition, groundwaters and stretches of coastal waters must be associated with a river basin (district).

Whereas the river basin is the geographical area related to the hydrological system, the river basin district must be designated by the Member States in accordance to the directive as the "**main unit for management of river basins**"[3].

One key purpose of the Directive is to prevent further deterioration of, and protect and enhance the status of aquatic ecosystems, and with regard to their water needs, terrestrial ecosystems and wetlands directly depending on the aquatic ecosystems. The success of the Directive in achieving this purpose and its related objectives will be mainly measured by the status of "water bodies". "Water bodies" are therefore the units that will be used for reporting and assessing compliance with the Directive's principal environmental objectives. However, it should be emphasised that the identification of a "water body" is a tool not an objective in itself.

The "water body" should be a coherent sub-unit in the river basin (district) to which the environmental objectives of the directive must apply. Hence, the main purpose of identifying "water bodies" is to enable the status to be accurately described and compared to environmental objectives[4].

It should be clear that the identification of water bodies is, first and foremost, based on geographical and hydrological determinants. However, the identification and subsequent classification of water bodies must provide for a sufficiently accurate description of this defined geographic area to enable an unambiguous comparison to objectives of the Directive. This is because the environmental objectives of the Directive, and the measures needed to achieve them, apply to "water bodies". A key descriptor in this context is the "status" of those bodies. If water bodies are identified that do not permit an accurate description of the status of aquatic ecosystems, Member States will be unable to apply the Directive's objectives correctly (Figure 1). At the same time, an endless sub-division of water bodies should be avoided in order to reduce administrative burden if it does not fulfil any purpose as regards the proper implementation of the Directive. In addition, the aggregation of water bodies may, under certain circumstances, also help to reduce meaningless administrative burden, in particular for smaller water bodies (cf. Chapter 5).

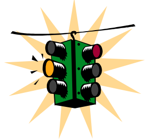
---

[1] *Articles 2 (1), (2) and (3)*

[2] *Articles 2 (13), (15), (10), and (12) respectively*

[3] *Article 2 (15)*

[4] *An estimate of the status of water bodies will be required to assess the likelihood that they will fail to meet the environmental quality objectives set for them under Article 4 [Article 5; Annex II 1.5 & 2]. The status of water bodies must be classified using information from the monitoring programmes [Article 8, Annex V 1.3, 2.2 & 2.4]. The status of water bodies must be reported in the river basin management plans [Article 13, Annex VII] and, where necessary, measures must be prepared [Article 11, Annex VI].*



Look out! **The Directive only requires sub-divisions of surface water and groundwater that are necessary for the clear, consistent and effective application of its objectives. Sub-divisions of surface water and groundwater into smaller and smaller water bodies that do not support this purpose should be avoided.**

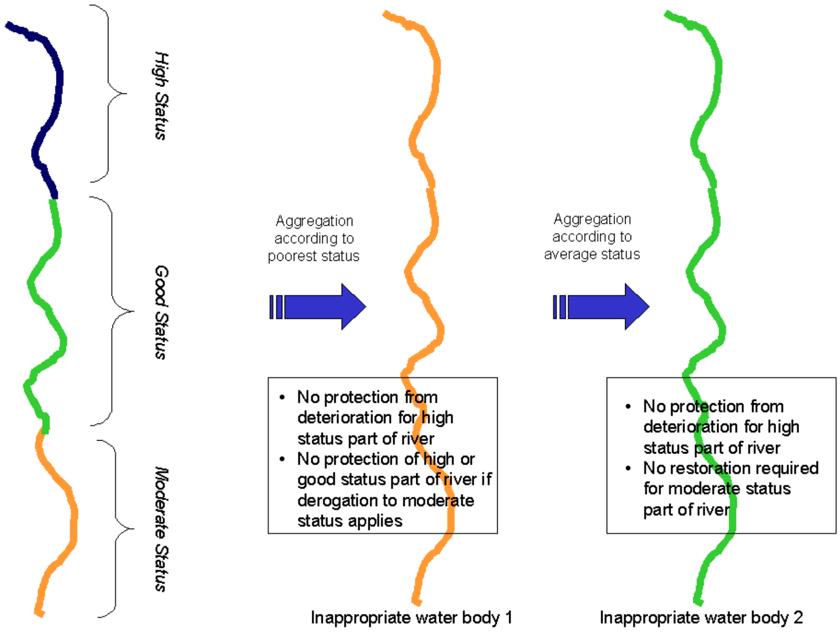


Figure 1: Illustration of the implications for the objectives of the Directive if "water bodies" do not provide for the accurate description of surface water status

2.2 Timetable and refinement for the identification of water bodies

The identification of water bodies should be an iterative and on-going process. The water bodies that Member States are required to identify by 22 December 2004[6] and report to the Commission by 22 March 2005[5] will be only a first step. Where necessary, water body identification should be verified and refined in the period before the publication of each river basin management plan.

The Directive requires Member States to identify "water bodies" as part of the analysis of the characteristics of the river basin districts[6]. The first such analysis must be complete by 22 December 2004. The analysis must be reviewed, and where necessary, updated by 22 December 2013 and then every six years.

However, identifying water bodies that will provide for an accurate description of the status of surface water and groundwater will require information from the Article 5 analyses and reviews, and the Article 8 monitoring programmes. Some of the necessary information will not be available before 2004. The information that is available is likely to be updated and improved in the period prior to the publication of each river basin management plan.

---

[5] *Article 15.2*

[6] *Article 5, Annex II 1.1 & 2*

It is evident that for the first RBMP, all waters must be assigned to water bodies and their status must be described[7]. However, practical approaches may be required in particular for large numbers of pristine waters in remote areas where it can be demonstrated that no significant pressure exist (see also Section 5).

In conclusion, verification and refinement steps of water body identification should be foreseen in the implementation process.

[7] *cf. WFD CIS Guidance Document No 7.*

3 Specific Guidance on surface water bodies

3.1 Definition of body of surface water

Article 2.10 of the Directive provides the following definition of a body of surface water:

"Body of surface water" means a ***discrete and significant element*** *of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.*

The application of the definition requires the sub-division of surface water[8] in river basin (districts[9]) into "discrete and significant elements". Although examples of such elements are given ("such as a lake, a reservoir, a stream, river or canal "), the Directive does not provide explicit guidance on how to identify the elements that should be regarded as "discrete and significant", and hence "water bodies". For example, it does not specify how to identify **part** of a river, stream or canal that represents a "**discrete and significant element"**.

The use of the terms "discrete and significant" in the definition of "surface water body" means that "water bodies" are not arbitrary sub-divisions of river basin districts. Each water body should be identified on the basis of its "discreteness and significance" in the context of the Directive's purposes, objectives and provisions.

3.2 Technical interpretation of discrete and significant element

General considerations in relation to the definition and the characterisation requirements for surface water bodies[10] establish a number of specific requirements relevant to the identification of discrete and significant elements. These also present a certain hierarchy of definitions which should be in the identification process. They are summarised in the following paragraphs.

3.2.1 Discrete element

For a surface water body to be a discrete element of surface water, they must not overlap with each other or be composed of elements of surface water that are not contiguous.

It is evident that a water body must be discrete **and** significant at the same time, the element of discreteness is not sufficient on its own. In addition, the considerations regarding the aggregation of water bodies may be applied under certain circumstances, in particular for small "water bodies" (cf. Chapter 5).

---

[8] *Article 2.1*

[9] *Article 3.1*

[10] *Annex II 1*

3.2.2 Surface water categories

A surface water body must not be split between different surface water categories (rivers[11], lakes[12], transitional waters[13] and coastal waters[14]). It must be of one category or another [15]. The boundary of a water body may be established where two different category "meet" (Figure 2).

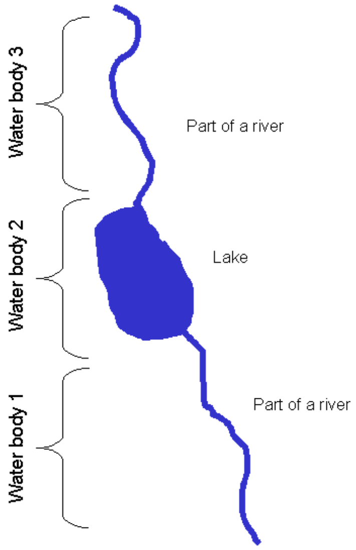

Figure 2: The boundaries to the categories of surface water create boundaries to water bodies

3.2.3 Typology[16]

A surface water body must not cross the boundaries between surface water body types. It must be of one type or another since one purpose of characterising surface water bodies is to differentiate them into types[17].

3.2.4 Physical characteristics delineating discrete and significant elements

Physical features (geographical or hydromorphological) that are likely to be significant in relation to the objectives of the Directive should be used to identify discrete elements of surface water.

---

[11] *Article 2.4*

[12] *Article 2.5*

[13] *Article 2.6*

[14] *Article 2.7*

[15] *Annex II 1.1(i)*

[16] *CIS WGs 2.3 and 2.4 are developing Guidance on the application of typology systems (WFD CIS Guidance Document No. 10 and 5)*

[17] *Annex II 1.1 (ii)*

Geographical or hydromorphological features can significantly influence surface water ecosystems and their vulnerability to human activities. These features can also differentiate discrete elements of surface water. For example, the confluence of one part of a river with another could clearly demarcate a geographically and hydromorphologically distinct boundary to a water body (Figure 3).

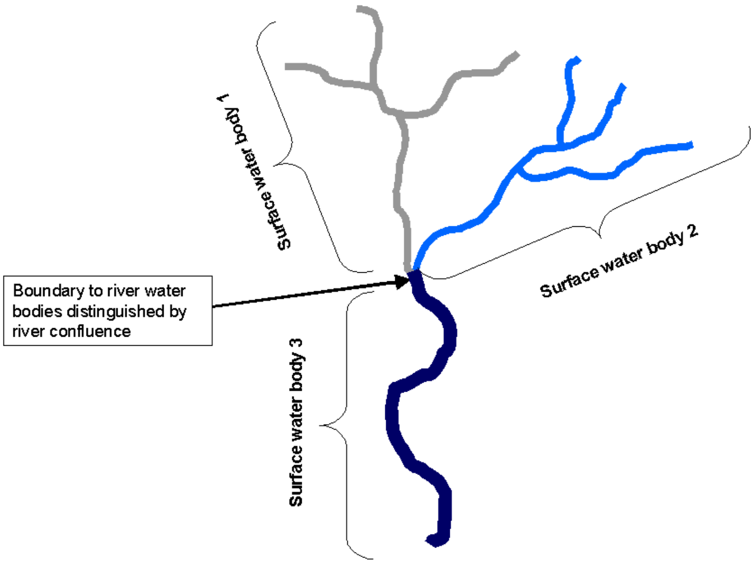

Figure 3: Example of the sub-division of a river on the basis of physical features – in this case a river confluence.

However, the Directive does not exclude other elements, such as a part of a lake or part of transitional water, from being considered as water bodies. For example, if part of a lake is of a different type to the rest of the lake, the lake must be sub-divided into more than one surface water body (Figure 4).

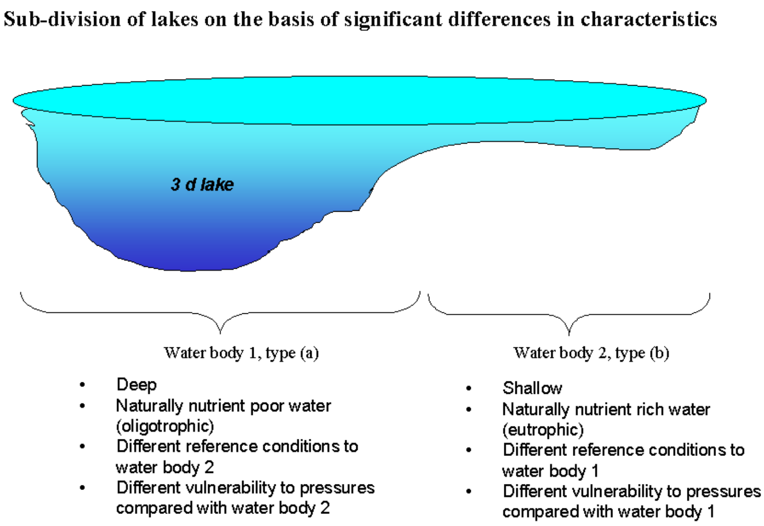

Figure 4: Sub-division of a lake on the basis of a type boundary

3.2.5 Heavily modified and artificial water bodies[18]

Heavily modified water bodies may be identified and designated where good ecological status is not being achieved because of impacts on the hydromorphological characteristics of a surface water resulting from physical alterations (Figure 5).

Heavily modified and artificial water bodies[19] must be (at least) provisionally identified during the characterisation of surface waters[20]. Their identification and designation should be finalised for the purposes of the first river basin planning cycle on publication of the river basin management plans in 2009. The designations must be reviewed every six years[21].

The identification of heavily modified water bodies must be based on the designation criteria set out in Article 4.3. In principle, the boundaries of heavily modified water bodies are primarily delineated by the extent of changes to the hydromorphological characteristics that (a) result from physical alterations by human activity and (b) prevent the achievement of good ecological status.

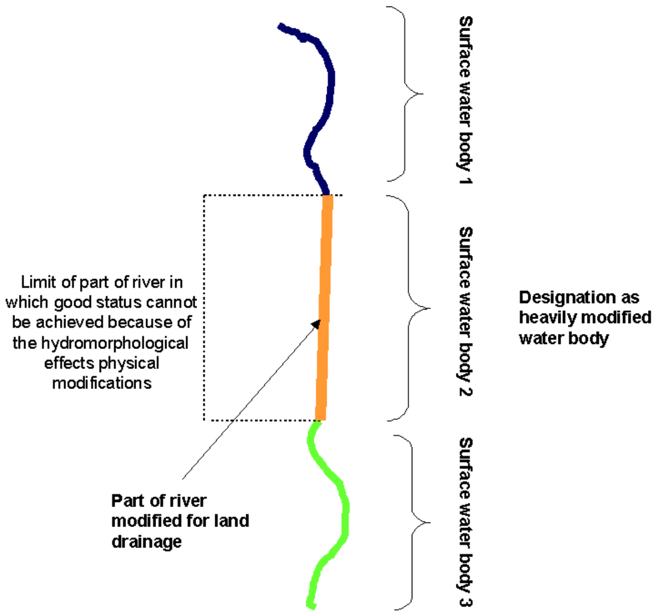

Figure 5: The establishment of water body boundaries through the identification and subsequent designation of heavily modified water bodies

3.2.6 Summary

The above-mentioned criteria can be directly drawn from the Directive. They represent a hierarchy of definitions that is already sufficient to enable a first identification of "water bodies" in the river basin (districts). As first step, the water category and the water body type

---

[18] CIS Working Group 2.2 is developing detailed Guidance on the identification and designation of heavily modified water bodies (WFD CIS Guidance Document No. 4)

[19] Article 2.9

[20] Annex II 1.1(i)

[21] Article 4.3

should be used to draw the boundaries resulting in discrete "water bodies". In a subsequent step, geographical and hydromorphological elements could be considered. However, if such an approach does not lead to a meaningful delineation of "water bodies", other criteria could be used. These other criteria are described in the subsequent Section.

3.3 Other criteria for delineating surface water bodies

The Water Framework Directive provides for the above-mentioned criteria (cf. Section 3.2) to identify water bodies. However, there are other considerations or parameters which will help to improve the delineation of meaningful water body boundaries. One requirement that is implicit in the Directive is that the purpose of identifying "water bodies" is to enable the **status**[22] of surface waters to be accurately described. Related to this requirement, there are considerations regarding **pressures** and **impacts**. Furthermore, different **uses** (e.g. drinking waters) and existing or new **protected areas** (e.g. Natura 2000 sites) may be used in the refinement of the "water body" identification. The subsequent Sections will focus on aspects of status and protected areas. However, it should be noted that the questions of pressures, status and impacts are closely inter-linked. In the absence of sufficient information on the water status, the results of the pressure and impact analysis may be used for identifying meaningful water body boundaries (WFD CIS Guidance Document No. 3). This will mainly apply for the preparation of the first characterisation.

Member States may identify "surface water bodies" using additional criteria designed to take account of local circumstances and therefore assist in the river basin management planning process.

3.3.1 Status criteria

A discrete element of surface water should not contain significant elements of different status. A "water body" must be capable of being assigned to a single ecological status class with sufficient confidence and precision through the Directive's monitoring programmes[23].

Although effects of human activities will always vary no matter what the size of a water body, major changes in the status of surface water should be used to delineate surface water body boundaries as necessary to ensure that the identification of water bodies provides for an accurate description of surface water status (see Section 2 and Figure 6).

It is clearly possible to progressively subdivide waters into smaller and smaller units that would impose significant logistic burdens. However, it is not possible to define the scale below which subdivision is inappropriate. It will be necessary to balance the requirement to adequately describe water status with the need to avoid the fragmentation of surface waters into unmanageable numbers of water bodies. In addition, the aggregation of water bodies may be appropriate, under certain circumstances, to reduce meaningless administrative burden (cf. Chapter 5). In the end, it is a matter for Members States to decide on the basis of the characteristics of each River Basin District.

Initially, Member States will not have sufficient information to accurately define the status of waters. Consequently, especially during the period prior to the publication of the first River Basin Management Plan, it may be appropriate to use the analysis on pressures and impacts

[22] *respectively **potential** for artificial and heavily modified water bodies*

[23] *WFD CIS Guidance Document No.s 5 6, 7 and 10 provide Guidance on the classification of ecological status and monitoring.*

as a surrogate for status. As understanding of status improves, the boundaries of water bodies can be adjusted. Contiguous elements of surface water within a type that are of the same status may be recombined to avoid unnecessary sub-division of surface waters.

Finally, it is emphasised that the scale chosen for a particular "water body" will have influence on the management of the active involvement of stakeholders and the public (WFD CIS Guidance Document No. 8 provides guidance on Public Participation).

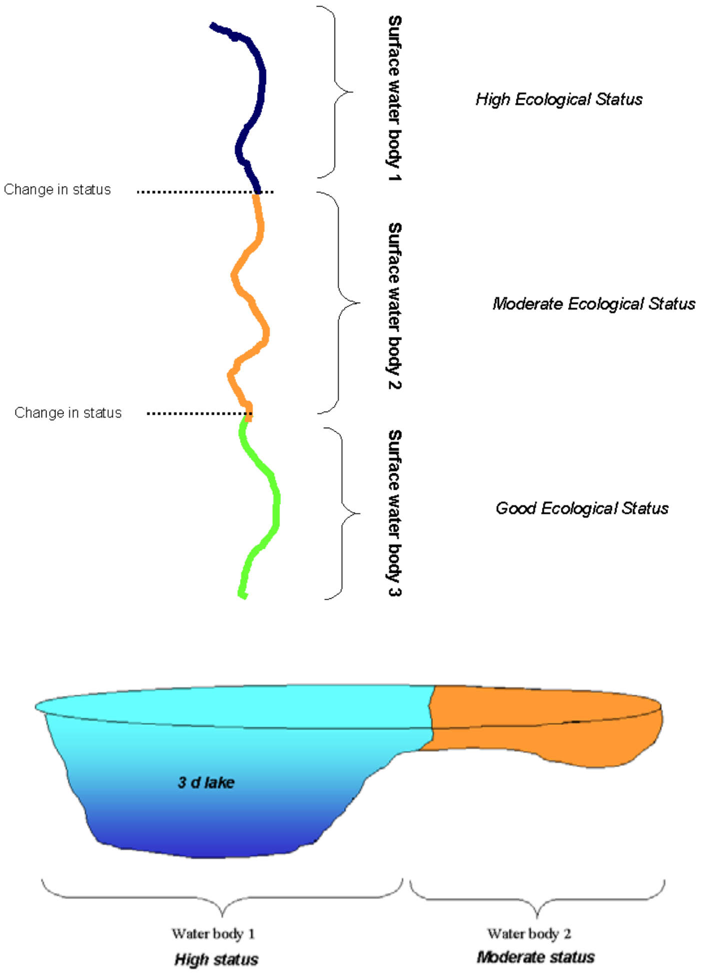

Figure 6: Identification of water bodies according to differences in status

3.3.2 Protected areas

Protected areas are identified under various pieces of legislation such as *inter alia* Natura 2000 sites designated under the Habitat Directive - (92/43/EC). Under the Water Framework Directive, all the protected areas must be considered for an integrated river basin management[24]. Specific objectives[25] were defined and various provisions specify more specific requirements for protected areas (e.g. monitoring[26]). In consequence, there are additional objectives to be considered for water bodies which are also fully part of a protected

[24] *Article 6, 7 and Annex IV*

[25] *Article 4 (1) c*

[26] *Annex V, point 1.3.5*

area. Hence, the existing boundaries of protected areas may be considered for the identification of water bodies under the Water Framework Directive.

The boundaries of water bodies and protected areas will, in most cases, not coincide because both geographical areas are being defined for different purposes on the basis of different criteria. In case a water body would not fully be inside or outside a protected area, it may be considered to sub-divide the water bodies into two parts so that the boundaries coincide.

3.4 Suggested process for the practical application of the term surface water body.

The principles described above for the identification of surface water bodies can be applied in a hierarchical process (see Figure 7).

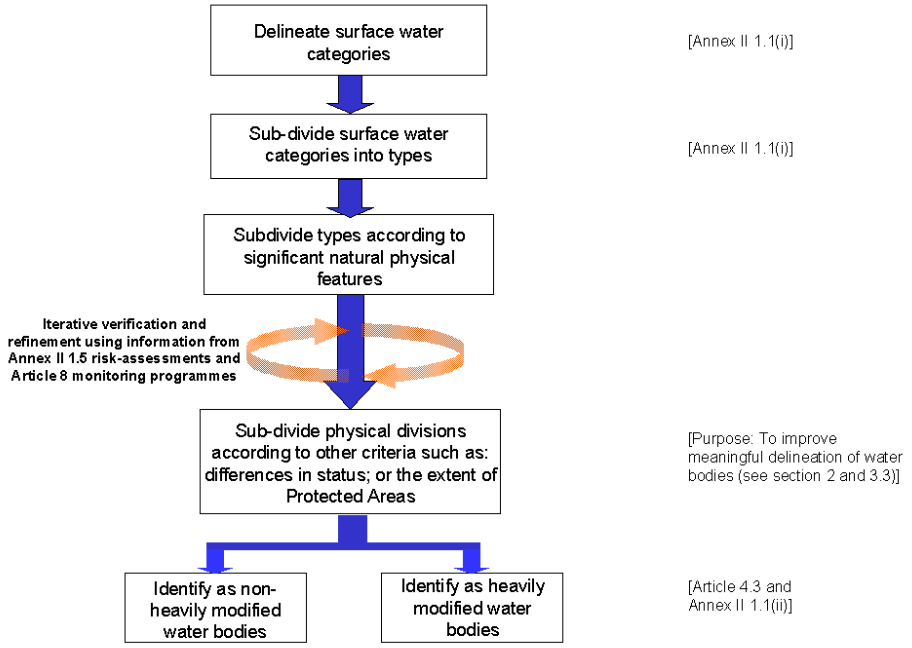

Figure 7: Summary of suggested hierarchical approach to the identification of surface water bodies

To ensure that water bodies do not cross the boundaries of surface water categories (Paragraph 3.2.2), the **suggested first step** in delineating surface water bodies is to identify the boundaries of the surface water categories.

To ensure that water bodies do not cross the boundaries of surface water types (Paragraph 3.2.3), the **suggested second step** in delineating surface water bodies is to identify the boundaries of the surface water types in each river basin district.

To ensure that water bodies represent discrete and significant elements of surface waters, the **suggested third step** in delineating them is to identify boundaries using distinct physical features (Paragraph 3.2.4) that are (a) likely to be significant in the context of aquatic ecosystem characteristics, and (b) are consistent with the examples of discrete and significant elements of surface water given in the Directive's definition (see Section 5.1).

In order to ensure that water bodies are identified in a meaningful way, the **suggested fourth step** in identifying surface water bodies is to identify boundaries on the basis of other relevant criteria (cf. Section 3.3). This approach is also necessary for the identification of heavily modified water bodies (see Section 3.2.5). Initially, in the case of absence of information on status, the pressure and impact assessment[27] procedure required under Article 5 will provide estimates of status changes (refer to WFD CIS Guidance Document No.3). The monitoring programmes[28] will provide the information necessary to confirm status-based boundaries. Hence, an iterative approach for identifying water bodies should be applied. At the same time, it is evident that the delineation of water bodies must be finally agreed at a certain point in time in order to enable the preparation of the river basin management plan. The competent authorities of a river basin district will have to ensure that a balance between an iterative identification and the final assignment of water bodies is achieved.

3.5 Small elements of surface water

The purpose of the Directive is to establish a framework for the protection of **all** waters including inland surface waters, transitional waters, coastal waters and groundwater[29]. Member States must ensure that the implementation of the Directive's provisions achieves this purpose. However, surface waters include a large number of very small waters for which the administrative burden for the management of these waters may be enormous. .

The Directive does not include a threshold for very small "water bodies". However, the Directive sets out two systems for differentiating water bodies into types[30], System A and System B. Only the System A typology specifies values for size descriptors for rivers and lakes. The smallest size range for a System A river type is 10 – 100 km^2 catchment area[31]. The smallest size range for a System A lake type is 0.5 – 1 km^2 surface area[32]. No sizes for small transitional and coastal waters are given. The application of system B must achieve, at least, the same level of differentiation as system A. It is therefore recommended to use the size of small rivers and lakes according to system A. However, it is recognised that in some regions where there are many small water bodies, this general approach will need to be adapted. Having said that, it may be appropriate to aggregate water bodies into groups for certain purposes as outlined in Chapter 5 in order to avoid unnecessary administrative burden.

However, there are still large numbers of discrete rivers and lakes that are smaller than these thresholds. A possible approach for the protection of these waters is outlined below.

Member States have flexibility to decide whether the purposes of the Directive, which apply to all surface waters, can be achieved without the identification of every minor but discrete and significant element of surface water as a water body.

[27] *Annex II 1.5*

[28] *Article 8*

[29] *Article 1*

[30] *Annex II 1.2*

[31] *Annex II 1.2.1*

[32] *Annex II 1.2.2*

A suggested approach (see Figure 8) is to:

- include small elements of surface water as part of a contiguous larger water body of the same surface water category and of the same type, where possible;
- where this is not possible, screen small elements of surface water for identification as water bodies according to their significance in the context of the Directive's purposes and provisions (e.g. ecological importance; importance to the objectives of a Protected Area, significant adverse impacts on other surface waters in the river basin district). In such a case, small elements; (1) belonging to the same category and type, (2) influenced by the same pressure category and level and (3) having an influence on another well-delimited water body, may be grouped for assessment and reporting purposes;
- for those small elements of surface water not identified as surface water bodies, protect, and where necessary improve them to the extent needed to achieve the Directive's objectives for water bodies to which they are directly or indirectly connected (i.e. apply the necessary basic control measures under Article 11)[33].

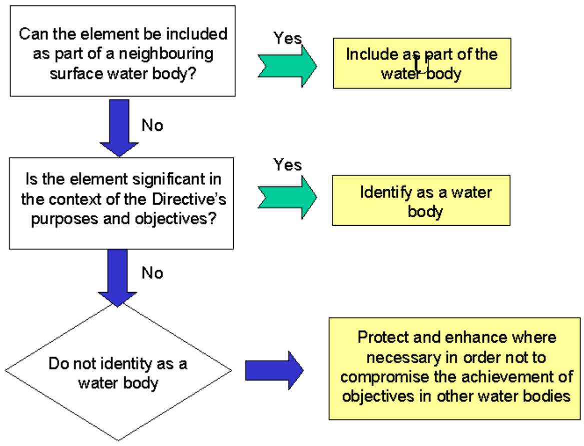

Figure 8: A suggested approach to ensuring appropriate protection of smallest surface waters

3.6 Components of a "surface water body" and wetlands

A "surface water body" comprises the quality elements described in the Directive for the classification of ecological status[34].

[33] *The Article 4.1(a)(iii) priority substances objectives apply to all surface waters regardless of whether they are identified as surface water bodies.*

[34] *Annex V 1.1 & Annex V 1.2*

In concrete terms this means that, e.g., a river water body comprises:

(a) the hydromorphological quality elements, which include the water flow, the bed of the channel, that part of the land adjacent to the channel that's structure and condition is directly relevant to the achievement of the values for the biological quality elements (i.e. the riparian zone); and

(b) the relevant biological elements.

In relation to wetlands, this means that those wetlands must be associated with a "water body", which are directly influencing the status of the related "water body". The boundaries of such wetlands must be identified in a pragmatic way in order to meet the requirement of a "discrete and significant" element.

The question of wetlands in the context of the Water Framework Directive will be subject to a separate Guidance Documents (currently in preparation) under the umbrella of the Common Implementation Strategy. It is recommended that this Guidance on wetlands, which will emerge in the first half of 2003, should develop the understanding of wetlands as a component of a surface water in more detail.

4 Specific Guidance on bodies of groundwater

4.1 Definitions

The application of the term body of groundwater must be understood in the context of the hierarchy of relevant definitions provided under Article 2 of the Directive.

- Article 2.2: ***Groundwater*** *means all water, which is below the surface of the ground in the saturated zone and in direct contact with the ground or subsoil;*
- Article 2.11: ***Aquifer*** *means a subsurface layer or layers of rock or other geological strata of sufficient porosity and permeability to allow either a significant flow of groundwater or the abstraction of significant quantities of groundwater;*
- Article 2.12: ***Body of groundwater*** *means a distinct volume of groundwater within an aquifer or aquifers.*

A body of groundwater must be within an aquifer or aquifers. However, not all groundwater is necessarily within an aquifer.

The environmental objectives of preventing deterioration of[35],and protecting, enhancing and restoring[36] good groundwater status apply only to bodies of groundwater. However, all groundwater is subject to the objectives of preventing or limiting inputs of pollutants[37] and reversing any significant and sustained upward trend in the concentration of any pollutant[38].

4.2 Aquifers

As a consequence of the hierarchy of definitions (Section 4.1), the **suggested first step** in the identification of bodies of groundwater requires a general interpretation of the term aquifer, in respect what constitutes a significant flow of groundwater and what volume of abstraction would qualify as a significant quantity (see Figure 9).

4.2.1 Significant flow

The significance of groundwater flow should be understood in the context of the purpose and provisions of the Directive. Accordingly, a significant flow of groundwater is one that, were it from reaching an associated surface water body or a directly dependant terrestrial ecosystem, would result in a significant diminution in the ecological or chemical quality of that surface water body or significant damage to the directly dependent terrestrial ecosystems.

A key purpose of the Directive is to prevent further deterioration of, and protect and enhance the status of aquatic ecosystems, and with regard to their water needs, terrestrial ecosystems directly depending on aquatic ecosystems[39]. The objective of protecting and restoring good groundwater status[40] is designed to help achieve this purpose. It applies to all

[35] *Article 4.1(b)(i)*

[36] *Article 4.1(b)(ii)*

[37] *Article 4.1(b)(i)*

[38] *Article 4.1(b)(iii)*

[39] *Article 1(a)*

[40] *Annex V 2.1.2 & 2.3.2*

bodies of groundwater. Consequently, to ensure that the purpose of the Directive can be achieved, the definition of significant flow must encompass all groundwater flow that is important to aquatic and terrestrial ecosystems. Geological strata that permit such flow should therefore qualify as aquifers.

4.2.2 Abstraction of significant quantities of groundwater

Article 7 requires the identification of all groundwater bodies used, or intended to be used, for the abstraction of more than 10 m^3 of drinking water a day as an average. By implication, this volume could be regarded as a significant quantity of groundwater. Geological strata capable of permitting such levels of abstraction (even only locally) would therefore qualify as aquifers.

If either of the criteria described in Paragraphs 4.2.1 or 4.2.2 are satisfied, the geological strata should be regarded as an aquifer. Most geological strata would be expected to qualify as aquifers as most supply or are intended to supply 10 m^3 a day as an average or could serve 50 or more people.

However, it is clear that the requirements are different as regards those groundwater bodies which are being used or are intended to be used for drinking water abstraction (cf. Article 7) and those bodies where groundwater is abstracted for other uses (cf. Annex II 2.3). For the latter, not all groundwater bodies would be identified. The criteria in Annex II 2.3 specify, that only those groundwater bodies must be addressed "*which cross the boundary between two or more Member States or are identified [...] as being at risk of failing to meet the objectives set for each body under Article 4".*

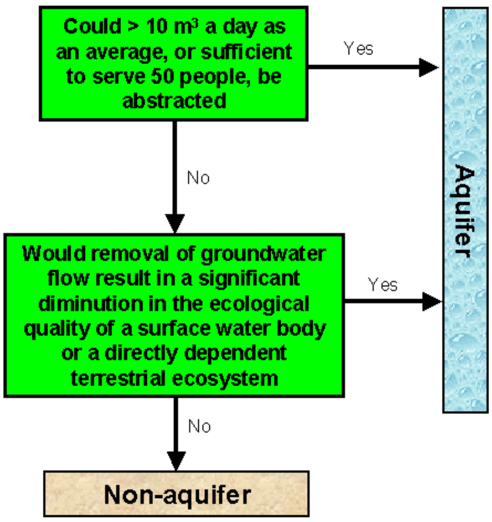

Figure 9: The Directive's definition of aquifer requires two criteria to be considered in determining whether geological strata qualify as aquifers. If either of the criteria is met, the strata will constitute an aquifer or aquifers. In practice, the criteria mean that nearly all groundwater in the Community would be expected to be within aquifers.

4.3 Delineation of bodies of groundwater

The Directive's definition of the term body of groundwater does not provide explicit Guidance on how bodies should be delineated.

The delineation of bodies of groundwater must ensure that the relevant objectives of the Directive can be achieved. This does not mean that a body of groundwater must be delineated so that it is homogeneous in terms of its natural characteristics, or the concentrations of pollutants or level alterations within it. However, bodies should be delineated in a way that enables an appropriate description of the quantitative and chemical status of groundwater.

The delineation of bodies of groundwater should ensure that groundwater quantitative status[41] can be reliably assessed. In some circumstances, quantitative status may be determined using long-term monitoring data. In other cases, an estimation of the available groundwater resource will require a water balance calculation (see WFD CIS Guidance Document No. 7- Chapter 4). Delineating bodies of groundwater in such a way that any groundwater flow from one groundwater body to another (a) is so minor that it can be ignored in water balance calculations; or (b) can be estimated with adequate precision will facilitate the assessment of quantitative status.

Member States will need to take into account the particular characteristics of their aquifers when delineating bodies of groundwater. For example, the flow characteristics of some geological strata, such as karst and fractured bedrock, are much more complex and difficult to predict than others. The delineation of water bodies should therefore be regarded as an iterative process, refined over time to the extent needed to adequately assess and manage risks to the achievement of the Directive's objectives.

It may also be the case that there is substantial flow between strata with very different characteristics (e.g. karst and sandstone). The properties of these different strata may mean that they require very different management approaches to achieve the objectives of the Directive. In such cases, Member States may wish to delineate water body boundaries that coincide with the boundaries between the strata. In doing so, Member States should ensure that their ability to adequately assess quantitative status is not compromised.

4.3.1 Geological boundaries

Bearing in mind the above, the starting point for identifying the geographical boundaries of a groundwater body should be geological boundaries to flow, unless the description of status and the effective achievement of the Directive's environmental objectives for groundwater require sub-division into smaller groundwater bodies.

4.3.2 Other hydraulic boundaries

Sub-divisions of an aquifer or aquifers that cannot be based on geological boundaries should be based initially on groundwater highs or, where necessary, on groundwater flow lines (Figure 10).

4.3.3 Taking account of differences in status

The objectives for bodies of groundwater, and the measures required to achieve them, depend on the existing status of the bodies. The bodies should be units of one chemical and one quantitative status that can be characterised and managed to allow the effective achievement of the Directive's objectives. Major changes in the status of groundwater should therefore be taken into account when delineating groundwater body boundaries to ensure that, as far as practical, water bodies provide for an accurate description of groundwater status. In doing so, Member States should bear in mind the need to ensure that groundwater quantitative status can be reliably assessed (see Section 2). Where status is consistent, large bodies of groundwater may be delineated. Where status differences are reduced during

---

[41] Annex V 2.1.2. Quantitative status requires assessment of the available groundwater resource [Article 2.27]. This requires a water balance calculation.

a planning cycle, Member States may recombine subdivisions of groundwater of the same status for the purposes of subsequent planning cycles. **However, water bodies must at least be fixed for each plan period.**

Initially, Member States will not have sufficient information to accurately define the status of groundwater. Consequently, especially during the period prior to the publication of the first River Basin Management Plan, it may be appropriate to use the analysis of pressures and impacts[42] as an indicator of status. As understanding of status improves, the boundaries of groundwater bodies should be reviewed as part of the analyses required under Article 5 prior to the publication of each river basin management plan.

It is clearly possible to progressively subdivide the groundwater in aquifers into smaller and smaller units and thereby create significant logistical burdens. However, it is not possible to define a universally applicable scale below which subdivision is inappropriate.

The degree of subdivision of groundwater into bodies of groundwater is a matter for Members States to decide on the basis of the particular characteristics of their River Basin Districts. In making such decisions, it will be necessary for Member States to balance the requirement to adequately describe groundwater status with the need to avoid the fragmentation of aquifers into unmanageable numbers of water bodies.

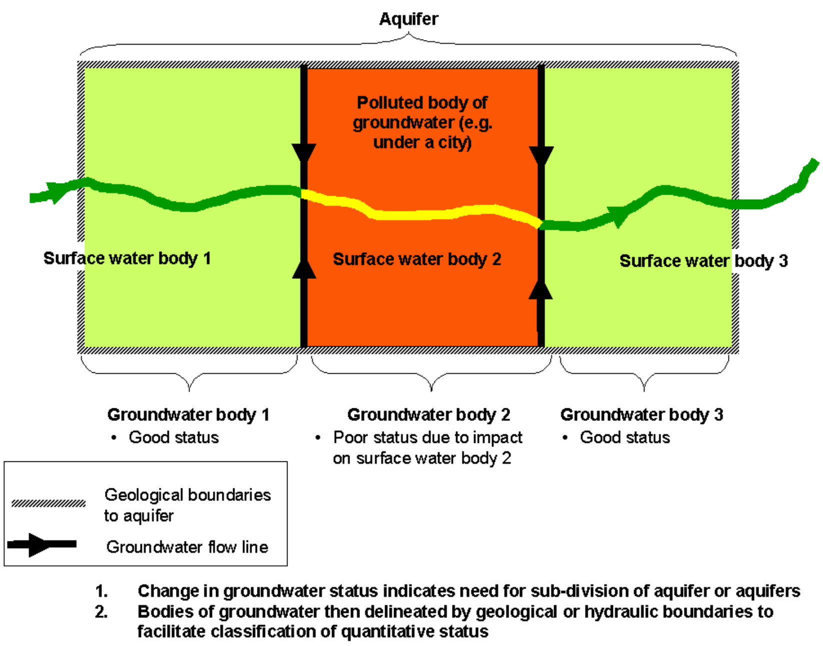

Figure 10: Sub-division of aquifers into bodies of groundwater using hydraulic boundaries

4.4 Upper and lower boundaries to bodies of groundwater

Groundwater bodies should be delineated in three dimensions[43].

The depth of groundwater within an aquifer or aquifers that needs to be protected and, where necessary, enhanced through its inclusion in a body of groundwater should depend on the risks to the Directive's objectives. This is a matter for Member States to decide based on

[42] *Article 5 and Annex II(2)*

[43] *e.g. Annex II 2.2*

their assessments of groundwater characteristics and the risks to the Directive's objectives[44]. It should be noted that all groundwater is subject to the 'prevent or limit' objective [Article 4.1(b)(i)] whether or not it is identified as being part of a body of groundwater.

Although most pressures will affect the relatively shallow component of a groundwater flow, groundwater flow at depth can still be important to surface ecosystems - even though this may be over an extended timescale. Human alterations to groundwater flow at depth can affect shallow groundwater and thus potentially the chemical and ecological quality of connected surface ecosystems. Deep groundwater may also be an important resource for drinking water or other uses. However, Member States would not be expected to identify deep groundwater as water bodies where that groundwater (a) could not adversely affect surface ecosystems; (b) are not used for groundwater abstraction; (c) was unsuitable for drinking water supply because of its natural qualities or because its abstraction would be technically unfeasible or disproportionately expensive; and (d) could not place the achievement any other relevant objectives at risk.

The Directive's definitions of aquifer and body of groundwater (see Section 4.1) permit groundwater bodies to be identified either (a) separately within different strata overlying each other in the vertical plane, or (b) as a single body of groundwater spanning the different strata. This flexibility enables Member States to adopt the most effective means of achieving the Directive's objectives given the characteristics of their aquifers and the pressures to which they are subjected. For example, where there are major differences in status of the groundwater in strata at different depths, it may be appropriate to identify different bodies of groundwater (i.e. one on top of another) to ensure the status of groundwater can be accurately described, and the Directive's objectives appropriately targeted.

Similar criteria should be applied in defining the upper and lower boundaries of the groundwater body as to the geographical boundaries (Section 4.3). In other words, to facilitate the estimation of quantitative status, the upper and lower boundaries should be based first on geological boundaries and then on other hydraulic boundaries such as flow lines.

4.5 Assignment to River Basin Districts

Groundwater bodies must be assigned to a River Basin District[45].

4.6 Targeting measures within bodies of groundwater

The analyses undertaken in accordance with Article 5 and Annex II of the Directive (see WFD CIS Guidance Document No. 3 - IMPRESS), and supplemented by information from the monitoring programmes established under Article 8 (see WFD CIS Guidance Document No. 7 - monitoring) will identify those bodies at risk of failing to achieve the Directive's objectives because of specific pressures. This information together with the identification of Protected Areas under Article 6 will enable Member States to target measures on the right pressures in the right parts of their bodies of groundwater. To assist this targeting, Member States may establish zones within which specific measures are required to achieve the Directive's objectives. For example, Article 7 indicates that Member States may establish safeguard zones to help protect water intended for human consumption[46].

4.7 Suggested process for the practical application of the term body of groundwater

Figure 11 suggests an iterative, hierarchical process for identifying bodies of groundwater based on the principles described in this Guidance paper.

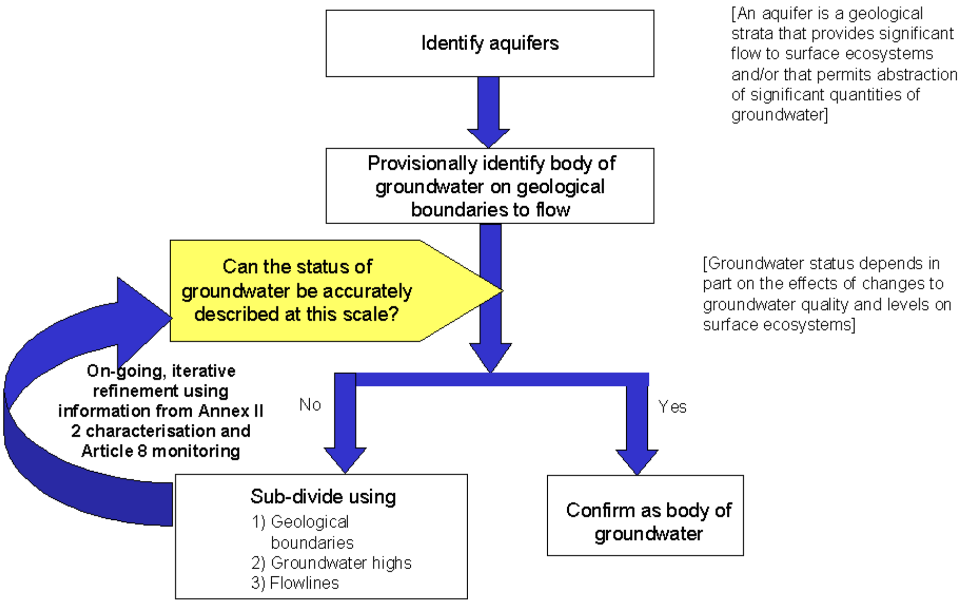

Figure 11: Summary of the suggested hierarchical approach to the identification of bodies of groundwater

5 Aggregation of water bodies

Surface water bodies or bodies of groundwater may each be grouped for the purposes of assessing the risk of failing to achieve the objectives set for them under Article 4 (pressures and impacts)(refer to WFD CIS Guidance Document No. 3)[47]. They may also be grouped for monitoring, reporting and management purposes where monitoring sufficient indicative or representative water bodies in the sub-groups of surface water or groundwater bodies provides for an acceptable level of confidence and precision in the results of monitoring, and in particular the classification of water body status refer to WFD CIS Guidance Document No. 7)[48].

It is clear that, for management purposes, it may be useful to aggregate water bodies. First practical indications suggest that such an aggregation will also be inevitable when it comes to reporting to the European Commission. At the same time, there are no criteria whether and when such an aggregation is acceptable.

Where contiguous elements of surface water within a type are of the same status, their combination in a single water body will provide for an accurate description of surface water status.

In addition, it will be necessary to apply this aggregation on the basis of clear criteria agreed on river basin district level and in a transparent way. Further details on whether and how aggregation of water bodies for the purpose of reporting is possible need to be discussed and elaborated in the context of the Expert Advisory Forum on Reporting. In the meantime it is recommended to focus particular attention on this issue when testing this Guidance Document, e.g. in the pilot river basins.

Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 3

Analysis of Pressures and Impacts

COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 3

Analysis of Pressures and Impacts

Produced by Working Group 2.1 - IMPRESS

Disclaimer:

This technical document has been developed through a collaborative programme involving the European Commission, all the Member States, the Accession Countries, Norway and other stakeholders and Non-Governmental Organisations. The document should be regarded as presenting an informal consensus position on best practice agreed by all partners. However, the document does not necessarily represent the official, formal position of any of the partners. Hence, the views expressed in the document do not necessarily represent the views of the European Commission.

ISSN 1725-1087

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, an informal working group dedicated to the identification of pressures and assessment of impacts within the characterisation of water bodies according to Article 5 of the Directive was set up in October 2001 and named IMPRESS. Germany and the United Kingdom have joint responsibility for the project management and secretariat of the working group, which is composed of technical experts from governmental and non-governmental organisations.

The present Guidance Document is the outcome of this working group. It contains the synthesis of the output of the IMPRESS group activities and discussions that have taken place since the official launch of IMPRESS in October 2001. It builds on the input and feedback from a wide range of experts and stakeholders that have been involved throughout the process of Guidance development through meetings, workshops or electronic communication media, without binding them in any way to its content.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders, Isobel Austin and Volker Mohaupt, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

Table of contents

Overview / Executive Summary

WHAT IS THE PURPOSE OF THIS GUIDANCE DOCUMENT?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the analysis of pressures and impacts within the characterisation of water bodies according to Article 5 in the broader context of the development of integrated river basin management plans as required by the Directive.

TO WHOM IS THIS GUIDANCE DOCUMENT ADDRESSED?

If this is your task, we believe the Guidance will help you in doing the job, whether you are:

- Undertaking the pressures and impacts analysis yourself;
- Leading and managing experts undertaking the pressures and impacts analysis;
- Participating as a stakeholder in the assessment process;
- Using the results of the pressures and impacts analysis for aidimg decision making and supporting the development of river basin management plans; or
- Reporting on the pressures and impacts analysis to the European Commission as required by the Directive.

WHAT CAN YOU FIND IN THIS GUIDANCE DOCUMENT?

Common understanding about pressures and impacts in the Water Framework Directive (Chapter 2)

- What is the role of the analysis of pressures and impacts within the implementation process of the directive?
- How the analysis contributes to the characterisation of water bodies, which has to be fulfilled according to Article 5 of the Directive, and how this analysis feeds into the development of monitoring programmes, river basin management plans and programmes of measures;
- What are the key terms of the analysis (e.g. significant pressures, water bodies at risk of failing the Directive's objectives)?
- What are the Directives objectives?

General approach for the analysis of pressures and impacts (Chapter 3)

- What is the overall approach and what are the key working steps proposed to undertake the analysis?
- Which are the methods proposed for surface waters to:
    - Identify driving forces, pressures and significant pressures?
    - Assess susceptibility of water bodies to pressures and the severity of impacts?
    - Evaluate the risk of failing objectives?
- Which are the methods proposed for groundwater to:

- Undertake the initial characterisation?
- Undertake the further characterisation for 'at risk' groundwater bodies and bodies that cross the boundaries of member states?

The Toolbox (Chapter 4)

- Which specific tools, such as data, classification systems and models, are available to aid the analysis of pressures and impacts?

Sources of data and information (Chapter 5)

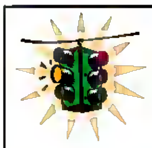
- Where do you find the information and data that will be required to undertake the analysis described in Section 3 or to support the tools mentioned in Section 4?

Examples of current practice (Chapter 6)

- What examples are available of current good practice in respect of at least one aspect of the analysis?

The methodology from this Guidance Document must be adapted to regional and national circumstances

The Guidance Document proposes an overall process and associated key steps. Due to the diversity of circumstances within the European Union, the way to undertake the analysis will vary from one river basin to the next. This proposed methodology will therefore need to be tailored to specific circumstances.



Look out!

What you will <u>not</u> find in this Guidance Document

The Guidance Document focuses on the "review of the impacts of human activity on the status of surface waters and on groundwater" according to Article 5 and Annex II (1.4, 1.5 and 2.). This then helps to develop River Basin Management Plans and Programmes of Measures. The Guidance focuses specifically on the 2004 requirements of the Directive. The Guidance does not focus on:

- How to designate heavily modified water bodies (see WFD CIS Guidance Document No 4 on Identification and Designation of Artificial and Heavily Modified Water Bodies);
- How to design monitoring programmes (see WFD CIS Guidance Document No 7 on Monitoring);
- How to develop any measure needed to achieve the objectives of the Directive (see WFD CIS Guidance Document No 9 on Best Practices in River Basin Planning).

1. Implementing the Directive: Setting the scene

This Section introduces the overall context for the implementation of the Water Framework Directive (WFD) and the initiatives that led to the production of this Guidance Document.

1.1 December 2000: A Milestone for Water Policy

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the WFD (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force.

The WFD is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the WFD.

1.2 The Water Framework Directive: new challenges in EU water policy

What is the purpose of the Directive?

The WFD establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which, according to Article 1:

- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

...and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);

- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (*Article 2 (22), Annex V*);
- To make operational the monitoring networks by 2006 (*Article 8*);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the WFD cost-effectively (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).

Member States may not always be able to achieve good water status for all water bodies within a RBD by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions, which must be specifically explained in the relevant RBMP, the WFD offers the possibility to Member States to engage into two further six-year cycles of planning and implementation of measures (i.e. to 2027). Where failure to achieve objectives is constrained by natural conditions, the period may be extended beyond 2027.

Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basim management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives,** combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources,** combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** be local, regional or national, for an effective management of all waters;
- **Integration of water management from different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.

1.3 What is being done to support implementation?

Activities to support the implementation of the WFD are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the WFD.

May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy (CIS).

The main objective of this strategy is to provide support to the implementation of the WFD by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance (see Annex I). A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision making body for the CIS.

The IMPRESS working group
In the context of this strategy, a working group dedicated to the identification of pressures and assessment of impacts within the characterisation of water bodies according to Article 5 of the Directive has been set up. The main (short-term) objective of this working group, launched in October 2001 and named IMPRESS, was the development of a non-legally binding and practical Guidance Document on this topic within the WFD. Germany and the United Kingdom have joint responsibility for the project management and secretariat of the working group, which is composed of technical experts from governmental and non-governmental organisations.

To ensure an adequate input and feedback during the Guidance development phase from a wider audience, and to evaluate earlier versions of the Guidance Document, the IMPRESS group has organised several discussions and feedback events such as meetings and workshops.

Developing the Guidance Document: an interactive process
Within a very short time period, a large number of experts and stakeholders have been involved at varying degrees in the development of this Guidance Document. The process for their involvement has included the following activities:

- **Regular meetings** of the 40-plus experts and stakeholder members of IMPRESS;
- **Regular interactions** with experts from other working groups of the Common Implementation Strategy, mainly those dealing with economic

analysis, designation of heavily modified water bodies, reference conditions, and monitoring.

You can contact the experts involved in the IMPRESS activities
The list of IMPRESS members with full contact details can be found in Annex III of this guidance. If you need assistance with your own activities, contact a member from IMPRESS in your country.

2. Analysis of Pressures and Impacts in the Water Framework Directive – Common Understanding

2.1 Recall of WFD requirements

2.1.1 Requirements in relation to pressure and impact analysis

The previous Chapter has made clear the *purpose* of the WFD, and the importance of *integration* in achieving its objectives. The necessity to analyse pressures and impacts is stated in Article 5 of the WFD which requires, for each river basin district:

- An analysis of its characteristics;
- A review of the impact of human activity on the status of surface waters and groundwater; and.
- An economic analysis of water use.

This Guidance addresses the second of these requirements, but must be fully integrated with the economic analysis, for which Guidance has been prepared by the Economic Analysis working group (WATECO) (refer to WFD CIS Guidance Document No 1). The WFD requires the tasks specified under Article 5 to be completed by 2004. They will then be reviewed by 2013, and subsequently every 6 years (2019, 2025…). Given the overall purpose of the WFD, the analysis undertaken in 2004 must consider both the current condition for each water body, and a prognosis for the period to 2015. Thus the WFD is initiating an on-going process of assessment, iteration and refinement.

A specification for the impact review is contained in WFD Annex II Section 1 for surface waters, and Annex II Section 2 for groundwaters (Figure 2.1).

Surface waters
The review process is described in five parts corresponding to the sub-sections within WFD Annex II Section 1, namely:

1. Characterisation of surface water body types;
2. Ecoregions and surface water body types;
3. Establishment of type-specific reference conditions for surface water body types;
4. **Identification of Pressures;** and,
5. **Assessment of Impacts.**

This Guidance Document addresses the final two parts of this process, but clearly relates closely to both the characterisation and the establishment of reference conditions. There are two separate working groups of the CIS providing Guidance on Reference Conditions for Inland Surface Waters (REFCOND) and Typology and Classification Systems of Transitional and Coastal Waters (COAST) (refer to WFD CIS Guidance Document No.s 10 and 5, respectively).

The WFD requires information to be collected and maintained on the type and magnitude of significant anthropogenic pressures, and indicates a broad categorisation of the pressures into:

- Point sources of pollution;

- Diffuse sources of pollution;
- Effects of modifying the flow regime through abstraction or regulation; and,
- Morphological alterations.

Any other pressures, i.e. those not falling within these categories, must also be identified. In addition there is a requirement to consider land use patterns (e.g. urban, industrial, agricultural, forestry etc) as these may be useful to indicate areas in which specific pressures are located.

The impact assessment should use both information from the review of pressures, and any other information, for example environmental monitoring data, to determine the likelihood that the surface water body will fail to meet its environmental quality objectives. For bodies at risk of failing their specified objectives, it will be necessary to consider the implementation of additional monitoring and a programme of measures.

Groundwaters
A different process is described within WFD Annex II, Section 2, but this again has five parts (Figure 2.1), namely:

1. **Initial characterisation**, including identification of pressures and risk of failing to achieve objectives;
2. **Further characterisation** for at risk groundwater bodies;
3. **Review of the impact of human activity on groundwaters** for trans-boundary and at risk groundwater bodies;
4. **Review of the impact of changes in groundwater levels** for groundwater bodies for which lower objectives are to be set according to Article 4.5; and,
5. **Review of the impact of pollution on groundwater quality** for which lower objectives are to be set.

This Guidance addresses all parts of this process. The pressures identified in WFD Annex II, Sub-section 2.1 correspond to the first three of the categories identified for surface waters, namely:

- Point sources of pollution;
- Diffuse sources of pollution; and,
- Changes in water levels and flow caused by abstraction or recharge.

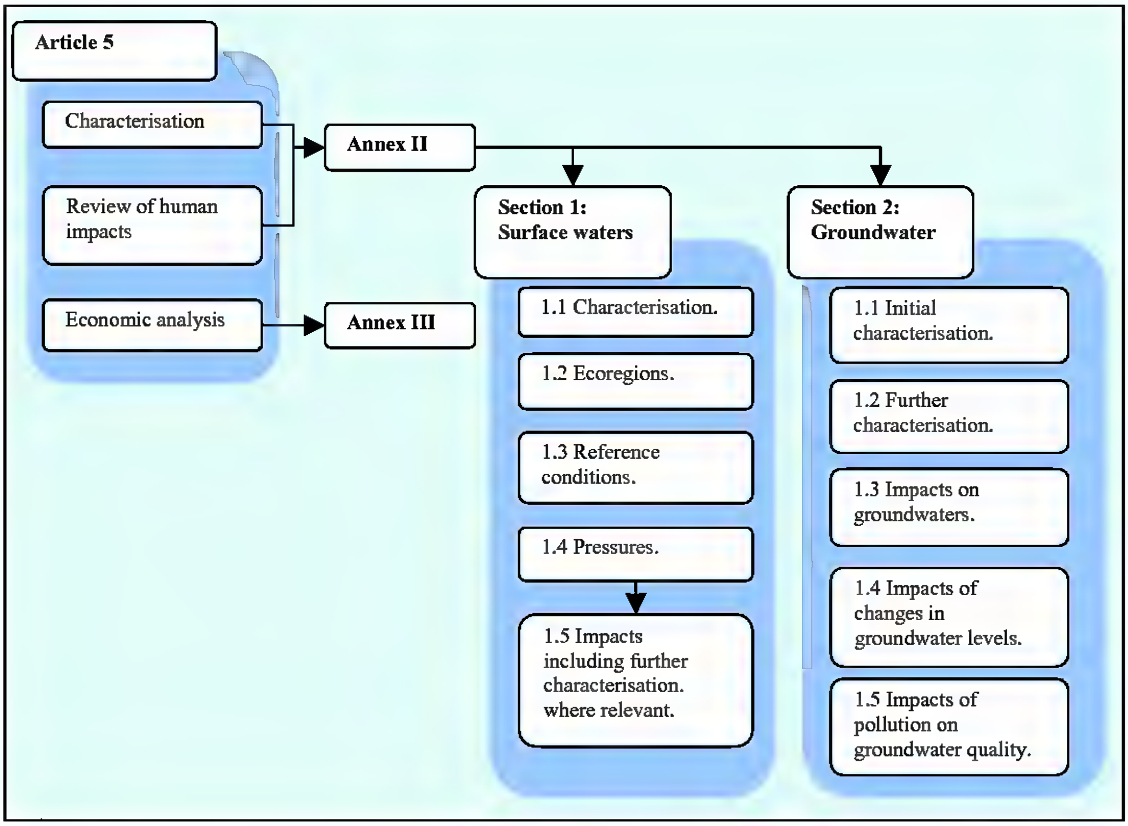


Figure 2.1 *The WFD specifies requirements for impact analysis separately, and differently, for surface and groundwaters.*

2.1.2 Links to other relevant requirements and related timescale

The review of pressures and impacts is only one element of the planning process, with other elements feeding into the review, or dependent on its outcome (Figure 2.2).

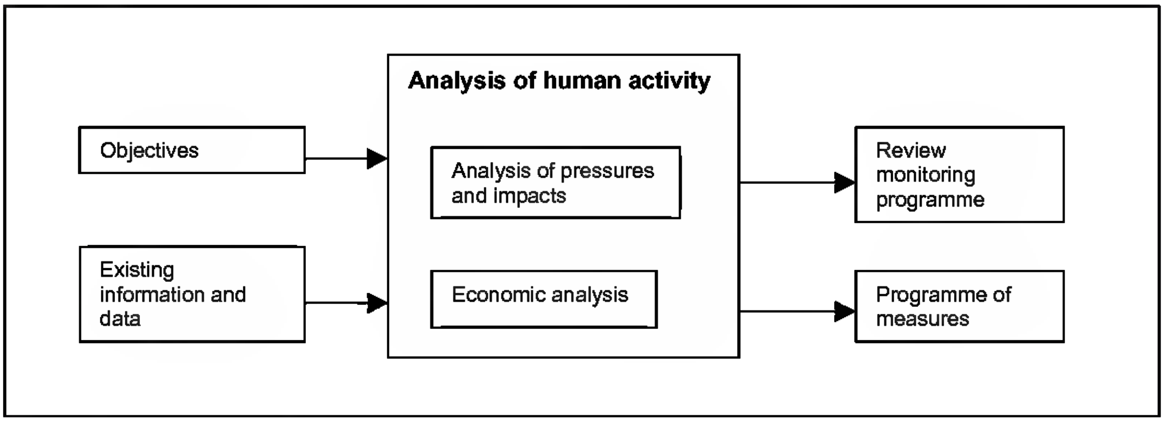

Figure 2.2 *Elements of the planning process.*

One of the most fundamental elements of this larger process is the setting of the environmental objectives (Article 4) since the review of pressures and impacts must identify water bodies that fail, or are at risk of failing, the specified objective. The objectives depend on both the overall objective to achieve good status by 2015, and possibly additional specific objectives that apply to *protected areas* as defined from other legislation. The objectives may also depend on the current status of the water body, since member states must, in general, prevent any deterioration in the status. The objectives are considered further in Section 2.3.

In the longer term, the achievement of the goals will be assessed through the monitoring of a water bodies' chemical and ecological state. The most important goal of the first review, required in 2004, is to understand the significant water management issues within each river basin and how they affect each individual water body. This may be considered a screening step prior to additional description and analysis at a later stage. This screening should identify issues to be addressed in the drawing up of the river basin management plan (RBMP), and it may also reveal a number of gaps in data or knowledge that should be filled during the process of drawing up the RBMP and the monitoring programme.

A factor that can affect the setting of objectives concerns the designation of a water body as artificial or heavily modified (Article 4). Guidance on such designation is available in WFD_CIS_Guidance_Document_No. 4. However, since designation of HMWBs will not be completed until 2009, the principles of the HMWB Guidance should be considered in undertaking the first pressures and impacts analysis. Indeed, the two processes should be seen as closely interacting parallel processes, and not independent activities.

The WFD establishes a number of objectives for surface waters and groundwater, and the pressures and impacts analyses must assess the risks of failing to achieve each of them. The objectives include new ecological objectives, the achievement of which may be compromised by a very wide range of pressures, including point source discharges, diffuse source discharges, water abstractions, water flow regulation, morphological alterations and artificial recharge of groundwater. These and any other pressures that could affect the status of aquatic ecosystems must be considered in the analyses.

The WFD requires the achievement of its principal objectives; good surface water status and good groundwater status, by the end of 2015 at the latest, unless Articles 4.3 – 4.7are applicable. Accordingly, the analyses of pressures and impacts must consider how pressures would be likely to develop prior to 2015 in ways that would place water bodies at risk of failing to achieve good status if appropriate programmes of measures were not designed and implemented. This will require consideration of the effects of existing legislation and forecasts of how the key economic factors that influence water uses will evolve over time, and how these changes may affect the pressures on the water environment (refer WFD CIS Guidance Document No. 3). Such forecasts should be provided by the economic analyses of water use required under Article 5. The pressures and impacts analyses will also need to identify which of the risks to the WFDs' objectives are expected to be addressed by the implementation of measures specified under other Community legislation. This information will enable the economic analyses to assess, and provide advice on, the most cost-effective combinations of measures that can be used to address the other risks to the achievement of the WFDs' objectives.

The WFDs' objective of preventing or limiting inputs of pollutants into groundwater [Article 4.1(b)(i)] does not specify which pollutants should be prevented from entry and to what extent others should be limited. It is therefore not clear how to assess the risks of failing to achieve this objective until clarification of its purposes is provided.

Such clarification may be provided in a daughter directive to be established under Article 17. This Daughter Directive is also expected to establish criteria for the identification of significant and sustained upward trends [Article 4.1(b)(iii)]. Until these criteria have been established, Member States will need to decide what constitutes a significant and sustained upward trend according to their own criteria.

The review of the pressures and impacts is required in the design of monitoring programmes which must be operational by 2006 (Article 8), and also to help develop programmes of measures which must be established by 2009, and made operational by 2012 (Article11). Article 14encourages the active involvement of all interested parties in the implementation of the WFD and requires Member States to *inform and consult the public*. Therefore, water agencies and authorities should make this review as transparent as possible. This Article specifically requires public consultation in the production of the RBMP, to which the pressures and impacts analysis makes a significant contribution.

Information sharing, consultation and public participation are requirements of the directive, and will also make implementation more effective. The Guidance Document on "Public Participation" provides further information about these forms of participation (WFD CIS Guidance Document No. 8).

Stakeholder participation is important as it can fulfil many functions, including:

- Developing a process agreed by all will increase the legitimacy of its outcome and thus facilitate an efficient and effective follow-up;
- Stakeholders can be a useful source of information and have expertise of direct use for the pressures and impact analysis (see Tables in Chapter 5);
- Survey of the public can be useful to understand how people value improvements in the environment and quality of our waters, and how far they are ready to pay for environmental improvements;
- Public involvement and the network of partners developed through participation can be useful to develop a sense of ownership over the River Basin Management Plans and may increase the effectiveness of measures taken to meet the Directive's objectives.

The Directive only specifies key dates for consultation, but rightly does not specify dates for the participation process, as this will depend on local institutions and socio-reference conditions set-up. However, it is recommended to start the participation process early (e.g. as part of the characterisation of the river basin before 2004) to improve its effectiveness.

See also Chapter 5 of this document showing who needs to get involved in carrying out and using the IMPRESS analysis.

Article 15 specifies the reporting requirements of the review undertaken under Article 5. Member states are required to provide summary reports of the reviews within three months of their completion (i.e. by March 2005 at the latest for the first review). Subsequently, reporting on these reviews will be contained in the RBMPs, which must be published first in 2009, and thereafter every six years (2015, 2021…). Therefore, from 2009 a schedule with a six-year cycle shall be established, with the review of pressures and impacts occurring two years prior to the publishing of the RBMP.

Article 6 requires that a register of *protected areas* is established by 2004, but this information is required at an earlier date to enable the review of pressures and impacts. The timescales and associated links are summarised in Table 2.1

Table 2.1 *Actions and dates by which they must be achieved (note that in practice many actions must be completed within a fixed period of the completion of a prerequisite task).*

Action	Date
Impact review completed by member states (Article 5, Article 15, Annex II)	2004
Register of protected areas established (Article 6)	2004
Summary reporting of impact review to Commission (Article 15)	2005
Monitoring programme operational (Article 8)	2006
First River Basin Management Plan completed (Article 15)	2009
Programme of measures established (Article 11)	2009
Programme of measures operational (Article 11)	2012

2.2 *Key terms*

While it is clear from the WFD that the impacts are the result of pressures, neither term is explicitly defined. For this reason a common understanding of the terms and the most effective approach has to be developed. In this Guidancethe widely-used Driver, Pressure, State, Impact, Response (DPSIR) analytical framework has been adopted with definitions as in Table 2.2, and illustrated using an example in Figure 2.3.

Table 2.2 *The DPSIR framework as used in the pressures and impacts analysis.*

Term	Definition
Driver	an anthropogenic activity that may have an environmental effect (e.g. agriculture, industry)
Pressure	the direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry)
State	the condition of the water body resulting from both natural and anthropogenic factors (i.e. physical, chemical and biological characteristics)
Impact	the environmental effect of the pressure (e.g. fish killed, ecosystem modified)
Response	the measures taken to improve the state of the water body (e.g. restricting abstraction, limiting point source discharges, developing best practice Guidance for agriculture)

It is clear from these definitions that in the analysis of *pressures* and *impacts*, it is necessary to include information on *drivers*, and changes in the *state*, but that *responses* need not be considered. The distinction made here between state and impact separates effects that are sometimes combined, or confused. One reason for this is that because many of the impacts are not easily measurable, state is often used as an indicator of, or surrogate for, impact. This is seen in many existing methodologies (e.g. quality targets and classification systems) in which physico-chemical parameters are used to quantify ecological status. While such methods imply a well-understood relationship between state and impact, in practice this is not the case, and is the subject of on-going scientific research. In addition to this uncertainty, the parameters defining ecological status will not be finally established until after the first pressure and impact review has to be completed. The approach adopted in this guidance, therefore, provides a framework for analysis that reflects current understanding of how aquatic ecosystems function, and enables future integration of specific ecological criteria.

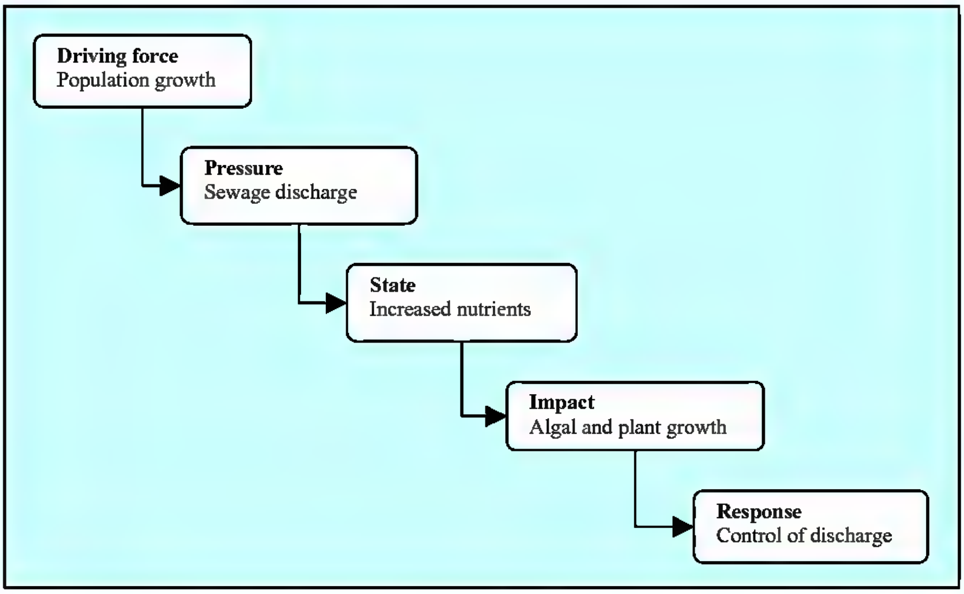

Figure 2.3 *An illustration of the DPSIR analytical framework (note that the response is not considered in the analysis of pressures and impacts described in this guidance).*

It is worth noting in the context of the DPSIR framework as described above, that objectives defined by the WFD relate to both the state and the impact, since, standards from other European water quality objective legislation relate to the concentration of pollutants in the water body (i.e. its state), while the biological elements of the WFD clearly indicate impacts.

Despite this problem of nomenclature, the meaning of the WFD is clear. If the water body fails to meet its objective, or is at risk of failing to meet its objective, then the cause of this failure (i.e. the pressure or combination of pressures) must be investigated. Thus *when the Directive states that significant pressures must be identified, this can be taken to mean any pressure that on its own, or in combination with other pressures, may lead to a failure to achieve the specified objective*. Such an interpretation introduces a scale dependence, which is considered in Section 2.3.2. It is also worth noting that the actual criterion used to assess significant pressures for both surface and groundwater is that they are *at risk of failing* to meet objectives. The process of analysing pressures and their impacts is a "risk assessment" process but in this Guidanceis always referred to as a pressures and impacts analysis.

Other terms are defined in the glossary in Annex II.

2.3 Relevant considerations

2.3.1 Water Body Definition

The requirements described above all relate to a *body of surface water*, or a *body of groundwater*. The WFD defines both of these terms, and as part of the definition notes that surface water bodies should be *discrete* but need not, for example, be a whole river, while groundwater bodies should be *distinct*. Draft Guidancehas been prepared within the CIS on the identification of discrete and distinct water bodies: *Horizontal Guidanceon the application of the term "water body" in the context of the Water Framework Directive* (WFD Guidance Document No. 2). This addresses scaling issues and the importance of defining water bodies with reference not only to water body type and morphological change, but also to pressures and impacts. In the absence of finalised definitions of water bodies, this Guidanceaddresses the *process* of pressure and impact analysis which should be independent of any outstanding issues relating to water body definition.

2.3.2 Scaling Issues

Different kinds of pressures do not impact the different water bodies at the same space and time scales. Hence the analysis of pressures must be carried out to ensure that a) the final reporting that is produced with the collected information is consistent with the WFD objectives and b) that data collection is feasible on the long term.

Most impacts cannot be monitored or even assessed directly. In many cases, their identification is derived from observation of changes in the state and the likelihood of these changes to be caused by known pressures. The correct time and space scales of data collection of both pressures and states are the most important points that make it possible to establish sound (therefore recognised as true) relationships, and consequently appropriate programmes of measures. The assessment of the relevant space and time scales is made easier when considering that a pressure results from a load exerted during a certain time over a certain target, that has a particular size. For example, the abstraction of a certain volume of water may have no impact if pumped throughout the year but be a significant pressure if taken out of a river only during the summer months.

The correct identification of pressures requires consistent identification of the relevant targets, their size and the susceptibility to being impacted. The spatial scale is derived from this identification. For practical purposes, compromises must be made to minimize the burden of data collection. Considering the many data sources that are likely to provide ad-hoc data for pressure assessment, that can be used either for surface or groundwater impact analysis, some common rules are suggested.

Regarding the temporal scale, it is important to adopt appropriate temporal scales in the pressures and impacts analysis since some pressures may result in impacts many years in the future, and some future impacts will relate to past pressures that no longer exist. However, most data sources provide yearly data. This scale may often be satisfactory to address long-term impacts. For example, large lakes or groundwater bodies are impacted by cumulative inputs lasting up to dozens of years. By contrast, river or sea-shore pollution, tourism or agricultural abstraction impacts result from peak demand on limited resources. In the latter case, the yearly data does not provide information on significant pressures over a shorter time scale.

Correctly addressing all impacts requires, with respect to time scale:

- Within-year data, indicating the annual pattern, to at least comprise the mean value, the peak value and its duration, the optimum being a monthly value,
- Long-term between-years data, if relevant, including diffuse sources to rivers (e.g., the release from sediments of toxic substances discharged through a former industrial activity).

Regarding spatial scales, the important features of data are the location, especially if the water body comprises very different components (e.g. main river channel and its tributaries, recharge area of a confined groundwater etc) that respond differently to the pressure. Pressure location can be analysed as precise information or as density information. In the first case, the relevant component of the water body is identified. In the latter, the area on which the pressure is exerted must be identified and small enough to make it possible to link the pressure to its target. For example, considering confined groundwater, the important data is the emissions on the recharge area only, not over the total extent of the water body.

These principles are further clarified in the following Chapters.

2.3.3 Different starting points

The timetable for completing the first pressures and impacts analyses and reporting their results is very short. The first analyses will therefore rely heavily on existing information on pressures and impacts and existing assessment methods. Because previous Community water legislation has been focused on pollution, the information and expertise on other pressures and their impacts is very variable between and even within Member States, depending on national legislation and policies.

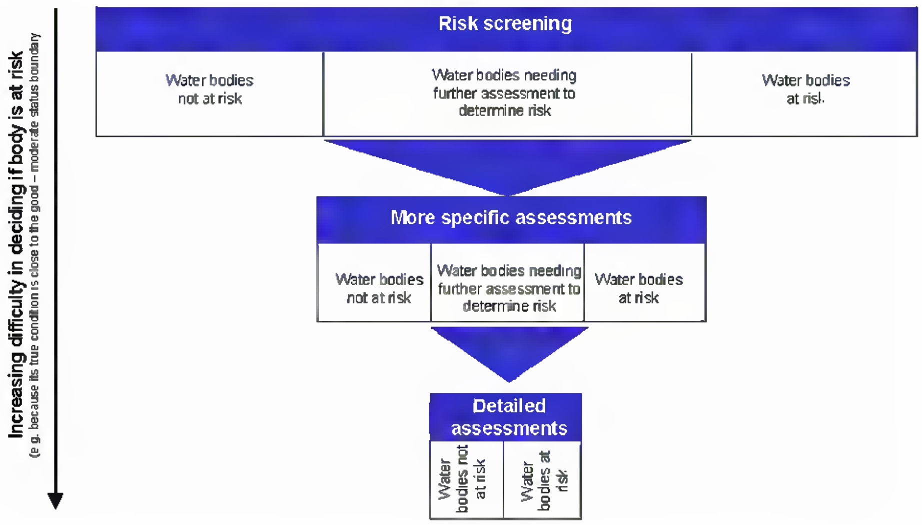

Figure 2.1 *The pressures and impacts analyses should be focused in such a way that the effort involved in assessing whether any body, or group of bodies, is at risk of failing to achieve its environmental objectives is proportionate to the difficulties involved in making that judgement.*

2.3.4 Grouping water bodies

Grouping water bodies, provided this is done on a sound scientific basis, will also be important in ensuring the most cost effective approach to the pressures and impacts analyses. The ability to group bodies will depend on the characteristics of the river basin district and the type and extent of pressures on it.

2.3.5 Taking account of uncertainty

The first pressures and impacts analyses must be complete by the end of 2004. However, the environmental conditions required to meet most of the Directive's objectives will not have been firmly defined by this date. For example, the values for the boundaries between the ecological status classes for surface waters are not expected to be finally determined until after the end of the intercalibration exercise (WFD Annex V 1.4) and the start of the monitoring programmes in 2006 (Article 8). The environmental quality standards for the priority substances, which form part of the definition of good surface water chemical status, will not be finalised until the agreement of Article 16 daughter directives. Elements of the groundwater objectives also await clarification in the Article 17 daughter directive. The confidence and precision in the estimated environmental effects of different pressure types will also be very variable, depending to a great extent on the quality of national and local information and assessment expertise. This is because consideration of many of the pressures and impacts relevant under the Water_Framework_Directive has not previously been required by other Community water legislation.

Member States will need to complete the first analyses using appropriate estimates for pressures and impacts but they should be aware, and take account of, the uncertainties in the environmental conditions required to meet the Directives' objectives and the uncertainties in the estimated impacts.

The consequence of these uncertainties is that Member States' judgements on which bodies are at risk, and which are not, are likely to contain more errors in the first pressures and impacts report (the 'IMPRESS' report) than will be the case in subsequent planning cycles. It will be important for Member States to be aware of the uncertainties so that their monitoring programmes can be designed and targeted to provide the information needed to improve the confidence in the assessments. Where the assessment contains significant uncertainty, those water bodies should be categorised as at risk of failing to meet their objectives. Obvious failing of pressures is not an uncertainty.

2.3.6 Understanding the objectives

So far it has been noted that pressures to be included in the analysis are those that, alone or in combination, cause impacts which prevent objectives being achieved. To do this clearly requires some understanding of the objectives, and this is addressed in this Section.

To summarise, the review of the impact of human activities has to include all environmental objectives of Article 4 WFD, which are:

- Achievement of good ecological status and good surface water chemical status;

- Achievement of good ecological potential and good surface water chemical status for artificial water bodies;
- Achievement of good groundwater status (i.e. good groundwater chemical status and good groundwater quantitative status);

and, if they lead to more stringent objectives:

- Prevention of deterioration in status of surface waters and groundwater;
- Achievement of objectives and standards for Protected Areas;
- Reversal of any significant and sustained upward trends in pollutant concentrations in groundwater; and
- Cessation of discharges of Priority Hazardous Substances into surface waters;

and, for the second review in 2013 and any following:

- Achievement of good ecological potential and good surface water chemical status for heavily modified (HMWBs).

The WFD defines four types of objective; ecological status, ecological potential, chemical status and quantitative status, but these are not all applicable to all water bodies (see Table 2.3). Groundwaters clearly have different objectives; there is no concept of ecological status, the definition of chemical status is quite different to the definition for surface waters, and uniquely for groundwaters, there is the separate assessment of quantitative status. However, as outlined below for surface waters, quantitative information is required as part of the hydromorphological assessment. Ecological potential is only applicable to surface water bodies designated as artificial or heavily modified. Prior to such designation, which need not be completed until 2009, analysis of pressures and impacts will most usually assume the criterion for a natural water body (i.e. ecological status).

The nature of the objectives are considered separately for surface and groundwaters in the following Sections. A number of general points can be made that apply to all water bodies:

I. For each of the applicable objectives the target is, generally, to achieve "good status" by 2015. Answering the question of whether a water body is at risk of failing to achieve this objective therefore involves two determinations; initially the current condition of the body needs to be evaluated, followed by an assessment of whether it is likely to achieve its objectives by 2015. For surface waters, the period until 2015 provides an opportunity to identify pressures, introduce measures to achieve the objective, and to carry out monitoring to demonstrate that it has been achieved. But, it also means that some account must be taken of changes to the pressures that occur during this period. While this is also true for groundwaters, the long residence times of water within many aquifers means that the analysis of pressures and impacts must take account of present day pressures causing problems at a future date. This issue is addressed specifically within the groundwater Section below.
II. Additional objectives may be applicable if other community legislation designates the water body as falling in a protected area; this too is discussed further below.
III. Numerical limits have not yet been set to define the boundaries in each of the different elements of status, although these will eventually be set based on the Guidance of the Reference Conditions working group and the Intercalibration study (WFD CIS Guidance Documents No.'s 10 and 6 respectively). In the meantime expert judgement within the competent authority must be used to set

interim values for use in the first round of assessments. It is recommended that where possible the interim values should be to reasonable estimates of the final values. Adopting values that are too strict could lead to unnecessary monitoring and measures, while adopting values that are too lax will delay necessary actions. Where expert judgement is used it should be open and transparent.

IV. While this Guidance describes the process of pressure and impacts analysis against these objectives, it should be noted that the WFD also provides for circumstances where there may be exemptions or relaxation of the provisions (Article 4, parts 6 and 7). In outline, these refer to temporary deterioration in the status, and deterioration caused by new sustainable development, respectively. However, such circumstances should be identified as part of the pressures and impacts analysis, and not taken as an *a priori* rationale for by-passing the analysis.

Table 2.3 Objectives applicable to different water body types.

	River	Lake	Transitional water	Coastal water	Heavily modified or artificial	Groundwater
Ecological status	✓	✓	✓	✓	×	×
Ecological potential	×	×	×	×	✓	×
Surface water chemical status	✓	✓	✓	✓	✓	✓
Ground water chemical status	×	×	×	×	×	✓
Groundwater quantitative status	×	×	×	×	×	✓

Objectives for surface waters

Ecological status and ecological potential both contain three elements; these are biological, chemical and physical (or physico-chemical), and hydromorphological. The overall ecological status is determined by the lower of the biological and chemical components. Note that the objective for surface waters is not just that good status is achieved, but also that no deterioration of quality occurs. Thus, if ecological status of a water body is currently assessed as "high", it must not deteriorate to "good" in the future.

Biological elements

This is again sub-divided into three components; flora, benthic invertebrates, and fish fauna (this component is excluded in coastal waters). Together these are used to place the water body in one of five classes; high, good, moderate, poor and bad. The process by which this classification is achieved is addressed by the REFCOND (refer to WFD CIS Guidance Document No. 10) and Intercalibration working groups (refer to WFD CIS Guidance Document No. 6) of the CIS. Generally high is "undisturbed" or "nearly undisturbed", good indicates "slight disturbance", moderate indicates "moderate disturbance", poor indicates "major alterations", and bad indicates "severe alterations".

Once the process is defined, the analysis of monitored data will allow the classification of the water body, and may trigger the requirement to investigate why the water body fails to meet its objective. While this is probably achievable, the reverse is far more problematic, i.e. it is likely to be much more difficult to say if a change in chemical or hydromorphological status will cause a downgrading in biological status (for example, the link between nutrient status and the abundance of fish is generally not well understood). One exception to this is for a massive exceedence (i.e. greatly beyond the built in safety factors) of a limit for a priority substance which has a direct toxic effect on an indicator species used in the biological assessment.

Chemical and physico-chemical elements
Two components, general and specific pollutants, are recognised (see Table 2.4). While for specific pollutants, environmental quality standards can be set (the WFD provides guidance), numerical limits do not exist for the general components. As noted for the biological elements, the relationship between these general aspects of water quality and biological status is poorly understood.

Table 2.4 Components of the chemical and physico-chemical element of the ecological assessment

Component	Sub-components	Class	Definition
General	Thermal conditions Oxygen conditions Salinity Acidification status Nutrients status Transparency (lakes only)	High Good Moderate	Totally or nearly totally undisturbed. With levels established to ensure functioning of ecosystems to achieve biological elements. Conditions consistent with the achievement specified for biological elements.
Specific pollutants (priority substances and other substances identified as being discharged in significant quantities)	Synthetic	High Good Moderate	Below detection limits. Within EQS limits. Conditions consistent with the achievement specified for biological elements.
	Non-synthetic	High Good Moderate	Below normal background level. Within EQS limits. Conditions consistent with the achievement specified for biological elements.

Hydromorphological elements
The components used in this assessment vary between water body type, but the classification is as for the general chemical elements (i.e. high, good and moderate) with similar definitions of the classes (Table 2.4). The hydromorphological elements are not used in the determination of ecological status, but could be the cause of the failure to achieve good or high ecological status.

Implications for the analysis of pressures and impacts for surface waters
While it necessary for the analysis to consider effects of pressures on the biological elements, there will be uncertainties in the links between biology, chemistry and hydromorphology. Member States should take account of these uncertainties in undertaking the assessments. Since the classification of the chemical and hydromorphological elements is linked to the biological condition (see Table 2.4), but without critical values being defined. What will be required, in the short term at least, is a set of numerical values for the general chemical components that are

deemed satisfactory by expert judgement, in a particular region or eco-region, to indicate risk of failing to achieve good ecological status. This Guidance will not propose such values, but by assuming they exist can describe methods of analysis, and draw attention to existing examples of such classifications.

Heavily modified water bodies and the timetable
For water bodies designated as artificial or heavily modified, the principal objective is to achieve good ecological potential rather than good ecological status. Water bodies intended to be designated as heavily modified must be subject to two risk assessments: (1) an assessment of the risk of failing good ecological status because of physical alterations, and (2) an assessment of the risk of failing good ecological potential. However, there are serious practical difficulties in completing both these assessments for all potential heavily modified water bodies before the end of 2004. Note that only water bodies failing good ecological status because of substantial physical alterations can be considered for designation as heavily modified water bodies under Article 4.3. The first pressures and impacts analyses will therefore identify potential heavily modified water bodies.

Objectives for groundwaters.

For groundwaters the objectives are essentially:

1. To implement measures to prevent or limit the input of pollutants into groundwater and to prevent the deterioration of the status of the groundwater body (groundwater status consists of two parts; quantitative status and chemical status and the overall status of groundwater is taken to be the poorer of the two);
2. To protect, enhance and restore all bodies of groundwater, and ensure a balance between abstraction and recharge of groundwater, with the aim of achieving good groundwater status by 2015 in accordance with the provisions laid down in Annex V;
3. To reverse any significant and sustained upward trend in the concentration of any pollutant resulting from the impact of human activity in order to progressively reduce pollution of groundwater.

If a groundwater body currently has good status but it is thought that pressures may cause its status to be rendered poor by 2015, then the body is "at risk" and will require further characterisation. It should be noted that a body currently determined to have poor status will automatically be "at risk".

Article 17 of the WFD requires the Commission to propose a daughter directive on groundwater, which is expected to establish criteria for defining significant trends in pollutant concentrations, and addition criteria for defining good groundwater chemical status. The daughter directive will also clarify the meaning of the requirement to "prevent or limit the input of pollutants into groundwater" (1 above).

Objectives for protected areas.

In addition to those objectives in Table 2.3, it is required that objectives for protected areas established under Community legislation should also be met. For example, if a water body falls within a Nitrate Vulnerable Zone then the objectives of the Nitrates Directive (1991/676/EEC) must be met. In this instance, for groundwaters the

Nitrates Directive gives the criterion as < 50 mg/l NO_3, and for surface waters, the criteria are derived from the Drinking Water Directive (75/440/EEC), which gives the same mandatory upper limit value of 50 mg/l NO_3. Thus while the WFD introduces the new concept of good ecological status, it also incorporates the numerical limits of earlier legislation (Table 2.5).

Article 7of WFD requires Member States to establish drinking water protected areas for bodies of groundwater and surface water providing more than 10m^3 a day as an average or serving more than 50 persons, or bodies that are intended for that use in the future. The objective for these areas is to avoid deterioration in quality in order to reduce the level of purification treatment required.

Table 2.5 Existing community legislation designating protected areas.

Directive	Reason for protection of waters
2000/60/EC (Water Framework Directive)	Drinking water protected areas.
76/160/EEC (Bathing water Directive)	Bathing waters
78/659/EEC (Freshwater fish Directive)	Fresh waters needing protection in order to support fish life.
79/923/EEC (Shellfish waters Directive)	Shellfish waters
79/409/EEC (Birds Directive)	To protect birdlife
92/43/EEC (Habitats Directive)	Natural habitats of wild fauna and flora
91/271/EEC (Urban Waste Water Treatment Directive)	Nutrient sensitive areas
91/676/EEC (Nitrates Directive)	Prevent nitrate pollution

The first stage in undertaking this element of the assessment required by the WFD is straightforward since the only information required is whether or not the water body is in a protected area. If so, the required analysis will have been carried out and reported. If not, no action is required. Existing legislation that can define protected areas is listed in Table 2.5. It has already been noted that compiling a register of such protected areas is required by the WFD.

However, for some protected areas, notably those designated as Natura 2000 sites under the Habitats Directive, the requirement is to meet the water-related biological criteria of a particular habitat. This is clearly a more complex undertaking than comparing with threshold values, as illustrated above for the Nitrates Directive, but again existing reports under the terms of the Directives should provide a basis for the analysis required.

Recap of the objectives

The environmental conditions required to meet the objectives applicable to a water body depend on the water body type, and are derived from a number of sources. The objectives can be existing fixed numerical limits, or derived from the concept of "good status" that requires more explicit definition. For each particular pressure and impact analysis it will be necessary to have such numerical limits for general chemical elements (e.g. dissolved oxygen) although none is contained in the WFD. Such values will need to be determined through expert judgement within the competent authority. It is recommended that such judgement tries to anticipate the values that are likely to be adopted in the longer term.

2.3.7 Wetlands

Wetland ecosystems are ecologically and functionally part of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in CIS horizontal Guidance Documents on water bodies (WFD Guidance Document No. 2) and further considered in Guidance on wetlands, currently under development.

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal Guidance on wetlands currently under development.

2.4 Summary of the process and actions required

Ideally, a pressures and impacts assessment will be a four-step process;

1. describing the "driving forces", especially land use, urban development, industry, agriculture and other activities which lead to pressures, without regard to their actual impacts;
2. identifying pressures with possible impacts on the water body and on water uses, by considering the magnitude of the pressures and the susceptibility of the water body;
3. assessing the impacts resulting from the pressure; and,
4. evaluating the likelihood of failing to meet the objective.

In the first instance (i.e. for 2004) the list of pressures and the assessment of impacts on a water body, and possibly on up- or downstream situated water bodies, shall ensure the identification of all of the potentially important problems. Assessing the likely impacts arising from each of the pressures will produce a list that can be used to identify points where monitoring is necessary to better understand if the water body is at risk of failing to achieve good status. This list then becomes a basis for developing a programme of measures which might be undertaken in order to achieve good status.

For the first stage, (i.e. for 2004) a screening approach is likely to simplify the tasks, as it means focusing on the search for pressures on those areas and pressure types that are likely to prevent meeting the objectives. However, this is a substantial task for the first review of the impact of human activities, and Member States should aim to achieve the best estimate of significant pressures in the time available. To improve confidence, the estimates of the type and magnitude of pressures should be crosschecked, where possible, with monitoring data and with information on the key drivers for the pressures. For example, estimates of point source inputs of organic matter from urban wastewater treatment systems made using information on discharges could be crosschecked with information on population sizes and average per capita inputs to assess whether the majority of relevant discharges have been identified.

The identification of significant pressures could involve a combined approach of assessing monitoring data, model usage and expert judgement. These pressures and furthermore those water bodies at risk of failing the environmental objectives shall be identified and reported. This reporting process must be practicable for Member States, but also demonstrate transparency of Member States' decision-making processes (e.g. in exercising its experts' judgement).

3. General approach for the analysis of pressures and impacts

3.1 Introduction

The preceding Chapters have described the scope and purpose of the WFD, and resolved issues relating to the general requirements to undertake a pressures and impacts analysis. The remainder of the Guidance provides advice on how this can be implemented. This Chapter explains the general approaches that can be taken according to water body type and data availability. In doing so it aims to show where the process and data requirements are common to the various water bodies within a river basin.

The key stages of the general approach as laid down in the WFD are:

- Identifying driving forces and pressures;
- Identifying the significant pressures;
- Assessing the impacts; and,
- Evaluating the likelihood of failing to meet the objectives.

These are addressed in the following Sections (3.2 to 3.6), and visualised in Figure 3.1. To undertake the four key stages, three supporting elements must be considered (shown on the left of Figure 3.1). The description of a water body and its catchment area will underpin the pressures and impacts analysis, and there are many types of information that may be useful, e.g. climate, geology, soil and land use. During the process, monitoring data relevant to the water body may also be introduced, and how this is used will be discussed in the Section on assessing the impacts (Section 3.4). A comparison of monitoring data with driving forces may also help to screen where pressures are likely to cause a failure in meeting objectives. It is also necessary to understand the objectives against which the actual state will be compared (see Section 2.3.6).

There will be many instances in which these key stages need not be undertaken as a linear sequence. An example of such a case would be where monitored data from the water body, which define an impact, can be used to refine the identification of significant pressures. While it may be appropriate to adopt a different sequence for the analysis, it is required that all key stages are addressed.

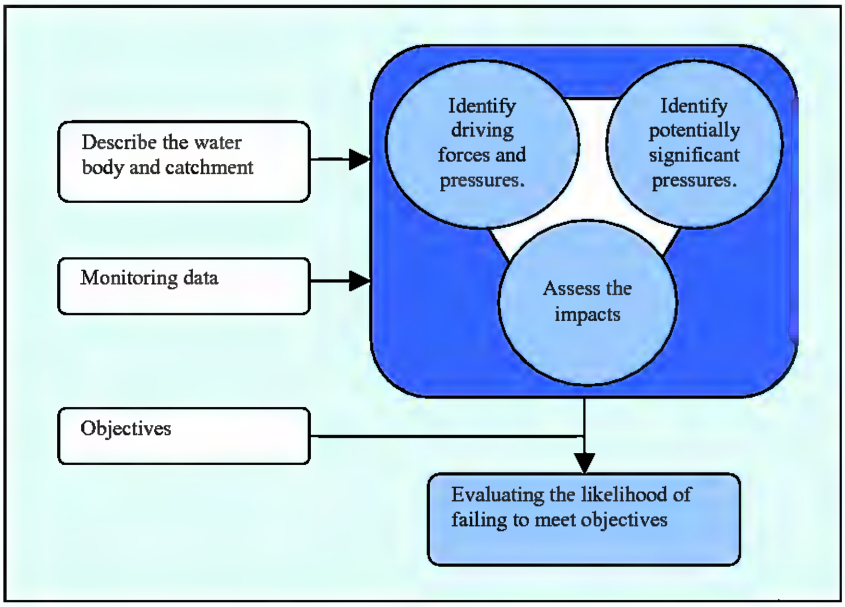

Figure 3.1 *Key components in the analysis of pressures and impacts. Those components on blue backgrounds on the right-hand side are the main components of the analysis, and are described in detail within this guidance, while those elements on white backgrounds on the left-hand side are supportive and are described only briefly within the guidance.*

In general this Guidance tries to apply similar considerations to surface and groundwaters. However, Section 3.9 considers issues that are particular to groundwaters, and Sections 3.11 and 3.12 provide reviews of the tasks required for the analysis for surface waters and groundwaters respectively. These may be regarded as checklists for the process with explanation, justification and rationale removed. Section 3.10 describes reporting requirements relating to the pressures and impacts analysis.

The subsequent Chapters provide more detailed information on tools (Chapter 4), data (Chapter 5), and illustrations based on case studies (Chapter 6).

3.1.1 Who needs to get involved in carrying out and using the pressures and impacts analysis

Assessing "who needs to get involved" requires addressing some of the following questions:

- Who can or will provide basic or additional input into the IMPRESS analysis?;
- Who will use the results of the pressures and inpacts analysis?; and,
- Who will be influenced by the follow-up of the results of the IMPRESS analysis?

Answers to these "Who" questions are likely to include a wide range of organisations, stakeholders, and individuals which will vary according to questions. For example, experts from Ministry of Environment or other ministries (land planning, nature protection units, GIS units, agriculture, etc.), experts from river basin agencies or regional authorities, managers in charge of developing river basin management plans, ministry heads of water departments, researchers and consultants, historians, the public and a wide range of stakeholders that have interest and/or developed expertise in specific fields (see Tables in Chapter 5) and are involved in water management and will, presumably, be involved in the creation of the RBMP.

Developing a stakeholder analysis with possible involvement of key stakeholders can be an appropriate step for finding answers to these questions (see "public participation" WFD CIS Guidance Document No. 8 Annex I). It also helps in identifying key steps in the analytical process when involvement or input from specific stakeholders is required (different "Who" for different steps).

Points 3.2 and 3.3 of this Guidance give a more detailed inventory of the relationships between certain driving forces and pressures allowing stakeholders of interest to be identified.

3.2 Identifying driving forces and pressures

In addition to a general description of the water body, it is essential to identify the driving forces that may be exerting pressures on the water body. A broad categorisation of driving forces is shown in Table 3.1. This is expanded into a more complete list of driving forces and pressures in Chapter 4, which can be used as a checklist to form an inventory of the relevant pressures. In using this checklist it may be helpful to note all pressures without concern for their significance.

Table 3.1 Broad categorisation by driving force of pressures to be considered (Note that this is expanded into a complete list of pressures in Table 4.1).

DIFFUSE SOURCE	urban drainage (including runoff) agriculture diffuse forestry other diffuse
POINT SOURCE	waste water industry mining contaminated land agriculture point waste management aquaculture
ACTIVITIES USING SPECIFIC SUBSTANCES	manufacture, use and emissions from all industrial/agricultural sectors
ABSTRACTION	reduction in flow
ARTIFICIAL RECHARGE	groundwater recharge
MORPHOLOGICAL (Refer also to WFD CIS Guidance Document No 4 on HMWB)	flow regulation river management transitional and coastal management other morphological
OTHER ANTHROPOGENIC	miscellaneous

Driving forces (DF) are sectors of activities that may produce a series of pressures, either as point and non-point sources. As screening data, DF are quantified by aggregated data, simple to obtain, for example: number of hectares of arable land, population density, etc., for a certain area. Comparing this DF data with appropriate aggregated monitoring information quickly allows assessment of the likelihood that the considered DF is related to environmental pressures. In that case, only the expected pressures should be investigated in greater details.

The screening procedure is not only a way to speed up data collection by focusing on those pressures that are reasonably expected. It provides an independent assessment of pressures and impact relationships, which is valuable especially if emission and abstraction registers are poorly populated.

Information describing driving forces and pressures will be required for both surface water and groundwater bodies, as, for example agricultural activity may exert a pressure on both surface water and groundwater bodies. Similarly, an activity may exert a pressure on a number of downstream water bodies. For these reasons it is sensible to collate the data on the basis of river basins, or river basin districts, and then to abstract from this the particular information relevant to any individual water body. Clearly the use of a GIS will facilitate this process. However, this Guidance does not address the management of this information since this is the remit of the Geographical Information Systems Working Group within the CIS (see WFD CIS Guidance Document No 9).

3.3 *Identifying significant pressures*

3.3.1 Introduction

The inventory of pressures is likely to contain many that have no, or little, impact on the water body. In the case of surface waters, the WFD recognises this by only requiring significant pressures to be identified, and within this Guidance significant is interpreted as meaning that the pressure contributes to an impact that may result in the failing of an objective. For groundwaters, the initial characterisation requires a general analysis of pressures, corresponding to that described in Section 3.2, but again set in the context of evaluating the risk of failing to meet objectives. Thus, although the processes are described separately and differently for surface and groundwaters, a similar general approach to the identification of pressures that require further investigation can be adopted.

This requires an understanding of the nature of the impact that may result from a pressure, and appropriate methods to monitor or assess the relationship between impact and pressure. Possible impacts are considered below using the major pressure headings from Table 3.1.

Pollution pressures from diffuse and point sources

A pollution pressure results from an activity that may directly cause deterioration in the status of a water body. In most cases, such a pressure relates to the addition, or release, of substances into the environment. This can be the discharge of a waste product, but may also be the side-effect or by-product of some other activity, such as the leaching of nutrients from agricultural land. A pollution pressure may also be caused by an action such as a change in land use, for example sediment fluxes are modified by urbanisation, forestry, and a change between winter and spring planting of crops. The most usual categorisation of pollution pressures is to distinguish between diffuse and point sources (see Tables 3.2 and 3.3). However, the distinction between point and diffuse sources is not always clear, and may again relate to spatial scale. For example, areas of contaminated land might be considered as either diffuse or point sources of pollution.

In case of diffuse pollution driving forces are usually not directly related to pressures, but pollution reaches water bodies on hydrologically driven pathways.

Table 3.2 Examples of diffuse source pressures and their impacts.

Activity or Driving force	Pathway causing Pressure	Possible change in state or impact
Agriculture	Nutrient loss from agriculture by • surface runoff • soil erosion • artificial drainage flow • leaching (*i.e.* interflow, spring water and groundwater) (includes excess fertilisers and manures and mineralization of residues)	Nutrients modify ecosystem
	Pesticide loss by pathways mentioned above	Toxicity, contamination of potable water supplies
	Sediment loss by soil, bank and riverbed erosion	Smothering of bed, alteration of invertebrate assemblage, loss of spawning grounds
Industry discharges to the atmosphere	Deposition of compounds of nitrogen and sulphur.	Acidification of surface and groundwater bodies. Eutrophication
Transportation	Pollutant spillages	Gross pollution of water bodies
	Use of salt as de-icer	Elevated chloride concentration
	Use of herbicides	
	Engine exhausts	Increase in acidifying chemicals in atmosphere and hence deposition

Table 3.3 Example point source pressures and their impacts.

Activity or Driving force	Pressure	Possible change in state or impact
Industrial (IPPC and non-IPPC)	Effluent disposal to surface and groundwaters	Toxic substances have direct effect, increased suspended solids, organic matter alters oxygen regime, nutrients modify ecosystem
Urban activity	Effluent disposal to surface and groundwaters	As above
Landfill	Chemical fluxes in leachate	As above
Animal burial pits (e.g. following epidemic)	Contaminated leachate	As above
Former land use	Contaminated land	Various
Thermal power generation	Return of cooling waters cause alteration to thermal regime	Elevated temperatures, reduced dissolved oxygen, changes in biogeochemical process rates
	Biocides in cooling water	Direct toxic effect on aquatic fauna.
Dredging	Sediment disposal	Smothering of bed, alteration of invertebrate assemblage
	Removal of substrate	Loss of habitat
Fish farming	Feeding, medication, escaping	Nutrients, diseases, veterinary products, artificial fish population, modified food web

Quantitative resource pressures

Quantitative status is only referred to specifically within the WFD for groundwater bodies, but quantitative pressures must be assessed for all water bodies. For surface waters these pressures are used to assess hydromorphological status. In all water bodies quantitative pressures are also important as they have an effect on dilution, residence time, and storage. Examples of quantitative pressures are contained in Table 3.4.

Table 3.4 Example quantitative pressures and their impacts.

Activity or Driving force	Pressure	Possible change in state or impact
Agriculture and land use change	Modified water use by vegetation. Land sealing	Altered recharge of groundwater body
Abstraction for irrigation, public & private supply	Reduction in flow or aquifer storage	Reduced dilution of chemical fluxes. Reduced storage. Modified flow and ecological regimes. Saline intrusion. Modified dependent terrestrial ecosystem.
Artificial recharge	Increased storage	Increased outflow. Contamination of groundwater.
Water transfer	Increased flow in receiving water	Modified thermal, flow and ecological regimes

Hydromorphological pressures

Hydromorphological pressures can have a direct impact on surface waters in addition to the impact on quantitative status. Examples are contained in Table 3.5.

Table 3.5 Example hydromorphological pressures and their impacts.

Activity or Driving force	Pressure	Possible change in state or impact
Dredging	Sediment disposal	Smothering of bed, alteration of invertebrate assemblage
	Removal of substrate	Loss of habitat
	Change in water level	Change in water table, loss of wetlands, loss of spawning areas.
Physical barriers (dams, weirs etc.)	Variation in flow characteristics (e.g. volume, velocity, depth) both up and downstream of barrier.	Altered flow regime and habitat.
Channel modification (e.g. straightening)	Variation in flow characteristics (e.g. volume, velocity, depth)	Altered flow regime and habitat.

Biological pressures

Biological pressures are those that can have a direct impact on living resources, either quantitatively or qualitatively.

Table 3.6 Example biological pressures and their impacts.

Activity or Driving force	Pressure	Possible change in state or impact
Fisheries	Fishing	Reduced fish fauna, especially on migratory and amphibiotic fish
	Fish stocking	Genetic contamination of wild populations
Introduction of alien species	Competition with indigenous species	Substitution of populations, destruction of habitats, food competition

3.3.2 Methods

The assessment of whether a pressure on a water body is significant must be based on a knowledge of the pressures within the catchment area, together with some form of conceptual understanding, of water flow, chemical transfers, and biological functioning of the water body within the catchment system. In other words there must be some knowledge that a pressure may cause an impact because of the way the catchment system functions. This understanding coupled to the list of all pressures and the particular characteristics of the catchment makes it possible to identify the significant pressures. However this approach often requires two stages. In the first one, correlation assessment can be carried out. It has the advantage of using monitored data and doesn't require complex hypotheses. When necessary and appropriate, strict causality assessment may then be required using, for instance, numerical modelling, that will simulate the impact of numerous pressures. However these tools are seldom reliable, since they are based on hypotheses on the functioning of the ecosystem. Some likelihood assessment and models are considered in the Section on assessing impacts.

An alternative is that the conceptual understanding is embodied in a set of simple rules that indicate directly if a pressure is significant. One approach of this type is to compare the magnitude of the pressure with a criterion, or threshold, relevant to the water body type. Such an approach cannot be valid using one set of thresholds across Europe since this fails to recognise the particular characteristics of the water body and its vulnerability to the pressure. This approach effectively combines the pressure identification with the impact analysis since, if any threshold is exceeded, the water body is assessed as likely to fail its objectives. While simple, these methods can be an effective method of encapsulating expert judgement, and be based on sound science. These methods are described in more detail and with examples in Section 4.3. It can be more effective if coupled to state monitoring, as suggested in the examples.

A successful pressures and impacts study will not be one that follows prescriptive guidance. It will be a study in which there is a proper understanding of the objectives, a good description of the water body and its catchment area (including monitoring data), and a knowledge of how the catchment-system functions (Figure 3.2). One should be aware of the relations between water bodies within a river basin district, e.g. relations concerning pollution of downstream lakes and coastal waters (eutrophication, sediment pollution, bioaccumulation) or upstream river continuity issues. In such cases pressures only causing impacts far outside the water body itself should be included in the analysis as well.

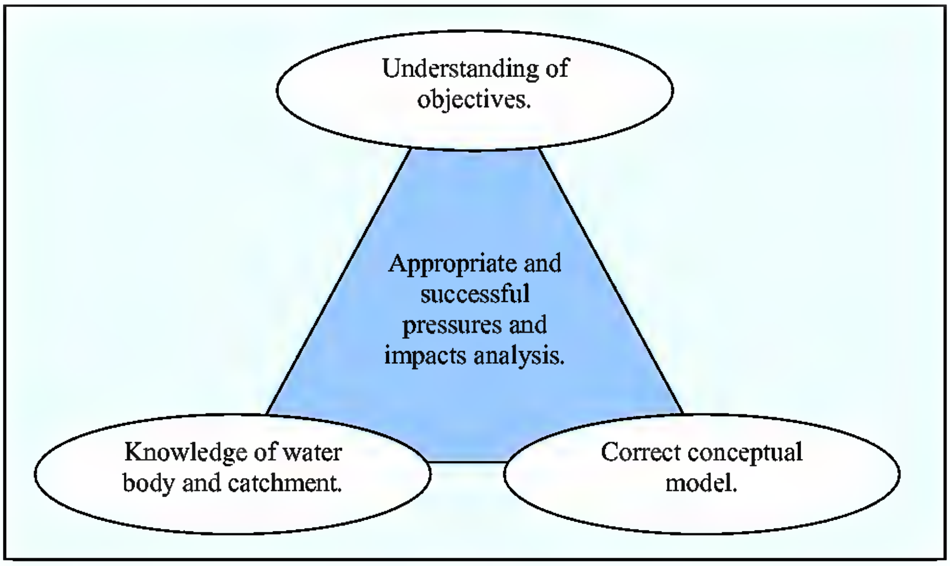

Figure 3.2 *The three prerequisites for an appropriate and successful pressures and impacts analysis.*

3.3.3 Variations in pressures and impacts

By definition the pressure of point sources cannot be spatially uniform, but it is probably also true that the pressures from diffuse sources, and quantitative pressures, are spatially variable within the catchment area of a water body.

As already mentioned, it is also the case that a specific pressure will not always cause a particular impact. Scale, both temporal and spatial, is one of the issues that that will determine the impact of a pressure. Other characteristics of the catchment area of the water body may also have an influence and of course the particular characteristic will relate to the nature of the pressure. For example, the impact of acid rain will be greater on the catchment located on granite geology with thin soils that have little acid neutralisation capacity, than on a catchment with calcareous (limestone or chalk) geology and soils with high acid neutralisation capacity. This effect is also recognised for other pressures, for example, the particular problems of nitrates within nitrate vulnerable zones, and the concept of groundwater vulnerability to pollution, which explores many characteristics associated with the groundwater body.

Recognising this variability leads to two conclusions. Firstly, it is easier to provide guidance on identifying all pressures (i.e. potential pressures) than on identifying significant pressures (i.e. those that may cause an impact likely to cause a failure of an objective). The latter will generally require a case-by-case assessment that considers the characteristics of the particular water body and its catchment area.

Secondly, in situations where the variability in the pressures and their impacts could result in different parts of a water body having different status, it may be appropriate to redefine the boundaries of the water bodies in order to develop a practical programme of measures for each one. Where this is done, redesignation must follow the 'rules' for water body delineation set out in Commission Guidance (d'Eugenio, 2002).

3.4 Assessing the impacts

Assessing the impacts on a water body requires some quantitative information to describe the state of the water body itself, and/or the pressures acting on it. The type of analysis will be dependent on what data are available. Regardless of the particular process to be adopted, and as with the identification of significant pressures described above, the assessment requires a conceptual understanding of what causes impacts. For example, at its simplest this can be, that if effluent is discharged to a river, lake, or coastal water, there is likely to be at least a local change in the water quality, which might be adequately estimated by a conservative mixing model. In many situations a simple approach of this type may be completely suitable for assessing the impact of a pressure. However, in real situations there will be a vast range of catchment types, water body types, interacting pressures, process conceptualisations, data requirements and possible impacts, and adopting such a simple model in all cases may be naïve.

It is also the case that what initially appears a simple assessment can have hidden complexities. For example, the impact on the quantitative status of a groundwater body from the pressure of an abstraction might be investigated by a simple water balance model in which the change in storage is the difference between the recharge rate and the sum of the outflow plus abstraction. One criterion for good quantitative status is that both the outflow and the abstraction can be sustained in the long term. The level at which the outflow must be maintained is such that good ecological status is achieved in any associated surface waters. Thus, what appears to be a simple water balance of a groundwater body actually requires knowledge and understanding of the ecological status and ecological flow requirements of an associated surface water body.

For the pressures and impacts analysis the conclusion cannot be that this analysis can only be achieved by constructing a detailed, process-based, numerical computer model of the entire linked surface and groundwater system. This type of approach may be possible, in some situations and examples are described in the Chapter on tools (Section 4). In practice, the information required to adopt the modelling approach will rarely be available at present, and probably not generally in the foreseeable future. By implication, the initial analysis will usually be based on less demanding methods for which the required data are available, e.g. pressure screening tools (see Section 4.2 and 4.3). Such analyses will be subject to refinement as further analysis is needed to determine risk, relevant data become available, and useable tools are developed.

Using observed data to assess impacts

In situations where data are available for the water body itself, it may be possible to make a direct assessment of the impact. The types of data that might be used are as diverse as the impacts themselves (see Table 3.7).

Data itself is not enough to assess a possible impact: a correct indicator of the expected impact must be constructed. Moreover, it must be kept in mind that most pressures do not create a clear-cut impact, but substantially change the probability of adverse conditions. This is, for example, the case of hydrological regime perturbations: the natural hydrological regime is not favourable to fish life 100% of the time. The impact assessment requires an estimate of which change in the probability of occurrence of favourable circumstances represents a threat to the ecosystem. Commonly available hydrologic indicators are not helpful. For example, a fish ladder is efficient if the discharge is between certain limits, during certain times and at a precise moment of the year, when migratory fish are present. This requires specific calculation, based on daily discharge statistics and expert opinion (i.e. which discharge values at what time).

Water quality statistics present specific difficulties as well. Comparison in state (i.e. is there an impact?) requires comparison between series of data. To carry out a meaningful comparison, the internal structure of the data must be considered in order to allow for normal variability. Removing the seasonal and the hydrologic component of annual data dramatically reduces the calculated variance and allows comparison to be made between data sets monitored at short time intervals. These sophisticated statistical techniques may not be familiar to European water experts.

Table 3.7 *Possible impacts or changes in state that can be identified from monitoring data.*

BIOLOGICAL QUALITY ELEMENTS	
macrophytes	composition abundance
phytoplankton	composition abundance biomass
planktonic blooms	frequency intensity
benthic invertebrates	composition abundance
fish	composition abundance age structure
eutrophication	chlorophyll concentration
HYDROMORPHOLOGICAL QUALITY ELEMENTS	
hydrological regime	quantity and dynamics of water flow connection to groundwater bodies residence time
tidal regime	freshwater flow direction of dominant currents wave exposure
river continuity	
morphology	depth and width variation quantity, structure and substrate of the bed structure of the riparian zone, lake shore or intertidal zone
CHEMICAL AND PHYSICO-CHEMICAL QUALITY ELEMENTS	
transparency	concentration of total suspended solids turbidity Secchi disc transparency (m)
thermal conditions	temperature (°C)
oxygenation conditions	concentration
conductivity	conductance converted to concentration of total dissolved solids
salinity	concentration
nutrient status	concentration of nitrogen and phosphorus, loads in view of sea protection

CHEMICAL AND PHYSICO-CHEMICAL QUALITY ELEMENTS cont'd	
acidification status	pH alkalinity acid neutralising capacity (ANC)
priority substances	concentration
other pollutants	concentration

Modelling approaches

Modelling approaches allow impacts to be estimated, and should therefore be considered subordinate, or complementary, to monitored data from the water body. For the river network itself numerous modelling techniques have been developed from the original work on dissolved oxygen and BOD published in 1925 by Streeter and Phelps. Simple models of this type are widely available but differ in the range of chemical determinands modelled, the processes represented, and their numerical frameworks. Such models, if applied appropriately, are generally good at representing the water quality along a river in which the inflows from tributaries and point sources are well known or can be estimated reliably. An example application is contained in the Chapter on tools.

A limitation of such river models is that they represent diffuse source inputs as discrete point sources, and to run the model these must be defined, either using data or a diffuse (catchment) model. The diffuse model itself can be simple, for example nutrient loss can be based on export coefficients that represent the activity within the catchment area. Such a model is in fact quantifying the pressures that arise from diffuse sources, rather than the impact on a water body, and is described in this sense in the Chapter on tools (Section 4). This Section also describes tools that can estimate the point source loads to receiving water bodies.

Simple and reliable modelling approaches are available for all of the water body types recognised by the WFD. These models can represent a single domain (i.e. river, lake, transitional water, coastal water, or groundwater), or encompass many, or all, domains within a single framework. These models can represent various aspects of the flow regime, hydromorphology, and hydrochemistry of the water body, either separately or within an integrated framework. Examples of water body models are contained in Section 4.4.

Of course the complexity of all of these different domain models can be increased greatly from the relatively simple implementations described above. However, it is certainly not the case that a simple model will always be less accurate than a complex model.

Models also exist to characterize stream habitat, and many of them can be used to predict habitat conditions at various flow conditions. The expected output of this type of model can vary from being purely descriptive of the stream physical template, to having some biological assessment applications. Physical descriptive models are developed to evaluate the degree of alteration of a given stream channel in relation to some reference conditions. Biologically-based models are developed to infer the standing stock of a given species from the physical characteristics of a given stream. Nevertheless, in between these two extremes there exists a range of habitat models addressed to obtain other outputs as habitat usage of species, habitat quality (e.g. ecological potential for key species) or duration period of habitat suitability.

Using observed data to refine the assessment of impacts and pressures

Monitoring data may indicate that there are no current impacts. This information itself reveals that none of the pressures identified in the initial screening process is significant, or that the time lag required for a pressure to give rise to an impact has not yet passed. The latter is likely to be of particular importance when assessing groundwater bodies in which pollutants travel very slowly. Such data could also be used within a model as a check that the inputs to, and processes within, the model correctly reproduce the observed data.

When the observed data for a water body does not indicate that a pressure is causing an impact, there may be a causal relationship with an impact on other water bodies within the same river basin district. For example, just meeting the environmental objectives in upstream areas will not leave sufficient room for compliance with the same objectives in downstream areas. This requires communication and co-operation between several parts of the river basin district.

In situations where observed data shows there is an impact, knowledge of the nature of the impact should be helpful in undertaking the pressures and impacts analysis. There are three cases to consider:

1. The traditional situation in which the impact is quantified in terms of a chemical, or physico-chemical, parameter exceeding a threshold. This should be relatively straightforward to address using a simple conceptual model of known activities, and associated pressures. The analysis is rather similar to the approaches described above except that the result is known and essentially serves to validate the various assumptions that have been made in the process;
2. The impact is quantified in terms of a biological effect, but the physico-chemical or hydromorphological pressure that is causing it is not understood. In this case the pressures and impacts analysis can be undertaken in the expectation that the cause will be identified, and can be addressed even though the link is not fully understood. This would probably be accompanied by further biological investigation into probable causes; and,
3. Between these two cases would be a biological effect where the probable physico-chemical or hydromorphological effect is at least partly understood. In this instance the analysis might proceed as in 1, but with less robust information to inform the validity of the process.

Understanding the last two of these situations depends greatly on the information to come from the REFCOND working group and the CIS Intercalibration Study (refer WFD CIS Guidance Document No.s 10 and 6, respectively).

In all three of these situations it is perhaps easier to understand how a pollution pressure causes a change in physico-chemical state which may cause an impact on biological status, and consider the links both forwards from pressure to impact, and backwards from impact to pressure. For hydromorphological pressures the links are less clear. The HMWB Guidance offers some assistance in relating biological indicators to different types of hydromorphological pressure (Table 3.8).

Table 3.8 Biological indicators of morphological pressures (adapted from WFD CIS Guidance Document No 4 on HMWB).

Indicator	Pressure
Benthic invertebrate fauna and fish	Hydropower generation impacts in freshwater systems
Long distance migrating fish species	Disruption in river continuity inducing lag in migratory process
Macrophytes	Flow from reservoirs Regulated lakes (change in flow regime)
Benthic invertebrates and macrophytes/phytobenthos	Linear physical alterations, such as flood works.

3.5 Selecting relevant pollutants on river basin level

3.5.1 Introduction

In Section 2.3.6 of this guidance, an introduction was given as regards the rather complex approach for dealing with chemical pollutants within the concept of the "good ecological status" and "good chemical status" of the WFD. Whereas the "priority substances" are clearly identified in Annex X, one key question in the context of the analysis of pressures and impacts is the selection of **specific pollutants** (other than priority substances) for which data on pressures must be collected in order to assess whether there are impacts for the different water bodies in a river basin (district).

The subsequent paragraphs provide a generic approach that may be used for the selection of a list of relevant specific pollutants for water bodies within a river basin (hereafter referred to as "relevant pollutants"). More specific examples are provided in Annex IV of this guidance. It is evident, that such an approach may need to be adapted and refined for the specific situation in each river basin.

At this point, it should be clarified that the requirements of the WFD are related to several objectives for individual pollutants in a water body. However, it will be necessary to follow a three (or more) stage approach in order take account of the different scales of pollution problems in the aquatic environment:

1. **European level**: the "priority substances" (Annex X) represent a list of European relevance. These substances must be considered in the pressure and impact analysis and the "risk of failing the objectives" must be investigated for all water bodies;
2. **River basin (district) level**: a list of those relevant pollutants may be established which are likely to have a "risk of failing the objectives" in a large number of water bodies within that basin and where downstream effects (including the marine environment) may need to be considered. Such substances may be called "relevant pollutants for a river basin";
3. **Sub-river basin and water body level**: pollutants which cause an impact through a significant regional and local pressure, i.e. in one or few water bodies, may need to be considered in addition to the above-mentioned levels.

Hence, the issue on how to select a list of relevant pollutants is related to significant pressures or impacts. In the ideal case, there may be a clear relationship between a pollutant released to the environment at a number of well-known sources and causing a visible or measurable effect on the biology of a water body. This supposes at least a good knowledge of the uses or the sources of the pollutant on the pressure side, the occurrence of the pollutant on the status side and/or the effects on the impact side. However, given the high number of pollutants, there is a considerable gap of information and data for many pollutants, in particular:

- In many cases and for a lot of pollutants, pressures cannot be related to status or impact due to lack of data;
- Only a limited number of pollutants are continuously or regularly monitored;
- The relation between pollutants and impact covers the whole field of ecotoxicology; for example should acute/chronic or combined effects be reported?

Nevertheless, the analysis of pressures and impacts is the first important step towards the identification of those pollutants which are being regulated further in the context of the WFD, i.e., *inter alia*, monitoring and programme of measures.

The starting point in the WFD is the list of 'main pollutants' mentioned in annex VIII. This list can be considered equivalent to the "universe of chemicals", hence no chemical substance or pollutant can be excluded from the beginning.

The challenge is to develop an iterative approach which narrows the endless list of substances down to a manageable number of pollutants in a pragmatic and targeted step-by-step way ("from coarse to fine"). The final aim is to target the measures and the monitoring to those substances first which most affect the aquatic environment on the different levels mentioned above. In that respect, the "environmental quality standard" (EQS) set in accordance to Annex V, 1.2.6 is the most important benchmark since it represents the boundary between "good" and "moderate" status. However, there are a number of other objectives which have to be assessed in the context of the pressure and impact analysis such as the "no deterioration", the reduction of pollution as regards the trend and the avoidance of failing good status downstream.

The list of relevant pollutants may change during the different steps in the implementation of the WFD mainly due to a refinement of the analysis and assessments.

First, a list of pollutants needs to be established for which the pressure and impact analysis is carried out (completed by 2004). Only if a defined "list of candidate substances" is established, it is possible to collect data on significant pressures and impacts. For this first analysis, it may not be possible to derive EQSs for all candidate substances. In this case, alternative screening benchmarks are acceptable.

Second, the selection of those pollutants is required for which additional information is gathered through "surveillance monitoring" (by 2006). These substances may be a sub-list of pollutants for which the level of certainty in the pressure and impact analysis may not be sufficient.

Finally, the list of relevant pollutants must be identified for which measures are prepared (by 2007/2008).

During this process, it is important that the evolution of the relevant pollutants remains transparent and clearly linked to the objectives and the requirements of the WFD.

As a final remark, it should be mentioned that the WFD Annex V states that priority and other substances should be identified which are "discharged" into the water body. Unfortunately, the term discharge is not defined in the WFD but only under the Dangerous Substances Directive (Council Directive 76/464/EEC) as, in general terms, the "introduction into waters". In contrast, the term "discharge" is often used for point sources from effluents. Given that Annex II clearly requires the identification of all (significant) pressures from point and diffuse sources and given that the WFD mostly talks about "discharges, emissions and losses", it is evident that a broad interpretation which covers all sources and pathways into the aquatic environment must be considered throughout the WFD.

3.5.2 Generic Approach

The generic approach is detailed in Table 3.9 and illustrated in Figure 3.3. Note that these steps are presented in a linear, way but in fact interact which each other in a more complex way (as implied by the arrows in Figure 3.3).

Table 3.9 The generic approach to the identification of specific pollutants.

1. Starting point
The indicative list of the main pollutants set out in Annex VIII of the Directive. Only those pollutants under points 1 to 9 need further consideration as potential specific pollutants. The pollutants under points 10, 11 and 12 of the Annex are the general physico-chemical quality elements and are considered separately.
2. Screening
A screening of all available information on pollution sources, impacts of pollutants and production and usage of pollutants in order to identify those pollutants that are being discharged into water bodies in the river basin district. In the screening step, two sub-steps can be distinguished: a) collation of information, and b) deriving a list of pollutants.
2a. Collation of information
Data: ➢ Source/sectoral analyses: production processes, usage, treatment, emissions,; ➢ Impacts: change of the occurrence of pollutants in the water body (water quality monitoring data, special surveys; ➢ Pollutants: intrinsic properties of the pollutants affecting their likely pathways into the water environment. Information from existing obligations and programmes: ➢ Priority substances; ➢ 76/464; ➢ UNEP POPs list; ➢ EPER; ➢ COMPPS; ➢ Results of 793/93, users lists, etc.
2b. Deriving a list of pollutants
Assessment of information collated under Step 2a will result in a working list of those pollutants identified as being discharged into water bodies. Most of these pollutants will be selected by the combination of a top-down and bottom-up approach (see further Chapter 6, WRc-example on 'Selection of relevant pollutants (river-basin substances) experiences from Council Directive 76/464). Pollutants for which there is adequate confidence that they are not being discharged into water bodies may be excluded from further consideration.
3. Test for relevance

Step 2 deals only with the identification of pollutants being discharged into water bodies. Step 3 selects from these those pollutants that are likely to cause, or to already be causing, harm to the environment. This will depend on the intrinsic properties of the pollutants, their fate and behaviour in the environment and the magnitude of their discharges. Selection should ideally be based on an assessment of the environmental significance of the concentrations (and trends in concentrations) estimated for the pollutants or their breakdown products in the water bodies. However, effects data or an assessment of the significance of predicted loads may also be relevant in the selection process.

Two sub-steps are envisaged in the test for relevance a) estimating concentrations in water bodies; and b) comparing the estimated concentrations with suitable 'benchmarks'.

3a. Obtaining data on concentrations in, and loads to surface water bodies

By monitoring: i.e. measured data;

By modelling: i.e. estimated data (obtained by models varying from simple calculations to complex models as mentioned in Chapter 4. Tools).

3h. Comparing concentrations with benchmarks

Pollutants identified under Step 2 may be excluded where their concentrations are estimated to be lower than the most relevant critical value such as estimated LC50, NOEC, PNEC, EQS or critical load.

EQSs: are supposed to reflect the good status condition of a water body. They must be derived from ecotoxicological data. Exceeding EQS-values would be considered harmful to the environment. Where possible, monitored or estimated concentrations should be compared with the appropriate EQS;
Critical loads: identified for some reduction programmes (e.g. North Sea Conference) require load reduction for some pollutants. Only critical (i.e. environmentally significant) loads need be considered in identifying the specific pollutants.
Remarks:

Existing FQSs do not always reflect the actual effects concentrations. In addition, EQSs have not been derived for all potential specific pollutants. The best estimate for the EQS should be used based on the most recent ecotoxicological data. Effects data from monitoring programmes should be taken into account where available.
Natural background concentrations may exceed EQSs for non-synthetic pollutants.
Potential accumulations in sediment or biota should be considered.
Detection limits must be disregarded, as they have no discriminating basis in the context of environmental significance.

4. Safety net

A safety net is needed to ensure that pollutants that may be environmentally significant are not incorrectly excluded from the list of specific pollutants during Step 3 above. For example, the safety net should consider:

- Whether a number of small (individually minor) pollution sources may be expected to have a significant combined effect;
- Trends that may indicate an increasing importance of a pollutant, even though the FQS is not currently exceeded;
- The presence of pollutants with similar modes of toxic action and hence potentially additive effects.

For some pollutants the assessments made in Steps 2 and 3 may not provide adequate confidence that a pollutant is either not being discharged or not presenting a significant environmental risk. For example, confidence may be low if the tests for environmental significance under Step 3 are based on EQSs that were derived using insufficient or inadequate ecotoxicological data. In such cases, the uncertainty should be taken into account in deciding whether to identify the pollutant as a specific pollutant, and appropriate further investigations should be made to improve confidence in the selection procedure.

5 Final outcome

The final outcome must be a list of specific pollutants relevant to a river basin district or to particular water bodies within a river basin district.

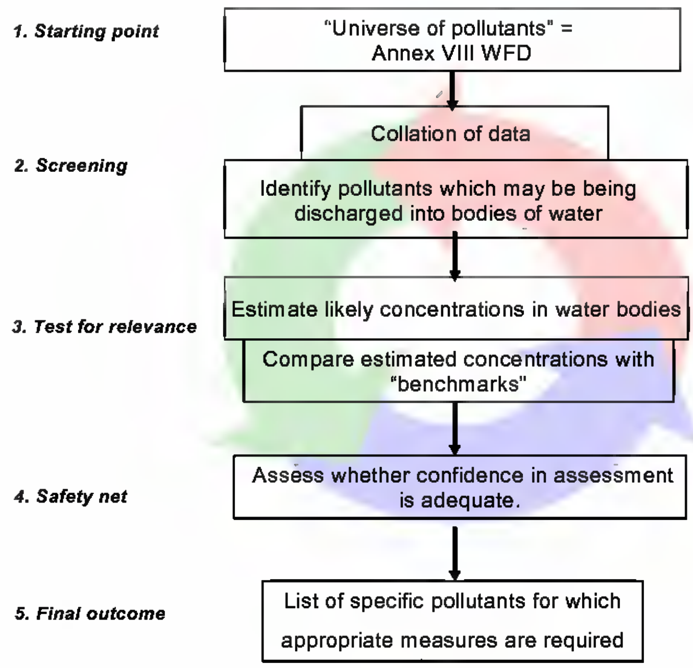

Figure 3.3 Steps needed to derive a selected list of pollutants

3.6 Evaluating the risk of failing the objectives

In theory, evaluating the risk of failing objectives should be a straightforward comparison of the state of the water body with threshold values that define the objective. This Guidance has proposed some general approaches to the estimation of the state of the water body, and most notably to elements relating to chemical and physical attributes. At present the threshold values are known for those elements of status that relate to protected areas and dangerous substances (Council Directive 76/464/EEC). For other aspects of status these values are not yet known e.g. the threshold values that define good chemical status.

In the period prior to the definition of these thresholds it will be necessary to use some interim thresholds defined by expert judgement, and applicable within eco-regions or smaller geographical units. For surface waters, and ground waters where the ecological status of an associated surface water body must be considered, a particular issue is to bridge the gap in understanding between biological status and physico-chemical conditions. This has been partially addressed by classification systems that exist within member states but at present they must be taken as indicative of conditions which could correspond to any particular biological status. While these classification systems differ in their detail, the classes are often labelled according to an overall assessment of status. For example, the best class may be *natural, background* or *excellent*. Below this there is usually a differentiation between a class that is slightly impacted, but has generally acceptable status (perhaps labelled *good*), and a class with greater impact that is seen as unacceptable (labelled *fair* or *moderate*). This distinction between good and moderate in the existing scheme could be used in the analysis prior to 2004 to separate bodies not at risk from those that are risk of failing WFD objectives.

It should be noted that such classification schemes generally only contain physico-chemical elements and therefore do not directly include morphological pressures. Thus while such a scheme might correctly reflect the state of the water body, it might hide the cause, e.g. a change in water chemistry could be caused by a change in flow regime.

To be usable these national schemes should meet one or more of the following requirements, which are related to the objectives of the WFD.

- The state data used for classification should
  for surface water (ecological status):
    - be closely related to the biological elements described in WFD Annex V;
    - be a relevant pollutant on river basin level;

  for surface water (chemical status):
    - be substances of WFD Annex X ;

  for groundwater:
    - describe the status (chemical and quantitative);
- The classification should have classes for
  - the background/natural state for surface waters;
  - a targeted state (e.g. "good status") below which the water body would be "at risk";
  - below classes which fail the target.
- The used quality objectives should be taken from EU-legislation and/or estimated Environmental Quality Standards in accordance with the procedure set out in WFD Annex V.

Examples of these schemes for impact assessment are presented in Annex IV, 4.

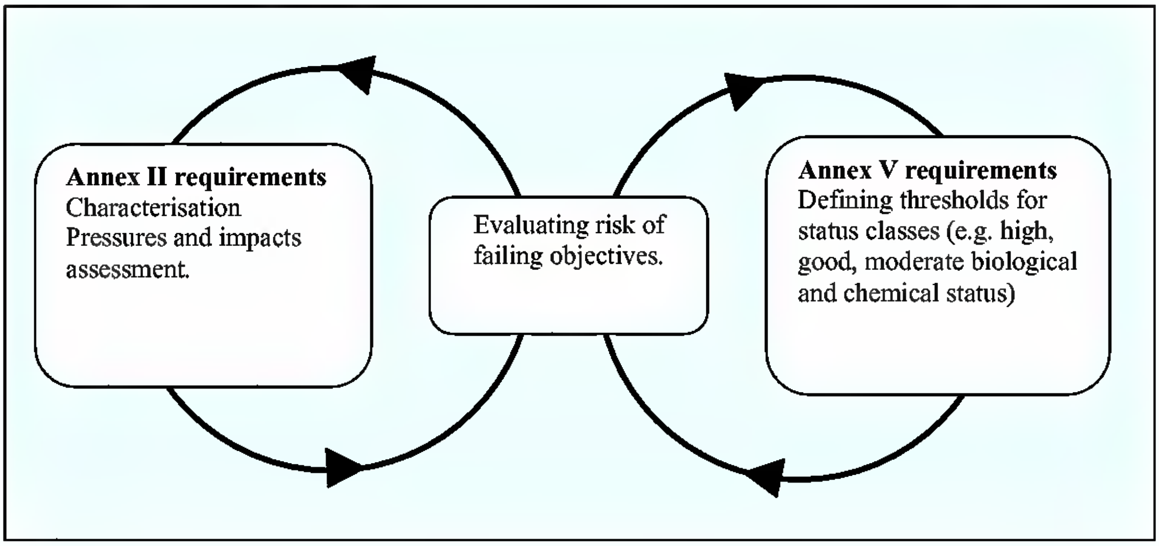

Figure 3.4 The iterative evaluation of the risk of failing objectives

For groundwater bodies, the use of monitoring data for evaluating the risk of failing to achieve good chemical status needs careful consideration, having regard to the specific environmental objective(s) that could lead to a failure to achieve good status.

It is clear that the process of evaluating the risk of failure is to some degree an iterative collaboration between those undertaking the pressures and impact analysis, and those defining thresholds for the as yet undefined elements of status (Figure 3.4).

3.7 Conceptual model approach

(Note: Model is used in this Chapter as a synonym for "understanding" and does not usually mean "numerical model"!).

A conceptual understanding of the flow system, chemical and, in the case of surface water, also the ecological variations within a water body and the interaction between groundwater and surface ecosystems is essential for characterisation.

A significant strength of the approach is that it allows a wide variety of data types (including, for example physical, biological and chemical data) to be integrated into a coherent understanding of the system. As new data are obtained they help to refine, or change, the model; conversely the model may indicate errors and inadequacies in the data.

A conceptual model is dynamic, evolving with time as new data are obtained and as the model is tested. Its development and refinement should adopt an iterative approach. The approach therefore fits in well with the various levels of knowledge required at different stages of the WFD. For example a basic model will be appropriate for initial characterisation; this (if appropriate) will be refined and improved during further characterisation, and again during the review cycle of the RBMP.

The construction of basic conceptual models of groundwater flow and chemical systems, and then of groundwater bodies must be undertaken early in the process of initial groundwater characterisation. This will include the delineation of the groundwater body boundaries and an initial understanding of the nature of the flow and geochemical system and interaction with surface water bodies and terrestrial ecosystems. It will also involve water quality information and an early assessment of pressures. In essence the model should describe the nature of the aquifer system, both in terms of quantity and quality, and the likely consequences of pressures. It is vital, even at the stage of groundwater body delineation that a coherent understanding of the body is reached. All data concerning the nature of the groundwater body collected during the characterisation process should be tested against the conceptual model, both to refine the model and to check for data errors.

3.8 Use of analogous water bodies

In situations with no observed data, one possible means to evaluate status is to use a similar *analogous* site for which data are available, and to assume that the assessment made from the observed data can be applied validly to both sites. To be most useful in the concept of the WFD pressures and impacts analysis the site for which data are available must have good status, since a failure may require more detailed study. The possibility of grouping water bodies for the purpose of pressure and impact analysis and monitoring is addressed in the *Horizontal Guidance on "Water Bodies"* (WFD Guidance Document No. 2), for example, bodies subject to similar pressures and with similar characteristics could be grouped.

A key concern in considering whether a site with data can be taken as analogous to the study site is the importance of proximity. Proximity in itself often indicates that many features of the two catchments will be similar (e.g. ecology, topography, geology, climate, channel characteristics and land use). However, since these characteristics can also change abruptly, proximity cannot be taken on its own as an indication of similarity. Indeed, it can be the case that a more distant catchment in fact provides a better analogy than a neighbouring catchment.

The assessment of similarity is probably best made on the basis of transparent and accountable expert judgement of the general characteristics. However, it is possible to formalise this process by having a numerical evaluation of each characteristic and combining these to give some form of objective measure of similarity. Such a scheme would require some local weighting of the characteristics included, and would therefore need to be developed regionally within Europe.

Major point source discharges, or other anthropogenic modifications that take effect at a particular location (e.g. abstraction, or impoundment) in either the study, or potential analogue catchment, will almost certainly mean that this approach cannot be used, since the particular characteristics of the point source impact will be highly dependent on the location within the catchment.

3.9 Specific considerations for the characterisation of groundwater bodies

The pressures on a groundwater body may have an impact, or measurable effect, upon it. The nature of the impact will depend on factors such as the type and severity of the pressure and the degree to which the groundwater body is susceptible to the pressure. Additionally, the geographical scale (e.g. distribution and density of pressures) and timescale effects (e.g. time lag for pollutants released at the land surface to reach the water table or migrate within an aquifer) are important considerations in assessing the risks to the groundwater body as a whole, and over time. The result of a pressure causing an impact may often be manifested in monitoring data after a considerable delay. For example, pesticide application to a wide area of land surface over a groundwater body may lead to increased concentrations of the pesticide in the groundwater many years after it was released. Monitoring information should be used, where available, to validate estimates of impacts obtained from pressure analyses.

Assessing impacts of pressures

Once the likely activities handling pollutants, abstracting from, or discharging to groundwater have been identified, the problem remains of translating this information into a measure of "pressure". There are two main issues to be addressed:

- For a given activity potentially producing a pollutant, how can the intensity and distribution of the activity be translated into a pressure?; and;
- How can the pressures assessed from different activities be combined to produce a measure of total pressure on the groundwater body?

Assessing the impact of pressures on groundwater bodies - initial characterisation

It is suggested that the concept of "potential impact" is introduced to describe the effects that a pressure is likely to have on a groundwater body, and that potential impact is used in the evaluation of whether the body is "at risk" of failing the Article 4 objectives. This concept recognises that, with the constraints on the characterisation process, it will not always be possible to accurately measure the impact by monitoring groundwater levels and quality. For pollution pressures the potential impact is judged by considering the pollution pressure (where this occurs at the ground surface) in combination with a measure of the vulnerability of the groundwater body to pollution (Figure 3.6). Thus, for example, a high pollution pressure caused by anthropogenic activities at the ground surface above an aquifer ***may*** have little impact on a groundwater body within the aquifer ***if*** that body is protected by a significant thickness of low permeability overburden. For quantitative pressures, such as abstraction, the potential impact of the pressure on the body is likely to involve reductions in water level and reduced outflows. These may be estimated using the conceptual model of the flow system, and undertaking a water balance for the groundwater body.

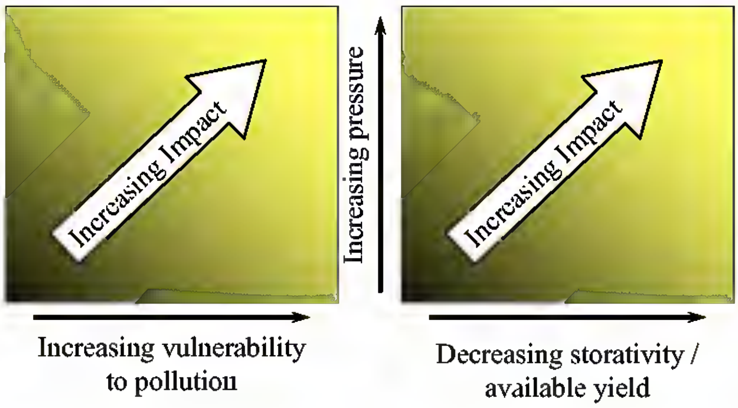

Figure 3.6 *Impact is a consequence of both the magnitude of the pollution or abstraction pressure and the susceptibility of the groundwater to that pressure.*

The assessment will typically be made following refinement of the conceptual model. Using that conceptual model, a decision must be made as to whether it is likely that the groundwater body is likely to fail to achieve good chemical status and, separately, good quantitative status. The overall assessment of whether the groundwater body is 'at risk' adopts the poorer predicted status, where they differ.

Assessments of the potential impacts resulting from pressures should be validated in areas where monitoring data are available. The data should also be used to ascertain any trends in water chemistry.

Assessing the impact of pressures on groundwater bodies - further characterisation

A "review of the impact of human activity" for 'at risk' groundwater bodies and those crossing Member State boundaries is explicitly required by WFD Annex II, Section 2.3.

The approach recommended follows that outlined for initial characterisation, but requires the collection of more detailed information and data, such as that detailed in Annex II, 2.3.

The wording of Annex II suggests that the information specified shall be included "where relevant". In this context "relevant" is taken to mean relevant to the assessment of risk of failure to meet Article 4 objectives. It does not give licence to avoid collecting information. The concept of "relevance" also involves questions of the level of detail that should be sought and, for human activities, the timescale over which the effects of the activity may be deemed relevant. In deciding these matters it is important to refer back to the purpose of further characterisation - to improve the assessment of risk and identify any measures to be required under Article 11. Thus, if the collection of more detailed information of a particular type is likely to improve the conceptual model sufficiently to enable the risk assessment to be enhanced, and if the extra detail can be obtained then the data should be collected.

3.10 Recommendations on reporting on the pressure and impact analysis

Article 15 (2) requires Member States to submit a summary report of the pressures and impact analyses to the Commission within three months of their completion (i.e. the first report must be submitted by March 2005).

This Section provides initial recommendations on the content and presentation of the summary report, in order to support consistency and comparability of results across the Community. All recommendations will be discussed within the EAF Reporting, which will provide the final Guidance on all reporting commitments.

The summary report has several aims:

- It fulfills Directive's reporting obligations with regard to the pressures and impacts analyses by Member States;
- If a common format is used this will provide a comparable basis for harmonization of water management on a river basin scale between countries within international RBDs;
- Provides a transparent overview of the analysis & results to communicate with government, stakeholders and the public.

The summary report sent to the Commission should be concise and give an overview of water bodies, their current state and the specific conditions of the RBD. The summary report will be complemented by reporting obligations within the respective RBDs. Suggested elements of the reporting required for 2005 are contained in Table 3.9.

Table 3.9 *Elements of reporting according to Article 15 "Review of the impact of human activity on the status of surface waters and on groundwater"*

- Short summary of relevant characteristics of the RBD (map of river basin district, protected areas, main water bodies, land use map);
- Summary of methods used (tools, thresholds, classifications) and assumptions made within the analyses;
- Cross reference to the other reporting obligations (article 5).

<u>Pressures and Impacts report:</u>
It is recommended that the following is produced as a report:

- Overall map of water bodies which are assessed to be at risk of failing their environmental objectives;
- Summary map for each general pressure type identified in Annex II identifying where (in which water bodies) that pressure type is identified as one of the main causes of the risk of failing to achieve the environmental objectives (i.e. for which the pressure is a significant pressure);
- The summary map should also include an indication of the variation in the level of uncertainty achieved in the pressure analysis;
- These maps may be presented in GIS format. This will be discussed with the GIS working group.

As an alternative the following could be produced:

- Overall map of water bodies which are assessed to be at risk of failing their environmental objectives;
- Supplementary table showing the main sources of pressures (e.g. substances);
- Summary table on number or area /percentage of water bodies which are at risk of failing their environmental objectives;
- Summary of major issues/pressures in the river basin district.

Regardless of the reporting format, the summary report should also include information on:

- applied methods, tools, thresholds, environmental quality objectives, classification schemes etc. used within the analyses;
- the amount of (un)certainty of analysis and results. The detailed RBD report may contain further information on the relative contribution of monitoring data, models and expert judgement within each analysis.

Further, more detailed information should be available on demand for public and stakeholder consultation. It is expected that this information may include:

- An overview of the available data on actual status of water bodies (chemical, ecological status) related to environmental objectives (a list of water bodies which are presently failing their environmental objectives);
- A list of the significant pressures in the district, subdivided according to Annex II, 1.4;
- A description of impacts and their connection to pressures;
- Delineation of the results of the pressure and impact analysis with maps:
    - overview map with river basin districts, locality and boundaries of water bodies;
    - maps of significant pressures in the river basin district;
    - maps of water bodies which are assessed to be at risk of failing the objectives in 2015.

The way this information is stored and made available will of course depend on nationally used data and reporting facilities.

Further reporting requirements may arise from the process of developing the RBMPs according to Article 13, WFD.

3.11 Review for surface water

For surface waters the WFD contains many specific requirements for the pressures and impacts analysis, while certain other aspects require interpretation and guidance. Thus while some particular substances and activities are identified, it is left open as to what constitutes a *significant* pressure. By taking this to mean any pressure that may contribute to the failure to achieve an objective, it is clear that understanding the objectives that are applicable to a water body is the foundation for the pressures and impacts analysis. Since at the outset of the analysis it is not known if an activity can contribute to such a failure, some knowledge is required of all activities within the catchment area. The analysis will then help to identify those that are significant, and must be based on some form of conceptual understanding, or model, of how the activity creates a pressure which causes an impact. The DPSIR framework provides a useful structure for this process.

The nature of the conceptual understanding coupled with knowledge of the water body's characteristics, will determine the type of pressures and impacts analysis that can be done. In practice a range of analyses will be used ranging from the simple to the complex. In some instances the simple methods may provide the only available option, but they may also be used as screening tools to decide whether more complex methods are necessary, or as the first stage in a recursive process.

These major elements can be broken down into list of key tasks and this is presented as a summary checklist as in the text box opposite.

Summary of key tasks for surface water

Data collation for river basin (prerequisite to the pressures and impacts analysis)::

- Access or establish database and data management systems on activities within the river basin district, and existing monitoring data.

Basic information specific to water body:

- Abstract information on driving forces in the catchment area of the water body;
- Identify pressures caused by the driving forces taking particular regard to those pressures listed under Annex II 1.4;
- Abstract data specific to the water body, including quantitative, hydromorphological, physical, chemical and biological data;
- Identify dependent water bodies and water bodies on which the water body under consideration is dependent as well as their basins;
- If relevant, ensure links with data managers of upstream and downstream water bodies, including foreign organisations.

Additional existing information and analyses:

- Review existing analyses of water monitoring, status, management plans etc.;
- Information collected under existing European Community legislation (use register of protected areas, Article 6) and national legislation;
- Review whether available methods are capable of producing the required assessments.

Objectives (Article 4)::

- Determine objectives pertinent to water body.
- Assess the existing monitoring data (biological, physico-chemical and hydromorphological), against the environmental objectives, or assumed equivalent objectives;
- Consider if analogous catchment approach helpful.

Pressures and impacts analysis, to be complete by 2004::

- Develop appropriate conceptual understanding considering characteristic of water body, catchment area, activities, driving forces, pressures, and objectives;
- Select appropriate tools based on conceptual understanding and data availability;
- Assess vulnerability of water body and dependent water bodies to impact from the identified pressures, to assess whether the water body is at risk of failing to achieve objectives;
- Explore the variability of pressures and impacts within the catchment of the water body – variability may indicate that it would be helpful to subdivide the water body for the purpose of developing a practical programme of measures;
- Ensure variability is not caused by uncertainty in source data or methods;
- Take forward the analysis by exploring changes and trends in activities and pressure anticipated in the period to 2015 and beyond;
- If failure is likely, review exemptions that may be applicable (provisional identification as heavily modified Article 4.3, temporary deterioration Article 4.6).;
- Review all steps above as (i) more, or better, data become available, (ii) new assessment tools become available, and (iii) as experience and expertise develop.

Outputs:

- Report on pressures and impacts analysis within 3 months of completion (Article 15, Chapter 3.10).;
- First list of water bodies "at risk";
- Use the results of the analysis to inform development of monitoring programme (Article 8) and programme of measures (Article 11).

3.12 Review for groundwater

A summary checklist of key tasks for the characterisation of groundwater bodies appears in the following text box.

Summary of key tasks for groundwater

Initial characterisation.

Using existing data:

- Collate data on pressures on the groundwater body, taking particular regard to those pressures listed under Annex II, 2, 2.1;
- Collate information on impacts on the groundwater, taking particular regard to those pressures listed under Annex II, 2, 2.1, and having special regard to the natural condition;
- Review existing groundwater monitoring data (chemical and water level), and data on dependent surface waters and ecosystems, having regard to the known pressures and impacts on the groundwater body, and the environmental objectives that are relevant to the body (Art. 4).;
- The development of a conceptual model of the groundwater flow, which also incorporates flow to/from associated surface waters, and a model for the chemical system are recommended as the basis for understanding and documenting the groundwater body, and to aid decision making;
- Assess vulnerability of groundwater to pollution from the recorded pollution pressures, to assess whether the groundwater body is likely to be at risk of failing to achieve good chemical status;
- Assess the water balance of the groundwater body, having regard to the recorded quantitative pressures, to assess whether the groundwater body is likely to be at risk of failing to achieve good quantitative status;
- Consider possible relationships between the groundwater body and connected wetlands;
- Consider both chemical and quantitative status to decide whether the groundwater body is likely to be at risk of failing to achieve good status, including an assessment of time-lag of pollutants in aquifers;
- A review of the delineation of the groundwater body may be undertaken if the data on pressures and impacts indicates that it may be helpful to subdivide bodies for the purpose of developing a practical programme of measures. However, any subdivision should conform to the 'rules' on groundwater body definition contained within Commission guidance.

Where there are no monitoring data for a groundwater body, the likely presence or absence of pressures and impacts should be considered when making a decision of the likely status of the groundwater body. Where it is clear from monitoring data that the groundwater body is 'at risk', or where there is inadequate data to make a decision with reasonable confidence that a groundwater body is 'at risk', the process should continue to Further Characterisation.

Further characterisation.

The key stages replicate Initial characterisation but relies on additional data and more sophisticated analysis techniques.

4. Tools to assist the analysis of pressures and impacts

4.1 Introduction and Overview

This Chapter focuses on the tools needed to carry out the General Approach as outlined in Chapter 3 and mentions some of those tools already available. At present there is no single tool capable of performing a complete pressure and impacts analysis for all types of water body, and it is very unlikely that such a tool will eventually exist. Therefore, this Guidance describes specific tools that consider one particular component of the process or environment (e.g. pressure assessment, surface water, groundwater, biology). The results from more than one tool may have to be integrated to undertake a complete pressure and impact analysis of a water body.

Before using any tool you must be sure that it is fit for the purpose for which you want to use it. You should have a clear objective defined, i.e. what questions you want to answer, and should select a tool that is capable of simulating the pressure and impact being considered and of providing the required results. You should be aware of the capabilities and limitations of each tool. The Guidance gives hints for those decisions.

In each Section and the Annex IV one or more example tool or model is described, but it is necessary to stress that they are just that – *examples not* IMPRESS *recommended or endorsed tools*. Most of the tools described are currently used within member states for functions similar, or possibly identical, to those required by the WFD, and in general such usage was mandatory for a tool to be included. Many more tools exist, and no doubt will become available in the future.

To be included in this Guidance the tool must to some degree be formalised into a set of rules or procedures. However, these will have been based on some form of expert judgement, perhaps in the form of, for example, a consensus widely held amongst practitioners, the current state of scientific knowledge, or an individual's experience and expertise. It would be wrong, therefore, to think that the tools described here are necessarily better than the expert judgement of the individual undertaking the pressure and impacts analysis. The value of local knowledge and experience should not be underestimated or dismissed in favour of a more formal process imported from elsewhere. Those undertaking the analyses should consider involving stakeholders since they are likely to introduce complementary knowledge and experience.

The toolbox considers a pressure checklist (Section 4.2) and screening approaches (Section 4.3). The pressure checklist contains an uncompleted list of pressures that should be considered as part of the pressures and impacts assessment. The use of screening techniques is understood to be most helpful in the short-term implementation of the Directive. The corresponding Section focuses on examples of how to use certain techniques with the aim to simplify the approach of the analysis.

The general approach is based on a logical succession of key stages, which realisation requires full availability of data and tools. In contrast, Section 4.4 also considers the current state, where a great deal of these required means is not available, or just not identified. Hence, it focuses on the identification of the tools that are required to respond to specific questions. This identification is carried out by analysing the relationships between pressures and impacts as well as those between state and impacts, as regards the objectives of the Directive.

In Section 4.4 the need for tools is compared with the existence. This is clustered into three categories:

1. The fully available tools, that have been to some degree formalised into a set of rules or procedures. These tools are, when possible, exemplified through their actual application that includes the conditions under which they can be applied. In this case, full description is presented in Annex IV;
2. Tools still being at a laboratory or pilot stage. This category includes defined methods which have not yet been implemented into an operational system. They require further development and engineering to be operational. However some tools can be replaced by some form of expert judgement;
3. The non existing tools. In this case, the need for development, possibly including research is indicated to pinpoint the possible gaps in application.

The Annex V contains four Sections that relate to types of tool identified within the General Approach. These types are:

- Pressure screening and assessment;
- Quantification of pollution pressures;
- Tools to combine pressures with impact assessment - Water body models; and
- Impact assessment.

4.2 Pressure Checklist

The pressure checklist contains an uncompleted list of pressures that should be considered as part of the WFD pressures and impacts assessment. The list can be considered as a reminder of the driving forces and the pressures that should be considered and therefore represents a precursor to the actual pressures and impacts analysis. The driving forces and pressures within this table are listed mixed and independent from whether paths, or sources of substance entries etc. are mentioned.

The pressure checklist is presented in two stages. First, in Table 4.1 the pressures have been grouped into four main classes of driving forces that may impact the different water body categories and prevent them from meeting the objectives. A tentative indication of these likely-to-be relationships is reported in the Table 4.1. This table is an entry to the following uncompleted list of pressures in Table 4.2, as the numbers in the first column of Table 4.1 refer to the corresponding lines in Table 4.2. Please note that Table 4.2 mirrors the structure of Table 3.1.

Table 4.1 Pressures to be considered. See Table 4.2 for more details.

		Water Body Category				**OBJECTIVES**				
n°	**DRIVING FORCES**	Rivers	Lakes	Coastal/Transitional	Groundwater	WFD (biota)	Tap water, NO3	Bathing, recreation	Habitats, Birds	Shell/fish farming
10	**Pollution**									
11	Household	x	x	x	x	x	x	x		
12	Industry (operating, historical)	x	x	x	x	x	x			
13	Agriculture	x	x	x	x	x	x	x	x	
14	Aquiculture /fish farming	x		x		x				
15	Forestry	x	x	x	x					
16	Impervious areas	x	x	x		x		x		
17	Mines, quarries	x			x	x				
18	Dump, storage sites	x		x	x	x			x	
19	Transports	x		x					x	
20	**Alteration of hydrologic regime**									
21	Abstraction (agri, industry, household)	x	x		x	x	x			x
22	Flow regulation works	x		x		x			x	
23	Hydropower works	x		x		x			x	
24	Fish farming	x				x				
25	Cooling	x								x
26	Flow enhancement (transfers)	x			x	x			x	
30	**Morphology (changes in)**									
31	Agricultural activities	x	x	x		x			x	x
32	Urban settlements	x	x	x		x	x		x	
33	Industrial areas	x	x	x		x			x	
34	Flood protection	x		x		x				
35	Operation, maintenance	x		x		x				
36	Navigation	x		x					x	
40	**Biology**									
41	Fishing/angling	x	x	x		x				
42	Fish/shellfish farming	x	x	x		x				x
43	Emptying ponds	x	x						x	x

Table 4.2 Uncompleted list of Pressures to be considered

n°	SOURCE	Source within the source type
10	DIFFUSE SOURCE	
12	urban drainage (including runoff)	industrial/commercial estates
11		urban areas (including sewer networks)
16		airports
19		trunk roads
19		railway tracks and facilities
19		harbours
13	agriculture diffuse	arable, improved grassland, mixed farming
13		crops with intensive nutrient or pesticide usage or long bare soil periods (e.g. corn, potato, sugar beets, vine, hops, fruits, vegetables)
13		over grazing – leading to erosion
13		horticulture, including greenhouses
13		application of agricultural waste to land
15	forestry	peat mining
15		planting/ground preparation
15		felling
15		pesticide applications
15		fertilizer applications

n°	SOURCE	Source within the source type
22		drainage
19		oil pollution
11	other diffuse	sewage sludge recycling to land
		atmospheric deposition
19		dredge spoil disposal into surface waters
19		shipping/navigation
	POINT SOURCE	
11	waste water	municipal waste water primarily domestic
11		municipal waste water with a major industrial component
11		storm water and emergency overflows
11		private waste water primarily domestic
11		private waste water with a major industrial component
19		harbours
12	industry	gas/petrol
12		chemicals (organic and inorganic)
12		pulp, paper & boards
12		woollens/textiles
12		iron and steel
12		food processing
12		brewing/distilling
12		electronics and other chlorinated solvent users
12		wood yards/timber treatment
12		construction
25		power generation
12		leather tanning
19		Shipyards
12		other manufacturing processes
17	mining	active deep mine
17		active open cast coal site/quarry
17		gas and oil exploration and production
15		peat extraction
17		abandoned coal (and other) mines
17		abandoned coal (and other) mine spoil heaps (bings)
17		tailings dams
18	contaminated land	old landfill sites
18		urban industrial site (organic and inorganic)
18		rural sites
18		military sites
13	agriculture point	slurry
13		silage and other feeds
13		sheep dip use and disposal
13		manure depots
12		farm chemicals
19		agricultural fuel oils
19		agricultural industries
18	waste management	operating landfill site
18		operating waste transfer stations, scrap yards etc.

4.3 Screening approach within the general approach

The objective of the screening approach is to point out with simple assessments those water bodies that are clearly "at risk" or "not at risk" of failing to meet the objectives in 2015. This may happen either if the current state is good enough *or* too bad, *and* if there is no expected change in pressures. Compared to the general approach, the screening approach may be carried out in any order (assess state, assess lack or certainty of impact), using driving force assessment as substitute of pressures. Consequently, the screening approach preferably stands on existing data, not on modelling; otherwise the required transparency of the approach would not be met.

Three examples of screening techniques should be mentioned for the following cases:

1. If only pressure data are available, their screening can be used as hint of a risk of failing objective;
2. If driving forces are correctly assessed and computed on small areas, and can be used to stratify observation data;
3. If only observation data (state) is available. In this case, a pressure analysis supposed to be applied where unwanted state is observed

Examples for Case 1: In case state data are not sufficient enough to assess actual impact, techniques using only pressure data must be used. The LAWA pressure screening procedure was developed for the purpose of compiling the significant pressures, indicating which water bodies might be at risk and which elements of status (biological, substances) are to be considered in the monitoring programme. In some cases, data that have already been compiled on the basis of other directives (e.g. urban wastewater directive) can be used. This procedure is a useful check-list of what is likely to have an impact.

A second part of this LAWA screening procedure is mentioned in the Annex dealing with the assessment of impacts.

Table 4.3 Example criteria for significant pressures: German LAWA Pressure screening tool

Pressures: point sources	Criteria
Public sewage-treatment plants >2000 PE (derived from Urban Wastewater Treatment Directive)	- Annual volume of water discharge; - Population (P) and population equivalents (PE); - Substance loads according to Annex I of the German Wastewater Directive; - Annual loads of priority substances, substances of the quality objective directive, and river basin-specific substances, insofar as these substances are limited by water directives.
Industrial direct discharge	- Statement of systems according to IPPC Directive = pollutants according to EPER; - Annual loads of plants with obligation to report according to IPPC Directive: consideration of the particular size threshold for the annual load of 26 substances (cf. Table 1: Size thresholds; EPER); - Annual loads of priority substances, substances of the quality objective directive, and river basin-specific substances, insofar as these substances are limited by water directives; - Food industry facilities >4000 EP.
Storm water / combined wastewater discharges	- Discharge of wastewater from an urban area >10 km²; - Urban areas can be estimated e.g. basing on CORINE-landcover, multiplied with discharge coefficients.
Discharges with heat load	Discharges with heat load > 10 MW.
Salt discharges	Discharges > 1 kg/s chloride.
Pressures: diffuse sources	**Criteria**
Diffuse sources in general are surveyed while the inventory taking for groundwaters. Normally these data can be used also for the description of surface water bodies (this does not apply to erosion from surfaces with a gradient > 2%. If no results from description of groundwaters are available, the following values can be used for an estimation of diffuse pressures:	
	- Urban land > 15 % - Agriculture = 40 % - Sugar beets, potatoes and corn = 20%of agricultural land - Special crop land (vineyards, fruits, vegetables,..) = 5 % of agricultural land - Contaminated land = Individual case
Water abstraction	**Criteria**
	Abstraction without recirculation > 50 l/s
Water flow regulation	**Criteria**
Anthropogenic barriers	Parameter "anthropogenic barriers" (Stream habitat survey): ≥ 6
Backwater	Parameter "backwater" (Stream habitat survey): = 7
	Diversion stretches > x km
Morphological alterations	**Criteria**
Morphological alterations	Stream habitat survey and comparable data

The OECD-Vollenweider approach of lake classification was developed to assess the probability that a lake reaches a certain trophic state as a result of nutrient (principally Phosphorus) inputs. It can be used as screening tool, especially when the actual state can be compared with a possible natural one. The procedure is not longer described in this guideline, as it can be found in literature and national classification systems for lakes.

Example for Case 2: The EuroWaternet (EEA, see Chapter 6 and Annex V) uses the driving forces to stratify the pool of river monitoring stations. The representative observation data set obtained shows clear-cut differences in water quality according to the likelihood of pressures resulting from the presence of driving forces on catchments. Provided the basis for stratification is constructed with small elementary areas (e.g., in France, average size is 90 km^2), they constitute a proxy of the statistical population of water bodies catchments.

The representative observation data set can be used to assess time trends (for nitrate, ammonium, etc.). The use of simple filtering techniques allows to remove the interannual changes in river discharge, thus providing a statistical estimate of the trend under the "business as usual" scenario.

This approach uses only monitored data and simple driving force data, namely CORINE *land cover* and population census.

Example for Case 3: In case only monitoring data are available, the water quality classification results are usable as screening tools. Users will need to take account the limitations of these schemes in relation to the scope of the Directive's objectives. Requirements are listed in Chapter 3.5. Examples are included in the Annex to Chapter 4.

One Example – the German LAWA impact assessment tool - proposes to use thresholds for summaries of classification results for a water body as screening tools. Another example - the water quality accounts (WQA) technique (see Chapter 6) - may help to identify which kind of pressure is likely to be involved. The WQA processes quality indexes from the measured concentrations, thus making different water quality issues comparable, if the used classifications are comparable. The issues which determine the overall state of the water body can be pinpointed by comparing the water quality issues. Even though WQA and EuroWaternet start with the same data (from monitoring points), they yield complementary assessments of river quality issues that provide a powerful screening of water bodies causing problems.

The HMWB Guidance offers some tools to identify hydromorphological pressures and their impacts (see WFD CIS Guidance Document No. 4 on Heavily modified Water Bodies / HMWB). Chapter 3.4 and the Annex to Chapter 4 summarise the knowledge about main uses (driving forces), connected physical alterations and impacts.

4.4 Basic Considerations about Use of Numerical Models

Mathematical models of ecological, hydrogeological and geochemical systems may be used to simulate the movement of water, and the fate and transport of pollutants within water bodies. Models take a variety of forms and the question(s) that need to be answered (e.g. 'what is the likely chemical status of a groundwater body?'), the data availability and the time and funds available are all relevant considerations in deciding what complexity of model is used. In general the more complex the model, the greater the data requirements and the greater the time and costs needed to complete it. As a consequence, the accuracy of a robust numerical model may be greater than that which can be achieved using a simpler model. However, in the context of water body characterisation under the WFD there are many questions that may be answered adequately with a simple model.

An iterative approach is recommended, where assessors begin with simple conceptual understandings or analytical models and shift to mathematical models only where water bodies appear to be at risk, or where a detailed programme of measures is being developed. In many cases simple analytical models will be adequate to allow an assessment of contaminant behavior, however in certain situation more complex numerical models will be required.

Assessors may use numeric models to make predictions about combined point and diffuse source pollution effects on the wider groundwater body and on dependent surface waters and ecosystems, and to predict the effects of abstractions and artificial recharges on water resources. In addition, development of a numeric model helps assessors to:

- identify data and knowledge limitations;
- predict the impacts from a number of pollution pressures on remote receptors;
- predict the impacts from a number of abstraction or artificial recharge pressures on water resources, including any impacts on surface water bodies and dependent aquatic ecosystems;
- make predictions on the fate and transport of pollutants;
- include spatial and temporal variability in model predictions (which is often not possible with simpler analytical models).

4.5 Identification of tools: Comparison of need with existence and Examples

The IMPRESS guideline deals with impacts and pressures. Hence the tools are identified according to two leads: either they make it possible to quantify the pressure, supposedly leading to an impact or they enable to assess the state (the impact being assessed through change in state).

This identification is carried out for the main water body categories, i.e., rivers, lakes and ponds, groundwater and transitional waters. Some tools may obviously be common to several categories. To simplify the search, the pressures were grouped by identical function (e.g. nutrient discharges), notwithstanding the sources themselves.

The identification of tools is illustrated by constructing four matrixes, one per water body category. All tables have the same structure: the objectives are reported as column headers, and the pressures in lines. Each cell represents a "group of tools" that are understood to provide the expected information. The colour code of the cell qualifies the existence of at *least one tool* capable of quantifying the pressure and assessing the related impacts. Meaningless cells are indicated "NA for "not applicable". The state assessment is considered as a general tool related to category components, and is reported in a header line of each matrix.

4.5.1 Tools for rivers

Table 4.4 Assessment of the degree of availability of tools needed for riverine water bodies

RIVERS	WFD				Protected areas

State assessment	1	1	1	2	1	1	2	For instance LAWA, Finnish assessment tool, E&W grids, SEQ-eau. Water accounts and Eurowaternet to aggregate results.

Note, that existing classifications usually don't assess the difference of biological elements to the natural status as required by WFD, Annex V, 1.2. Therefore their results are of restricted value, but should be used in the first assessment in 2004 (further explanation in Chapter 3.6).

Pressure and impact quantification tools are available only for a *limited number of pressure types*, mostly dealing with organic and nutrient pollution loads. Considering the groups of tools, only 10% of these groups can be exemplified by implemented tools. On the contrary, a large number of groups (about 45% each) still require efforts either for implementation or scientific development, mainly in morphology linked assessments.

Quantifying the pressure would ideally be done using monitoring data. However such data do not exist in many circumstances, or are not monitored. Hence, the existing tools use alternative information to quantify the pressure. For agricultural pressure information on soil type, agricultural activity and management strategy are processed whereas for sewage effluents it might require the population equivalent of the inputs to the plant and the type of processing.

The output from the tool must be combined with another tool that combines the information on pressures, with a representation of the receiving water body. Thus, for example, the pressure resulting from an abstraction is first quantified, and then combined with information on a river system to determine the actual impact.

The currently implemented tools addressing **pollution pressures** (examples are taken from MONERIS, Nopolu, SENTWA, see Annex IV) are not fundamentally different. According to country requirements, and reporting needs, some processes are more or less detailed, as shown below, (more detailed presentation and references are provided in Annex IV):

- The German MONERIS (Modeling Nutrient Emissions in River Systems) estimates by various pathways the nutrient inputs into river basins of the German Baltic Sea catchment area. The model is based on a geographical information system (GIS), which includes digital maps as well as extensive statistical information and monitoring data in rivers, groundwater, drainage and point source effluents. The main pathways of water pollution are considered and, in the absence of ad hoc knowledge and data, they are processed thanks to lumped coefficients. One special feature of the model development is that the different sub-models were validated by using independent data sets, for example the groundwater model was developed with the observed nitrogen concentrations in the groundwater and not on the basis of the observed nutrient loads in the rivers;
- The Nopolu system encompasses a full description of the water-related characteristics of any territory, e.g. metropolitan France in which it is progressively implemented. Hydrologic and administrative apportionment relationships are managed by the system by the way of specific links (large cities discharging in a far away river) or by crossing information derived from GIS tables such as CORINE *land cover*. An important characteristic of the system is the possibility to aggregate and disaggregate results at any scale, thus responding to specific reporting requirement. The system is oriented towards assessment of state, pressure quantification and impact analysis, focusing on a thorough exploitation of observed data. The calculation of emissions aims at computing the real loads, taking stock of both monitoring data from large sources and statistical aggregates for area sources;
- The SENTWA model 'System for the evaluation of the nutrient transport to surface water' simulates the nutrient emissions from agriculture ("manuring") to surface water. It is a semi-empirical model that quantifies orders of magnitudes of nutrient emissions. It quantifies the load total N and total P (kg or ton N/P; kg or ton N/P per ha) on an annual or monthly basis and per river catchment in Belgian Flanders.

A current effort to compare models of pollution pressure by nutrients is carried out by the EUROHARP initiative (details are available on the http://www.euroharp.org site). Unfortunately, the work schedule does not match the 2004 reporting, but should help in later phases of the implementation of the directive.

A large number of tools for modelling impacts in rivers, of which SIMCAT (see annex) is an example, have been developed and calibrated. These models are however mostly developed to simulate physico-chemical mechanisms, and do not help assess the new issues introduced by the Directive.

No implemented tool capable of assessing the impact of changes in hydrological regime or morphology could be identified. However, the previous available discharge and elevation data could be used to design ad hoc indicators. For example, pike spawning conditions, fish ladder efficiency or dam filling impact, etc. can be assessed using statistics computed from daily discharge data and simple elevation – discharge relationships. The main gap is the current lack of reference data that apply to each considered water body: what is the water elevation over the meadow, what is the discharge on the equipped weir, how many "small" floods are there?

State assessment tools are often well documented and available. They use monitoring data which can be applied and the likely impacts derived from them.

Most countries have developed their own classification systems that show some differences in concept. The Finnish water quality classification system (see Annex IV) has been developed in order to give information on water usability for human purposes. It takes into account only ecological quality elements, which have a direct impact on water usability. It treats all water bodies similarly, not making any difference between different water categories or water body types. Classification is based mostly on chemical quality elements, but also on some biological elements such as hygienic indicators, chlorophyll and algal blooms. Criteria and threshold concentrations can be found in the Annex.

The England and Wales River Ecosystem Classification scheme, which thresholds are presented in the Annex, uses an 8 physico-chemical determinant grid that applies to monitoring points. The physico-chemical quantities used can be obtained from observed data or modeled output. Classes 1 and 2 are considered representing conditions suitable for salmonid and cyprinid fish populations.

The German assessment tool, set up by LAWA (State Working Group on Water) assesses the state of a water body from available environmental monitoring. Contrasting with other tools, it considers aggregated criteria, including the trophic state of the river network. An estimation of the probability that good ecological or chemical conditions will not be achieved within a period of observation is carried out according to the rule detailed in the Annex.

The French SEQ aims to consider all compartments of the water system (rivers, lakes, groundwater, transitional) and their components (water, biology, morphology). The state is assessed by comparing threshold values established for relevant groups of determinants considering the type of use. This approach takes stock of all available information and regulations, at the expense of a certain degree of complexity. More details are provided in Annex IV.

Summary related to tools suitable for rivers
Many tools are available, but unfortunately they focus on classical pollution that can be computed and modelled. Many developments are required for hydrological pressures. In this case, a common set of indicators could be defined, backed up by local identification of relevant threshold values. Morphology and biological pressures, that are not well understood, require developments to address ecological state assessment, including links with habitats and bird life in riparian areas.

4.5.2 Tools for lakes and ponds

Table 4.5 Assessment of the degree of availability of tools needed for lakes water bodies.

Pressure and impact quantification tools quantifying pollution loads are no different from those applicable to rivers and they are not discussed again here. The most general tool providing impact assessment is the OECD model (known as "Vollenweider's model"), already mentioned in the "screening section". It can be used for more precise assessments than just screening, provided that more accurate input loads and renewal time are available.

Since many lakes result from dam construction, the impact of withdrawals on water quality has been investigated in many countries. Selective withdrawal models were used in the 1980's to implement dam management rules capable of changing the thermal stratification of stored waters and limit eutrophication.

In parallel, many studies were devoted to the understanding of the relationships between water level changes (due to water use) and the biological functioning of banks. The purpose was twofold: increase the amenity of the water body, especially during the tourist season, and lower the adverse impacts of reservoir construction.

Despite the fact that the results of these approaches cannot be considered as fully implemented tools, they can be used as basis for investigation, especially if the experts who worked on these water bodies are still in position to help implement the Directive.

State assessment tools are implemented on a routine basis in only a limited number of countries that monitor these waters. Most deal primarily with eutrophication issues, resulting in abundant literature. For assessment of the risk of failing objectives for waters used for drinking water and bathing, data on compliance with the EU-directives 75/440/EEC (surface water intended for abstraction of drinking water) and 76/160/EWG (bathing waters) could be used.

Summary related to tools suitable for lakes
Considering the groups of tools, virtually none can be exemplified by implemented tools. About half of them still require effort for implementation, the remaining requiring scientific development, mainly in hydrological regime linked assessments. Again there is a lack of tools describing impacts on the difference of species composition and abundance to the natural state of biological elements.

4.5.3 Tools for groundwater

Groundwater vulnerability maps or indices are useful tools for assessing the likely impact of pollution pressures during the characterisation process. By taking account of a range of factors, the susceptibility, or vulnerability, of groundwater to pollution from pollution pressure on the land surface can be ranked. Typically vulnerability-ranking methods take account of a range of parameters, including:

- Presence, nature and thickness of soils, including attenuating properties;
- Presence, nature and thickness of superficial (drift) deposits, including attenuating properties;
- Groundwater flow mechanism in the aquifer (e.g. matrix, fracture, dual porosity dominated);
- Depth to the water table.

Groundwater vulnerability maps, based on a regional assessment using an index-based system can be used as a screening tool to rapidly assess the relative scale of impacts arising from pressures. They may be useful for assessing whether groundwater bodies are 'at risk' from pollution sources at initial characterisation.

Groundwater vulnerability assessments may be combined with models of diffuse pollution source behaviour, such as those developed for nitrates in The Netherlands (**STONE;** details are available under the http://www.riza.nl/projecten_nl.html site) or for pesticides in the UK (**POPPIE;** details are available under the http://www.meds-sdmm.dfo-mpo.gc.ca/meds/Prog_Int/ICES/ICES_e.htm site), to consider the overall risks to water quality on a groundwater body scale.

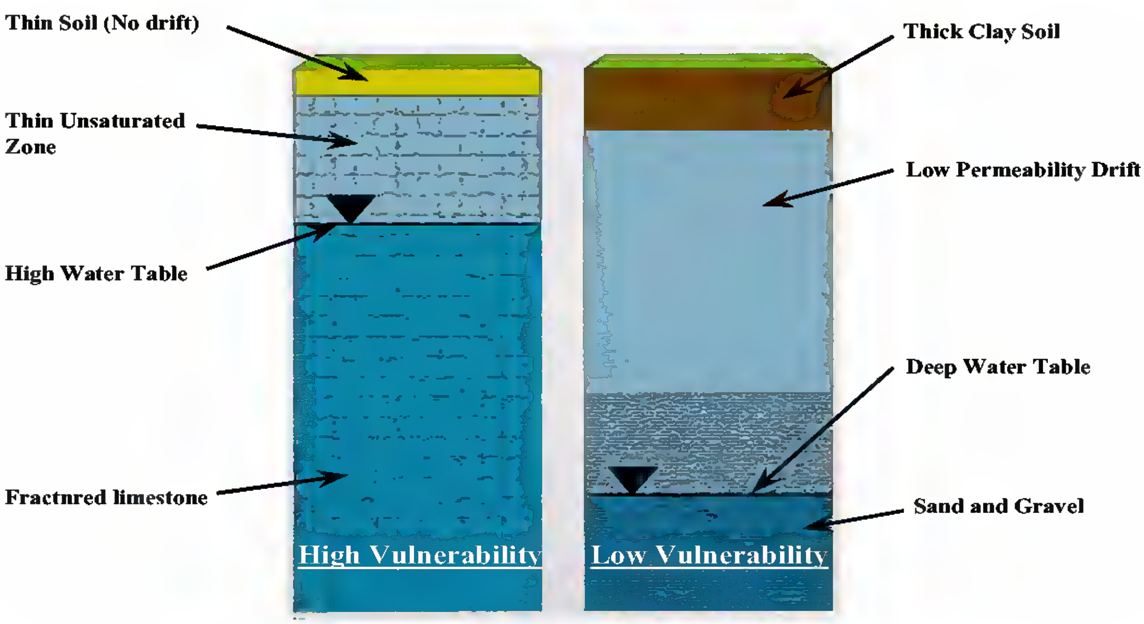

Figure 4.1 *High and low vulnerability groundwater bodies (Courtesy of UK Groundwater Forum).*

Groundwater models: Groundwater flow modelling is useful for three principal purposes. Firstly, it may be helpful for predicting the likely impacts of abstractions and artificial recharges on the groundwater body and associated water bodies, and subsequently assessing the whether the groundwater body is likely to achieve good quantitative status. Secondly, the development of a robust groundwater flow model is a necessary prerequisite to any contaminant transport modelling undertaken as part of the analysis of the pollution pressures on that body. Finally, the model is valuable later in the WFD process for developing an effective programme of measures and for management of the water body.

Groundwater flow models also, typically, simulate the interaction of groundwater with other parts of the hydrological cycle. Interactions between the groundwater and surface waters and wetlands may be simulated, which is vital for predicting the interactions between surface water bodies and their assigned groundwater bodies.
Groundwater resource models take many forms, from simple, normally analytical water balance models of the water inputs and outputs to a groundwater body, to complex numerical models of the groundwater flow system within a body.

Simple models include standard analytical solutions for the effects of abstractions of water table elevation. Commonly available tools such as **Aquifer Win**[32] (details are available on the http://www. aquiferanalysis.com/modelsum.thm site) and **P-Test** are already available that allow analysis of borehole pumping data to predict the impacts on water levels.

For regional studies or where more complex analysis is needed **MODFLOW** (details are available on the http://water.usgs.gov/software/modflow.html site) a numeric groundwater flow model produced by United States Geological Survey is widely used and is available as freeware. Alternative codes, such as **MIKE-SHE** (details are available on the http://www.dhisoftware.com/mikeshe/ site) are also used in a number of Member States to simulate groundwater flow on a catchment scale.

When the groundwater flow regime is understood it is possible to then consider the effects of pollution pressures. A range of tools already exist that may be helpful, including **ConSim** (details are available under the http://www.environment-agency.gov.uk/subjects/waters/groundwater site) an analytical model produced by the Environment Agency (England & Wales) that uses probabilistic techniques to predict the impact on groundwater quality from soil contamination and surface discharges. Where more complex codes are appropriate **MODFLOW** (details are available under the http://water.usgs.gov/software/modflow.html site) can be combined with freeware contaminant transport codes, **MT3D** or **MT3DMS** (details are available under the http://hydro.geo.ua.edu/mt3d/site) to predict the impacts from point source pollution. Proprietary pre-processors are also available for **MODFLOW.**

For diffuse pollution, existing numerical models are less helpful, however, groundwater vulnerability assessments are a valuable tool for assessing risks to groundwater quality in these circumstances. The Water Framework Directive does not differentiate between groundwater in different strata – all groundwater requires the same degree of protection from pollution. However, the impact that a pollution pressure is likely to have on groundwater varies from site to site, depending on the hydrogeological properties of the underlying soil, drift and solid geological strata. Consequently, for a given pollution pressure, the impact on the status of a groundwater body, and the potential programme of measures will vary in different aquifers.

4.5.4 Tools for transitional waters

State assessment tools are not yet fully developed, and maybe they are not completely defined since no full agreement exists across the scientific community. The best addressed issues are again those linked to causes of eutrophication and beneficial uses that are driven by obligations in relation with public health.

Pressure and impact quantification tools related to nutrient discharges were described in the river Section. The most prominent difference is the existence of the HARP/Nut and HARP/Haz guidelines agreed by the Ospar Convention, with the exception of Harp/Nut GL6, currently assessed within the Euroharp programme previously mentioned (see Annex).

The Harp/Nut guidelines are not a "tool", but they provide a coherent framework for quantifying the nutrient (and organic matter) loads discharged to sea and transitional waters, compared and calibrated with riverine fluxes where this comparison applies. This point is important to mention since the results are therefore very transparent, thus facilitating information of the public. The pollution assessment tools previously mentioned explicitly refer to these guidelines and compute outputs meeting the format requirements of the guidelines: by means (sewer, treatment plant, etc.) and by source (domestic, industrial, etc.) thus preparing the definition of measured programmes to combat pollution.

However, some adjustment should be made to allow reporting by water body, since Ospar asks for inputs to the sea only.

Table 4.6 *Assessment of the degree of availability of tools needed for coastal & transitional water bodies.*

COASTAL – TRANSITIONAL	WFD				Protected areas			
Tools categories : 1: Tools available and implemented; 2: Tools available but not implemented; 3: No available tool	Physico-chemistry	Flora	Invertebrates	Fish	Shellfish farming	Bathing / recreation	Habitats, Birds	Remarks about methods and required data

State assessment	1	2	3	2	1	1	3	For instance SEQ-ETM

Important impacts on transitional waters are related to changes in hydrological and tidal regime resulting from river and estuarine damming and from harbours and navigation works. One example using expert judgement for impact assessment is included in the Annex to Chapter 6.

Summary related to tools suitable for coastal and transitional waters
There is a lack of pressure and impact assessment tools in this water body type. More than on half of the tool groups fall into the third case, where research is needed, the other half requiring implementation.

4.5 Summary conclusion

Even though the identification of available tools could not be completed, it can be clearly seen that many requirements of the directive cannot be addressed simply by selecting and implementing a purchased computer programme.

A positive conclusion is that the screening tools cover a reasonable spectrum of water body category, pressures and objectives. Some of them are capable of providing trend analysis, under the baseline scenario. In can therefore be expected that the analysis demanded in 2004 could mostly be fulfilled on the basis of existing tools.

The negative conclusion is that the original points of the directive, assessing the pressures that cause impact on biology and ecological status, are not covered by available tools and that their development will require research in many cases, not only engineering.

The points discussed in this Chapter deserve further investigation. It is suggested that the working group should keep in touch in order to share the experience of implementation. This would enable continued identification of the needs, availability and practicability of tools required to implement the guidelines.

5. Information needs and data sources

The description of the general approach required for the analysis of impacts and pressures has noted the many types of information and data that will be required. These can be divided into those that are generally descriptive of the drainage basin and its water bodies (i.e. they are not specifically related to either pressures or impacts), data that describe pressures, and data that describe impacts. Thus far the data requirements have been specified generally for surface waters, with rather greater detail for groundwaters.

With all information and data it is likely that the best and most readily accessible sources are national or regional datasets within the member state. It is ***not*** the intention of this Guidance to list such sources. The Guidance does indicate ***what*** types of data may be useful in the analysis of impacts and pressures, ***why*** the data may be useful, and gives a ***European-scale source*** for the information, if one exists. Therefore the column "Source" in the following tables is not filled in completely. Competent authorities undertaking pressures and impacts analysis may need to be innovative in order to collect sufficient data, for example by asking stakeholders groups who may hold useful records (fishermen and angling groups will hold data about fish catches, for instance; local wildlife groups will hold useful ecological data).

It is recommended that, where possible, data is collected in digital form and used within a GIS.

ANNEX II, 1.1 "Characterisation of surface water body types" and 1.2, "Ecoregions and surface water body types" are assumed to have been completed before the pressures and impacts analysis begins. Therefore this Chapter focuses on sources of information relevant to 1.4, Identification of Pressures, and 1.5, Assessment of Impacts.

The type of data, which has to be collected, shall at first consist of data about the water body (type, morphology, geographical and meteorological terms, biological and physico-chemical conditions), because this is the starting point for an analysis of pressures and impacts. In addition data about the existing uses (data about pressures from urban, industrial and agricultural point and diffuse sources, about water abstractions, water flow regulation, morphology and land use) and about the state of a water body are necessary.

Because of the short timetable for completion of the first pressures and impacts analysis, this should mainly use existing data, collected on the basis of criteria which are suitable for execution, supplementing this with newly gathered information where necessary. The collected data can be used according to Chapter 4 (Tools) for the pressure and impact analysis. To assess the risk of failing the environmental objectives, the ecological status and therefore the biological and chemical status and the vulnerability of a water body must be evaluated. Data must be collected which provide a description of the water body and its catchment, an identification of the anthropogenic pressures and an estimation of the impacts on the basis of monitored biology and chemistry.

Each Member State will have differing types, sources and amounts of information. It is possible to identify a number of categories of data which will be common for all Member States. An important category are the other existing EC Directives, partly mentioned in the WFD, Annex II, 1.4. These directives provide information on a particular type of pressure (e.g. the Urban Waste Water Directive) or they contain environmental standards (e.g. the Nitrate Directive). Such directives provide information on different pressures. Other types of information can be existing National Requirements, such as National Classification Schemes, inventories required by National Legislation, etc.

In Table 5.2.1 "Information of pressures" and Table 5.2.2 "Information of impacts" the directives which are mentioned in the WFD Annex II, 1.4 and therefore must be considered, are listed first.

5.1 General Information

5.1.1 Descriptive information relevant to waterbodies

Data type	Use	SW	GW	Source
Water bodies				
Type of water body	Starting point for pressure and impact analysis.	✔	✔	
Spatial extent		✔	✔	
Meteorological				
Rainfall	Water balances.	✔	✔	National Meteorological Services, EEA, other European
Temperature		✔	×	
Geographical				
Topography	Identify drainage areas for water bodies.	✔	✔	Mapping services, EEA, other European
Solid geology	Aquifer characteristics. Water chemistry	✔	✔	National Geological Surveys and Institutes
Drift geology	Vulnerability of underlying aquifer. Run-off and drainage characteristics of catchment	✔	✔	National Geological Surveys and Institutes
Soils	Vulnerability of underlying aquifer. Run-off and drainage characteristics of catchment	✔	✔	National Soil Surveys and Institutes
Soil slope (%)	Run-off and drainage characteristics of catchment	✔	×	
Channel morphology, nature of seabed	Estimate the status and the susceptibility of a water body or to assess pressures	✔	×	
Land use				
Urban areas	Preliminary screening for point pollution sources.	✔	✔	National and regional statistical services, CORINE-Landcover (EEA)
Agriculture	Preliminary screening for point and diffuse pollution sources.	✔	✔	Agricultural administration, ,National and agricultural services, CORINE-Landcover, (EEA)
Industrial land	Preliminary screening for point pollution sources.	✔	✔	CORINE-Landcover, (EEA)
Mining/quarrying	Preliminary screening for point pollution sources	✔	✔	
Commercial forestry	Preliminary screening for point and diffuse pollution sources.	✔	✔	CORINE-Landcover, (EEA)

Data type	Use	SW	GW	Source
Fallow land	Preliminary screening for diffuse pollution sources.	✔	✔	CORINE-Landcover (EEA)
Recreation, e.g. golf courses	Preliminary screening for point and diffuse sources	✔	✔	
(Pattern of utilisation)	Preliminary screening for point and diffuse pollution sources.	✔	✔	

5.1.2 Key stakeholders that could be involved in the IMPRESS analysis

Key Stakeholders	Where they can help with information and expertise
Experts from Ministries (agriculture, transport, planning, economy,...	➢ Provide data for characterisation (for both groundwater and surface water):: - hydrological knowledge on behaviour of (ground) water bodies; - driving forces; - pressures; - changes in the state of the water body; - the impact of the pressures on the water status. ➢ Identification of key stakeholders; ➢ Assessing implementation and effect of existing community legislation, in general but also in relation to protected areas; ➢ Characterising water uses and their importance with regard to pressures; ➢ Defining coherent methodologies for assessing key variables at Member State level.
Water Service Suppliers , Water using sectors & stakeholders (farmers, industrialists, etc.)	➢ Provide data for characterisation (see above); ➢ Provide input for assessment of pressures.
Environmental NGOs	➢ Identifying key environmental issues; ➢ Assessing environmental impacts.
Stakeholders/civil society/public	➢ Providing specific input for the assessment of pressures.
Researchers/Experts (usually as consultants of the mentioned stakeholders)	➢ Assessing the impacts of pressures on water status (e.g. via modelling).

5.2 Information on pressures

5.2.1 Information on point sources of pollution

Data type	Use	Source
Urban Wastewater Directive (91/271/EEC) Data and Reports	Assessment of Urban Wastewater sites and their discharges. The monitored parameters are BOD5, COD, total suspended solids and for discharges to sensitive areas which are subject to eutrophication total phosphorus and total nitrogen.	National Data Storages and Reports
Integrated Pollution Prevention Directive (96/61/EC) Data and Reports	Collate sites authorised under the IPPC Directive and their discharges. At further characterisation consider detailed nature of activity.	National Data Storages and Reports, EPER

Data type	Use	Source
Activities authorised for purpose of Directive 76/464/EEC – Water pollution by discharges of certain dangerous substances	Collate locations of activities authorised under this Directive. At further characterisation consider detailed nature of activity	National Data Storages and Reports, EPER
Drinking Water Directive 75/440/EC	Information on quality of surface waters which are used as drinking water (physical, chemical and microbiological parameters are observed at regular intervals)	National Data Storages and Reports
Bathing Water Directive 76/160/EEC	Information on water quality of water bodies which serve as bathing waters (microbiological, physical, chemical parameters and other substances, which indicate pollution, are observed)	National Data Storages and Reports
Directive 78/659/EEC on the quality of fresh waters needing protection or improvement in order to support fish life	Information on the quality of fresh waters (physical and chemical parameters are observed) regarding fish life	National Data Storages and Reports
Directive 79/923/EEC on the quality required of shellfish waters	The Directive set the minimum quality criteria which must be met by shellfish waters (coastal and brackish waters): the physico-chemical and microbiological parameters; the mandatory limit values and the guide values of these parameters; the minimum sampling frequency and the reference methods of analysis of these waters.	National Data Storages and Reports
Activities authorised for purpose of the Groundwater Directive (80/68/EEC)	Collate locations of activities authorised under the Groundwater Directive. At further characterisation consider detailed nature of disposal activity	National Data Storages and Reports, EPER
Agricultural fertiliser application / sales data. Use data where readily available.		Agricultural administration
Activities authorised for purpose of Directive 1999/31/EC	Directive on the landfilling of waste. The Directive provides information on the amount of waste ending up at landfill sites. Collate locations of activities regulated for the Directive on landfilling. At further characterisation consider detailed nature of activity.	National Data Storages and Reports, EPER
Sites regulated under Major Accidents Hazards (Seveso) Directive (96/82/EC)	The aim of the Directive is the prevention of major accidents. This involves dangerous substance limitation. Collate locations of activities regulated for the Major Accidents Hazards Directive. At further characterisation consider detailed nature of activity.	National Data Storages and Reports, EPER
Nitrate Directive (91/676/EEC) designated areas	Assessment of releases of agricultural nitrates	National Data Storages and Reports
OSPAR Guidelines for Harmonised Quantification and Reporting Procedures for Nutrients (HARP-NUT)	Assessment of nitrate discharges	National Data Storages and Reports
OSPAR Guidelines for Harmonised Quantification and Reporting Procedures for Hazardous Substances (HARP-HAZ)	Assessment of discharges of hazardous substances	National Data Storages and Reports
Animal disease epidemic burial pits	Identify locations of burial of significant numbers (>50) of animal carcasses for	Veterinary surveillance

Data type	Use	Source
	disease control purposes	
Known point sources from contaminated land, old landfills, mines etc.	Identify key sites that are likely point sources, but are not regulated under above directives	
Storm-water overflows from sewerage systems	Identify storm overflows that discharge to ground	Water management administrations
Sub-aerial deposition	Identify regions subject to atmospheric deposition (e.g. acid rain)	
Railway lines (herbicides) and road verges	Identify railway lines and herbicides applied	
Oil distribution pipelines	Identify location of sub-surface oil pipelines	
Soakaways from major roads	Identify where major highways (motorways etc.) drain to ground. At further characterisation identify pollution prevention measures.	
Potentially polluting activities (e.g. industry, opencast mining, petrol stations)	Identify areas where there are numerous potential point sources	
Rates of discharges to ground	Further detail on discharges identified above (further characterisation)	
Chemical composition of discharges	Effluent composition (further characterisation)	

5.2.2 Information on diffuse sources of pollution

Data type	Use	Source
Nitrate Directive (91/676/EEC) designated areas	Identify areas of aquifer with high, or rising, nitrate concentrations	National Data Storages and Reports
Pesticides Licensing Directive (91/414/EC)	Information on pesticide usage	Pesticide Licensing Administrations
Directive 98/8/EC on Biocidal Products	Information on usage of Biocidal Products.	National Data Storages and Reports
Drinking Water Directive 75/440/EC	see 5.2.1 "Point sources" (some of the mentioned data can give information on different pressures or impacts, so they possibly are listed multiple)	National Data Storages and Reports
Bathing Water Directive 76/160/EEC	see 5.2.1 "Point sources"	National Data Storages and Reports
Directive 76/464/EEC – Water pollution by discharges of certain dangerous substances	see 5.2.1 "Point sources"	National Data Storages and Reports
Directive 78/659/EEC on the quality of fresh waters needing protection or improvement in order to support fish life	see 5.2.1 "Point sources"	National Data Storages and Reports
Directive 79/923/EEC on the quality required of shellfish waters	see 5.2.1 "Point sources"	National Data Storages and Reports
Agricultural fertiliser application / sales data. Use data where readily available		Agricultural administration
OSPAR Guidelines for Harmonised Quantification and Reporting Procedures for Nutrients (HARP-NUT)	Assessment of nitrate entries	National Data Storages and Reports
OSPAR Guidelines for Harmonised Quantification and Reporting Procedures for Hazardous Substances (HARP-HAZ)	Assessment of entries of hazardous substances	National Data Storages and Reports
Sub-aerial deposition (EMEP)	see 5.2.1 "Point sources"	

Data type	Use	Source
Railway lines and road verges (herbicides)	see 5.2.1 "Point sources"	
Oil filled pipelines	see 5.2.1 "Point sources"	
Chemical composition of discharges	see 5.2.1 "Point sources"	

5.2.3 Information on water abstraction

Data type	Use	Source
Water abstractions in the RBD: - amount of abstraction; - mean daily flow and low-flow river discharge; - lake level changes; - physico-chemical conditions; - sediment conditions; - existing or proposed schemes for artificial recharge of groundwater; It has to be considered that water abstractions possibly can be illegal.	Identify (or estimate in the case of illegal abstractions) abstractions with significant effect on the water body (water resources, chemical status, morphology)	Water management administrations, drinking water supply companies
Water abstraction in the RBD used for potable supply	Identify individual abstractions used for potable supply abstracting > XX m³/d or supplying > XX persons. Needed to identify drinking water protected areas	Water management administrations, drinking water supply companies
Drinking Water Directive 75/440/EC	Possible information on locations of abstracted water	National Data Storages and Reports
Activities authorised for purpose of Directive 80/68/EEC	Collate locations of activities authorised under the Groundwater Directive. At further characterisation consider detailed nature of activity	National Data Storages and Reports

5.2.4 Information on water flow regulation

Data type	Use	Source
Information on changes in the natural flow regime or of groundwater level	Identifying regulations with significant effect on natural flow regime or groundwater level	Water management administrations
Amount and succession of weirs in the RBD	Assessment of river continuity for water organism.	Water management administrations, navigation authorities
Number and capacity of reservoirs in the RBD	Assessment of river continuity and natural flow regime	Water management administrations
Not passable artificial barriers, e.g. dams	Assessment of river continuity for water organism.	Water management administrations
Range of backwaters	Assessment of river continuity for water organism.	Water management administrations
River profile, river bank structures / Stream habitat survey	Assessment of morphology and possible impact on biology	Water management administrations
Groundwater level		Water management administrations
Flow regulation with flow spills		Water management administrations
Flood-protection structures	Assessment of morphology and possible impact on biology	Water management administrations

5.2.5 Information on morphological pressures

Data type	Use	Source
River bank structures / Stream Habitat Survey	Assessment of morphology and possible impact on biology	Water management administrations
Amount and succession of weirs in the RBD	See 5.2.4."Water flow regulation"	Water management administrations, navigation authorities
Range of backwaters	See 5.2.4."Water flow regulation"	Water management administrations
Not passable artificial barriers	See 5.2.4."Water flow regulation"	
River profile	See 5.2.4."Water flow regulation"	
Flood-protection structures	See 5.2.4."Water flow regulation"	
Development on floodplains		

5.2.6 Information on pressures from land use patterns

Data type	Use	Source
Urban areas	Estimation of substance entries, modified flow regimes, soil erosion etc.	Agricultural administration, National data storages, National and regional statistical services, National and agricultural services, CORINE-Landcover
Agriculture (if possible subdivided in: • Cultivated land; • Sugar beets, potatoes & corn; • Special crop land; • Animal unit equivalents per hectare);		
Industrial land		
Mining, quarrying		
Recreation, e.g. golf course, aquatic theme parks		
Commercial forestries		
Fallow land (Pattern of utilisation)		

5.2.7 Information on other pressures

Data type	Use	Source
Other existing EC legislation		National Data Storages and Reports
Polders / reclaimed land		
Invasive species		Nature authorities and wildlife groups
Artificial recharges of groundwater in the RBD	Identify artificial recharge schemes to ascertain impact on groundwater levels; groundwater contamination	Water management administrations

5.3 *Information on impacts*

5.3.1 Information on susceptibility / vulnerability of water bodies

Data type	Use	Source
Statistical climate data	Information on susceptibility of water bodies, e.g. regarding substance- or heat-discharger	Climatic data
Stream Habitat Survey (rivers) including depth, amount of weirs etc.	Characterisation of rivers	Environmental data
Flow rates (rivers)	Characterisation of rivers	Measurement of discharge
Morphology (lakes): - mean water depth - mean water width - type of stratification (mixis)	Characterisation of lakes	Environmental data

Data type	Use	Source
- volume, residence-time (Vollenweider-model)		
Groundwater vulnerability data	Data on soil and drift presence and type. Depth to water table. Groundwater flow mechanism (e.g. fracture or matrix flow dominated system)	National Geological or Soil Survey / Institute)
Directives on Bathing Water (76/160/EEC) and Drinking Water (98/83/EC)	Susceptibility due to the existing uses.	National Data Storages and Reports
Birds directive (79/409/EEC)	Possible information on vulnerability of the area	National Data Storages and Reports
Natural habitats of wild fauna and flora Directive (92/43/EEC)		
Measurements of concentrations of possible pollutants in a water body	Information on susceptibility of the water body regarding pollutant discharges	Environmental data

5.3.2 Environmental data

Data type	Use	Source
Directives on Bathing Water (76/160/EEC) and Drinking Water (98/83/EC)	Assessment of status.	National Data Storages and Reports
Criteria according to the Fish-Life-Directive 78/659/EEC	Observation underneath relevant heat-discharger, regarding the temperature	National Data Storages and Reports
Physico-chemical substances Annex VIII of the WFD and criteria given by the 76/464/EEC-Directive	Assessment of chemical status	National Data Storages and Reports
Groundwater quality monitoring data - substances with article 17 standards; - conductivity; - substances relevant for article 4 objectives of dependent systems.	Review existing data from groundwater abstraction and monitoring boreholes for evidence of impacts	National water quality monitoring programmes; requisite surveillance of activities under Directive 80/86
Information on the chemical status of the water body from e.g. National Classification Schemes, "State of the environment" type reports, etc.	Assessment of chemical status	National Data Storages and Reports
Information on the biological status of the water body from e.g. National Classification Schemes, "State of the environment" type reports, etc.	Assessment of status	National Data Storages and Reports
Information on e.g. animal and plant species from International conventions such as the Ramsar Bureau, the Emerald network, information that has been gathered or other classifications such as UNESCO World Heritage Sites, Biosphere Reserves etc.	Assessment of status	
Phytoplankton (ANNEX V, WFD) - Trophic status	Assessment of eutrophication.	
Macrophytes and Phytobenthos (ANNEX V, WFD)	Assessment of morphology and organic pressures	Environmental surveillance, including that by wildlife groups

Data type	Use	Source
Benthic invertebrate Fauna (ANNEX V, WFD): - Saprobic status; - AQEM-Evaluation.	Assessment of organic pressures	Environmental surveillance, including that by wildlife groups
Fish fauna: Species composition and abundance	Assessment of the river-continuity and morphology	Environmental surveillance, including that by wildlife groups, fisherman, angling groups, etc.
Stream habitat survey	Assessment of the morphology of rivers	Water management administration

6. Examples of current practice relevant to the WFD pressures and impacts analysis

Annex V contains case studies presented by members of the IMPRESS working group as examples of current practice (summarised in Table 6.1 below). In providing the case studies the group members accept responsibility to provide further information, regarding what was actually undertaken with the study, how this has been taken forward since completion, and how similar methods can be used elsewhere.

It should be stressed that they are not presented as best practice examples in implementing the pressures and impacts analysis required by WFD. This is for two reasons. Firstly few, if any, pressures and impacts analysis have been undertaken in response to the WFD. The case studies are therefore based on previous analyses that conform, at least in part, to WFD requirements but without being driven by them. Secondly, the examples have not been assessed by IMPRESS as meeting the WFD criteria. They are intended to reflect what is done within the Member States, and to facilitate contact between users of the Guidance working in similar technical, operational or geographical areas.

It is hoped that the examples presented here are the seed for a living document that is supplemented by examples of the actual analyses required by the WFD. Thus with time, the content should move from reflecting current practice, to present case studies that truly represent best practice, and which can be considered exemplary in all aspects.

Table 6.1 *Summary of examples of current practice contained in Annex V.*

	Title	Link to guidance	Techniques used	Link to tools	Case study	Transfer -ability	Water body
1	Selection of **specific pollutants** by using ongoing implementation work of Council Directive 76/464/EEC[1] (Discharge of Dangerous Substances – DSD)	Relevant pollutions identification					
2 Belgium	Water Quality Plans in Flanders	Pollution Pressure quantification tool (4.3)	GIS Coefficient models	✓ SENTWA ✓ SIMCAT × Belgian Biotic Index/Prati Index	No	Yes	Surface
3 France	Water Integrated Emissions Inventory	Pressure quantification tool (4.3)	Coefficient models	No	Yes	Yes	Surface
4 Spain	Cartographic modelling	Water use pressure	GIS Water balance	No	Yes	Yes	
5 Portugal	Diffuse pollution case study River Guadiana	Quantification of pollution pressures	GIS Hydrological model		Yes	Yes	River
6 Denmark	Groundwater abstraction	Lowering groundwater table	2 & 3D models	No	No	Yes	Ground- water
7 Norway	Application of the River System Simulator for optimising environmental flow in the River Maana	Flow regulation, hydro-morphological pressures	Various models	× ENMAG HEC-RAS × QUAL2E × RICE × HABITAT	Yes	Yes	River
8 Spain	An approach for assessing alterations in the river water flows produced by reservoirs	Flow regulation	Modelling	No	Yes	Yes	
9 Netherlands	How to report on morphological alterations related to human pressures	Hydromorphology		No	Yes	Yes	Transitional & coastal
10 France	Screening and impact assessment using EuroWaternet methodology	Diffuse pressures	Statistical analysis	No	Yes	Yes	
11 France	Quantifying impact of pressures and likelihood of meeting objectives by means of the Water Accounts methodology.	Pressure screening	Thresholds	LAWA screening tool	No	No	River
12 Portugal	Water quality modelling in River Tejo	Impact modelling	Modelling	(QUAL2E model)	Yes	Yes	River
13 Germany	Criteria for the investigation of signification pressures and evaluation of their impacts for the purpose of reporting to the EU Commission.	Pressure screening tool and impact assessment tool	Thresholds	LAWA screening tool	No	Yes	Surface
14 Germany	Groβe Aue Development of a River Basin Management Plan	Pressure quantification, hydromorphological pressures	Statistical analysis	Models	Yes	Partly	Surface, Ground-water
15 Germany	Pilot project Middle Rhine: Development of a River Basin Management Plan	Pressure and impact assessment	Thresholds, Modelling	LAWA screening tool	Yes	Partly	Surface

[1] Council Directive 76/464/EEC on pollution caused by certain dangerous substances discharged into the aquatic environment of the Community (OJ L 129, 18/05/1976, p. 23).

7. Concluding remarks

In its fourth official meeting (Lisbon 10/11 Sept 2002) the IMPRESS group discussed outstanding issues, issues not agreed and further work required. This Chapter summarises the results of this discussion.

Outstanding Issues: None

Further work required:

Short term actions (2002-3):
Threshold pressure screening criteria: Investigate whether threshold criteria should be developed by individual Member States to allow the pressures and impacts analysis to progress consistently across Europe.

Workshops on pressure and impacts analyses: Practitioners would benefit from opportunities to exchange expertise and experience gained as the first pressures and impacts analyses are undertaken. This should continue into the mid term with a second workshop once the initial assessments have been made and reported.

Template for reporting: Consistent reporting would be achieved by developing a template for reporting requirements.

Readability: It is appreciated by the IMPRESS group that the Guidance Document would benefit from an edit to improve readability. Such an edit should not change the content of the guidance.

Mid term actions (2004-5):
Maintenance of IMPRESS Case Studies Information System: The case studies included in the Guidance should be maintained as a reference source for practitioners. A particular benefit of this would be that new case studies could reflect *best practice* in implementing the directive, whereas those included at present reflect current practice that is in accordance with requirements of the directive.

Identification of other tools: There will be an on-going requirement to identify and co-ordimate tools for use within the pressures and impacts analysis.

Links to programme of measures, reference conditions and monitoring requirements: These are all important links that must function correctly for successful implementation of the Directive as a whole, but have been addressed within separate CIS working groups. These is also a need to identify measures that best address pressures and impacts to give cost effective mitigation of impacts to restore ecology.

ANNEX II GLOSSARY

Term	Definition
Abstraction	The deliberate removal of water from a water body, either surface or groundwater.
Artificial recharge	The deliberate introduction by man of water into the subsurface
Baseline scenario	Projection of the development of a chosen set of factors in the absence of policy interventions.
Diffuse Source Pollution[2]	Pollution which originates from various activities, and which cannot be traced to a single source and originates from a spatially extensive land use (e.g. agriculture, settlements, transport, industry). Examples for diffuse source pollution are atmospheric deposition, run-off from agriculture, erosion, drainage and groundwater flow.
DPSIR	The Driver, Pressure, State, Impact and Response framework for environmental analysis
Driver	An anthropogenic activity that may have an environmental effect (e.g. agriculture, industry), also driving force
flux	A transfer of a substances through a medium
Hydromorphology	The physical characteristics of the shape, the boundaries and the content of a water body. The hydromorphological quality elements for classification of ecological status are listed in Annex V.1.1 and are further defined in Annex V.1.2 of the Water Framework Directive.
Impact	The environmental effect of a pressure (e.g. fish killed, ecosystem modified).
load	The transfer of material, dissolved or particulate, associated with a flow of water
Point source pollution	Pollution arising from a discrete source , e.g. the discharge from a sewage treatment works
Pressure[3]	The direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry of surface and groundwater bodies.
Response	The measures taken to improve the state of the water body (e.g. restricting abstraction, limiting point source discharges, developing best practice Guidance for agriculture).
Significant pressure	In the context of the WFD, a pressure that, on its own, or in combination with other pressures, would be liable to cause a failure to achieve the environmental objectives set out under Article 4.
State	The condition of the water body resulting from both natural and anthropogenic factors (i.e. physical, chemical and biological characteristics)
Status	The physical, chemical, biological, or ecological behaviour of a water body

[2] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[3] Interim working definition. Discussions in the context of the WFD implementation are ongoing

ANNEX IV PRESENTATION OF EXAMPLES FOR TOOLS (ANNEX TO CHAPTER 4)

0. Overview

The annex contains a list of tools mentioned in the main text, indicating their scope and some summaries of the tools themselves.

The tools may be presented in this annex, reported in Chapter 6 (Examples of current practice) or have been mentioned without summary. This is indicated in the table below. This table indicates the scope of the tool and which water body category it covers. The tools presented in this annex follow the order of the table.

Table Annex V.1: list, scope and location of summaries related to tools

Tool name	Location	Tool scope			Water body category			
		screening	Pressure & impact	State assessment	R	L	GW	C
1) Pressure Screening and Assessment Tools								
Pressure Checklist	Chapter 4	X			X	X	X	X
HMWB	This Annex	X	Morphology		x			
EuroWaternet	Best Practices Examples	X		X	x	(x)	(x)	
LAWA Pressure Screening Tool	Chapter 4	X			X			
Water Quality Accounts	Best Practices Examples	X		X	x

2) Tools for Quantification of Pollution Pressures								
OSPAR	This Annex		Pollution		x			x
MONERIS	This Annex		Pollution		x		x	x
SENTWA	This Annex		Pollution		x		x	
Nopolu	This Annex		Pollution	X	x	X	x	x
3) Tools to Combine Pressures with Impact Assessment - Water Body Models								
SIMCAT	This Annex		Impact		x			
Groundwater models	See Chapter 4		Pollution, Transport					
4) Impact Assessment Tools								
Finnish assessment tool	This Annex			X	x	x		
England & Wales	This Annex			X	x			
LAWA assessment tool	This Annex			X	x			
French SEQ-"water body category"	This Annex			X	x	x	x	x

Before using any tool you must be sure that it is fit for the purpose for which you want to use it. You should have a clear objective defined, i.e. what questions you want to answer, and should select a tool that is capable of simulating the pressure and impact being considered and of providing the required results. You should be aware of the capabilities and limitations of each tool.

In the next Sections example tools or models are described, but it is necessary to stress that most of the tools described are currently used within member states for functions similar, or possibly identical, to those required by the WFD, and in general such usage was mandatory for a tool to be included. Many more tools exist, and no doubt will become available in the future.

Pressure assessment tools are applicable for most elements of the environment and are used to perform two principal functions. The first is to enable a preliminary assessment of whether a potential impact is worth considering further within the pressure and impacts analysis. It is likely that any such an assessment will be reviewed later in the analysis, particularly if observed impacts cannot be attributed wholly to those pressures initially deemed worth considering.

The second function is only applicable in rare situations in which no other information exists. In such cases, pressure assessment may be the only means to assess the risk of failing objectives. Such an assessment would be subject to review in the light of the data monitoring programme required by the WFD. This is most likely to be the case for groundwater bodies because of the time lag before pressures are manifested as observable impacts in the environment.

Care must be taken in the use of such pressure screening tools, since they cannot properly account for the vulnerability of different water bodies that result both through issues related to scale and the characteristics of the water body's catchment area.

1. Pressure Screening and Assessment Tools

Note: Most of the pressure tools are already described in other Sections of this Guidance due to their importance for the general approach and the practicability needs of the first characterization.

- **<u>HMWB pressure identification tool</u>**

The HMWB Guidance offers some tools to identify hydromorphological pressures and impacts. In Table Annex IV.2 main uses and the connected physical alterations are given.

Table Annex IV.2: Overview of main specified uses, physical alterations and impacts on hydromorphology and biology

Specified Uses	**Navi-gation**	**Flood protection**	**Hydro-power generation**	**Agri-culture/ Forestry/ Fishfarms**	**Water-supply**	**Recreation**	**Urbani-sation**
Physical Alterations (pressures)							
Dams & weirs	X	X	X	X	X	X	
Channel maintenance/dredging/removing of material	X		X	X		X	
Shipping channels	X						
Channelisation/straightening	X	X	X	X	X		X
Bank reinforcement/fixation/ embankments	X	X	X		X		X
Land drainage				X			X
Land claim				X			X
Creation of back waters through embankments	X					X	X
Impacts on hydromorphology and biology							
Disruption in river continuum & sediment transport	X	X	X	X	X	X	
Change in river profile	X	X	X	X			X
Detachment of ox-bow lakes/wetlands	X	X	X	X	X		X
Restriction/Loss of flood plains		X	X				X
Low/reduced flows			X	X	X		
Direct mechanical damage to fauna/flora	X		X			X	
Artificial discharge regime		X	X	X	X		
Change in groundwater level			X	X			X
Soil erosion/silting	X		X	X			X

2. Tools for Quantification of Pollution Pressures

- OSPAR Harmonised Quantification and Reporting Procedures for Nutrients and Hazardous Substances (HARP-NUT and HARP-HAZ)

Methods of assessing, quantification and reporting sources of nitrogen, phosphorus and hazardous substances are agreed in OSPAR in the HARP-Process (Harmonised Quantification and Reporting Procedures).
For **Nutrients** the following guidelines are available:
1. HARP framework and approach;
2. Aquaculture;
3. Industry;
4. Sewage Treatment Works and Sewerage (including storm waters and their overflow);
5. Households Not Connected to Sewerage;
6. Diffuse Sources and Natural Background Losses;
7. Riverine Load;
8. Source Apportionment;
9. Retention in River Catchments.

Guideline 6: *Quantification and Reporting of Diffuse Anthropogenic Sources, and Background Losses* mentions the following diffuse nitrogen and phosphorus loss pathways to surface waters (see analogous Figure 4.1):
- Losses by surface runoff (transport of dissolved nitrogen and phosphorus);
- Losses by soil erosion (transport of particular, adsorbed nitrogen and phosphorus);
- Bank and riverbed erosion;
- Losses by artificial drainage flow (through drainage pipes/tile drainage);
- Losses by leaching (net mineralisation, percolating waters *i.e.* interflow, tile drain flow, spring water and groundwater); and
- Direct atmospheric deposition on inland surface waters.

This guideline describes principles behind the estimation of losses from both diffuse anthropogenic sources, and natural background losses. Appended to the Guideline are examples based on methods used in Switzerland and Germany, the UK, Denmark, the Netherlands and Ireland.

The **Hazardous Substances** Guidelines include:
1. Overall HARP-HAZ Guidance Document;
2. Brominated Flame Retardants;
3. Cadmium;
4. Dioxins;
5. Lead;
6. Lindane;
7. Mercury and Mercury Compounds;
8. Nonylphenols (NP) and Nonyphenolethoxylates (NPE) and Related Substances;
9. Polycyclic Aromatic Hydrocarbons (PAH);
10. Uncontrolled PCB-containing products.

These guidelines include information on the following groups of sources of the mentioned substances:
- Agriculture;
- Transport/Infrastructure;

- Building Materials;
- Households;
- Industry (IPPC);
- Industry (non-IPPC);
- Waste Disposal;
- Contaminated Land;
- Other direct diffuse sources.

It is worth noting that the HARP-NUT guideline 6 on diffuse sources of nutrients was the only one not fully agreed within the OSPAR framework. These, and other methods, are currently being assessed within the EUROHARP project (http://www.euroharp.org/index.htm). EUROHARP will compare nine different contemporary methodologies for quantifying diffuse losses of N and P, on a total of seventeen study catchments across gradients in European climate, soils, topography, hydrology and land use. The selected methodologies are applicable at catchment scale and are currently used by European research institutes to inform policy makers at national and international levels. A primary objective of EUROHARP is to provide end-users (national and international European environmental policy-makers) with a thorough scientific evaluation of the nine contemporary quantification tools and their ability to estimate diffuse nutrient (N, P) losses to surface freshwater systems and coastal waters; and thereby facilitate the implementation of the Water Framework Directive.

Prior to the completion of this review, users are advised to select the most appropriate methodology for their circumstances. This requires some assessment of the inputs of N and P to the soil, and understanding of the processes and pathways through which they are lost from the soil. Since N and P losses can vary substantially, land cover and land use data are essential for the analysis, possible sources of these are the European-wide co-ordinated data-sets CORINE Land cover (Co-ordination of Information on the Environment) and NUTS (Nomenclature for Statistical Territorial Units). Data on atmospheric deposition may be obtained from EMEP (Co-operative Programme for Monitoring and Evaluation of the Long-Range Transmission of Air pollutants in Europe).

The methods generally use export coefficients that are related to one or more of the following: crop type, stocking density, soil type, climate, eco-region and slope.

- MONERIS

Germany used the model MONERIS (Modelling Nutrient Emissions in River Systems) for the estimation of the nutrient inputs into river basins of the German Baltic Sea catchment area by various diffuse pathways. The model is based on a geographical information system (GIS), which includes digital maps as well as extensive statistical information and monitoring data in rivers, groundwater, drainage and point source effluents. A detailed description of the German Emission method including all of the pathways is contained in the report "Nutrient Emissions into River Basins of Germany", which was published in UBA Texte 23/00 in 2000.

Whereas waste water treatment plants and industrial sources are directly discharged into the rivers, diffuse emissions into surface waters are caused by the sum of different pathways, which are realised by separate flow components (see Figure Annex IV.1). This separation of the components of diffuse sources is necessary, because nutrient concentrations and relevant processes for the pathways are mostly very different. Consequently six diffuse pathways are considered in the model, for which the losses were determined separately:

- atmospheric deposition;
- erosion;
- surface runoff;
- groundwater;
- tile drainage;
- paved urban areas.

Along the pathway from the source of the emission into the river substances are governed by manifold processes of transformation, retention and loss. Knowledge of these processes of transformation and retention is necessary to quantify and to predict nutrient discharges/losses into the rivers in relation to their sources. Since current knowledge of the processes and the up to now limited database especially for river basins of medium and large size, the description of the processes can not be done by detailed dynamic models.

Therefore, MONERIS estimates the different pathways with already existing and new conceptual approaches, which are developed especially for the modelling in the medium and large spatial scale. Topics of the model development were:

- to develop a GIS-supported method for regional differentiated estimation of discharges/losses from point and diffuse sources for river basins of a size of more than 500 km²;
- to establish a sub-model for regionally differentiated estimation of nutrient discharges from waste water treatment plants and industries by a countrywide detailed inventory of these waste water treatment plants and industries;
- to establish a sub-model for inputs of nutrients and suspended solids caused by erosion, which can be applied to all investigated river basins. This model is based on the modified uniform soil loss equation but considers only those areas, which are relevant for input into the river system. The sub-model was validated with observed loads of suspended solids and particulate phosphorus for river basins;
- to develop a sub-model which allows the estimation of groundwater concentrations of nitrogen from the nitrogen surplus in agricultural areas by means of a retention function. This retention function is dependent on the hydrogeological conditions, the rate of groundwater recharge and the nitrogen surplus itself. The retention model includes first raw estimates of the residence time of water within the unsaturated zone and aquifer of the river basins;
- to develop a GIS-supported sub-model for regionally differentiated estimation of the agricultural areas modified by tile drainage. The sub-model is based on soil types and a classification of soil water conditions and is validated by overlaying digitised maps of tile drained areas with a soil map;
- to establish a sub-model for different pathways of nutrient discharges/losses within urban areas considering the regional differences in the sewer systems and the development of storage volume especially for combined sewer systems; and
- to establish a sub-model for nutrient retention and losses in surface waters, which can be applied for all river basins. This model is based on the dependency of the nutrient

retention on the hydraulic load or the specific runoff in the river system. The model allows the estimation of the nutrient loads from the nutrient inputs in a river basin. Therefore, a direct comparison of calculated and observed nutrient loads is possible for river basins upstream of a monitoring station.

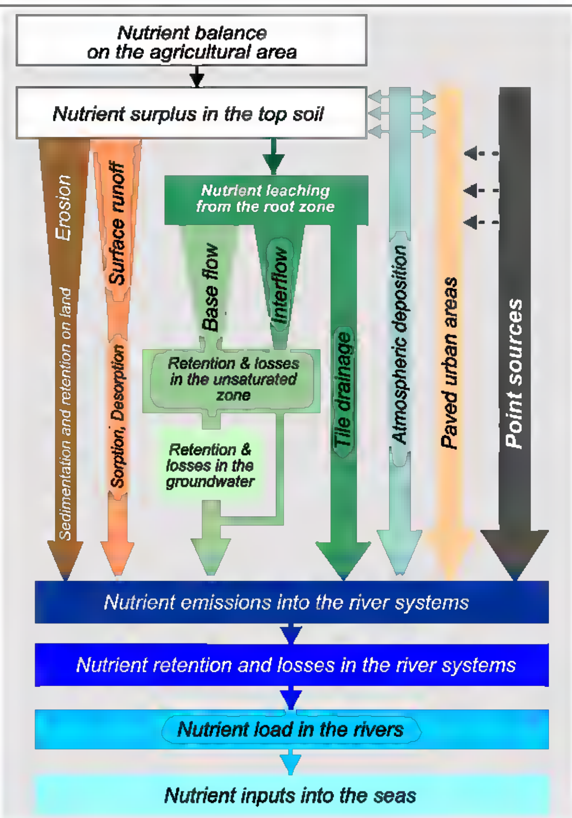

Figure Annex IV.1 Pathways and processes within MONERIS.

One special topic of the model development was that the different sub-models were be validated by using independent data sets, for example the groundwater model was developed with the observed nitrogen concentrations in the groundwater and not on the basis of the observed nutrient loads in the rivers.

The use of a GIS allows a regional differentiated quantification of nutrient discharges/losses into river systems. Therefore, estimates were not only carried out for large river basins. The MONERIS model was applied to 300 German river basins with a size between 100 and 5000 km² for the time period 1985, 1995 and 2000.

- SENTWA (System for the evaluation of the nutrient transport to surface water)

The SENTWA model 'System for the evaluation of the nutrient transport to surface water' is a model to simulate the nutrient emissions from agriculture (manuring) to the surface water. This model is formulated by the CODA (Centre for research in veterinary medicine and agrochemicals) from the Federal Ministry of Agriculture in 1993 on the basis of a German pilot study in the Elbe region. The CODA has adjusted the model for Belgium and has refined the model by validation and calibration of the model for the Regions 'Zwalm' (sandy loam) and 'Mark' (sandy) in Flanders (Belgium) (in 1997) by order of the Flemish Environment Agency (VMM).

It is a semi-empirical model that quantifies orders of magnitudes of the nutrient emissions from agriculture. It quantifies the load total N and total P (kg or ton N/P; kg or ton N/P per ha) on an annual or monthly basis and per river catchment. There are 11 river catchments in Flanders.

The model is designed as a tool for supporting and evaluation of the policy of agriculture/environment.

The model consists of 7 routes of emissions:

- Atmospheric losses;
- Direct losses :
    - direct losses by use of fertilizer (chemical manure);
    - direct losses by grazing of animals (organic manure);
    - direct losses by stabling animals (organic manure);
    - direct losses by saps of manure or silo's;
- Drainage losses (these are the losses at normal agricultural manuring);
- Ground water losses (these are the losses at normal agricultural manuring);
- Excess losses (these are the losses at excessive manuring);
- Erosion losses;
- Run off losses.

First, these losses are calculated on an annual basis (on the scale of the municipality) and then they are divided among the months taking into account different factors such as precipitation, use of fertilizer, agricultural practice, etc.

Which input is demanded?

Data of agricultural land use and of different kind of animals (cattle);
Data on excretion coefficients for the different kind of animals (cattle);
Data of use of fertiliser;
Data on transport of manure;
Data on precipitation;
Data on the yields of different crops;
Data on manuring standards;

These input factors are available on the scale of municipality, or provinces, or agricultural region developments:

- In 1999-2000 the model was rewritten in a more user-friendly way and in another programme language (DELPHI instead of DBASE) as instructed by VMM;
- In 2000-2001 ERM was commissioned by VMM to study the different parameters, factors, coefficients used in SENTWA in order to ameliorate the model if possible and useful;
- In the summer of 2002, the new calculations with the ameliorated model were carried out.;
- In the autumn of 2002, a refinement of the model for drainage losses, ground water losses and excess losses will be wound up. The calibration will be done for the agricultural region of the polder lands;
- <u>NOPOLU System (for example used to check in France EEA/ETC-W) emissions assessment methodology</u>.

Since 1993, Ifen (French national focal point of EEA) uses the NOPOLU system to handle data related to catchments and produce relevant data.

The system is based on full (although progressively implemented) description of the hydrologic and administrative features of metropolitan France. The catchments are analysed through 6210 polygons (aggregated up to 6 water agencies / 55 main catchments) and the administrative layers are analysed through more than 36,000 municipalities. The relationships between both definitions is managed by the system, by the way of specific links (big cities discharging in a far away river) or by crossing tables derived from CORINE *land cover*.

Data currently managed are river discharge, river monitoring data, rainfall (including efficient rainfall), water abstractions, industrial activities (including production, emission data, waste water treatment plants), urban activities (population, WWTP functioning, sewerage, including industries connected).

The main characteristic is that the system is highly integrated in order to facilitate cross comparison of results, with the objective to fulfil OSPAR guidelines as well as conforming with Directives. A second important feature is that:

- The system seeks individual data related to an item (e.g. WWTP running data), and if these are lacking it replaces them with standard values that can be highly regionalised. This is to prevent bias quantification, hence it is not totally "data provision dependent";
- Single system of GIS management is in use: the same data is used on the same areas to compute Water quality accounts, EuroWaternet representative networks as well as agricultural surplus, industrial emissions or riverine fluxes.

With regard to quantification of pressures, the main outputs are the quantification of pollution discharges (urban, industrial, agricultural), direct and diffuse that was set up and checked over by the Loire-Bretagne water agency in 1999.

The outputs can be provided at any scale and modality. For example, industrial emissions can be produced under the NACE (information is available under the http://nace.org/nace/content/AboutNace/aboutnaceindex.aspnomenclature site) by NUTS3, and disaggregated as direct discharge, through industrial treatment facility or via urban sewers. They can also be summed at any point of the catchments, to compare with the riverine fluxes, also calculated in NOPOLU, by processing river discharge and river chemical data.

The structure of the system is oriented to full transparency and disprovability, thanks to intermediate results. Hence, the agricultural pollution module firstly calculates the surplus that can be compared with independent data, and then the transfer, which is reconciled with urban and industrial discharges and riverine fluxes.

NOPOLU is constructed around Access 2000 (open to Oracle client/server) databases, most procedures are in Visual Basic, and it can process any external module (including APL). It is maintained by Beture-Cerec, subsidiary of JAAKKO PÖYRY.

3. Tools to Combine Pressures with Impact Assessment - Water Body Models

The tools described in the other Sections of this Annex enable some assessment of the likely significance of the pressure being considered, either by directly inferring that the water body is at risk of failing to meet its objectives, or by highlighting that the pressure requires further investigation.

Often the output from these tools must be combined with another tool that combines the information on pressures with a representation of the receiving water body. Thus, for example, the pressure resulting from an abstraction is first quantified, and then combined with information on a river system to determine the actual impact.

A great many models exist that may be useful in undertaking the pressures and impacts analysis required by the WFD. This Guidance cannot provide a comprehensive catalogue of these models, or recommend particular models. The following Sections are intended to inform the reader of the various types of model that exist, and that may be useful in a particular situation.

The models are often based on domains (i.e. characteristic areas), and most cases the domain relates to a water body type (e.g. river, lake, coastal water). These individual domain models can be linked together in various ways to represent a larger system, for example, a diffuse model (perhaps a pressure quantification tool described in Section 4.30) may be linked to river models and groundwater models to represent the whole hydrological system within a catchment area. Other models represent many domains within a single framework.

Many current projects at both national and European scale have the objective of providing detailed information on modelling techniques in support of the WFD. One prominent is BMW (Benchmarking Models for the WFD, http://www.vyh.fi/eng/research/euproj/bmw/homepage.htm). While, these project are unlikely to report until after the initial impact assessment should be completed, they may provide information on useful modelling techniques.

- **Hybrid Monte-Carlo deterministic model for rivers - SIMCAT**

This type of modeling tool places a deterministic description of transportation and in-stream processes within a Monte-Carlo framework. A large number of independent model runs are used to generate distributions of the water quality within the river network. To achieve this, the model requires all inputs (tributaries, discharges and abstractions) to be specified as either constant, normal, log-normal, 3-parameter shifted log-normal, or non-parametric distributions, on either an annual or monthly basis. Each model run samples of these distributions, either randomly, or using user-defined correlations between flow and quality, between discharge flow and flow in the receiving river, or between flow in tributaries and flow in the main river. From the derived distributions SIMCAT abstracts the mean and 95%ile or 90%ile for each determinand. Confidence limits are also provided.

SIMCAT does not solve the advection-dispersion equations, using instead a simple load addition formula at each reach to calculate concentration, and a flow-velocity relationship to calculate movement downstream. Pollutants are assumed to be instantly and uniformly mixed in the receiving water and to travel at the same velocity as the water in the receiving reach.

The model includes chloride, BOD, ammonia and DO as standard determinands. Chemical processes included are re-aeration, the decay of BOD, and nitrification of ammonia (based on a modified Streeter-Phelps equation) Processes are represented by first order decay with temperature sensitivity. All decay and re-aeration parameters, and velocity relationships can be specified separately for each reach.

Calibration can be either manual or using the model's internal calibration routine, which adjusts the fit of the model's output to measured data by adjusting parameters and diffuse flow. In auto-calibration mode, SIMCAT feeds in extra river flows so that the results match those at flow gauges, as a function of river length, and calculates a series of adjustments to quality parameters to match model quality distributions with those at monitoring stations.

The sequence of auto-calibration is that model results are first compared with data at a monitoring station. A set of adjustments to parameters and velocity which would allow exact agreement with measured data is calculated, and the model then goes back to the upstream monitoring station quality data and repeats its downstream calculations, using the new values for parameters, flow and velocity. The new model results are compared with the monitoring station data, and the process repeated, if necessary.

- ***Existing use***

SIMCAT is a model which has been developed in-house for the Environment Agency (England and Wales) and is widely used in water quality planning. Once a model is calibrated, it may be used by less experienced staff, as the model run method and output are simple and clear. A catchment model should, however, always be calibrated by competent technical staff, and carefully checked, as errors in the interpretation of input data, can, in this type of model where calibration is based solely on input data, lead to an erroneous calibration and thus misinterpretation of results.

- ***Relevance to pressures and impacts analysis***

This type of tool is primarily intended for investigation of impacts on general chemical quality of rivers from point sources of pollution. It enables the impact of the pressure from each source to be assessed individually and in combination. The diffuse loading can also be derived.

- ***Reference and Documentation***

The model manual provides a step by step guidance through the model set-up process. There is a Section on the model's statistical background which is comprehensive. The manual also gives the form of all the decay parameters used in the model, the time of travel equations and the methods of assessing confidence limits.

4. Impact Assessment Tools

- **<u>Finland national classification of water quality</u>**

The present Finnish water quality classification system has been developed in order to give information on water usability for human purposes, taking into account only those ecological quality elements, which have a direct impact on water usability. It treats all water bodies similarly, not making any difference between different water categories or water body types. Classification is mostly based on chemical quality elements, but also some biological elements (hygienic indicators, chlorophyll and algal blooms). Criteria and threshold concentrations can be found in Table Annex IVb.3.

Table Annex IV.3 : The Finnish national classification system.

Class	Class interpretation	Variables and their threshold values
I excellent	The watercourse is in natural condition, usually oligotrophic, clear or with some humus. Highiy suitable for all modes of uses.	colour < 50 mg Pt/l transparency > 2.5 m turbidity < 1.5 FTU faecal coliforms or faecal streptococci < 10 CFU/100 ml total phosphorus < 12 µg/l mean chlorophyll-α in the growing season < 3 µg/l
II good	The watercourse is in near-natural condition or slightly eutrophic. Water is still suitable for most modes of uses.	oxygen concentration in epilimnion 80-100%, no oxygen deficiency in hypolimnion colour 50-100 mg Pt/l (< 200 in natural humic waters) transparency 1-2.5 m faecal indicator bacteria < 50 CFU/100 ml total phosphorus < 30 µg/l mean chlorophyll-α in the growing season < 10 µg/l
III satisfactory	The watercourse is slightly affected by wastewaters, non-point loading or other changing activity, or is appreciably eutrophic due to natural causes. The watercourse is usually satisfactory for most modes of uses.	oxygen concentration in epilimnion 70-120%, some oxygen deficiency may occur in the hypolimnion colour < 150 mg Pt/l faecal indicator bacteria < 100 CFU/100 ml total phosphorus < 50 µg/l mean chlorophyll-α in the growing season < 20 µg/l
IV fair	The watercourse is strongly affected by wastewaters, non-point loading or some other changing activity. Water is suitable only for modes of use having few water quality requirements.	oxygen concentration in epilimnion 40-150%, oxygen deficiency in the hypolimnion faecal indicator bacteria < 1000 CFU/100 ml total phosphorus 50-100 µg/l mean chlorophyll-α in the growing season 20-50 µg/l algal blooms common concentrations of elements representing a health hazard: As < 50 µg/l, Hg < 2 µg/l, Cd < 5 µg/l, Cr < 50 µg/l, Pb < 50 µg/l total cyanide < 50 µg/l off-flavours often found in fish
V bad	The watercourse is extensively polluted by wastewaters, non-point loading or other changing activity Poorly suited to any form of watercourse use.	major problems of oxygen balance, oxygen saturation in the epilimnion during summer may exceed 150%; on the other hand total oxygen depletion at the surface may occur; at the end of the stratification season the whole hypolimnion may be anaerobic faecal indicator bacteria > 1000 CFU/100 ml total phosphorus > 100 µg/l mean chlorophyll-α in the growing season > 50 µg/l one or more of the following exceeds the threshold limit specific for class IV: As, Hg, Cd, Cr, Pb or total cyanide mercury concentration in predatory fish species >1 mg/kg oil film on the water surface often observed

- **Environment Agency (England and Wales) River Ecosystem Classification**

The England and Wales River Ecosystem Classification scheme is presented in Table Annex IV.4. The physico-chemical quantities used can be obtained from observed data or modelled output. Classes 1 and 2 are considered represent conditions suitable for salmonid and cyprinid fish populations.

Table Annex IV.4:The river ecosystem classification used by the Environment Agency of England and Wales

Class	Dissolved oxygen % saturation 10th %ile	BOD mg l^{-1} 90th %ile	Total ammonia mg N l^{-1} 90th %ile	Un-ionised ammonia mg N l^{-1} 95th %ile	pH lower limit 5th %ile to upper limit 95th %ile	Hardness mg l^{-1} $CaCO_3$	Dissolved copper µg l^{-1} 95th %ile	Total zinc µg l^{-1} 95th %ile
1	80	2.5	0.25	0.021	6.0-9.0	≤ 10 >10, ≤ 50 > 50, ≤ 100 > 100	5 22 40 112	30 200 300 500
2	70	4.0	0.6	0.021	6.0-9.0	≤ 10 >10, ≤ 50 >50, ≤ 100 > 100	5 22 40 112	30 200 300 500
3	60	6.0	1.3	0.021	6.0-9.0	≤ 10 >10, ≤ 50 >50, ≤ 100 > 100	5 22 40 112	30 200 300 500
4	50	8.0	2.5		6.0-9.0	≤ 10 >10, ≤ 50 >50, ≤ 100 > 100	5 22 40 112	30 200 300 500
5	20	15.0	9.0					

- **German impact assessment tool (LAWA)**

Data on the state of a water body available from environmental surveillance should be examined. Primarily data on the state of a water body will be considered to evaluate the impacts of the pressures and will be judged according to quality objectives and aggregation criteria. If these are insufficient, an assessment or consideration of a model based on established pressures is necessary. An estimation of probability that the good ecological or chemical conditions will not be achieved within a period of observation will be made on the basis of the criteria presented in Table Annex IV.5.

Table Annex IV.5: Information necessary for the assessment of impacts (LAWA)

Indicator	Threshold values
Saprobic status	> 30% of stream network > national biological quality level (here: biological quality level II)
Trophic status	> 30% of stream network > national quality level (here: trophic class > II, assessment basing on concentrations of Nitrate-N > 6 mg/l and Phosphate-P > 0,2 mg/l; 50-percentile
Physicochemical substances	Exceeding existing quality objectives or quality criteria of EU directive 76/464/EEC and knowledge about entries of priority substances
Warming	According to the EU Fish-Life Directive: - max. annual temperature: >21.5°C (salmonid water body) >28°C (cyprinid water body) - max. winter temperature: >10°C (salmonid water body) >10°C (cyprinid water body) - max. warming up: 1.5 K (salmonid water body) 3.0 K (cyprinid water body)
Salinisation	Median: Cl =400 mg/l

Indicator	Threshold values
Morphology	• River habitat survey -- overview method: More than 30% of the river distances within the management unit are surveyed with structural quality classes 6 or 7 for the compartment "river bed (consisting of the parameters: - curvature - bank fixation - anthropogenic barriers - water flow regulation - bank vegetation • Impairment of river continuity (anthropogenic barriers, backwater) >30% of stream network

- **French SEQ based quality assessment approach**

The French approach is based on three major concepts, all consistent with EEA and Eurostat recommendations. These concepts are:

- a water quality assessment scheme (SEQ system) encompassing water, biology and physical media. It applies to running, still, transitional and groundwater;
- a procedure to produce water quality statistics, implemented after the EEA EuroWaternet full recommendations and a procedure to produce water quality accounts, implemented after Eurostat/UNECE general methodology.

The SEQ system proper provides quality assessment for each monitoring point from observed data. It comprises three working tools:

1. System for evaluation of the quality of water (SEQ-Water) which assesses water physico-chemical quality and which has been used in France since 1999;
2. SEQ-Bio that assesses the biological quality of the stream;
3. SEQ-Physical that assesses the artificialization level of the stream.

The basic principle backing the SEQ approach is that the different uses or functions of any water body must be assessed through determinants of the same kind or through having the same effect. For example, to assess the stream water quality, SEQ-Water distinguishes 15 descriptors ("altérations"), each one of them grouping relevant determinants. The assessment is carried out using threshold tables (see Table Annex IV.6 for an example) that define class limits. The index is calculated through an algebraic function adjusted to the threshold values.

SEQ-system then calculates the indexes (scale 0-100) for the potential ability of water to biology, (which are closely connected to the physico-chemical component of the ecological status described by the directive), and the indexes of the potential ability of water for use (such as drinking water, leisure and aquatic leisure, and so on, according to the needs).

The index can be presented in a second step as 5 classes. These classes are represented with the classical description of five colours (blue, green, yellow, orange, red). The classes represent the same degree of water body impact. Therefore, classes can be compared between descriptors and functions, thus allowing complex aggregation methods to be applied in a second stage.

Table Annex IV.6: Example of the SEQ assessment grid, descriptor "salinisation", use: drinking water, medium: groundwater (source: http://www.eaufrance.tm.fr/francais/etudes/pdf/etude80.pdf).

Alteration Mineralisation et salinite

Parametres	Unites	bleu clair	bleu fonce	jaune	rouge
Conductivite (1)	µS/cm a 20°c	≥ 180 et ≤ 400	> 400 et ≤ 2500	< 180 ou > 2500 et ≤ 4000	> 4000
Durete	d°F	≥ 8 et ≤ 40		< 8 ou >40	
pH		≥ 6,5 et ≤ 8,5	> 8,5 et ≤ 9,0	< 6,5 et ≥ 5,5 ou > 9,0 et ≤ 9,5	< 5,5 ou > 9,5
Residu sec (1)	mg/l	≥ 140 et ≤ 300	> 300 et ≤ 2000	< 140 ou > 2000 et ≤ 3000	> 3000
Chlorures (2)	mg/l	25	250		> 250
Sulfates (2)	mg/l	25	250		> 250
Calcium	mg/l	≥ 32 et ≤ 160		< 32 ou >160	
Fluorures	mg/l	≥ 0,7 et ≤ 1,5	< 0,7	> 1,5 et ≤ 10	> 10
Magnesium	mg/l	30	50	400	
Potassium	mg/l	10	12	70	
Sodium	mg/l	20	200		
TAC	d°F	≥ 8 et ≤ 40		< 8 ou >40	

(1) au moins l'un des deux paramètres doit être pris en compte.
(2) au moins l'un des deux paramètres doit être pris en compte.

The SEQ version 2 will soon be released, with a new computerised tool. It will include all 33 priority substances defined in annex X of the directive.

Full details are available in the PDF document that can be downloaded from http://www.eaufrance.tm.fr/ (downloading from the pages is only possible in French).

ANNEX V CASE STUDIES

A summary of the following case studies is contained in Chapter 6 of the main Guidance Document.

Title: **No: 1**

Selection of **specific pollutants** by using ongoing implementation work of Council Directive 76/464/EEC[4] (Discharge of Dangerous Substances – DSD)

Type of impact:

Increasing loads of chemicals, toxicity, ecotoxicity, accumulation and secondary poisoning

Type of pressure:

Point and diffuse sources of chemicals

Type of analysis or tool:

The Water Framework Directive requires the establishment of measures for against pollution in order to reach the objectives. On one hand, the priority substances (Annex X) are regulated in accordance to Article 16. On the other hand, other specific pollutants need to be identified on a river basin (district) scale (cf. Section 3.5 of the guidance).

Council Directive 76/464/EEC already provides for such a mechanism under Article 7 where Member States shall establish pollution reduction programmes for relevant pollutants of list II of that Directive. These so-called "list II substances" must also be selected out of a number of pollutant groups which are similar to the one in Annex VIII WFD.

It is recommended (and to some extent mandatory) to make best use of the implementation of this requirement of 76/464/EEC for the first analysis of pressures and impacts under the Water Framework Directive because, in particular:

- ✓ the transitional provisions (cf. Art. 22 (2) to (6)) require the implementation of 76/464/EEC is required as a minimum requirement and smooth transition must be ensured since the directive requirement will only be repealed in 2013;
- ✓ the rulings of the European Court of Justice which need to be respected;
- ✓ the experience and knowledge available in the Member States and Candidate Countries (which are currently identifying pollution reduction programmes as part of their accession commitment).

Further information on the relation of 76/464/EEC and WFD is available (see references).

Information and data requirements

Depending on the approach used, the following information will be needed, in particular:

- ✓ intrinsic properties (e.g. physico-chemical properties, persistence, (eco-)toxicity, bioaccumulation);
- ✓ emission inventories (e.g. European Pollutants Emission Register (EPER)[5], Article 11 of Directive 76/464);
- ✓ marketing and use data;

[4] Council Directive 76/464/EEC on pollution caused by certain dangerous substances discharged into the aquatic environment of the Community (OJ L 129, 18/05/1976, p. 23).
[5] Commission Decision 2000/479/EC of 17 July 2000 (OJ L 192, p. 36).

- ✓ existing monitoring data (until 2006);
- ✓ surveillance, operational and investigative monitoring data (beyond 2006);
- ✓ Potential sources and emission routes;
- ✓ Fate and behaviour models;

Brief description including figures

The generic group of pollutants listed in Annex VIII cover a large number of individual substances. It is up to the Member States to establish an appropriate list of "**specific pollutants**" to be assessed for their relevance. However, the methodology for identifying **specific pollutants** is not specified in the Directive.

It is therefore recommended that the identification of **specific pollutants** under the Water Framework Directive should be further developed from the approaches used under Directive 76/464/EEC and the priority setting procedures elaborated for the selection of the priority substances.

It is evident that the 33 (group of) priority substances[6] and the eight list I substances[7] of 76/464/EEC which are not included in the Annex X WFD in the pressure and impact analysis since they will form the "chemical status".

For other **specific pollutants**, the starting point should be the substances identified as list II substances under Article 7 of 76/464/EEC. In addition, a candidate list of pollutants may be established which should be the starting point of a screening and priority setting process involving several steps.

Finally, the prioritisation process developed on European level, the so-called COMMPS[8] process, could be of additional use for the final selection of **specific pollutants** on a river basin scale. Moreover, the output of the Expert Advisory Forum on Priority Substances may also be useful for the pressure and impact analysis for other **specific pollutants**.

Based on the experiences of the implementation of the Directive 76/464/EEC, Member States have applied a wide range of approaches to identify "relevant list II substances".

However, it abstract terms, there are two generic approaches, which could be adopted for identifying potentially relevant pollutants:

- **Top-down approach** – this approach starts with the "universe of chemicals" and relies on all the available knowledge of the substances in order to screen for those substances which are of relevance in a river basin (district);

- **Bottom-up approach** – this focuses on those areas where existing monitoring data (biological and chemical) clearly identifies that the objectives may not be achieved. In addition, a specific, targeted and time-limited screening monitoring may complement the available information.

In most cases, a combination of both approaches is used by Member States.

Title: **No: 2**

WATER QUALITY PLANS IN FLANDERS (Belgium)

Type of impact:

Status and change of water quality of surface waters.

Type of pressure:

Point and diffuse sources from households, industry and agriculture (and WWTP)

Type of analysis or tool:

Point source – households: number inhabitants x pollution factor (PE)
Point source – industry (only main companies): sampling results of discharges
Point source – agriculture:

- inhabitants is included in households;
- animals: inventories (number of animals x excretion factors).

Point source WWTP: sampling results of discharges
Diffuse source – households: number inhabitants x pollution factor x reduction factor
Diffuse source – agriculture: SENTWA-model (calculation of losses of nutrients)
Load reduction: GWQP-mass balance ; SIMCAT-model (WRc – water quality model)
Status of waterbodies: Biological (Belgian Biotic Index), Physical-chemical (Prati-index)

Information and data requirements

Basic information: map of catchment areas, PE-equivalents, EQS, list of industrial main polluters.

Variables: number of inhabitants, industrial and WWTP discharges, livestock inventories, manure transport, inventories of the actual and planned sanitation projects, water quality data, water flow, load and removal rates of WWTPs, production and removal of WWTP sludge, permitted industrial loads, costs of the sanitation projects.

Brief description including figures

With exception of the driving forces, the approach is an application for water quality of the DPSIR-framework. On catchment level, the pressures (discharges and inflows) and the effect of it on the quality of water bodies are assessed, considering point and diffuse source pollution from households, industry, agriculture and WWTP. The actual status and evolution for the last decade of the water quality of the water bodies is described.

At pressure (discharges and inflow) and status level a series of general physical and chemical pollutants (Q, BOD, COD, N, P, SM, O_2, etc.) (and in some cases also heavy metals) have been reported and loads have been calculated. For 3 parameters (COD, nitrogen, phosphorous) calculation of pollution loads result in 'load balances'. This makes it possible to calculate load reductions (at inflow and discharge level) in order to meet the environmental quality standards (EQS) (see Figure).

The policy instruments are described and result in a number of measures that can be used in a scenario or cost analysis (see Figure). A first attempt for scenario analyses has been made and a scenario has been defined for households, industry and agriculture. For that, measures have to be quantified. The result of this exercise reveals if the proposed measures are sufficient to reach the EQS in the future.

The outcome results in 2 types of reports. A summary report, in which the load balances (and in particular load reductions) are stressed, and an extended technical-scientific document, describing all aspects of water quality considered. This TS-document consists of a manual, describing the framework and all sources and tools used, and the report containing all basic information, results and conclusions. In annex a list of tables and figures is added.

This method is/will be applied to the approx. 260 stream catchments (hydrographical zones) within the 11 distinct river catchments of Flanders. The data collated in 34 tables provides information in a comprehensive way on sampling/monitoring of waste water and water quality, loads and load reductions, as well as a description of the catchments, the functioning of the WWTP-infrastructure, the water uses, etc. in relation to the target groups.

Important and useful are in particular:

- the framework, relating all aspects of water quality (see Figure as a flowchart). This framework is dynamic as it allows expansion with new topics e.g. analyses of cost-effectiveness;
- the use of pressure indicators (ratios) which enables results to be compared – on the one hand - from the pollution sources on the level of discharges, inflow and after sanitation measures have been completed, and – on the other hand – between the pollution sources (households, industry and agriculture), regardless the surface area covered;
- the availability of information on catchment level, to be summed on any other higher hydrographic level (e.g. river basin);
- the calculation of load reductions (see Figure: inflow reduction), tested against different EQS. Hydrographical zones may be ranked according to the reduction priorities tested against several legal or ecological EQS of COD, N and P. *Example: tested against an EQS of 0.3 mg/l P, load reduction within the river Nete basin must reach 85% or 1.924 kg/d; the contribution of the households to this is about 25% or 481 kg/d; the reduction is specifically high (> 75%) in 10 hydrographical zones.*

<u>Abbreviations:</u> COD: Chemical Oxygen Demand, EQS: Environment Quality Standard, GWQP: (General) Water Quality Plan, N: nitrogen, P: phosphorous, PE: population equivalent, WWTP: waste water treatment plant.

Title: **No: 3**

WATER INTEGRATED EMISSIONS INVENTORY (ETC-WATER) (France)

Type of impact:

Increasing loads of pollutants, eutrophication

Type of pressure:

Point and diffuse sources of OM, P, and N from households, industry and agriculture.

Type of analysis or tool:

Use and organisation of the already existing national and international statistical sources for the purpose of emission calculations.

Information and data requirements

NB: all data can be considered at a regional and time level and adjusted from monitoring for any actual source or type of source (point/diffuse).

Point source – households: number inhabitants x pollution factor (PE)

Point source WWTP: sampling results of discharges

Point source – industry ((only companies >400 fiscal PE)): Loads by pollution factor and sampling results of discharges

Point source – agriculture: animals: inventories (number of animals x excretion factors), per species, region.

Diffuse source – households: number inhabitants x pollution factor x reduction factor, impervious urban areas

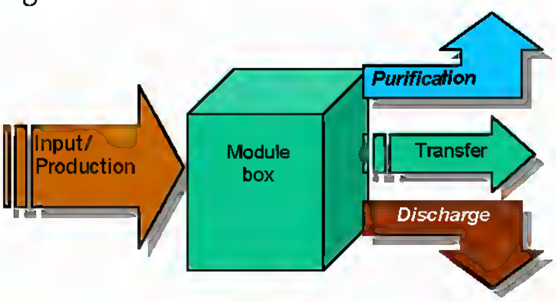
Diffuse source – industry : impervious industrial areas

Diffuse source – agriculture: - Use of fertilisers; model for calculation of losses of nutrients.

Brief description including figures

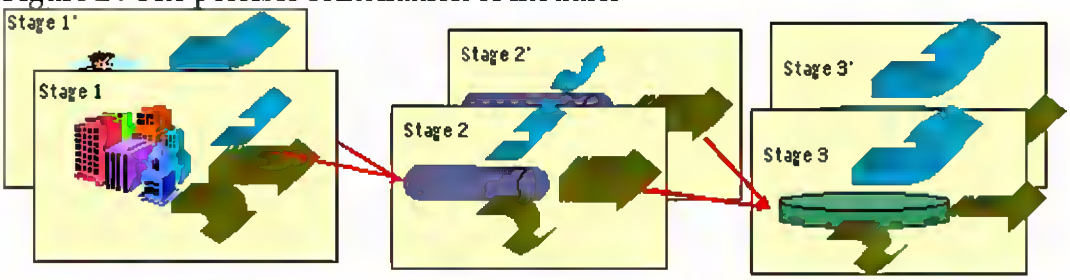
The methodology

Figure 1: The basic module



All emissions are computed as network of elementary modules, to systematise calculations (Fig. 1).
A module receives or produces a certain amount of pollution, purifies a part of it, discharges another part and transfers the remaining quantity to the module downstream (Fig. 2).
This schematisation allows any type of aggregation and presentation of final results (e.g., part of industrial effluents purified in domestic treatment plants.)

Figure 2 : One possible combination of modules



Depending on the organisation of the information system, each country has its own procedures and different data and information are available. This can also be the case at the national or regional level. To overcome these difficulties, the methodology developed in the Loire Bretagne Basin in France proposes to use the best possible data available at the most disaggregated level and coefficients when the data do not exist. The main advantage of this is to have a clear overview of the existing information system. The inventory can be completed and improved when data becomes available or the quality of this data improves and nonetheless to produce information, even if the raw data do not exist in a suitable form.

This of course needs some expert judgement and also a clear presentation of the calculation steps but allows the use of data and information coming from different organisations. This is also economically sound in using the best information and data already available.

Another main idea of the methodology is that the different types of emissions can be described with the same conceptual model. Any emission process is analysed as a combination of modules or steps, thus enabling simple data processing and multi-purpose reporting.

The application

Using this methodology, the project was applied on the so-called „Loire-Bretagne Water Agency" with the following geographical unit, temporal unit, sources and substances.

The area concerned by the Loire-Bretagne water agency extends over 156,217 km2. At the catchment level, the territory is broken down into 16 catchments, 12 for the Loire river and its tributaries, 3 for Brittany and 1 for Vendée.

At the administrative level, it extends over 10 Regions (NUTS2) and 31 "départements" (NUTS3), both being only partly included in the Water agency area. The 7281 municipalities (NUTS5) are totally included in the aforesaid area and the data were considered at this level.

Agriculture is one of the main activities: two-thirds of French livestock is grown on this area, as well as two-thirds of the slaughtering and meat processing activity. Half of the national milk production and derivatives also comes from this area.

Measurement habits concerning water in France are based on the mean value of the month of maximal activity and given in tons per day. However, many statistical data are available only yearly, based on the civil year and the data are considered at this level.

The methodology has the ambition to build a unique system and thus to cover all the sources. For the purpose of this exercise, Ifen decided to collect only the data on emissions liable to reach the inland waters quickly. The sources identified were agriculture, industries and domestic.

The three substances studied are organic matter, and the nutrients Phosphorus and Nitrogen.

The data used have many different sources, the main criteria is the potential availability for the whole country with the same organisation.

The main interest of the methodology is to consider all the main sources and all the data available concerning these. It integrates all the available data to provide trends and evaluations of the relative part of each source in the overall pollution.

It's easy to change one hypothesis or one set of data and recalculate the results. Another point to highlight is that all the hypothesis and calculations are transparent and can be adapted to one specific condition or the use of one specific calculation model.

Some results

Figures 3 and 4 show the results at an administrative level that is the „departements" (pink lines and one chart for each). For the administrators of those regions it is important to know the proportion of emissions or raw pollution between sources and the main source of each substance. In this example the main source of organic matter is domestic. Regarding the quantities assessed, there is a huge difference between the raw and the global pollution: many processes occur along the transfer of the pollutant from its production to its discharge into water. The flexibility of the approach allows the results to be utilised at different administrative levels like the region or the „departement". This is also possible at the hydrographic level: the 16 catchments of the Loire-Bretagne Water Agency.

Finally, it is also possible to aggregate different sources or to focus only on one source to allow the comparison between zones as regards the quantities discharged into waters.

In fact the only limit of these exercises is the original scale of the data: if the original data is available at the regional level, it is not possible to represent the results at a smaller geographical scale like the „commune" level. It is then very important to use the most disaggregated data to allow the maximum flexibility.

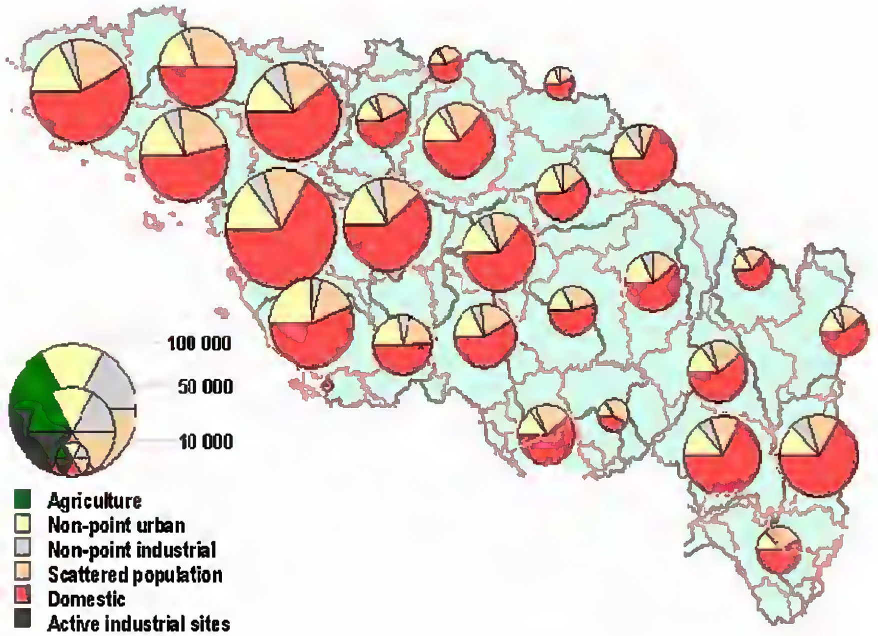


Figure 3: organic matter raw pollution apportionment between departements (BOD5 in kg/day)

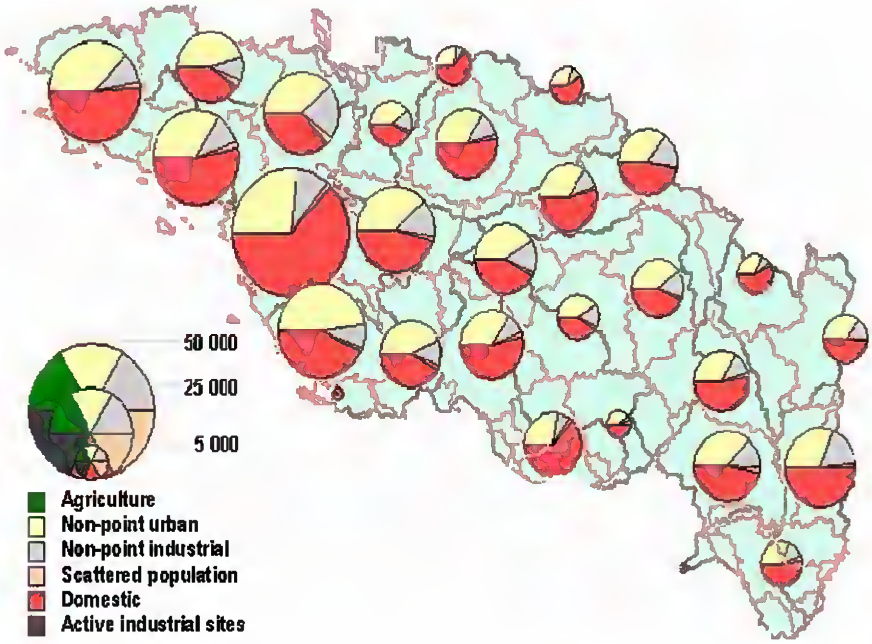

Figure 4: Organic matter global pollution apportionment between departements (BOD5 in kg/day)

CARTOGRAPHIC MODELLING OF WATER USE SYSTEM

Type of pressure:

Water abstraction

Type of analysis or tool:

Tools for Water Balance description ("Consumption and Water Management Indexes")

Information and data requirements

Maps of natural water resources, of water demands (urban, industrial, agricultural), of additional water from desalting processes and interbasin water transfers.

Brief description including figures

The objective of this practice is to have an evaluation of the pressure of spatial distribution of water demands on water resources.

A distributed model calculates the risk of water scarcity from the information of natural water resources and water demands. Figure 1 shows the procedure carried out by the model for each cell. The area selected for the cells of the grid used in the model is 1 km2, this gives a total for Spain of 500.000 cells.

The potential water resources available (surface and ground water) are determined from the natural resources (renewable resources generated in Spain), which are part of the natural water resources that represent the potential total water available.

The difference between total water resources and potential water resources represent the environmental requirements. These resources cannot be accounted to reach the productivity objectives of the system. Only the rest of the water resources (potential water resources) are the ones that can be used in the system and therefore are the only ones included in the water balance (between water resources and demands).

The additional water from desalination processes (Fig.2) should be added to the potential water resources.

Another factor that should be considered is whether any water transfers are presently in operation. These water transfers do not increase the potential water resources at national level but they modify their distribution (Fig.3).

The total demand (water abstraction) is the addition of urban, industrial and agricultural demands. However water returns should be taken into account, which come back to the natural water system and may be used downstream in the basin. This is the reason to separate the consumptive and non- consumptive fraction of each one of water uses. In this way the consumptive and non- consumptive water demand for each one of the water uses can be calculated. The addition of these two fractions gives the total demand (Fig.4).

For each one of the grid cells the water balance is calculated between the potential water resources and the total consumptive water demand. This balance allows maps to be obtained with the spatial distribution of water deficit and water surplus

(Fig.5 and Fig.6). These maps are only illustrative in character since they are the first approach to the problem. As it is known, water is not used in each cell in isolation.

Therefore a spatial aggregation is needed, which has been based on the water management units defined in the Basin Water Plans. This allows the water deficit and water surplus to be identified in the different management units included in each of the basins (Fig.7 and Fig.8). The aggregation of all grid cells of each basin shows the total balance of the basin (Fig.9 and Fig.10).

The processes explained above assumes that all the potential water resources generated in the system, plus the possible additional water from desalination processes and/or water transfers are fully used in the system.

The previous statement also assumes that the necessary infrastructure to use all the water resources are available and that the water is of the required quality for each use. Therefore the only water supply limits would come from limitations of the available water resources.

A system will be said to be in deficit when it cannot supply consumptive use demand, although it has the necessary infrastructure and the required water quality. On the other hand a system in surplus does not mean it has no water supply problems. This may occur if the necessary infrastructure required is not in place or if the required water quality has not been achieved.

To balance the water required with consumptive demands, it is assumed that water reuse in the system is the maximum possible.

This deficit and surplus are of different levels and will also depend on the size of the systems.

To try to clearly show the water management index and the water consumption index (Introduction à l´économie générale de léau Erhard-Cassegrain and Margat, 1983), they are used to show a map of water scarcity risk (Fig.11 and Fig.12).

The water management index is the result of dividing the total water demand and the potential water resources. It has to be pointed out that a water management index near or larger than "1" may not mean, in some cases, a water scarcity. This is because if the water abstractions are not concentrated in a specific area, part of the water returns might be used downstream.

The water consumption index is obtained by dividing the consumptive demand and the potential water resources. This ratio can also be used as an indicator of scarcity risk. A value greater than 0,5 could indicate "eventual" scarcity, in the other hand if the value is near 1 could mean that the scarcity is "structural". A low value of water consumption index indicates that water resources have a very low use.

It can be observed that the deficit system has a water scarcity of a structural type. In this system the potential water resource is systematically lower than the level of water consumption that is trying to reach.

But there are a number of systems that have water surplus but also have the risk of suffering an eventual water scarcity. The reason for this is that their levels of water consumption are relatively close to the potential water resources. In these systems a number of successive dry years might produce water supply problems because the lack of enough water resources in those years.

Title: **No: 5**

DIFFUSE POLLUTION CASE STUDY: GUADIANA RIVER WATERSHED (Portugal)

Type of impact:

Increase of nutrients loads that can lead to eutrophication problems

Type of pressure:

Diffuse sources of P and N based on land use.

Type of analysis or tool:

A simple methodology was developed on a grid-based water quantity and quality model for mean annual values. Integration of Geographical Information Systems (GIS) it is an important tool that will allow characterising the spatial variability of the watershed by using spatial analysis tools.

Information and data requirements

Physical watershed characteristics, land use and topographic, and hydrological characteristics, precipitation/runoff, together with values of nutrients exportation.

Brief description including figures

Methodology

The first step is to create a mean annual runoff grid based on a distributed hydrological model. In this work, the methodology used is described in GOMES (1997), which is based on Temez aggregate model, implemented cell by cell in A.M.L. language in Arc/Info-Grid. The equations of this model, which rule evapotranspiration, water retainance in soil, infiltration and runoff process, are applied to each cell. This model uses precipitation (mm) and potential evapotranspiration (mm) as input variables and has 3 parameters, a flow parameter, a maximum retention of water in soil (mm) and a maximum infiltration rate (mm).

Runoff (mm/year) = f (precipitation, evapotranspiration, parameters)

Pollutant loads need to be assigned to each cell in order to calculate loading of pollutants in a river system. The combination between distributed maps of the watershed characteristics, namely land use and geology, with the exportation coefficients of phosphorus, and will allow estimating of the nutrient content that reaches to the streamlines (Table I).

Table I Export values of phosphorus E_P and nitrogen E_N (mg m^{-2} $year^{-1}$) (Jørgensen, 1980)

Landuse	Ep Geological classification		En Geological classification	
	Igneous	Sedimentary	Igneous	Sedimentary
Forest				
Range	0.7 - 9.0	7.0 - 18.0	130 - 300	150 - 500
Mean	4.7	11.7	200	340
Forest + pasture				
Range	6.0 - 16.0	11.0 - 37.0	200 - 600	300 - 800
Mean	10.2	23.3	400	600
Agricultural areas				
Citrus	18.0		2240	
Pasture	15.0 - 75.0		100 - 850	
Cropland	22.0 - 100.0		500 - 1200	

The linkage between the coefficients of nutrients to the polygon coverage of land use will be converted to a grid with the same cell size as the runoff map and this will be the load map. Using spatial tools of a GIS will allow integration of the distributed runoff map and the digital terrain model (DTM) of the watershed to obtain the accumulated flow in the streamlines. The same amendments are made to the phosphorus load map. This will result in the annual concentration of phosphorus in the streamlines.

Concentration (mg/l) = Load (mg/year) / Flow (dm³/year)

After the calculation of the concentration values it's possible to compare them with nutrients data measured in the water quality sampling stations to validate this methodology. Nevertheless the nutrients measured in each station reflects the total pollution that reach the streamline – point and non-point.

Application

This methodology was applied to the Guadiana river, and only for phosphorus because it is the limiting factor which determines the development of eutrophication. This river is an international basin, with a total area of 66 860 km^2 and has it's headwaters in Spain, and only 11 600 km^2 of the area is our national basin.

This river has an important role in the south of Portugal, a region with drought problems. The agricultural activities and animals in pasture have a great impact in this basin as non-point pollution sources, which causes a large amount of nutrient exportation to the water and soil.

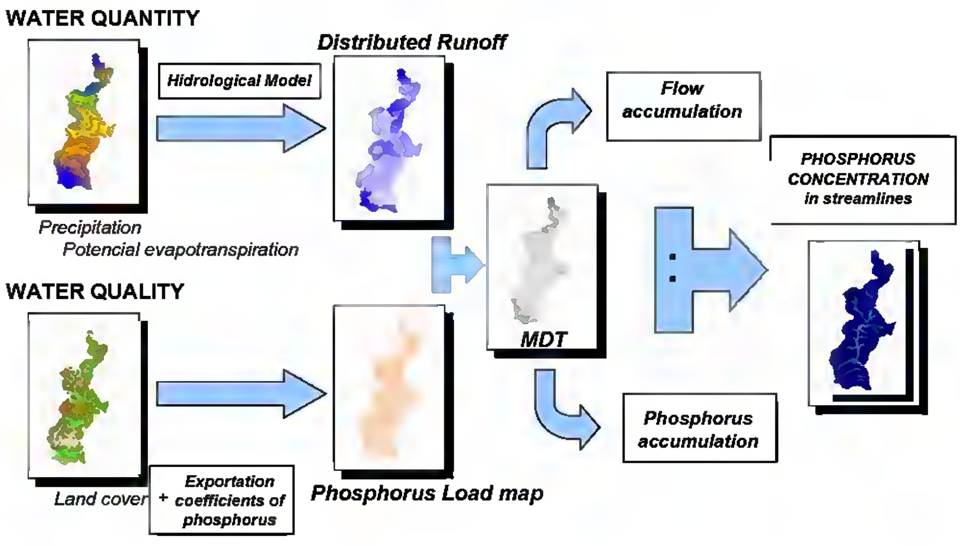

Figure 1 – Methodology application to Guadiana River (Portuguese basin).

Results

For modelling the runoff map it's necessary to have the distributed maps of precipitation and potential evapotranspiration. After calculating the distributed maps of runoff and phosphorus load (Figure 2) it's necessary to integrate these two variables in the streamlines. The accumulated flow and the accumulated phosphorus load in the streamlines is made by using a flow direction map originated from DTM, that shows the direction in each cell that the runoff takes to reach the streamlines. The concentration values are calculated in mg/l of P by dividing the load values with the flow values.

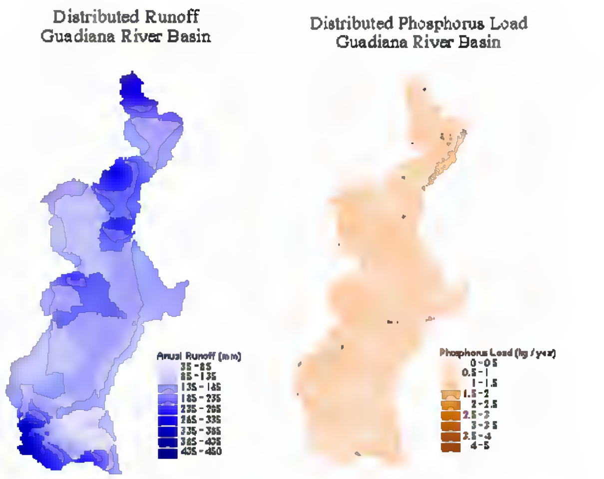

Figure 2 - The input distributed maps to calculation of phosphorus concentration.

A comparison between the estimated values of P and the observed values was made in the water quality sampling stations in the rivers (Figure 3). This Figure also shows the main point sources pollution, industrial and domestic. They are spread all over the basin but more concentrated in the North part.

By comparing these two values (observed versus estimated), we shouldn't forget that estimated value only takes in account the diffuse pollution provoked by land use. It's missing the correspondent impact of animals in pasture and point sources pollution to have the total phosphorus concentration in the rivers.

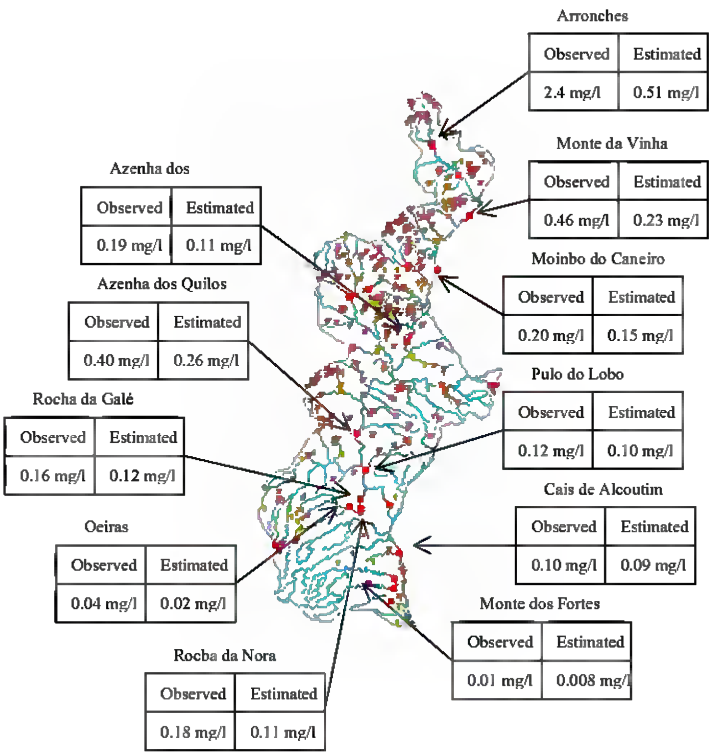

Figure 3 - Comparing the observed values with the estimated in the water quality stations.

In general it can be verified that the higher values of phosphorus concentration are in the North part of the basin and the estimated values are more approximated with the observed ones in the South. This can be explained because there are less point sources in this zone, which reflects the contribution of diffuse pollution.

Regarding sampling data, (Figure 4) it can be concluded that a dilution of the phosphorus concentration is observed as coming to the South part of the basin. Also, in terms of percentage, the estimated values related to the observed ones increase as they come towards the South part of the basin, which illustrates more contribution of the non-point pollution to the total amount of P.

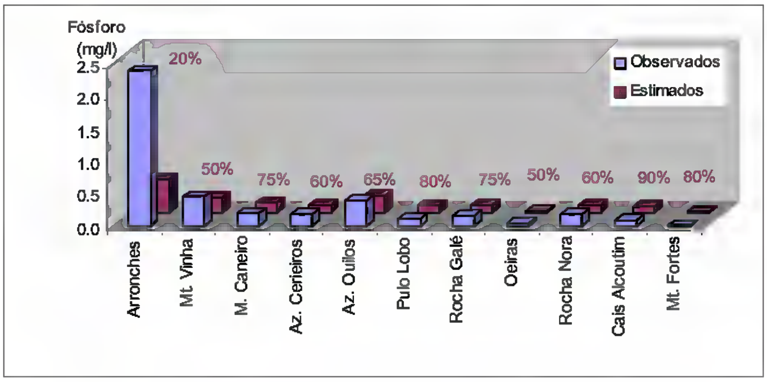

Figure 4 – Comparing phosphorus concentration (observed versus estimated) and their relation in terms of percent.

Title: **No: 6**

GROUNDWATER ABSTRACTIONS (Denmark)

Type of pressure:

Lowering of groundwater table, reduction of streamflow

Type of impact:

On groundwater: Alterations in directions of groundwater flow, possibly leading to saline intrusion. Also deterioration of groundwater quality as a result of e.g. upwelling, oxidation in upper layers, increased infiltration.

On surface waters: Reduced dilution of chemical fluxes from e.g. wastewater, modified ecological regimes (resulting from change in a long range of parameters, such as changes in temperature of water in streams as a result of reduced influx of groundwater!).

Type of analysis or tool:

Monitoring: Measurements of changes in both groundwater levels (soundings), and changes in groundwater chemistry (e.g. chloride, sulphate, iron, nickel) to quantify effect of groundwater abstraction.

Model Approach: 2- or 3-dimensional hydrologic models (numeric computer models) used to assess changes in groundwater flow as result of abstraction, and also to calculate water balances. More refined 3-dimensional models can be used-to assess interactions with surface waters and calculate e.g. changes in streamflow.

Information and data requirements

For the application of models often-extensive requirements have to be met for input data. These data are often derived from existing monitoring data and pumping tests of groundwater wells.

For an adequate representation of the hydrological system you need distributed values for a long range of parameters (e.g. hydraulic conductivity and porosity), that are specific for the hydrologic system modelled and also for the geographical setting, to ensure valid results of the model. The more complex and accurate the model, the more comprehensive the data-requirements.

Furthermore, data for both calibration and validation of models must be available in order to test, if the model can precisely reproduce the responses of the hydrological system. These data can often be extracted from monitoring data, so that one part of the monitoring data are used when setting up and calibrating the model, and another part of the data are held back for later validation of the model.

Brief description including figures

Whereas monitoring directly can document failure to achieve good status for both surface and groundwater bodies, especially for groundwater bodies there is often a need to complement the assessment of impacts with models and calculations of the future impacts due to the inherent time delay of pressures on groundwater bodies.

Water balance models can be used on catchment scale. Both as "simple" conceptual models, but also as more elaborate numerical computer models. They can be used to calculate both amounts in cubic meters available for abstraction, and in this relation also be used in quantification of impact on e.g. surface waters, typically on streams.

This is widely recognised in Denmark, where hydrological models are used both in permitting water abstractions under consideration of the risks of saltwater intrusion or damage on associated surface waters/ecosystems. But also when calculating if remediation is necessary for example to ensure acceptable streamflow – and how it is most appropriately done (e.g. if this should be in the form of reduced abstraction or pumping of groundwater to the stream). In the example below, streamflow has been modelled in the County of Roskilde at different stations in order to calibrate the model and determine the hydraulic and other parameters of the system. The model will subsequently be used to assess the maximum groundwater abstraction permissible under consideration of the environmental objectives of the stream. Especially the low discharges are critical in this respect.

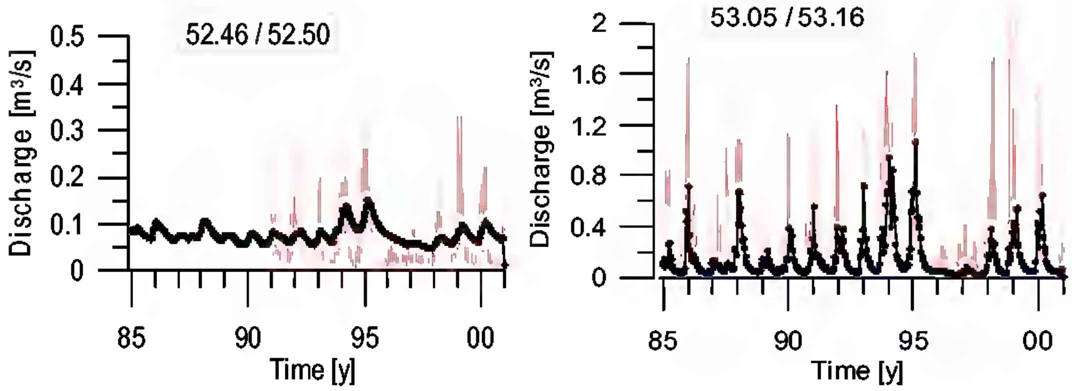

Figure 1: Calibration of hydraulic model on streamflow-data. Thick line: model results. Thin dashed line: recorded discharge. Left a poorly calibrated/determined, and therefore less precise, model. Right a well-calibrated/determined model.

(County of Roskilde (2002): Grundvandsmodel for Roskilde Amt by WaterTech a/s).

Also, the use of computer models makes it possible to make a qualified estimate of travel times for the impact of a given pressure in the form of pollution. This is relevant for assessing the impact on e.g. water supply wells, and also for other cases of groundwater pollution.

Lastly, computer models of hydrologic systems are in relation to groundwater used to delineate groundwater recharge areas. This is highly relevant in tracking the origin of a given impact and thereby the pressure/driving force, and, as a preventive measure, in spatial planning, so as to keep sensitive areas free from polluting activities.

Title: **No: 7**

APPLICATION OF THE RIVER SYSTEM SIMULATOR FOR OPTIMISING ENVIRONMENTAL FLOW IN THE RIVER MAANA (Norway)

Type of impact:

Altered flow regime

Type of pressure:

Water flow regulation

Type of analysis or tool:

The models ENMAG, HEC-RAS, QUAL2E, RICE and HABITAT in the River System Simulator (Alfredsen et al 1995) were used in this study.

The modelling approach was to set up and calibrate the model no flow release in the bypass Sections of the river, and simulate the impact of releasing 1 m3/s, 2.5 m3/s, 5.0 m3/s and 10 m3/s water as environmental flow.

How the decision was made based on the model

The scientists judged all model results manually, and a common integrated recommended flow was proposed.

In what ways did the application process represent state-of-the-art?

Three well-known and fully documented models (ENMAG, HEC-RAS and QUAL2E) and two newly developed models (RICE and HABITAT) were integrated with a common database and presentation tools in the River System Simulator. The integration represents the state-of-the-art.

Modeller-end-user communication

The end-user for the project, "The Eastern Telemark River Regulation Association", had established a reference group with participation of local and regional authorities, hydropower companies and local politicians. The project reported the progress to this reference group once a year. In the starting phase of the project, several meetings between two of the modellers and the end-users were arranged. The end-user had established a reference group. The final output of the project was seven scientific reports and one summary report.

Information and data requirements

The data collection strategy for hydraulic, habitat and fish data was to collect data intensively over shorter periods where water was released back into the river. Other data were collected on a continuous regular (monthly, daily and every 10 minutes) basis. Several of these models require the same input data. The following data were collected:

Technical and hydrological data for the power plants and the reservoirs in the system to run the ENMAG model.

Cross-section and water level data to run HEC-RAS, QUAL2E and RICE models.

River ice cover, water and air temperature data for the RICE model.

Data on the water quality parameters total P, total N, bacterial count, coliform and thermo tolerant coliform bacteria, pH, turbidity and water temperature were collected for the QUAL2E model at twelve sites along the river and at the outlet of several power plants. These data were collected once a month during a period of 14 months as well as during several periods of test water release to the river.

Water depth, current velocity and substrate size were collected for the HABITAT model along 5-12 transects at five fish habitat stations. Fish habitat use data was collected by snorkelling at the same stations during summer situations.

Brief description including figures

The River Maana in the central southern Norway about 150 west of Oslo is regulated with a large dam in the mountains and a total of 5 hydropower plants. The licence for the regulation was due for re-licensing, and this study was done to analyse environmental flow requirements with respect to water-covered area (aesthetics), trout rearing habitats, water quality, ice conditions and power production. The River System Simulator (Alfredsen 1995) was used to simulate and integrate the impacts of a range of 1-10 m3/s environmental flows to be released in the bypass sections of the two most downstream hydropower plants.

The affected bypass sections are of approximately 6 km and 8 km. Fish habitat simulations were done in detail at 5 selected representative reaches of 25, 48, 59, 60 and 286 m length. The other subjects were studied on the whole river part of 14 km.

Title: **No: 8**

AN APPROACH FOR ASSESSING ALTERATIONS IN THE RIVER WATER FLOWS PRODUCED BY RESERVOIRS

Type of pressure:

Water flow regulation

Type of analysis or tool:

Index for the maximum potential alteration of the natural water regime produced by water flow regulation.

Information and data requirements

- Map of water storage capacity upstream of any point of the hydrological network.
- Map of natural water yields.

Brief description including figures

The objective of this practice is have a straightforward index to evaluate the maximum potential alteration that could be produced by the water flow regulation.

The map of maximum potential alteration of the natural water regime produced by water flow regulation was made by calculating, using GIS techniques, the ratio between the map of annual water yields and the map of water storage capacity upstream of any point of the hydrological network.

Regulation dams can produce the greatest alteration on the temporal flow regime. Indeed regulation dams are constructed to modify the natural river discharge according to human requirements and such activity alters the natural water regime. The degree of degradation at any point of a river depends on three parameters: the volume regulated upstream of that point, the relative amount of water regulated related to the resources flowing through the river (in other words the storage-to-flow ratio), and the reservoir operational management.

The alterations produced by the management of the reservoir could be null if it reproduces the natural regime, or could make a total alteration of the regime if it stores all the resources and no water is released to the river. This latter case represents the worst effect that a dam can produce to the river flow, and it can be used to quantify the potential alteration of the natural water regime. First, a map of water storage capacity shows the volume of water that can be regulated upstream of each point. Then if the map of annual water yields is divided by the map of water storage capacity, the map of maximum potential alteration of the natural water regime produced by water flow regulation will be obtained.

Figure 1: map of water storage capacity shows the largest volumes exceeding 5.000 Mm^3, which are in the low courses of the large rivers (Guadalquivir, Ebro, Tajo, Duero and Guadiana), while there are some small basins which hardly reach 1.000 Mm^3 (Norte, Sur, C.I. de Cataluña, Galicia Costa and Segura).

Figure 2: shows the map of natural water yields

Figure 3: shows the map of maximum potential alterations by flow regulation. It presents a very different aspect compared to the water storage capacity map. Basins with very high absolute storage capacity, as the Ebro, show little altered regime due to its great natural contribution, while other rivers with also large contribution presents much greater possibilities of alteration (Tajo or Guadalquivir).

Furthermore, it must be recalled that we are referring to a maximum potential alterations, thus real alteration can be much lower than these. If one thinks, for example, in the frequent case of hydropower damming with high storage capacity and also high percentage of water returns, the potential alteration of natural waters regime downstream would be very high, but the real alteration produced would be very small.

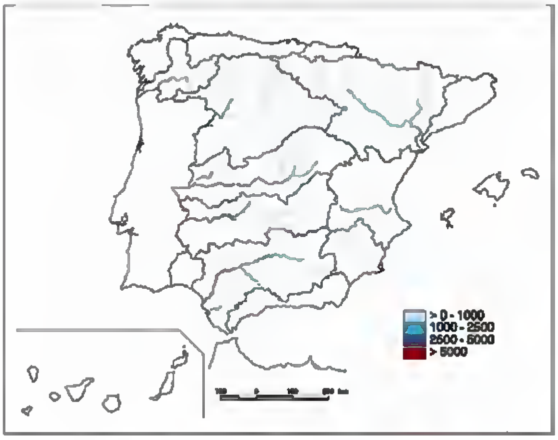

Figure 1: Map of water storage capacity upstream of any point of the hydrological network (Mm^3).

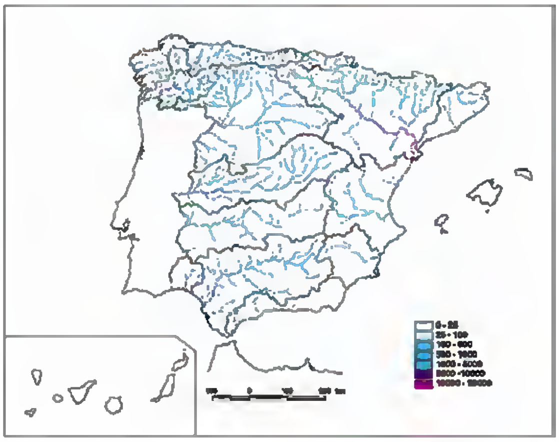

Figure 2: Map of natural water yields (Mm^3/year) Average (1940-1996)

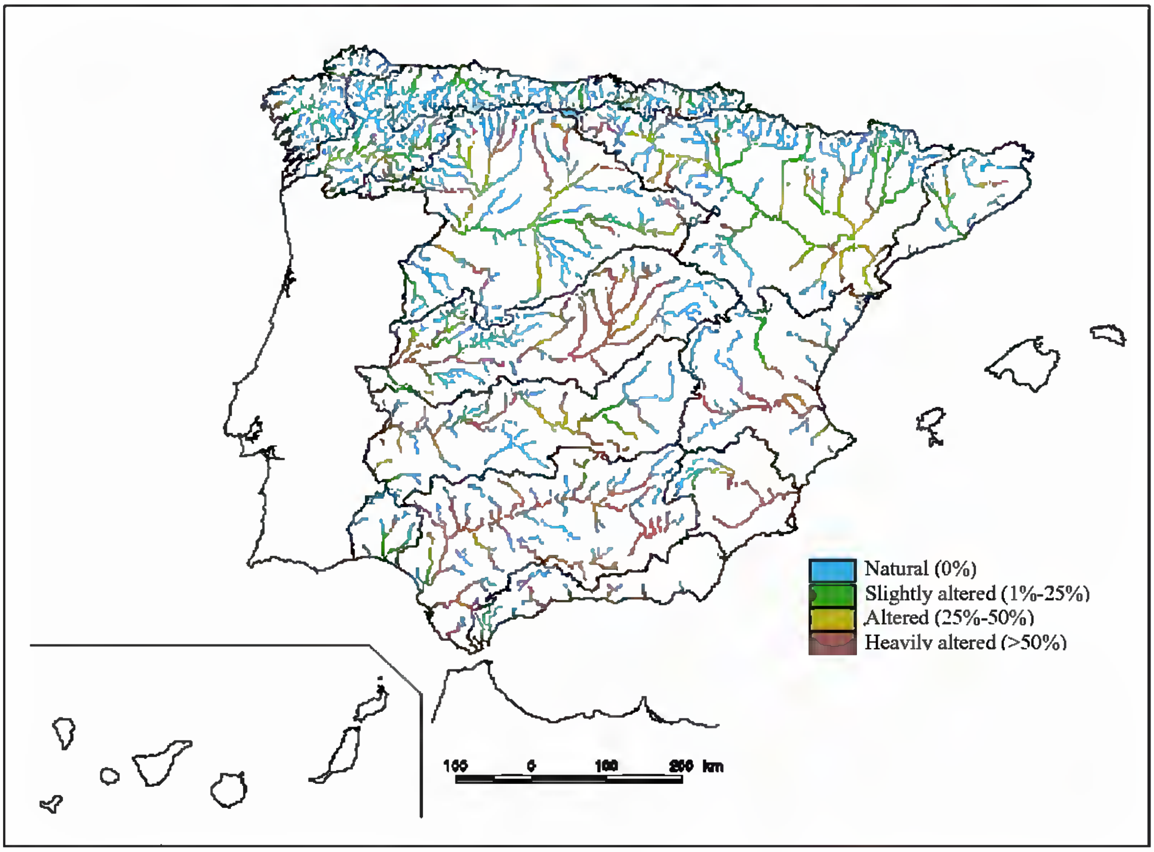

Figure 3: Map of maximum potential alterations by flow regulation.

Title: **No: 9**

HOW TO REPORT ON MORPHOLOGICAL ALTERATIONS RELATED TO HUMAN PRESSURES? (Netherlands)

Type of impact:

Altered flow regime results in significant changes of natural dynamics and habitat conditions.

Type of pressure:

Substantial change of estuarian flow characteristics resulting in morphological changes in the estuary

(Driver: Current and future demand for shipping requires deepening and widening of navigation channel in Westerscheldt estuary.)

Type of analysis or tool:

During the analysis there were no uniform criteria or reference conditions available from the HMWB-group or REFCOND for transitional and coastal waters. Therefor a set of objectives and indicators from the Long Term Vision for the Scheldt (TWG Scheldt Commission) is used as a preliminary set of reference conditions.

Information and data requirements

Data on habitat area (GIS), water depth, flow regime, sediment composition and sand transport.

Brief description including figures

The Westerscheldt is the major shipping channel to the ports of Antwerp and Vlissingen. In order to support economical developments the navigation channel has been deepened to grant access to larger ships and reduce dependency of the tidal changes. In the Westerscheldt estuary the continuous dredging and dumping activities related to this deepening have a major effect on the quality status of the system. Important effects are subsequent changes in morphology and habitat composition within the estuary. The Westerscheldt can be characterised as a transitional water and presumably as 'heavily modified'. This means with respect to the morphological state of the estuary that certain man-made alterations of the system are accepted as irreversible. This certainly reflects the presence of dikes for safety reasons and also to the navigation channel because of the economical importance. This implicates that the quality objective for this water body is the Good ecological potential, meaning the best possible ecological conditions within the irreversible changes.

The WFD requires an identification and analysis of the significant human pressures, including man-derived changes on hydromorphology. In order to structure the analysis 5 steps have been taken:

Step 1: system characterisation

The parameters of the most important system characteristics (annex II (par.1.2.3., V (par. 1.1.3. and 1.2.3) of the WFD have been used as a starting point for this description.

Step 2: establishing reference conditions and morphological quality objectives

A reference condition of the morphological status that sufficiently meets the WFD quality objective given by GEP had to be described. Such a reference condition was not sufficiently specified and quantified in the available literature. Since a static (geographical of historical) reference condition is not practical to use in a dynamic estuarine system, the objectives of the 'Long-term vision of the Scheldt estuary (LTV)' are used to derive significant pressures and impacts and to identify criteria to monitor system changes. The LTV focuses on the preservation of essential natural dynamics in an estuary. Two major system objectives are used for this purpose: (1) the multichannel system should be kept intact (2) there should be sufficient space for dynamic sedimentation / erosion processes and changes in habitats.

Step 3: Identification of significant pressures

The assessment whether a pressure on a water body is significant must be based on a general conceptual understanding of the pressures (e.g. water flow) and their impacts on the system (e.g. the related changes in morphology and the ecological functioning and habitats of the system). In the case of the Westerscheldt expert knowledge was used to firstly list all potentially relevant pressures and then in a second step to identify the most significant pressures. Significance only becomes meaningful if determined towards an objective or reference condition. The criterion used for the prioritising was the relevance of the pressure for reaching the system objectives as described in the LTV.

Step 4: Assessment of impacts

Important goal of the first review in 2004 is to identify the major pressures and their impacts. The pressure with the strongest impact is 'deepening and widening of the navigation channel'. Consequently this activity also has the largest potential to meet or fail the future objectives as formulated in the LTV.

Step 5: Identification of relevant indicators for monitoring impacts

The relationship between pressure and impact has been used to identify relevant indicators to monitor morphological changes. For the multi channel relevant indicators seem to be i.a. shore-length of tidal flats, intertidal area, ebb/flood domination, net sediment-transportation, relation primary channel transport versus secondary channel transport. For the objective of enough space for natural dynamics relevant indicators of the height of intertidal flats and lower salt marsh area have been suggested.

Unfortunately the relationship between pressure/ impacts and morphological criteria has not been established thoroughly enough to be able to derive an operational classification system yet, so much depends on expert knowledge. Nevertheless trends away from achieving good ecological status can already clearly be identified for this indicative parameters. (see the graph on increase of area of higher salt marshes which mean that the area of relevant lower salt marsh is strongly reducing). The first review in 2004 is a screening step. It designates the prime aspects that should be treated in the RBMP. For morphology it reveals a number of relevant gaps in knowledge that should be filled in the next steps towards the RBMPs.

Higher salt marsh area

SCREENING AND IMPACT ASSESSMENT USING EUROWATERNET METHODOLOGY FRENCH APPLICATION (France)

Type of impact:

Organic matter, nutrients, eutrophication, in rivers

Type of pressure:

Point and diffuse sources of OM, P, N, estimated trough their driving forces.

Type of analysis or tool:

Statistical technique to organise use of monitoring data and assess spatial and temporal relationships between pressures and impacts

Information and data requirements

Monitoring stations location and observation raw data,

Catchments structure,

CORINE *land cover*, administrative and catchment limit

Population per NUTS5

Other information can be entered in the stratification system

Brief description including figures

The methodology

Land cover types and population density define the main driving forces that impact river quality. The proportion and combination of land cover types and population density are used to define strata of potential pressures that make it possible to earmark each monitoring station. The stratification process takes into account the sub-catchment and the catchment size as well in order to select stations equally across the whole territory.

The stratification aims at clustering the monitoring stations by groups of identical input discharge. If the strata are well defined, then it is expected that the pollution density (as kg y^{-1} $(km^2)^{-1}$), on the one hand and standard discharge (in m^3 y^{-1} $(km^2)^{-1}$) on the other hand produce concentration data belonging to the same statistical population.

Under these hypotheses, the stratum means and stratum variance can be computed as combinations of point means and variances. Consequently, it becomes possible to compare strata, combinations of strata * catchment and time trends.

The application

Implementation of EuroWaternet in France is now fully operational. A detailed statistical study, using geostatistical processes (multidimensional kriging) demonstrated that 6 strata (dense urban, urban, mixed (urban + intense agricultural), intense agricultural, moderate agricultural, low impact) were sufficient to describe the drivers impacting rivers.

As response to EuroWaternet requirements, 512 sampling stations were selected. For domestic purposes, this selection was extended to ~1500 stations (number is slightly year dependent) which are used for representing the water quality issues, **when statistical indicators are involved.**

In a second stage, the methodology is used to define the optimum share of stations as function of pressures on catchments. An optimum network of 2500 stations was defined and is currently under closer examination. This result is not presented here, since it is not in line with pressures and impacts. However, it is emphasised that quality of monitoring greatly determines the accuracy of impact assessment.

Some results

The stratification can be reported as a map of stratum types per elementary catchment (currently 6210). The colour code in each catchment represents the cumulated expected impacts from the upstream part of the catchment.

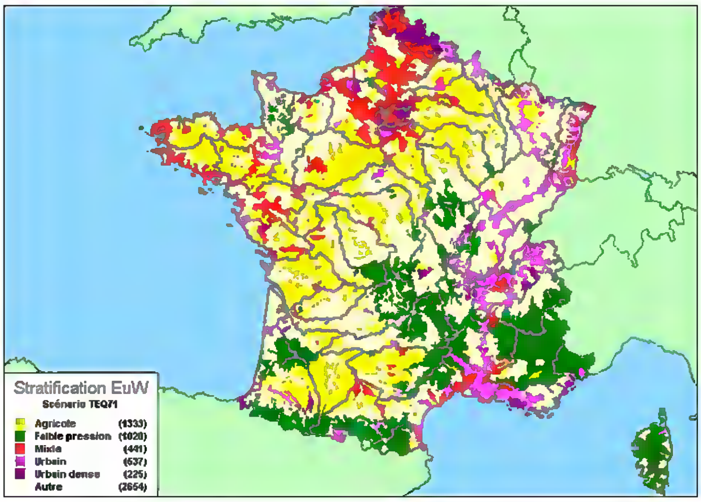

Fig. 1 Current EuroWaternet stratification types used in France.

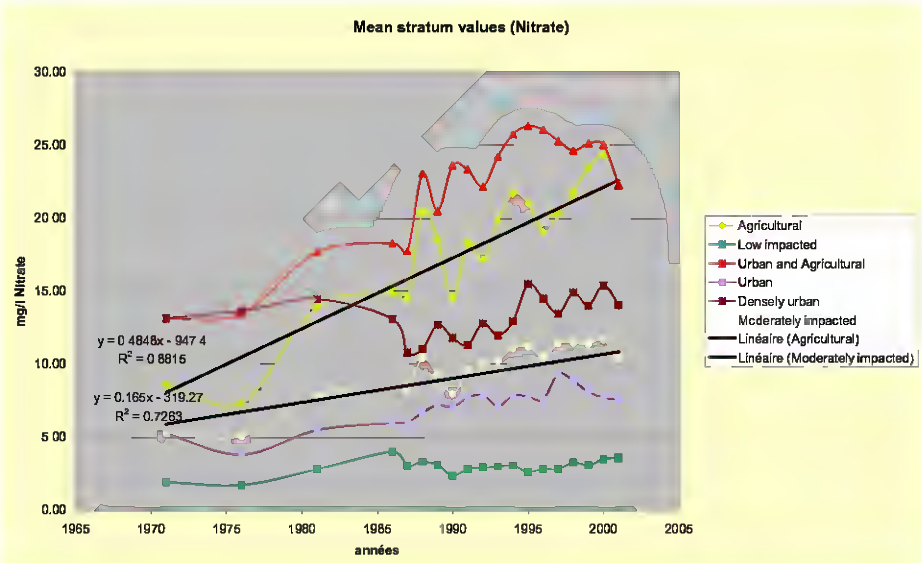
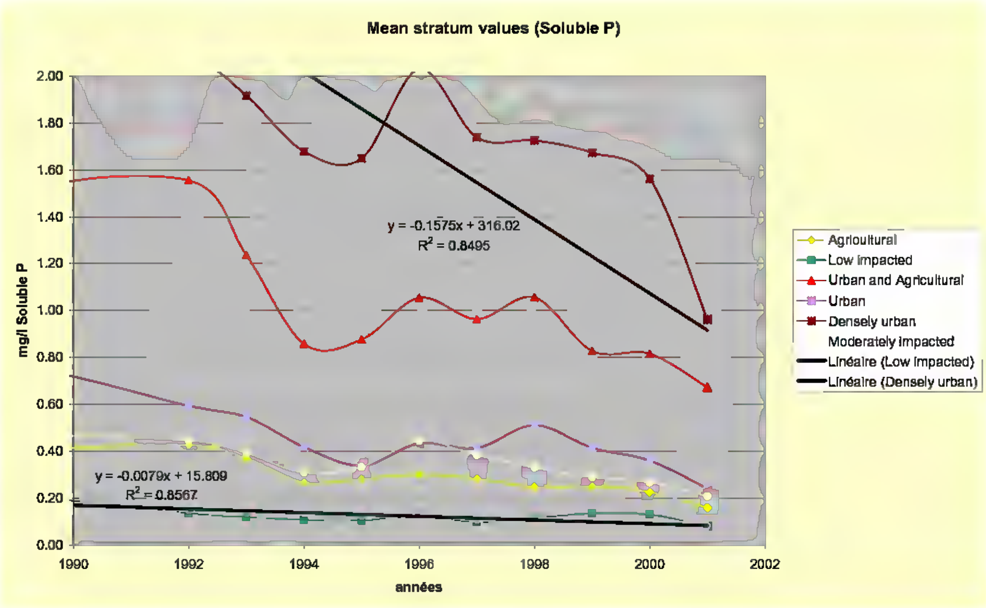
The stratum type applies to any station situated on the main channel of the river draining any of the 6210 elementary catchments defined. The greyed lines indicate the 55 operational catchments used to force point selection even across metropolitan France.

The foreign part of catchments are considered in the calculations.



In the above example, nitrate per stratum (in this case all French EuroWaternet points are processed) shows clear upwards trends in intense agricultural, mixed and moderately impacted (agricultural) strata. Hydrology effect is not removed from averages, this procedure emphasises the time trend, supposedly in relation with activities.



In the above example, soluble Phosphorus per stratum (in this case all French EuroWaternet points are processed) shows clear downwards trends in all strata. The improvement is very effective in the most impacted strata, in relation to sewage purification and decrease in detergent P-borne. Hydrology effect is not removed from averages. In this case, the quality of relationship would have been improved, since P averages are very sensitive to dilution.

In both exemplified cases, trends, with baseline scenario, can easily be carried out and indicate which water bodies would be at risk or not of failing objectives.

Title: **No: 11**

QUANTIFYING IMPACT OF PRESSURES AND LIKELIHOOD OF MEETING OBJECTIVES BY MEANS OF THE WATER ACCOUNTS METHODOLOGY (EUROSTAT). FRENCH APPLICATION (France)

Type of impact:

Organic matter, nutrients, eutrophication, pesticides, biological status in rivers

Type of pressure:

Point and diffuse sources of OM, P, N, etc estimated either through their driving forces or actual pressures.

Type of analysis or tool:

The Water Accounts methodology apportions the water quality assessments (not raw concentrations) in proportion of the size of water bodies. This method yields a quantity of quality that can compare with pressures (as loads) or with costs (as amount of money).

Information and data requirements

Monitoring stations location and observation raw data,

Quality assessment method to calculate quality indexes or classes,

Catchments structure and river network structure,

Standard discharges values (average, low flow values) to calculate weighting data.

Brief description including figures

The methodology

Water accounts methodology was designed first to build observation systems representative of the river network structure (whereas EuroWaternet yields representative sample of the monitoring network and responds to different objectives).

Several countries, including France, adapted it on behalf of Eurostat. The aim is to allow comparisons of quality state between catchments or NUTS areas and to make it possible to assess the cost of quality improvement.

The heart of the method is very simple: each river segment has a weight, calculated as length times the standard discharge. This quantity, named SRU (Standard River Unit / UMEC Unité de Mesure des Eaux Courantes) homologous to local energy content can therefore be added, compared and has a finite value, independent of map accuracy.

In a second step, quality assessed (or extrapolated) for each segment is processed as quantities of quality. Since quality classification schemes refer to classes, it becomes possible to match quality related to nitrate with quality expressed as biological indicator, provided the classification scheme is internally consistent.

The most developed state of methodology is now available, after recent French and EEA developments providing a full chain of production from monitoring data to aggregated indexes (catchment and NUTS) and b) comprehensive set of indicators as well as a trial in four countries (Ireland, UK, Slovenia and France).

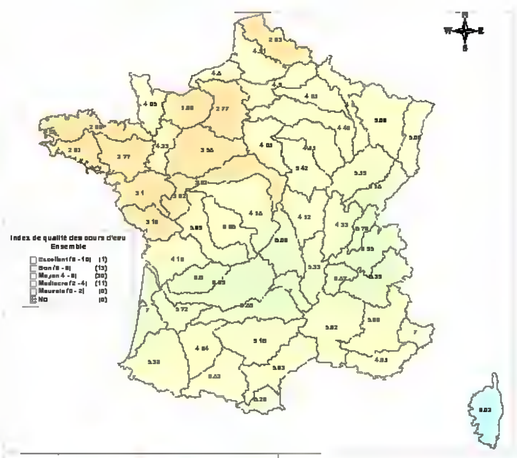
The application

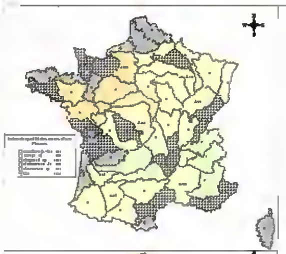
For the time being, the most comprehensive application was carried out in France. However, examples are given for other countries to demonstrate the flexibility of the method.

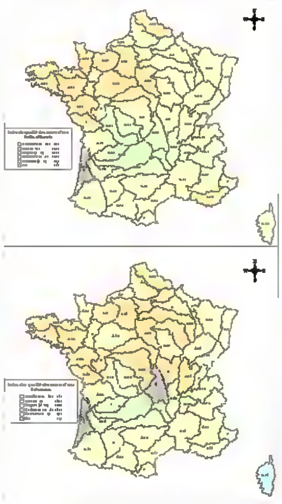
Thanks to the latest developments, the following information is provided by the application of the software available (in France NOPOLU).

- Quantity of SRU, per quality class, for the different assessment types, if relevant, per river rank, aggregated per catchment (any size type) or NUTS. These quantities directly compare with stock-like units: volume of discharge, amount of money;
- RQGI (River Quality Generalised Index), which is a generalised water quality class encompassing the distribution of quality classes over the aggregation domain (from all river types of a country to a river size class of a catchment);
- Pattern Index, indicating what is the profile of a quality problem of the considered domain of aggregation (mediocre everywhere, good with "black spots", etc.);
- Relative importance index, obtained by comparing the SRU resulting from different quality assessments. For example, comparing nitrate and eutrophication. Quantitative information, for all aggregation units becomes available. Of course, changes in time can be compared as well.

Some results

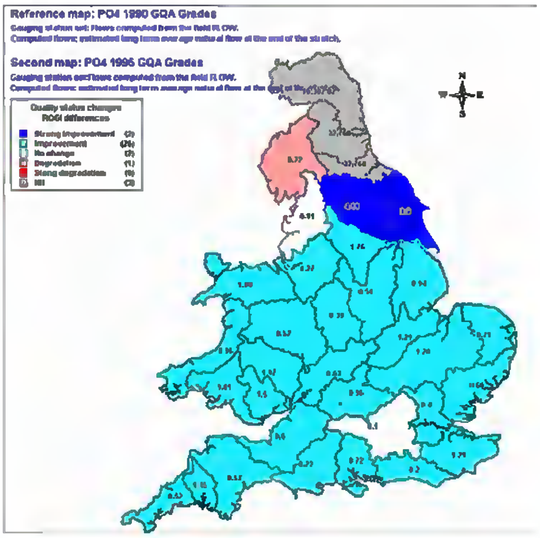


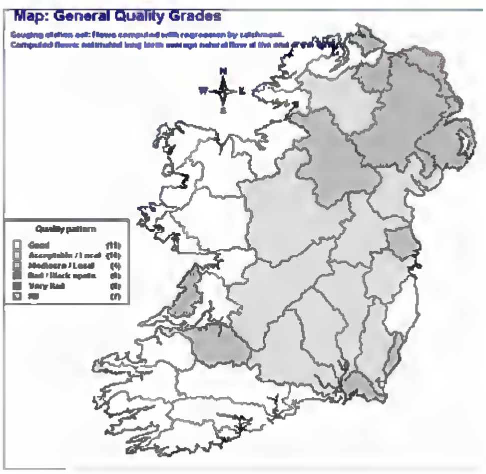




The five maps above (from the 2002 French State of the Environment report) show the aggregated **RQGI**, all rivers (left), for the 55 reporting catchments, and the RQGI broken down in four size classes (left, right, up, down; largest, large, medium and small rivers)

The right bottom map represents the changes in water index in England and Wales, per catchment, with respect to phosphorus contamination of waters. The range of colours indicate improvement (blue) or degradation (red).





The other figure, on the right, shows the pattern of river quality in the Republic of Ireland, considering biological quality. The patterns suggest that local pollutions are responsible for the observed mismatches with good quality objectives. This can facilitate orientation of assessments and further action plans.

Title: **No: 12**

WATER QUALITY MODELLING IN TEJO RIVER (Portugal)

Type of impact:

Analysis of water quality in the main river

Type of pressure:

Water quality in tributaries and loads from point sources

Type of analysis or tool:

The water quality model adopted for the simulation of the river was the Enhanced Stream Water Quality Model QUAL2E model (EPA, 1987).

Information and data requirements

Information and data on flows and on water quality were obtained on the Networks Monitoring. Loads from point sources (urban wastewater and main industries).

Brief description including figures

Methodology and Application

Tejo river basin is one of the largest in the Iberian Peninsula, with an area of about 80 629 km², being 55 769 km² (69%) in Spain, and 24 860 km² (31%) in Portugal. This river travels along 230 km in Portugal and discharges to Atlantic Ocean, after crossing Lisbon City.

In the last years the natural regime has changed and the flow from Spain has decreased significantly due to the construction of a large number of reservoirs and the increase of water demands. As a consequence, the water quality characteristics, within the basin, have also been significantly changed during the recent past due to anthropogenic actions.

Concerning the production of drinking water, the greater Lisbon area and several municipalities in the lower Tejo region, with a population of more than two million people, are supplied by several surface water abstractions. Due to great social, ecological and economic importance, the Tejo watershed has been studied with the purpose of identifying the relevant point and non-point pollution sources, to characterise water quality and adequacy to the observed and proposed uses. With all this information available it's possible to apply and calibrate models to simulate the evolution of water quality, for different scenarios of hydrologic conditions and pollutant loads.

Several water quality models were evaluated for suitability to the Tejo River. The water quality model adopted for the simulation of the river was QUAL2E model (EPA, 1987), which was considered to be more adequate to the program goal and the available data.

The river reach studied is between the boundary section, used as headwater, and the beginning of the estuary (last element in the system), with a length of 150 km. A computational element length of 2 km was chosen as sufficient to describe spatial detail along the river. In the river reach under study there are two dams, Fratel and Belver. Due to their hydraulic characteristics and operational conditions they were treated as a stream segment were the flow is unidimensional and is not affected by stratification. Phisiographic data was based on transversal profiles surveyed in the 1970's. Information and data on flows were obtained on the Freshwater Network Monitoring. Figure 1 shows the reaches and computational elements considered. Also illustrated are the 25 point loads considered and localisation of dams.

Figure 1 – Reaches, computational elements and 25 point loads considered, and localisation of the dams.

Currently, there are 50 water quality sampling stations in the Tejo watershed, where sampling is done monthly. The Tejo river model input used observations of water quality at stations located at the national border (headwater in the model) and at the last element in the system (beginning of the estuary). QUAL2E can incorporate fixed downstream constituent concentrations into the algorithm. When no direct observations were available, inflows and associated concentrations of water quality were estimated. Estimate values of these flows were made by hydrologic balances of river segments, based on the locations of sampling stations. Nutrient concentrations in flows entering the river were estimated with the available data.

The Tejo River model calibration utilised prototype observations of water quality for nine sampling stations. Annual means and summer means were selected to represent two hydrologic and climatologic regimes. Summertime characteristics with low flow conditions were simulated, permitting to analyse the behaviour of the river in the worst conditions of wastewater discharge with increase of pollutant loads to the system. Several calibration data sets corresponding to specific sampling data in summertime were selected to provide a variety of hydrologic conditions.

Results

A geometric representation of the hydraulic characteristics of the stream channel was used. Stream velocities and flows determined by the model were found to be suitable to represent the Tejo River. The two dams present in the first 50 km of the river are responsible for the low velocities observed.

Figures 2 and 3 illustrate the results of the application of QUAL2E to the Tejo River for summer conditions. The results are analysed taking in account the field observations, the major uses of the river and compared to water quality objectives set by national and international legislation. Calibration sequence for quality variables was temperature, dissolved oxygen, BOD, phosphates, nitrates and ammonia. Results of calibration were generally good, except for ammonia.

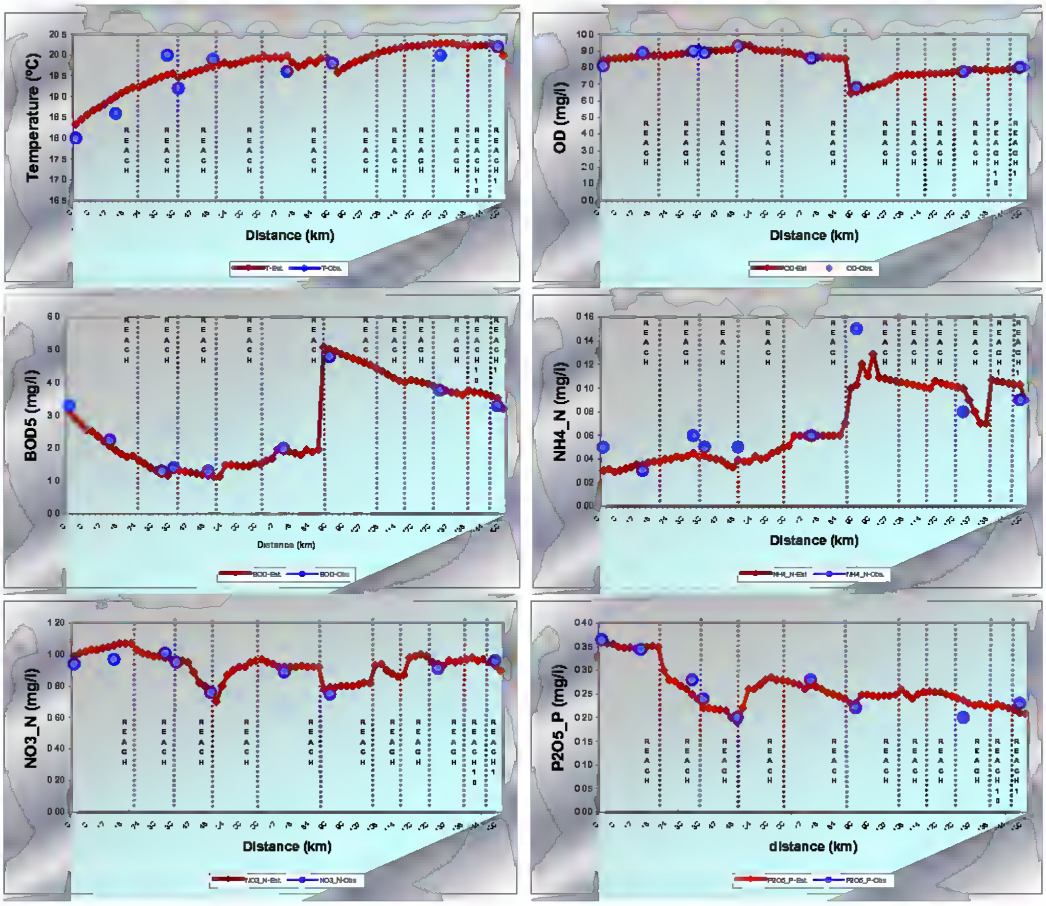

Figure 2 - Comparison between QUAL2E output and observed values in the sampling stations of Tejo.

The profiles obtained for the parameters (Figure 3) represent the actual impact on water quality from the different sources of pollution that affects the Tejo River. The big reservoirs in Spain have some effect by reducing BOD, but in terms of nutrients high amounts continue to reach to the border. This will affect the two reservoirs in the national part that have already problems of eutrophication. On other hand, in the national basin there are some problems, especially the impact of the paper industry and Zêzere plus Nabão Rivers, which have a representative flow. Also two important tributaries, Almonda and Alviela Rivers represent a significant contribution of pollution that affects the Tejo River more downstream.

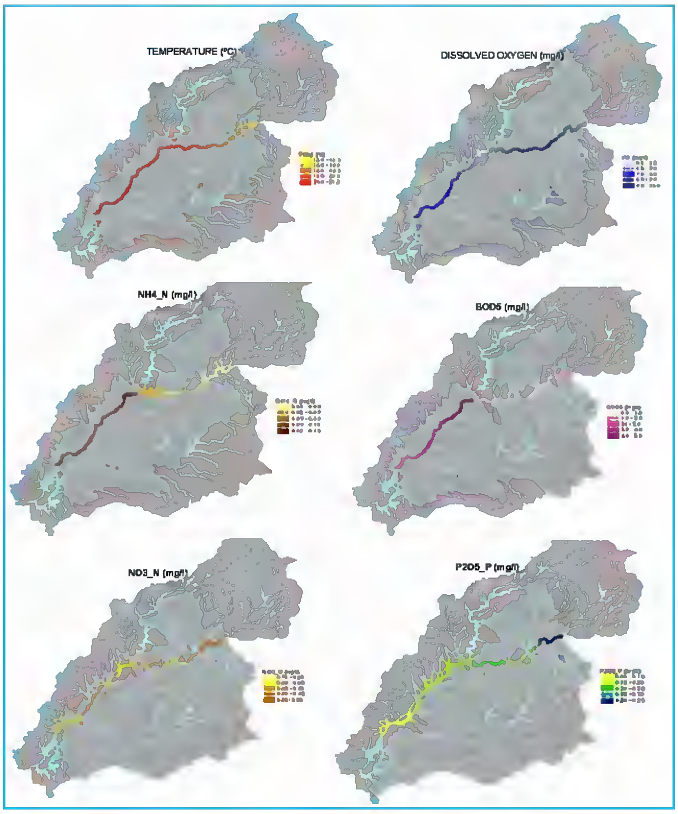

Figure 3 - Profiles of QUAL2E using GIS maps.

Title: **No: 13**

CRITERIA FOR THE INVESTIGATION OF SIGNIFICANT PRESSURES AND EVALUATION OF THEIR IMPACTS FOR PURPOSE OF REPORTING TO THE EU COMMISSION; - STRATEGY PAPER OF THE WORKING GROUP OF THE GERMAN STATES ON WATER (LAWA) – (Germany)

Type of impact:

Status and change of water quality (eutrophic and saprobic status, toxicity, rewarming), changes of habitat, changes of the hydrological regime

Type of pressure:

Point sources, diffuse sources, water flow regulation, morphological alterations, heat input

Type of analysis or tool:

Analysis of existing data on emissions and on the state of a water body, threshold values or balance models for diffuse sources; analysis of impacts based on quality objectives and threshold values, knowledge of experts

Information and data requirements

Data on emissions (communal waste water discharges, industrial waste water discharges) data on land use, data of the state of water body (physicochemical measurements, data on quality of waters and structures of the water body), data about water abstraction

Brief description including figures

For the purpose of investigating significant pressures and evaluating their impacts, a strategy paper was compiled in Germany by the State Working Group on Water (LAWA). The objective is an efficient procedure, agreed on by all states, for compiling the inventory in accordance with Annex II of the Water Framework Directive (WFD) by the end of 2004. For the first description, the strategy paper is oriented on the availability of meaningful and stable data. Should a more extensive description be required, more detailed data will be compiled and, if necessary, collected locally.

Table 1: Data to be collected for different pressures

PRESSURES	**Criteria**
Point sources	
• Public sewage-treatment plants >2000 PE (derived from Urban Wastewater Treatment Directive)	Annual volume of water discharge Population (P) and population equivalents (PE) Substance loads according to Annex I of the German Wastewater Directive Annual loads of priority substances, substances of the quality objective directive, and river basin-specific substances, insofar as these substances are limited by water directives
• Industrial direct discharge	Statement of systems according to IPPC Directive = pollutants according to EPER Annual loads of plants with obligation to report according to IPPC Directive: consideration of the particular size threshold for the annual load of 26 substances (cf. Table 1: Size thresholds; EPER) Annual loads of priority substances, substances of the quality objective directive, and river basin-specific substances, insofar as these substances are limited by water directives Food industry facilities >4000 EP
• Storm water / combined wastewater discharges	Discharge of wastewater from an urban area >10 km^2
• Discharges with heat load	Discharges with heat load >10 MW
• Salt discharges	Discharges >1 kg/s chloride
Diffuse sources	Not yet finally defined, coordination with criteria for endangerment of groundwater bodies
Water abstraction	Abstraction without recirculation >50 l/s
Water flow regulation	Procedure for small/medium-sized water bodies: o Parameter "anthropogenic barriers" (Stream habitat survey): ≥6 o Parameter "backwater" = 7 or according to general procedure: o Impassable anthropogenic barriers and backwater
Hydromorphological alterations	Based on the results of river habitat survey or similar investigations: "Water-body bed dynamics" with structural classes 6 and 7

For the purpose of compiling the significant pressures, the WFD indicates which substances and groups of substances are to be considered. In some cases, data that have already been compiled on the basis of other directives (e.g. communal wastewater directives) can be used. Table 1 illustrates what information is to be gathered for the various pressures.

Supplementary to the emissions data, data on the state of a water body available from environmental surveillance should be examined. Primarily data on the state of a water body will be considered to evaluate the impacts of the pressures and will be judged according to quality objectives and aggregation criteria. As a rule in Germany these data are present in the spatial density adjusted for the quality aspects and the site of the impact. If these are insufficient, an assessment or consideration of a model based on established pressures is necessary. An estimation of probability that the good ecological or chemical conditions will not be achieved within a period of observation will be made on the basis of the criteria presented in Table 2.

Table 2: Information necessary for the assessment of impacts

Indicator	Threshold values
Saprobic status	30% of stream network > national biological quality level (here: biological quality level II; indicator macrozoobenthos)
Trophic status	➢ 30% of stream network > national quality level (here: trophic class > II, indicator: chlorophyll a, pH, O2) ➢ also in discussion, but not yet finally defined: assessment by nutrient content/load of the rivers
Physicochemical substances	Exceeding existing quality objectives or quality criteria of EU directive 76/464/EEC and knowledge about entries of priority substances
Warming	According to the EU Fish-Life Directive: - max. annual temperature: >21.5°C (salmonid water body) >28°C (cyprinid water body) - max. winter temperature: >10°C (salmonid water body) >10°C (cyprinid water body) - max. warming up: 1.5 K (salmonid water body) 3.0 K (cyprinid water body)
Salinisation	Median: CI > 400 mg/1
Morphology	- River habitat survey -- overview method: More than 30% of the river distances within the management unit are surveyed with structural quality classes 6 or 7 for the compartment "river bed". - Impairment of river continuity >30% of stream network

The utilisation of the strategy paper has already been tested in the pilot projects "Große Aue" and "Middle-Rhine". The strategy paper will be continued from case to case in consideration of new developments.

CASE STUDY "GROßE AUE" – DEVELOPMENT OF A RIVER BASIN MANAGEMENT PLAN FOR THE CATCHMENT „GROßE AUE" WITHIN THE RIVER BASIN DISTRICT WESER

Type of pressure:

Urban discharges, land use, water flow regulation

Type of impact:

Urban discharges, land use: Increasing loads, alteration in saprobic status

Water flow regulation: Morphological alterations, migration barriers

Type of or tool:

Urban discharges, land use: Monitoring of all sewage treatment plants and combined stormwater discharges, evaluation of data from CORINE landcover. Combined assessment of point sources and diffuse sources, for nitrogen and phosphor with a mass balanced model as statistic tool (MOBINEG).

Water flow regulation: Two ways of river habitat survey

Information and data requirements:

Urban discharges: Sources of Data: StUA (environmental authority) Minden (North Rhine-Westphalia); Bezirksregierung (regional gouvernment) Hannover (Lower Saxony):

- Self-control with data-sets depending on the size of sewage water treatment plants;
- Officially controlled 4 times a year.

Land use: Sources of Data: Federal Statistical Agency, basing on Dates of:

- Landwirtschaftskammer (agricultural administration) North Rhine-Westphalia;
- Landwirtschaftskammer (agricultural administration) Lower Saxony.

Water flow regulation: River habitat survey

- River habitat survey North Rhine-Westphalia: Operational detailed assessment; basing on „on-location" knowledge; Scale: 100 m
- River habitat survey Lower Saxony: Overview method; basing on maps, aerial view, collected data; Scale: 1000 m.

Brief description including figures

Aim of these pilot-project of the implementation of the Water Framework Directive was:

- to investigate the driving forces and pressures in the catchment area of the "Große Aue" (northern German low-lands) for surface and ground water bodies;
- to exemplify a programme of measures for achieving the good ecological status;
- to compile an orientation guide for provision, organisation and interpretation of data;

As main pressures, urban discharges (point sources), land use (diffuse sources) and water flow regulation were identified. To assess the influences of point- and diffuse sources on the input of the nutrients nitrogen and phosphor into surface waters a combined mass balanced model, MOBINEG, was used. With this tool effects of sources can be displayed clearly:

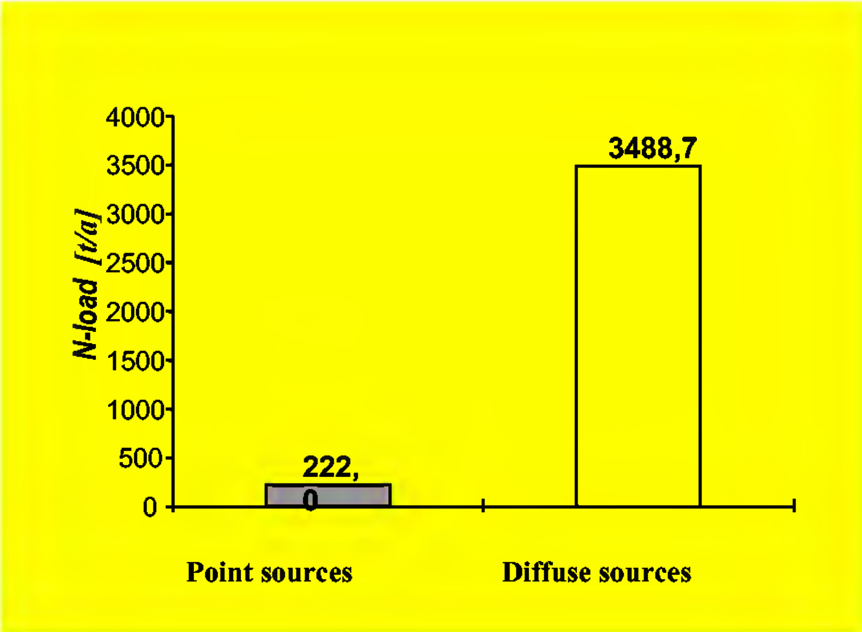

Fig. 1: N-loads from point- and diffuse sources in the catchment area of the river „Große Aue“

Referring to the diffuse discharges the cultivated areas are the main sources. Nearly 90 % of the diffuse nitrogen discharges to the surface water bodies come from cultivated areas.

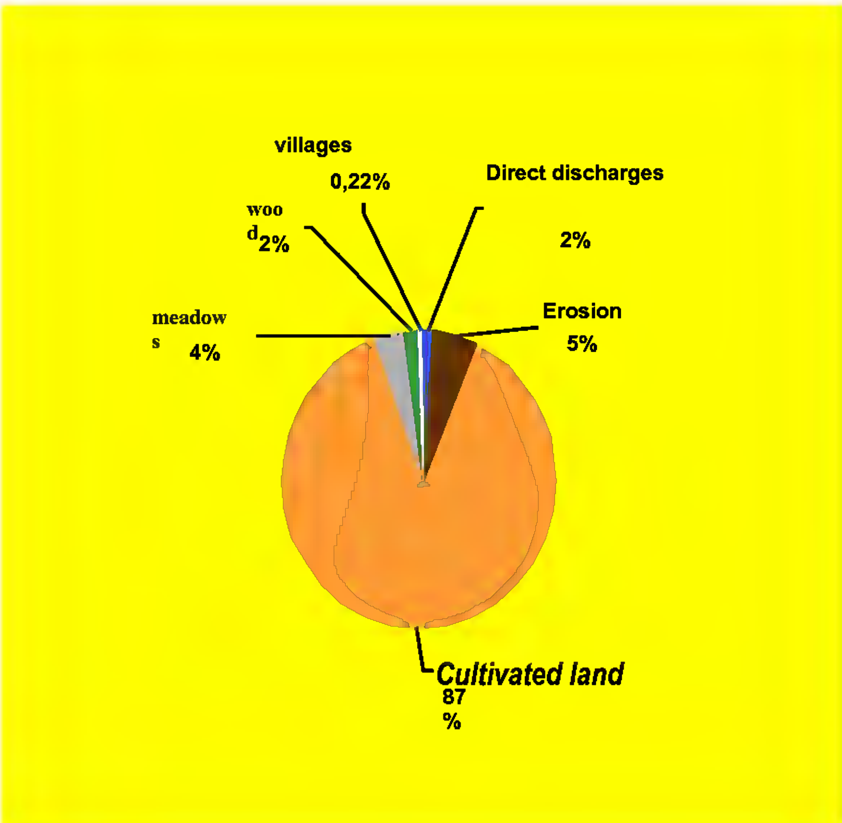

Fig. 2: Percentage of named diffuse sources concerning the N-loads in the catchment-area of the river „Große Aue“

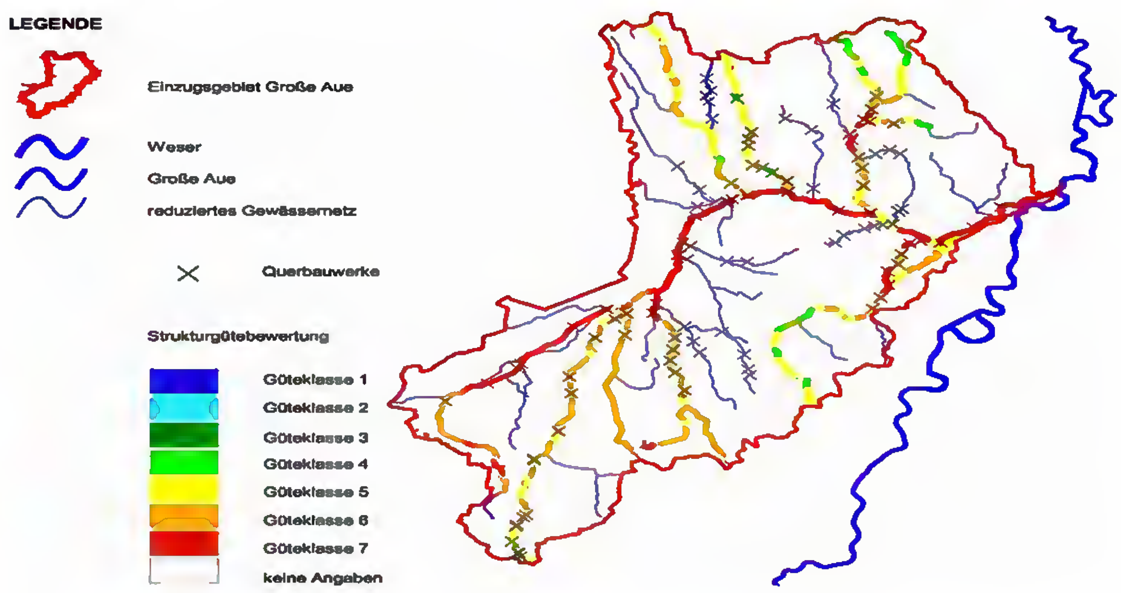
Within the scope of the case study „Große Aue" investigations on the flora and fauna of the river „Große Aue" and several studies have been carried out. The present composition of species shows some lack in indigenous species and migratory fish, which result from impairment of river continuity as well as hydromorphological alterations (flow regulation, flood protection). The results of the river habitat survey are shown in the form of a map which also includes information about the migration barriers:

Fig. 3: Results of the river habitat survey



In Germany for the reason of investigating significant pressures and assessing their impacts the State Working Group on Water (LAWA) developed a viable strategy paper. The objective is an efficient procedure, agreed on by all states, for compiling the inventory in accordance with Annex II of the WFD by the end of 2004. For the first description, the strategy paper is oriented on the availability of meaningful and robust data. Primarily data of the state of a water body (saprobic status, trophic status, physico-chemical substances, structure of a waterbody) will be used to assess the impacts of the pressures and will be judged according to quality objectives and aggregation criteria. The utilisation of the strategy paper has already been tested in the pilot project "Große Aue".

PILOT-PROJECT MIDDLE-RHINE: DEVELOPMENT OF RIVER BASIN MANAGEMENT PLAN

Type of impact:

Habitat alterations, modifications of the hydrological regime

Type of pressure:

Diffuse sources, water flow regulation, morphological alterations

Type of analysis or tool:

Analysis of available data of emission and of the state of a water body, balancing models, impact analysis basing on quality objectives and threshold values, expert knowledge

Information and data requirements:

Data of the state of a water body (physico-chemical measurements, water quality and structure of the water body), data about water abstraction, structural state of waters

Brief description including figures:

For purpose of surveying the significant pressures and assessing their impacts the LAWA-group in Germany developed a viable Strategy Paper (see previous example of current practice). With the "Middle-Rhine-Project" of the German federal states Hesse and Rhineland-Palatinate an example, following the LAWA-criteria, concerning the inventory taking according to ANNEX II of the WFD until the end of 2004, is given. Figure 1 shows the surveyed catchment area of the project:

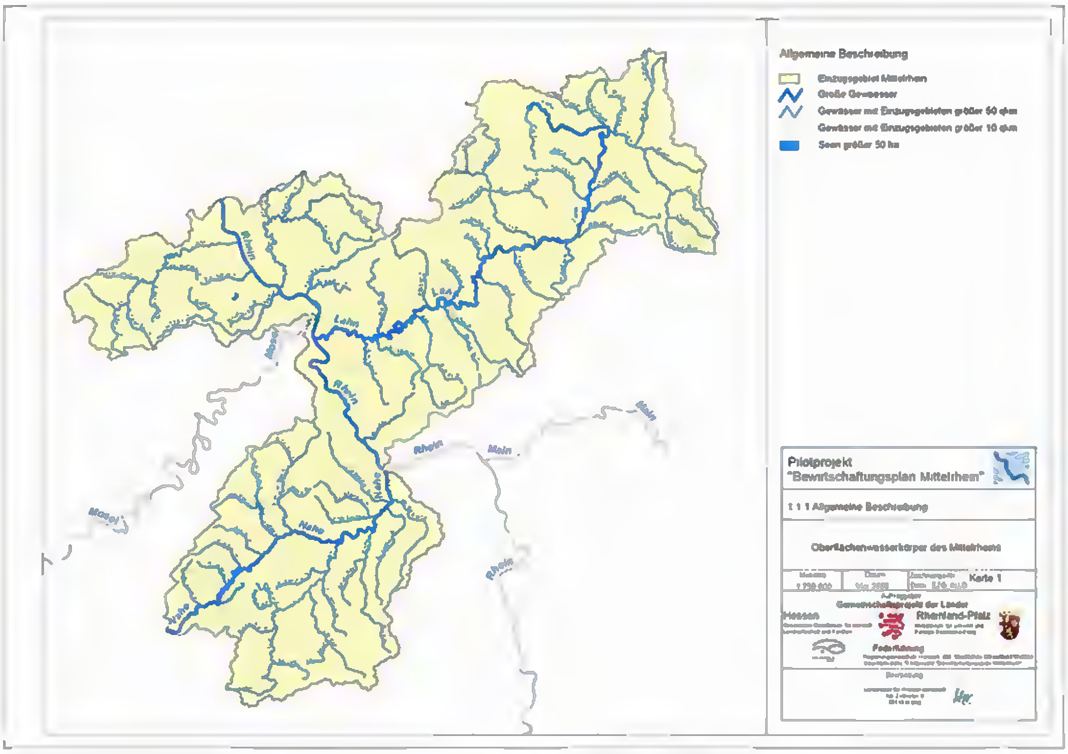

Figure 1: Catchment area of the "Middle-Rhine"

In the project some LAWA-criteria and their combinations concerning point and diffuse sources have been tested on the base of 10 km²-units. As an example the diffuse sources:

- Cultivated land > 50% (current value is still discussed);
- Urban land > 15%;
- Special crop land > 5%;
- Cultivated land > 50% and urban land > 15%;
- Cultivated land > 50% and special crop land > 5%;
- Special crop land > 5% and urban land > 15%;

have been tested. Figure 2 shows the significant areas:

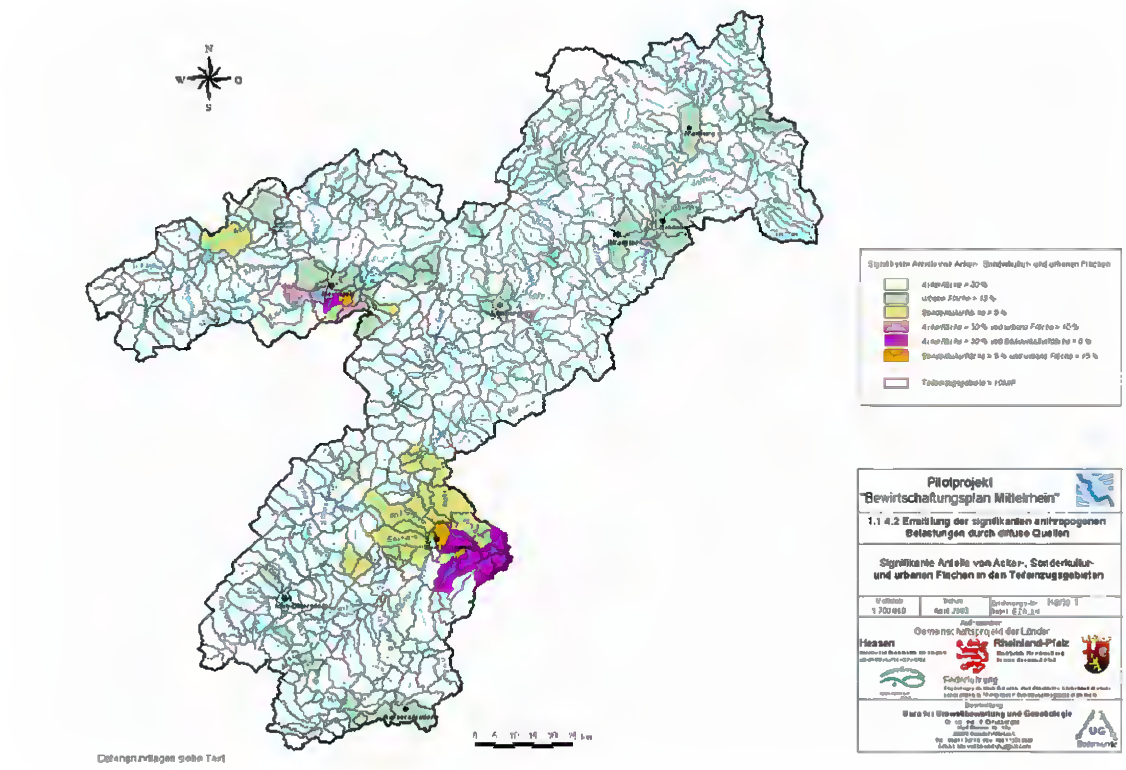

Figure 2: Significant areas concerning diffuse sources in the catchment area of the "Middle-Rhine"

In addition to the emission data, other available data on the state of a water body from environmental surveillance have been considered. For the assessment of the impacts, primary data on the state of a water body have been used. Concerning morphology the former LAWA-criteria regarding the of surveyed river distances (Stream habitat survey - method for little and medium size waters in Germany; LAWA (2000)) with:

- Structural quality class >4 in free landscape (has been adapted from 3 to 4)
- Structural quality class >5 in urban areas

have been tested.

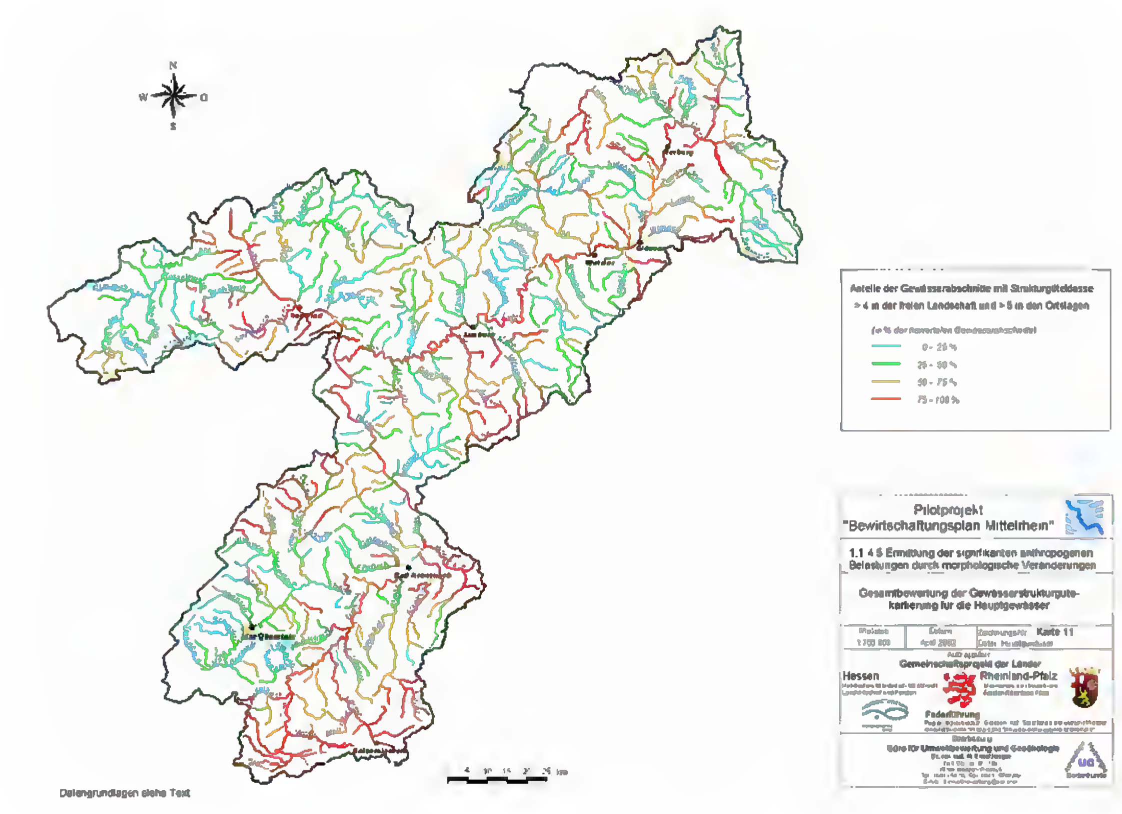

Figure 3: Amount of surveyed river distances with structural quality class >4 in free landscape or structural quality class >5 in urban areas in the catchment area of the "Middle-Rhine"

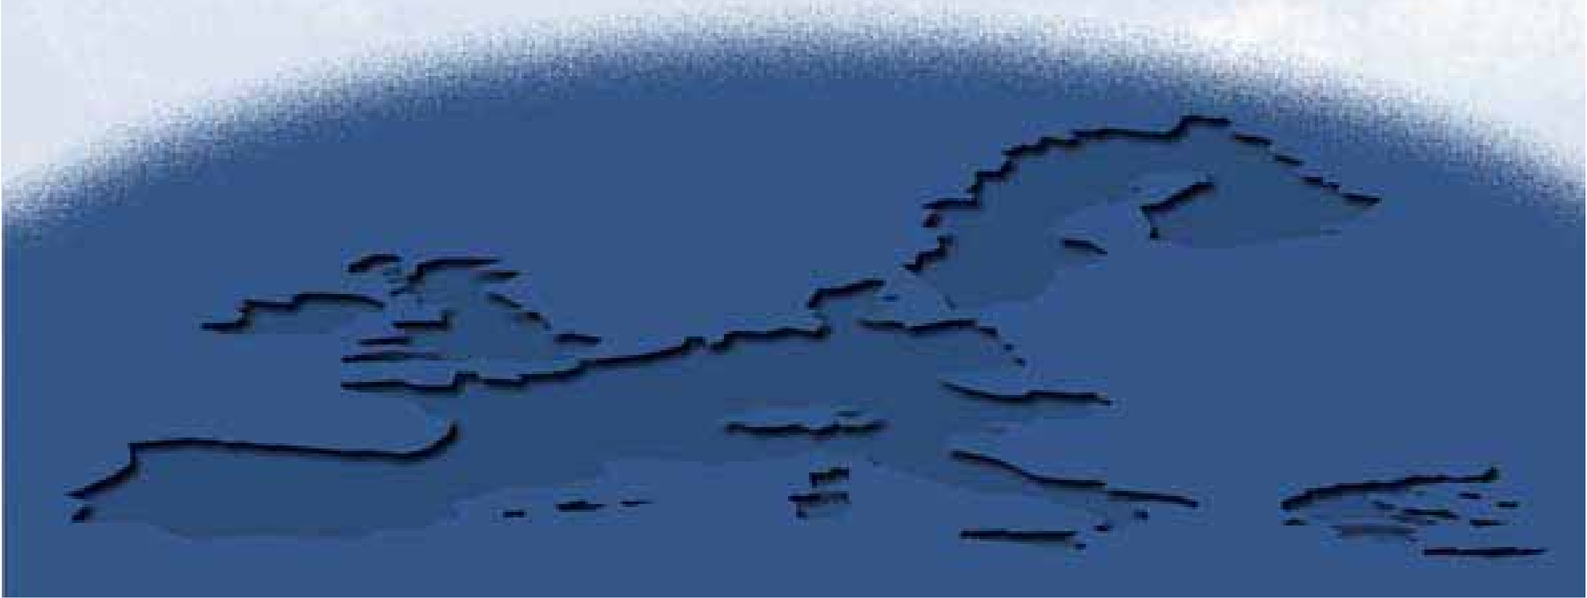
Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 4

Identification and Designation of Heavily Modified and Artificial Water Bodies



COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 4

Identification and Designation of Heavily Modified and Artificial Water Bodies

Produced by Working Group 2.2 - HMWB

Luxembourg: Office for Official Publications of the European Communities, 2003

FOREWORD

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC, "establishing a framework for Community action in the field of water policy" (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of the Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, an informal working group dedicated to the identification and designation of heavily modified and artificial water bodies within implementation of the Water Framework Directive was set up in April 2000 and named HMWB WG 2.2. The United Kingdom and Germany (Joint Chair) have the responsibility of the secretariat and co-ordination of the Working Group that is composed of representatives from 12 Member States and Norway as well as stakeholders and a limited number of Accession Country representatives.

The present Guidance Document is the outcome of this Working Group. It contains the main output of the HMWB Working Group activities and discussions that have taken place since April 2000. It builds on 34 case studies and on the input and feedback from a wide range of experts and stakeholders that have been involved throughout the process of the Guidance development through meetings, workshops, conferences or electronic communication media, without binding them in any way to its content.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders, Martin Marsden (Scottish Environment Protection Agency, UK), Dr. David Forrow (Environment Agency of England & Wales, UK), Dr. Ulrich Irmer and Dr. Bettina Rechenberg (Umweltbundesamt, D), for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a *living document* that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

1 STRUCTURE OF THE DOCUMENT

- ***Section 1*** gives an introduction to the purpose and key objectives of the Water Framework Directive and describes what has been done to support the implementation of Directive. For this purpose, the Section illustrates the development of a Common Implementation Strategy and the establishment of CIS Working Group (WG) 2.2 on HMWB, the activities and outputs of the Working Group and the purpose of this Guidance Document.

- ***Section 2*** offers explanations of the importance and consequences of AWB and HMWB designation in the implementation of the WFD and gives insight into the links between the HMWB & AWB WG and other CIS working groups.

- ***Section 3*** describes the overall HMWB & AWB designation process, giving a short description of the individual steps leading to the identification of HMWB and AWB. The Section describes the function of provisional identification in the first cycle of the River Basin Management and presents some important issues of the designation process.

- ***Section 4*** gives details of the six steps leading to the provisional identification of HMWB, from water body identification (step 1) to the question as to whether the changes in the water body characteristics are substantial and result from physical alterations by human activity (step 6).

- ***Section 5*** describes the steps 7-9, leading to the designation of HMWB.

- ***Section 6*** describes the requirement to establish reference conditions and environmental objectives on which status classification is based, and presents the steps leading to the establishment of appropriate values for the quality elements of MEP and GEP. The Section also describes the appropriate timing for identification of MEP and GEP (steps 10-11).

- ***Section 7*** summarises some important issues regarding measures and related cost considerations throughout the process. It sets the HMWB and AWB process into a time and river basin planning context and gives an outlook to the HMWB process in future RBMP-cycles.

- ***Annexes*** contain a glossary of important terms used in this Guidance Document, a Section on information required for the river basin management plan, a list of WFD citations relevant to HMWB and AWB designation, a list of references used in the production of the Guidance, a list of contact details of the Working Group members and a list of case studies produced in the context of the HMWB Working Group.

2 IMPLEMENTING THE DIRECTIVE: SETTING THE SCENE

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

2.1 DECEMBER 2000: A MILESTONE FOR WATER POLICY

2.1.1 A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that today form the foundation of the Water Framework Directive.

2.2 THE WATER FRAMEWORK DIRECTIVE: NEW CHALLENGES IN EU WATER POLICY

2.2.1 What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

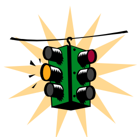
- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

2.2.2 …and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

2.2.3 What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory, assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 [Art. 3, Art. 24];
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 [Art. 5, Art. 6, Annex II, Annex III];
- To carry out, together with the European Commission, the intercalibration of the ecological status classification systems by 2006 [Art. 2(22), Annex V];
- To make operational the monitoring networks by 2006 [Art. 8];
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively [Art. 11, Annex III];
- To produce and publish River Basin Management Plans (RBMPs) for each RBD, including the designation of heavily modified water bodies, by 2009 [Art. 13, Art. 4(3)];
- To implement water pricing policies that enhance the sustainability of water resources by 2010 [Art. 9];
- To make the measures of the programme operational by 2012 [Art. 11];
- To implement the programmes of measures and achieve the environmental objectives by 2015 [Art. 4].



Look out!

Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

2.2.4 Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular about:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

2.2.5 Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of *integration* that is seen as the key to the management of water protection within the river basin district:

Integration of environmental objectives, combining qualitative and quantitative ecological objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;

Integration of all water resources, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;

Integration of all water uses, functions and values into a common policy framework, i.e. considering water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, as well as water as a social good;

Integration of disciplines, analyses and expertise, combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;

Integration of water legislation into a common and coherent framework. The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to match modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;

Integration of all significant management and ecological aspects relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;

Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach for achieving the environmental objectives of the Directive. Programmes of measures are defined in River Basin Management Plans developed for each river basin district;

Integration of stakeholders and the civil society in decision making, by promoting transparency and information to the public, and by offering a unique opportunity for involving stakeholders in the development of river basin management plans;

Integration of different decision-making levels that influence water resources and water status, be they local, regional or national, for an effective management of all waters;

Integration of water management from different Member States, for river basins shared by several countries, existing and/or future Member States of the European Union.

2.3 WHAT HAS BEEN DONE TO SUPPORT IMPLEMENTATION?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

2.3.1 May 2001 – Sweden: Member States, Norway and the European Commission agreed on a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance. A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission who take on the role of overall decision body for the Common Implementation Strategy.

2.3.2 The HMWB Working Group

In accordance with Article 4(3), the Water Framework Directive (WFD) allows Member States to designate surface water bodies, which have been physically altered by human activity, as "heavily modified" under specific circumstances. If the specified uses of such water bodies (i.e. navigation, hydropower, water supply or flood defence) or the "wider environment" would be significantly affected by the restoration measures required to achieve good ecological status and if no other better, technically feasible and cost-effective, environmental options exist, then these water bodies may be designated as "heavily modified" and good ecological potential is the environmental objective.

As part of the EU WFD Common Implementation Strategy (CIS), a working group was established to develop Guidance on the process of HMWB and AWB designation. The CIS Working Group 2.2 on "Heavily Modified Water Bodies" (HMWB) is jointly managed by the United Kingdom and Germany and involves the participation of 12 Member States (MS),[1] Norway, some Accession Countries[2] as well as a number of Stakeholders.[3] A number of distinct "sub projects" were progressed by the Working Group:

- Production of 12 "Guidance papers" by the joint chair of the HMWB WG that were discussed at several Working Group meetings;
- thirty-four case study projects, carried out in the MS and Norway, that tested the "Guidance papers";
- a synthesis of the case study reports;
- production of this HMWB & AWB Guidance Document;
- production of a policy summary; and
- production of a toolbox supporting the Guidance Document.

Based on the main uses within the case studies, two "case study subgroups" were established, one concentrating mainly on "navigation", the other one on "hydropower" (see Annex V). The Working Group members and/or contractors responsible for these case studies exchanged their experiences during their work in extra subgroup meetings and in email discussions.

2.3.3 Production of 12 Guidance papers

The joint chair of the HMWB WG produced 12 Guidance papers covering the key aspects of the HMWB & AWB identification and designation process. Four meetings were organised involving the Working Group members and the European Commission to discuss and agree on these Guidance papers and to exchange experiences. The meetings were held on 12th April, 10th October 2000, 4th September 2001 and 18-19th June 2002 in Brussels. The Guidance papers were to help the production of the case studies which tested these papers. The Guidance papers served as the basis for this Guidance Document.

2.3.4 Case Study Project

In thirty-four case studies from different Member States and Norway a draft provisional identification and designation process for heavily modified water bodies was tested, supported by reference to the Guidance papers produced by the joint chair

---

1 Austria, Belgium, Denmark, Spain, France, Germany, Greece, Netherlands, Portugal, Sweden, Finland and UK.

2 Hungary, Poland and Slovenia. The other seven Accession Countries are also members of the group but have so far not attended a working group meeting or the workshop.

3 EEB, EUREAU, Eurelectric and WWF.

of the HMWB WG. In these case studies, ecological reference conditions (maximum ecological potential) and objectives (good ecological potential) for HMWB were also defined, as far as possible. The case studies focused on the main specified uses (navigation, flood/coastal protection, hydropower generation, agriculture, forestry, urbanisation, recreation and water supply) that result in physical alterations across the MS. The case studies covered mainly rivers, only a few case studies were carried out on coastal waters (1), estuaries (2) and lakes (3). The case study projects started in October 2000 and were finalised in June 2002. For a list of case studies see Annex V.

2.3.5 European Synthesis Project

The synthesis project performed an analysis of the case studies and a synthesis of approaches taken in the individual case studies, identifying commonality and differences in approach. The analysis started in February 2002 and a first draft was distributed by the end of April 2002 (Hansen *et al.* 2002). A second draft will be produced as soon as possible and the final document will be published. The first draft of the synthesis project formed the basis for the production of this Guidance Document and the toolbox, providing examples of different designation approaches.

2.3.6 Production of the Guidance Document

Based on the draft synthesis report and on the twelve Working Group papers prepared by the Joint Chair (UK and D) and discussed during the first three meetings of this WG, a first draft Guidance on the designation of heavily modified and artificial water bodies was produced on 27th May 2002.[4] A workshop was held on the 30-31st May 2002 for Working Group members, case-study managers, and the other CIS WG members to discuss a number of outstanding issues of the draft Guidance Document. The discussions during the workshop served as a basis for the revision of the draft Guidance Document. A second draft[5] was then discussed at the last WG meeting in June 2002. A third draft[6] was produced and circulated to the WG for comments in August 2002. A final version of the Guidance[7] was produced and submitted to the Strategic Co-ordination Group meeting on 30th September 2002. It was then revised and presented to the Strategic Co-ordination Group meeting on 7-8th November 2002. This final version was agreed at the Water Directors meeting on 21st-22nd November 2002.

[5] Guidance Document on identification and designation of [Artificial and] Heavily Modified Water Bodies, Second draft, CIS Working Group 2.2 on Heavily Modified Water Bodies, 15 June 2002. Directly after the WG meeting in June, a Second Draft dated 20 June was sent to the WG, including a different version of Section 6.

[6] Guidance Document on identification and designation of Artificial and Heavily Modified Water Bodies, Third draft, CIS Working Group 2.2 on Heavily Modified Water Bodies, 2 August 2002.

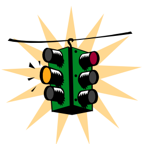
[7] Guidance Document on identification and designation of Artificial and Heavily Modified Water Bodies, Final draft, CIS Working Group 2.2 on Heavily Modified Water Bodies, 13 September 2002.

2.3.7 Production of the Policy Summary

The policy summary is an executive summary of the HMWB and AWB Guidance Document, addressed to the Water Directors. The document summarises the main issues of the HMWB and AWB designation process and is derived directly from the Guidance Document. It was presented and agreed at the Water Directors meeting together with the Guidance Document in November 2002.

2.3.8 Production of the Toolbox

To support the Guidance Document with practical examples illustrating the different steps of the HMWB and AWB designation process, a toolbox has been produced, extracting examples from the case studies. Working Group members have been asked to provide additional examples that help illustrate certain steps of the Guidance Document. A first draft was produced for the WG meeting in June 2002. A second draft was sent out for comments in October 2002 and a final toolbox has been issued in January 2003. The applicability of the toolbox will depend on the examples and will differ between the Member States. The toolbox does not constitute part of the Guidance Document and has hence not been subject to the agreement of the HMWB Working Group.



Look out! You can contact the experts involved in the HMWB activities.

The list of members of the Working Group with full contact details can be found in Annex 8.5. If you need more information on specific issues and input into your own activities, contact a member of the Working Group in your country. If you need more information on specific case studies, you can also directly contact the people in charge of carrying out these studies (contacts can be found in Table 5, Annex 8.6). You can find the case study reports on the following webpage:
http://www.sepa.org.uk/hmwbworkinggroup.

2.4 INTRODUCTION - A GUIDANCE DOCUMENT: WHAT FOR?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the identification and designation of artificial and heavily modified water bodies in the broader context of the development of integrated river basin management plans as required by the Directive.

The purpose of this Guidance is to introduce the requirements of the WFD with respect to HMWB and AWB identification and designation and to serve as a practical implementation guide for those who will be actively involved in the implementation of the WFD including the designation of HMWB and AWB. As the WFD does not always define or describe the terms and approaches to be used, and because some parts are ambiguous, this Guidance aims to develop a common understanding and interpretation of the WFD for the HMWB and AWB designation process and may, in part, describe pragmatic operational approaches to meet the WFD requirements.

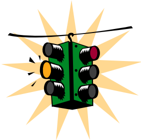
2.4.1 To whom is this Guidance Document addressed?

The Guidance Document is addressed to:

- administrative bodies responsible for implementing the WFD;
- administrative bodies influenced by the implementation of the WFD;
- planning engineers and other technical experts;
- interested public; and
- other stakeholders affected by the implementation of the WFD, especially with regards to the designation of HMWB (NGOs, water supply companies, hydropower, shipping, industry).

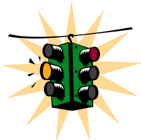
2.4.2 What can you find in this Guidance Document?

1. An introduction to the role of HMWB and AWB designation in the Water Framework Directive:
    - What are the key regulations of the Water Framework Directive concerning the identification and designation of HMWB and AWB? (see Annex III). What are the reference conditions and environmental objectives for these water bodies?
    - Links to other CIS working groups (see Section 3.2).
2. Practical Guidance on the stepwise approach of identifying and designating HMWB and AWB and setting reference conditions and environmental quality objectives:
    - Overall step-by-step approach of the HMWB and AWB identification and designation process (see Section 4).
    - Guidance on how to implement the different steps:
        - Provisional identification of HMWB (see Section 5);
        - Designation of HMWB and AWB (see Section 6);
        - Identification of reference conditions (MEP) and environmental quality objectives (GEP) for HMWB and AWB (see Section 7).
3. Cross-cutting issues and outlook (see Section 8).



Look out! The approaches and methodology in this Guidance Document must be adapted to regional and national circumstances.

The Guidance Document proposes an overall step-by-step approach. Because of the diversity of circumstances within the European Union, specific application may vary between the different water bodies across Europe. This proposed approach will therefore need to be tailored to specific circumstances.



Look out! What you will not find in this Guidance Document

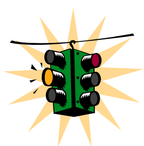
This Guidance Document is concerned with the designation of HMWB and AWB resulting from existing physical modifications. Implications from planned, new modifications [Art. 4(7)] are not considered in this document; the Guidance focuses on the first river basin management planning cycle (2008/9). The Guidance does not cover physically modified or artificial water bodies that Member States do not choose to designate. The Guidance is only concerned with water bodies where hydromorphological changes are a direct or indirect consequence of physical alterations which serve a specified use or the wider environmental interests.

3 HMWB AND AWB IN THE WATER FRAMEWORK DIRECTIVE

3.1 IMPORTANCE OF AWB AND HMWB IN THE IMPLEMENTATION OF THE WFD

For surface waters the overall goal of the Water Framework Directive (WFD) is for Member States to achieve "good ecological and chemical status" in all bodies of surface water by 2015. Some water bodies may not achieve this objective for different reasons. Under certain conditions the WFD permits Member States to identify and designate artificial water bodies (AWB) and heavily modified water bodies (HMWB) according to Article 4(3) WFD. The assignment of less stringent objectives to water bodies and an extension of the timing for achieving the objectives is possible under other particular circumstances. These derogations are laid out in Articles 4(4) and 4(5) of the WFD.

HMWB are bodies of water which, as a result of physical alterations by human activity, are substantially changed in character and cannot, therefore, meet "good ecological status" (GES). AWB are water bodies created by human activity. Instead of "good ecological status", the environmental objective for HMWB and for AWB is good ecological potential (GEP), which has to be achieved by 2015.



Look out! Purpose of Article 4(3) and its links to Article 4(4) and 4(5)

Article 4(3) is intended to be applied to major infrastructure projects associated with the listed specified uses. Such water bodies must be substantially changed in character because of hydromorphological alterations. Under these circumstances the tests specified in Article 4(3) may allow other objectives (GEP) for these waters because GES cannot be achieved

Article 4(5) deals with derogations for all waters including those concerned with hydromorphological alterations. Less stringent objectives can be set under specific circumstances. Article 4(4) allows for an extension of the deadline to achieve the environmental objective under certain conditions.

Where it is not possible to designate a water body subject to hydromorphological changes as HMWB then Article 4(4) or 4(5) derogations may apply. If a water body is designated as HMWB or AWB then Article 4(5) and/or 4(4) may be applied if GEP cannot be achieved.

The designation of HMWB and AWB is optional; Member States do not have to designate modified water bodies as HMWB or AWB.[8] The designation will not be an opportunity to avoid achieving ecological and chemical objectives, since GEP is an ecological objective which may often, in itself, be challenging to achieve.

The designation may, in some instances, help to protect wider environmental interests; e.g. when the removal of a modification would lead to the destruction of valuable environmental features. [9]

3.1.1 What is a Heavily Modified Water?

The concept of HMWB was introduced into the WFD in recognition that many water bodies in Europe have been subject to major physical alterations so as to allow for a range of water uses. Article 4(3)(a) lists the following types of activities which were considered likely to result in a water body being designated as a HMWB:

- navigation, including port facilities, or recreation;
- activities for the purposes of which water is stored, such as drinking-water supply, power generation or irrigation;
- water regulation, flood protection, land drainage;
- other equally important sustainable human development activities.

These specified uses tend to require considerable hydromorphological changes to water bodies of such a scale that restoration to "good ecological status" (GES) may not be achievable even in the long-term without preventing the continuation of the specified use. The concept of HMWB was created to allow for the continuation of these specified uses which provide valuable social and economic benefits but at the same time allow mitigation measures to improve water quality.

The designation tests can be applied when a:

- specified use results in a modification of a water body and restoration affects the specified use;
- non specified use results in the modification of a water body but restoration affects a specified use;
- non-specified or specified use results in the modification of a water body but restoration affects the wider environment.

8 Where modified or artificial waters are not designated the objective will be good ecological status.

9 The removal of a weir or dam may, for example, impact significant ecological (e.g. biodiversity) or historical (old mill) features. By designating the water body as heavily modified, the weir or dam probably will not have to be removed.

Article 2(9)

"Heavily modified water body means a body of surface water which as a result of physical alterations by human activity is substantially changed in character as designated by the Member State in accordance with the provisions of Annex II".

According to Article 2(9), there are three components to the definition of HMWB. To be a HMWB a water body must be:

- physically altered by human activity;
- substantially changed in character;
- designated under Annex II (Art. 4(3))[10].

The definition of HMWB provided in Article 2(9) emphasises that HMWB are considered to be water bodies that have been subject to physical alteration as a result of human activity. Article 4(3)(a) indicates that the relevant physical alterations result in hydromorphological changes that would have to be restored to achieve good ecological status. Consequently, this Guidance considers that hydromorphological changes result from physical alterations to the water body.

It is important to emphasise that changes in hydromorphology must be not only significant, but also result in a substantial change in the character of a water body, as typically found when a river is extensively modified for navigation, a lake modified for water storage or a transitional water when subject to major modifications for coastal defence. Such water bodies can be seen to be obviously modified and the modifications are neither temporary nor intermittent.

Considering the specified uses given under Article 4(3)(a) it is concluded that a "substantial" change in hydromorphology is one that is:

- extensive/widespread or profound; or
- very obvious in the sense of a major deviation from the hydromorphological characteristics that would have been there before the alterations.

It is clear that a water body could be described as substantially changed in character if <u>both</u> its morphology and hydrology were subject to substantial changes. It is less clear that a water body should be considered as substantially changed in character if only its morphology or its hydrology is substantially changed.

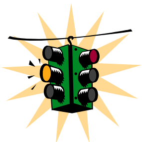
If the morphology of a water body is substantially changed in character, then the changes are likely to be long-term. Such changes in morphology are very likely to result in changes in hydrology, though these changes in hydrology may not necessarily

[10] The reference to Annex II is an error in the text. The early version of the WFD included the designation test in Annex II. The reference was not updated when the European Parliament Amendment moved the designation to Article 4(3).

be substantial. A common sense approach would suggest that such water bodies should be considered as substantially changed in character.

The situation is more difficult for water bodies subject to substantial changes in hydrology as such changes may only be temporary or short term. The water body may look substantially changed on one occasion but it may look like a normal water body on another occasion. In cases of temporary or intermittent substantial hydrological changes the water body is not to be considered substantially changed in character. Nevertheless, it may be that in some limited circumstances substantial hydrological alterations may result in long-term or permanent changes with additional substantial changes in morphology. In such specific cases, the application of the HMWB designation tests may be justified. Justification for the decision of a HMWB and AWB designation should always be provided.

Notwithstanding the agreed general approach described in the paragraph above, it was agreed that a slightly different approach could be taken for limited stretches of rivers, e.g. downstream of dams. Under these circumstances, substantial hydrological changes that are accompanied by subsequent non-substantial morphological changes would be sufficient to consider the water body for a provisional identification as HMWB.



Look out! A HMWB is substantially changed in character as a result of physical alterations

In the context of HMWB designation physical alterations mean any significant alterations that have resulted in substantial changes to the hydromorphology of a water body such that the water body is substantially changed in character. In general these hydromorphological characteristics are long-term and alter morphological <u>and</u> hydrological characteristics.

3.1.2 What is an artificial water body ?

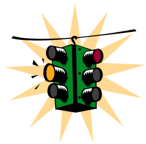
The WFD takes a very similar approach to AWB and HMWB. AWB must have been created by the same specified uses listed in Article 4(3)(a).

<u>Article 2(8)</u>

"Artificial water body means a body of surface water created by human activity".

A key question in order to differentiate between AWB and HMWB is the meaning of the word "created" as used in Article 2(8). More specifically, the question is whether "created" refers to creating a new water body from previously dry land (e.g. a canal), or whether it could also denote a water body that has changed in category (e.g. river into a lake as a consequence of damming, or coastal water into a freshwater lake due to reclaiming).

This Guidance interprets an AWB "as a surface water body which has been created in a location where no water body existed before and which has not been created by the direct physical alteration or movement or realignment of an existing water body". Note, this does not mean that there was only dry land present before. There may have been minor ponds, tributaries or ditches which were not regarded as discrete and significant elements of surface water. Where an existing water body is modified and moved to a new location (i.e. where previously there was dry land) it should still be regarded as a HMWB and not an AWB. The same applies to water bodies that have changed category as a result of physical modifications; such water bodies (e.g. a reservoir created by damming a river) are to be regarded as HMWB and not as AWB.



Look out! An AWB is created by human activity

An artificial water body is a surface water body which has been created in a location where no water body existed before and which has not been created by the direct physical alteration, movement or realignment of an existing water body.

3.1.3 Environmental objectives and designation of HMWB and AWB

Where a water body is substantially changed in character as a result of physical alterations by human activity, the WFD allows Member States to designate it as a HMWB. If a water body has been created by human activity then it may be designated as AWB. In order to designate a water body, it must undergo tests defined within Article 4(3). These tests require consideration of whether the restoration measures required to achieve "Good Ecological Status" (GES) have a significant adverse effect on the activity (use) and whether there are other means of undertaking the activity.

Once designated as HMWB or AWB, the environmental objectives are "good ecological potential" (GEP) and good chemical status, which also have to be achieved by 2015.

GEP is a less stringent objective than GES because it makes allowances for the ecological impacts resulting from those physical alterations that (i) are necessary to support a specified use or (ii) must be maintained to avoid adverse effects on the wider environment. This means that appropriate objectives can be set for the management of other pressures, including physical pressures, not associated with the specified use, while ensuring that the adverse ecological effects of the physical alteration can be appropriately mitigated without undermining the benefits they serve.

The objective setting process for HMWB and AWB should be in line with the same general principles as applied for natural water bodies.

The environmental objectives for natural, artificial and heavily modified water bodies are set in relation to reference conditions. For HMWB and AWB the reference condition is the maximum ecological potential (MEP).[11] The MEP is the state where the biological status reflects, as far as possible, that of the closest comparable surface water body taking into account the modified characteristics of the water body. With regards to its biological status the GEP accommodates "slight changes" from the MEP.

The designation of HMWB and AWB, the definition of the MEP, the identification of GEP as well as the programme of measures to achieve the relevant environmental objectives will be part of the River Basin Management Plans that are to be published by 2008 as first consultation drafts and 2009 as final plans. These have to be revised every six years.

3.2 LINKS TO OTHER WORKING GROUPS OF THE COMMON IMPLEMENTATION STRATEGY

It is important to read the HMWB & AWB Guidance in the context of the Guidance produced by the other CIS working groups. This Section describes the most important links between the HMWB and other working groups within the Common Implementation Strategy (CIS) and identifies those areas where a common understanding has been developed.

3.2.1 Pressures and Impacts Working Group 2.1 (IMPRESS)

The provisional identification of heavily modified water bodies is carried out in the characterisation process as specified in Article 5 and Annex II. The WG 2.1 IMPRESS provides the guidance on the description of pressures and impacts and the identification of water bodies which are at risk of failing their environmental objectives ("risk assessment") (WFD CIS Guidance Document No. 3).

It has been agreed that the HMWB Working Group would develop Guidance on that aspect of the characterisation process which is related to physical alterations of water bodies and their possible identification as HMWB. The HMWB & AWB Guidance together with the information provided by the HMWB case studies would then be used by IMPRESS to develop an integrated approach to the entire characterisation process. Within the overall risk assessment of IMPRESS, the HMWB WG will provide guidance on the identification and description of specified uses and related physical alterations (pressures) as well as their impacts on hydromorphology and biology.

Further integration of processes developed by the HMWB and IMPRESS working groups may be required. This should be done in co-operation with WG 2.9 on "best practice in river basin planning".

---

11 For natural water bodies the reference condition is the "high ecological status" (HES).

3.2.2 Freshwater reference condition Working Group 2.3 (REFCOND) & Coastal waters typology, reference and classification Working Group 2.4 (COAST)

The "status" and "potential" WFD objectives and classifications are based on similar principles. Reference conditions are identified and then similar normative definitions (Annex V) are used to define the deviation from reference for each classification category. It is clearly important to ensure that this deviation is of a similar scale for HMWB and AWB as it is for "natural" waters (WFD CIS Guidance Document No. 10 – REFCOND and WFD CIS Guidance Document No. 5 – COAST).

3.2.3 Intercalibration Working Group 2.5

The Intercalibration Working Group will ensure that the interpretation of the WFD's normative definitions of high, good and moderate (Annex V) result in comparable deviation from reference conditions (WFD CIS Guidance Document No. 6). In particular, the WG 2.5 should ensure that the sensitivity boundaries between the high/good and good/moderate borders are comparable across Europe. The reference conditions for HMWB and AWB are determined by the nearest natural equivalent to the modified water body. This means that reference conditions for HMWB and AWB will be variable depending on the degree and type of modification. Discussions between the HMWB and Intercalibration working groups have led to an agreement that in most cases intercalibration of ecological potential boundaries is not required. Nevertheless an intercalibration exercise for HMWB and AWB could be useful, if those water bodies are the dominating water types.

3.2.4 Economic Analysis Working Group 2.6 (WATECO)

Another part of the Article 5 characterisation process is the economic analysis of water use. This forms the basis of the Article 9 on recovery of costs for water services and the consideration of the Article 4(3) tests for HMWB designation and Article 4(4), (5) and (7) derogations. The HMWB and WATECO working groups have worked together to ensure that the Guidance on the HMWB & AWB designation tests is based on a common understanding which ensures consistent applications of economic terms across the WFD requirements (WFD CIS Guidance Document No. 1).

3.2.5 Monitoring Working Group 2.7

The monitoring regime forms the basis for the definition of status according to the WFD. The Guidance produced by the Monitoring Working Group will therefore assist Member States in understanding the monitoring requirements for the identification of potential HMWB (WFD CIS Guidance Document No. 7). In the first planning cycle, WFD-compliant monitoring/classification tools will not be available, so Guidance on best practice is needed to ensure that existing data/methods are used to the best effect. The monitoring group could also help to identify the appropriate monitoring approach for heavily modified and artificial waters. The HMWB & AWB Guidance will provide recommendations for the use of the most sensitive biological elements concerning physical alterations.

3.2.6 River Basin Management Best Practice Working Group 2.9

The HMWB and AWB designation process is only one aspect of the RBMP and must be fully integrated with the key components of the Plan, for example: setting environmental objectives and identification of the most cost effective combination of measures. The HMWB & AWB Guidance provides a timetable based on the Directive's requirements. However, substantial changes to this timetable will be necessary in order to ensure that the sequence of tasks required by the RBMP can be delivered (WFD CIS Guidance Document No.s 8 and 11). This revised timetable is provided within the Best Practice Guidance.

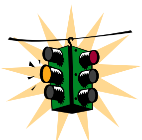
3.2.7 Geographical Information System Working Group 3.0 (GIS)

The links to the GIS Working Group are relatively straightforward and relate to the requirements to map the distribution of provisional identified HMWB and AWB (by 2004) and designated water bodies (in 2008/9) (WFD CIS Guidance Document No. 9). It may also be helpful to map the distribution of the relevant pressures which result in the designation of HMWB & AWB.

4 STEPWISE APPROACH FOR DESIGNATION OF HMWB AND AWB

A very large number of water bodies will have to be assessed for possible designation as AWB or HMWB between now and 2008/2009 (publication of the first draft/final RBMP) (for timing and RBMP see Sections 8.2, 8.3, and Annex II). It will be important therefore to ensure that the approaches and methods used for the designation process are practicable and comparable in all Member States. Moreover, it is important to develop appropriate options so that the complexity of the assessment methodology can be made proportionate to the circumstances. In the first planning cycle, there are serious practical difficulties in designating the HMWB, in defining MEP and GEP and in performing an assessment of the likelihood of not achieving the relevant environmental quality objectives in 2004 as required by Article 5 (and Annex II). The IMPRESS and HMWB working groups have therefore recommended, that for the provisional identification in 2004, the assessment for HMWB will be carried out against GES. This helps to overcome the practical difficulties of defining the MEP & GEP for HMWB at this early stage. For the assessments it might, under certain circumstances, be possible and advisable to group water bodies and assess them together.

Figure 1 illustrates the proposed overall stepwise approach to the identification and designation of HMWB and AWB as identified by HMWB-WG 2.2. In this Section, the steps of the general approach are summarised (steps 1 – 11), while the following Sections 5 - 7 describe the steps in more detail, including some proposed methods and explanations. It should be noted that step 1 and 3-5 are broader than the HMWB and AWB process. Step 1 is applicable to all water bodies and involves the application of the WFD CIS Guidance Document No. 2 on water body identification. Steps 3-5 are part of the broader Annex II (1.4 & 1.5) assessment of pressures and impacts, which is described in the IMPRESS Guidance (WFD CIS Guidance Document No. 3). **No additional work beyond that required under IMPRESS is required as part of these steps.**



Look out! Processes should be integrated to ensure consistency and avoid duplication in effort

The HMWB and AWB designation process described in this Guidance, when put into operational guidance by MS, should be integrated with other Guidance (e.g. CIS Guidance Document No. 3 - IMPRESS) to ensure consistency in approach and avoid duplication in effort.

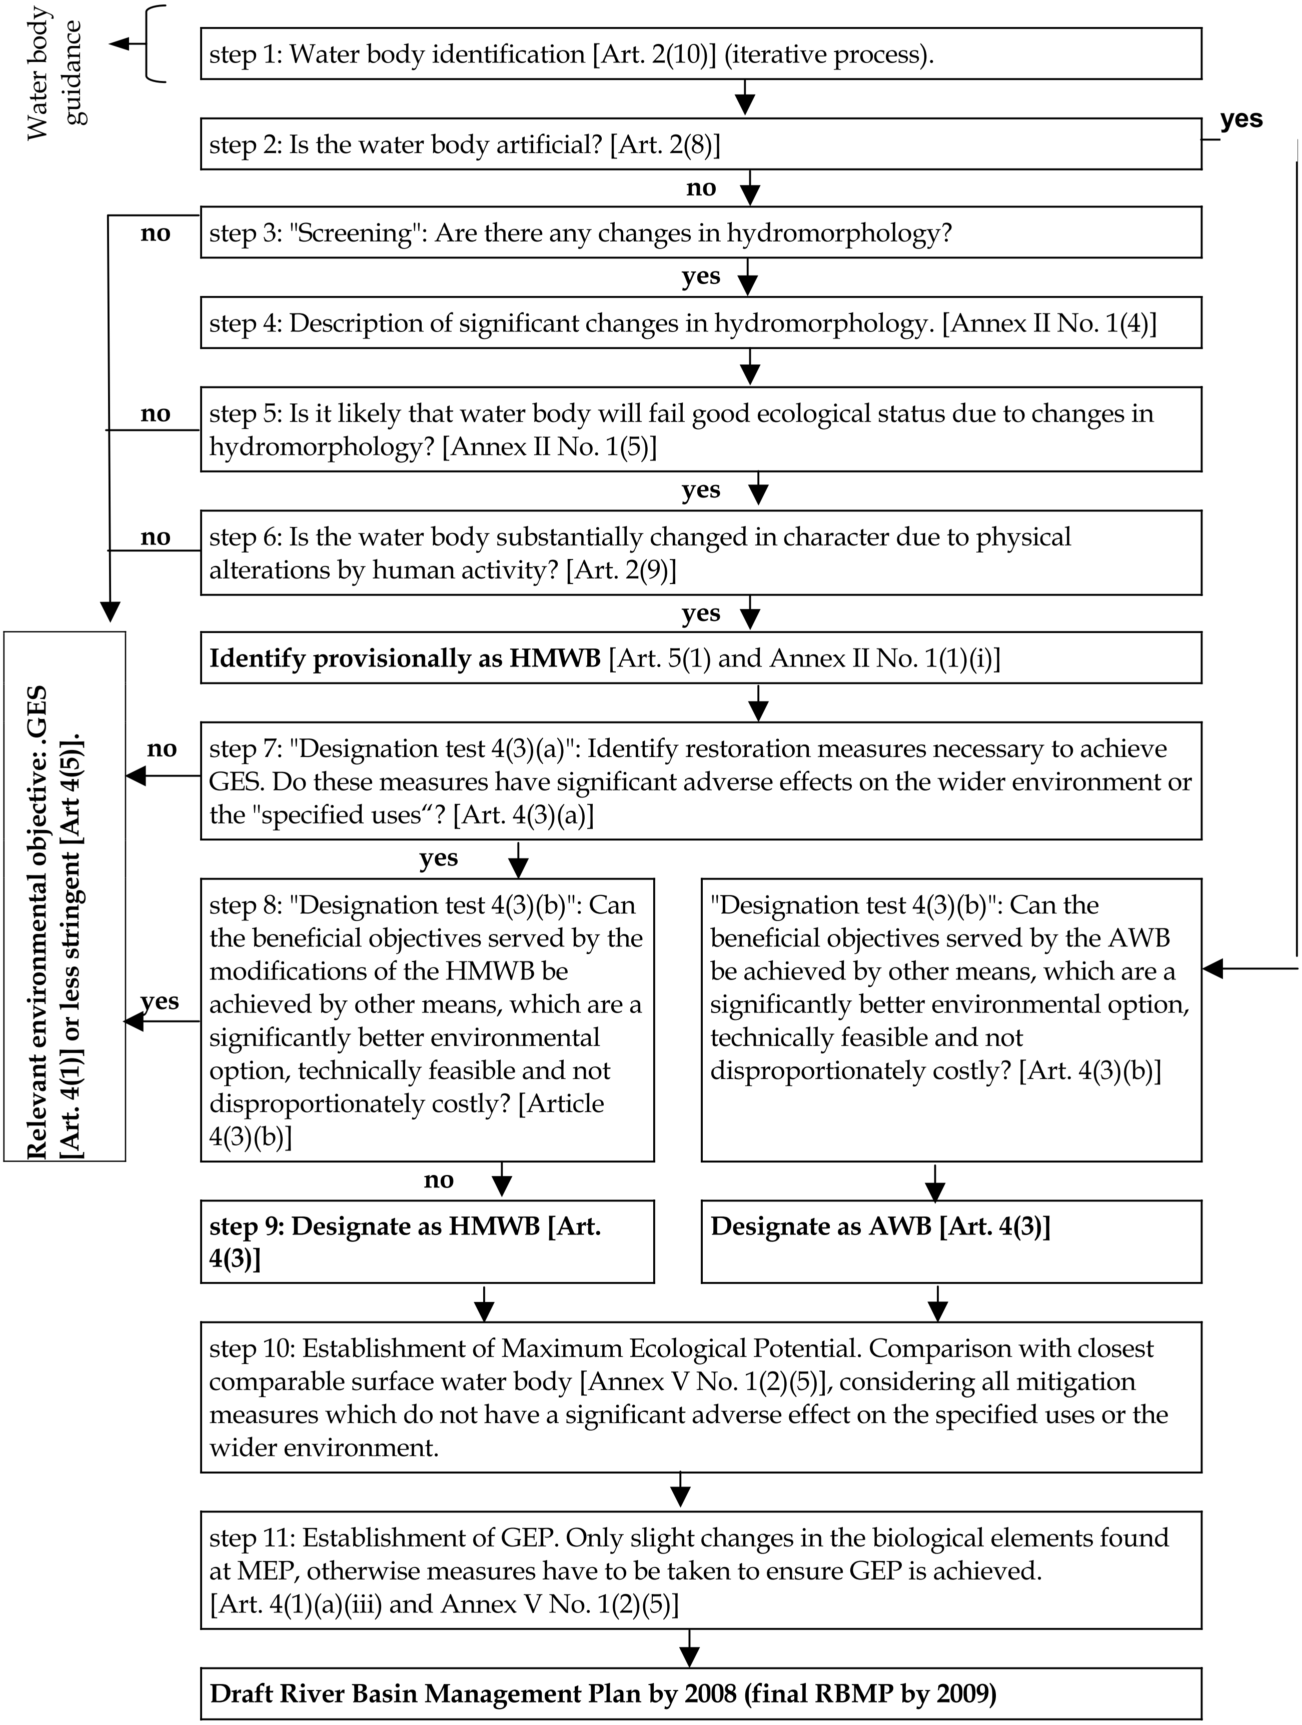


Figure 1: Steps of the HMWB & AWB identification and designation process

- **Step 1:** Distinct water bodies are to be identified and described according to the WFD CIS Guidance Document No. 2 on water body identification. Water body identification is an iterative procedure with possible adaptations in later stages of the designation process (mainly after step 6, the provisional identification of HMWB). The water body identification has to be done for all surface waters (natural, heavily modified and artificial waters), and is significant, because water bodies are the units for which status is being assessed, objectives established and achievement of objectives of the WFD checked.

- **Step 2:** The WFD gives distinct definitions for AWB and HMWB [Art. 2(8) and Art. 2(9) respectively]. In this second step it should be identified whether the water body concerned has been "created by human activity". If this is the case, Member States will have the option to identify it as AWB and consider it for designation or, in some circumstances, identify it as a natural water body. Where the intention is to designate as AWB, the first designation test (step 7) is not relevant and AWB should continue directly with the second designation test (step 8).

- **Step 3:** A screening process is proposed to reduce effort and time in identifying water bodies which should not be considered for the HMWB designation tests. This will include those water bodies that are likely to fail to achieve GES but which show no hydromorphological changes. This step is part of the Annex II (1.4) assessment of pressures.

- **Step 4:** For those water bodies which have not been "screened out" in step 3, significant changes in hydromorphology and resulting impacts should be further investigated and described. This includes the description of hydromorphological changes and the assessment of resulting impacts. This step is part of the Annex II (1.4 & 1.5) assessment of pressures and impacts.

- **Step 5:** Based on the information gathered in step 4 and an assessment of the ecological status of the water body, the likelihood of failing to achieve good ecological status (or an estimate of what GES may be, based on current knowledge) should be assessed. Within this step it has to be assessed whether the reasons for failing the GES are hydromorphological changes and not other pressures such as toxic substances or other quality problems. This step is part of the Annex II (1.5) assessment of impacts process to be completed by 22 December 2004.

The Guidance Document of IMPRESS[12] will give more explicit guidance for steps 3-5; in particular, guidance on the "risk assessment". The Monitoring Working Group will deal with the monitoring requirements for water bodies "at risk" as well as for all other water bodies.

- **Step 6:** The purpose of this step is to select those water bodies where the changes in hydromorphology result in the water body being substantially changed in character. Such water bodies can be provisionally identified as HMWB. The remaining water bodies likely to fail GES, which are not substantially changed in character, will be identified as natural water bodies. Environmental objectives for such water bodies will be GES or other less stringent environmental objectives.

12 WFD CIS Guidance Document No. 3 - IMPRESS.

It is only necessary to collect sufficient information during steps 1, 3, 4 & 5 to demonstrate that pressures and impacts result in a failure to achieve good status (as described by the WFD CIS Guidance Document No 3. - IMPRESS) and in step 6 (first step of the HMWB process) that the water body is substantially changed in character. These requirements can be satisfied in a simple descriptive manner in clear cut cases. For example, if a water body has irreversibly and definitely changed category, then it is easy to demonstrate that pressures and impacts prevent the achievement of GES (of the original water body category) and that it is substantially changed in character.

- **Steps 7-8-9**: Where Member States wish to designate a water body as heavily modified they must then consider them for the designation tests specified under Article 4(3)(a) & Article 4(3)(b). Artificial water bodies are only considered for the test under Article 4(3)(b). In the first "designation test" (**step 7**) necessary hydromorphological changes ("restoration measures") to achieve "good ecological status" should be identified. In the first test it has to be assessed whether these "measures" have significant adverse effects on either the "specified uses" or the "wider environment". If they do, then the second designation test (**step 8**) is to be carried out.

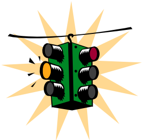
  The second designation test consists of several sub-tests. Firstly, "other means" to achieve the beneficial objective (e.g. replacement of surface water for drinking water supply with groundwater) are to be considered. Then, it has to be assessed whether the "other means" are a) technically feasible, b) a better environmental option and c) not disproportionately costly. If any of the sub-tests a), b) or c) are negative, the water bodies may be designated as heavily modified (**step 9**). If either the mitigation measures have no significant adverse effects (see step 7) or if "other means" can be found that fulfil the criteria a), b) or c) (see step 8), the water body must <u>not</u> be designated as heavily modified and the relevant environmental objective would be GES or a less stringent objective.

- **Steps 10-11:** These steps are not part of the designation process. However, they are relevant to AWB and HMWB only and are therefore covered in this Guidance Document. They concern the definition of reference conditions and the setting of the environmental quality objectives for heavily modified and artificial water bodies. In **step 10** the reference condition for HMWB and AWB, the Maximum Ecological Potential (MEP), is defined. Based on the MEP, the environmental quality objective, the Good Ecological Potential (GEP), is defined (**step 11**).

The information gathered in the different steps (1-11) summarised above will contribute to the RBMP. The RBMP will contain programmes of measures [Art. 11] that are required to ensure the achievement of the environmental objectives for natural, heavily modified and artificial water bodies.

In following the flow chart, it is clearly important to avoid unnecessary and superfluous administrative actions. For example, it will not always be necessary to undertake the assessment for each individual water body. Indeed in many situations it may be more effective to apply the tests to a group of water bodies where the environmental concerns and specified uses are similar. For example, for a river modified for navigation it may not be helpful to apply the process to individual water bodies. A larger scale assessment may produce a more effective and more complete assessment.

Similarly, for a major estuarine flood protection scheme, it may be more effectively assessed at the multi-water body level than by considering each individual water body.



Look out! Information on the measures and related costs and on timing and future RBMP cycles is given in Section 7!

Throughout the entire process different measures are considered in different steps. Related to these different measures there are differing cost considerations applicable; a summary is given in Section 8.1. Timing as well as changes in the future RBMP cycles are important when dealing with HMWB and AWB; these issues are covered in Sections 8.2 and 8.3.

5 STEPS LEADING TO THE PROVISIONAL IDENTIFICATION OF HMWB

5.1 INTRODUCTION

This Section considers steps 1 to 6 which lead to the provisional identification of HMWB in more detail.

These steps are part of the characterisation of River Basin District requirements as defined in Annex II of the WFD. Consequently the steps are closely linked to the work of the IMPRESS Working Group. A summary of the process is illustrated in Figure 2.

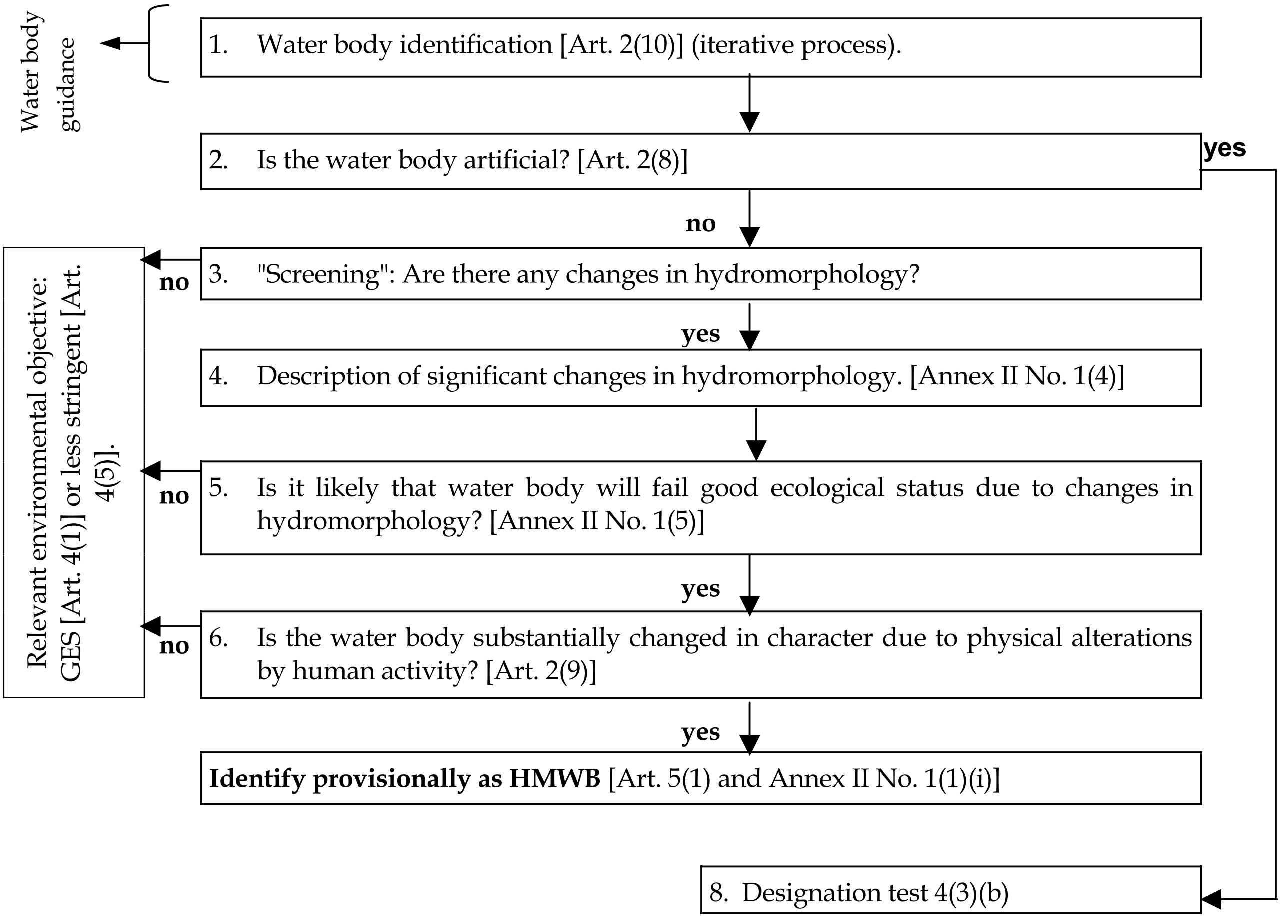


Figure 2: Steps leading to the provisional identification of HMWB

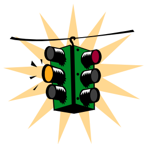
5.2 WATER BODY IDENTIFICATION (Step 1)

Water bodies have to be identified for all surface waters (natural, heavily modified and artificial waters). This step is of major importance for the implementation process, because water bodies represent the units that will be used for reporting and assessing compliance with the Directive's principal environmental objectives. Overall recommendations on how to identify distinct water bodies are given in the WFD CIS Guidance Document No. 2 on water body identification. This Guidance Document on HMWB and AWB discusses issues specifically relevant to water body identification for "physically altered" waters, as far as these are not included in the WFD CIS Guidance Document No. 2 (Examples in the toolbox).



Look out! Possibility to group water bodies for assessment

In some cases it will be possible to group water bodies for the identification and / or designation of HMWB and AWB. This could help to reduce the overall work load. The WFD CIS Guidance Document No. 2 on water bodies will indicate under which circumstances water bodies can be grouped for the assessments.

5.3 IS THE WATER BODY ARTIFICIAL (Step 2)?

The WFD gives distinct definitions for AWB and HMWB [Art. 2(8) and Art. 2(9) respectively] (see Section 3.1). In this second step it should be identified whether the water body concerned is an AWB, i.e. has been "created by human activity".

An artificial water body is defined, in this Guidance, as a surface water body which has been created in a location where no significant surface water existed before and which has not been created by the direct physical alteration of an existing water body or movement or realignment of an existing water body. Note, this does not mean that there was only dry land present before. There may have been minor ponds, tributaries or ditches, which were not regarded as a discrete and significant element of surface water and therefore not identified as a water body.

If the above characterisation of a water body is fulfilled, Member States will have the option to identify them as AWB and consider them for designation or, in some circumstances, identify them as natural water bodies. If a Member State considers that GES can be achieved in an AWB, then the Member State may wish to consider the AWB as a natural water body. This would allow GES to be defined for the water body rather than GEP (Examples in the toolbox).

5.3.1 Examples

AWB: Examples of AWB include canals constructed for navigation, drainage channels for irrigation, man-made ponds and dug ponds, harbours and docks, constructed dredging pools, gravel pits, surface mining lakes, storage reservoir for peak demand hydropower production or waters that are directed to the reservoir via diversions, and water bodies created by ancient human activities.

Not AWB: A water body that has changed category as a result of physical modifications is not an AWB, it is considered to be a HMWB (e.g. creation of a reservoir due to the damming of a river). AWB are not water bodies that have been moved or realigned, for example, a realigned river going through a newly developed channel on previously dry land. Such realignments involve the modification of an existing water body and consequently the new channels may be regarded as a HMWB.

Where the intention is to designate as AWB, the first designation test (step 7) is not relevant and the AWB should continue directly with the second designation test (step 8).

5.4 SCREENING (Step 3)

A screening process (step 3) is proposed to reduce effort and time in identifying water bodies which should not be considered for the HMWB designation tests. This will include those water bodies that are likely to fail to achieve GES but which show no hydromorphological changes (Examples in the toolbox).

5.5 SIGNIFICANT CHANGES IN HYDROMORPHOLOGY (Step 4)

For those water bodies which have not been "screened out" in step 3, significant anthropogenic pressures and the resulting impacts should be further investigated and described [Annex II No. 1.4]. This step 4 is part of the characterisation of surface waters as required in Art. 5(1) by December 2004.

5.5.1 This characterisation involves the identification and description of:

1. the main "specified uses" of the water body;
2. significant anthropogenic pressures [Annex II No. 1.4]; and
3. significant impacts of these pressures on hydromorphology [Annex II No. 1.5].

5.5.2 1. Identification and description of **the main "specified uses" of the water body:**

- navigation, including port facilities, or recreation;
- activities for the purposes of which water is stored, such as drinking-water supply, power generation or irrigation;
- water regulation, flood protection, land drainage; or
- other equally important sustainable development activities.

5.5.3 2. Identification and description of **significant anthropogenic pressures** [Annex II No. 1.4]:

Specified uses of water bodies generally result in pressures that might impact the status of the water body. In the context of HMWB and AWB identification and designation process, changes to hydromorphology resulting from "physical alterations" are relevant [Art. 2(9)].

Physical alterations include alterations in the morphology and hydrology of the water regime (compare glossary and step 6). For example, the most common physical alterations include dams and weirs, which disrupt the river continuum and cause alterations of the hydrologic and hydraulic regime. Physical alterations should usually serve a specified use, such as straightening for the purpose of navigation. However, physical alterations which do not serve a particular specified use any longer, should also be identified and described in the characterisation (e.g. weirs used to maintain water levels for mills which are no longer in use).

For the characterisation it is important to find out which pressures are of "significance", because only significant pressures (or physical alterations) are to be considered. Member States may use qualitative or quantitative approaches to describe the degree and level of significance of the physical alterations (Examples in the toolbox).

5.5.4 3. Identification and description of **significant impacts on hydromorphology** [Annex II No. 1.5]:

The significant impacts on hydromorphology should be further investigated. Both qualitative and quantitative appraisal techniques can be used for assessing impacts on hydromorphology resulting from physical alterations (Examples in the toolbox). The elements examined should include the elements required by the WFD [Annex V No. 1.1: river continuity, hydrological regime, morphological conditions, tidal regime], as far as data are available.

Special attention should be given to cumulative effects of hydromorphological changes. Small-scale hydromorphological changes may not cause extensive hydromorphological impacts on their own, but may have a significant impact when acting together. To assess the significant impacts on hydromorphology, an appropriate scale should be chosen (see also Guidance of the WG 2.1[13]). The following issues in scaling should be considered in assessing impacts and in the identification and designation of HMWB and AWB:

- Scaling due to impact assessment changes according to the pressure and impact characteristics, i.e. some pressures have lower thresholds for wide-scale impacts than others;
- Scaling may change according to the water body type and ecosystem susceptibility. Spatial and temporal scale (resolution of impact assessment) should be more precise in such water body types and specific ecosystems which are considered susceptible to the pressure.

[13] WFD CIS Guidance Document No, 3 "Analysis of Pressures and Impacts in the Water Framework Directive - Common Understanding", produced by the CIS WG 2.1.

5.6 LIKELIHOOD OF FAILING GOOD ECOLOGICAL STATUS (Step 5)

Based on the information gathered in step 4 and an assessment of the ecological status, the likelihood of failing to achieve good ecological status (or an estimate of what GES may be, based on current knowledge) should be assessed [Annex II No. 1.5]. This should consider whether the risk of failing GES is due to hydromorphological changes and not other pressures such as toxic substances or other quality problems. Step 5 is part of the "risk assessment"[14] process to be completed by 22 December 2004.

In order to assess the likelihood of failing to achieve GES, the ecological impacts of physical alterations on the water bodies in question should be estimated (Example in the toolbox). The effort expended in the assessments should be proportionate (i.e. a tiered assessment approach should be used). For water bodies which are likely not to achieve GES (e. g. water bodies which have changed category due to physical alterations), effort expended estimating GES should be limited and conclusions of non-achievement of GES should be rapidly reached. In these cases more effort can be expended in assessing GEP early and the risk of not achieving it could be investigated. Likewise, through risk screening, a conclusion on excluding those water bodies which are clearly going to reach GES from the HMWB or AWB identification and designation process should be reached early and with minimal effort.

5.6.1 Data requirements

For the implementation of the WFD a large amount of data is needed. The quality elements for water bodies are listed in Annex II No. 1 and include hydromorphological, chemical as well as biological data. The quality elements differ according to the water categories. For the HMWB identification and designation process data are not only necessary in step 5, but also in the different designation tests (steps 7 and 8), the establishment of MEP (step 10) and of GEP (step 11).

The assessment of the ecological status, necessary for the "risk assessment", can be based directly on biology. Alternatively indicative data (hydromorphological and physicochemical elements) can be used in situations where only these data are available (Example in Section 2.6 of the toolbox on provisional identification of regulated lakes in Finland is of relevance). According to the WFD, the biological status of a surface water is to be assessed using the appropriate elements in the different water categories [Annex V No. 1.1]. It is suggested that the preliminary assessment of the ecological status, to be completed by 2004, should be based on the most sensitive quality elements with respect to the existing physical alterations. It must be noted, however, that this procedure concentrates on the effects of physical alterations on some sensitive elements of the aquatic ecosystem.

To detect the reason for the possible failure of the environmental objective (i.e. the good status or potential) of a water body, indicative parameters differ according to the causes. The HMWB & AWB Guidance is particularly concerned with indicative data to

---

14 The "risk assessment" is undertaken as part of the Article 5 characterisation process and identifies the likelihood of water bodies to fail the environmental quality objectives set under Article 4.

detect hydromorphological changes. Effects resulting from other impacts (e.g. toxic effects on macroinvertebrates, eutrophication concerning macrophytes) should be differentiated as far as possible. Some suggestions on the suitability of biological elements as indicators for physical alterations are made below:

- Benthic invertebrate fauna and fish are the most relevant groups for the assessment of hydropower generation impacts in freshwater systems;
- Long distance migrating fish species can serve as a criteria for the assessment of disruption in river continuity;
- Macrophytes are good indicators of changes in flow downstream of reservoirs as well as for the assessment of regulated lakes because they are sensitive to water level fluctuation;
- For linear physical alterations such as coastal defence work, benthic invertebrates and macroalgae might be the most appropriate indicators.

Defining the extent of ecological damage in the manner required by the WFD will not be possible until common ecological monitoring is in place by 2006. Since step 5 of the HMWB identification and designation process should be completed by 2004 (in time for the initial characterisation as in Art. 5), assessments may be estimates based on existing biological monitoring data and ecological classification systems.

Wetlands

Wetland ecosystems are ecologically and functionally parts of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in the WFD CIS Guidance Document No. 2 on water bodies and further considered in the Guidance on wetlands (currently under preparation).

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of the river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within the programmes of measures is examined further in a separate horizontal Guidance paper on wetlands (currently under preparation).

Look out! Links to other CIS working groups

Guidance on how to define reference conditions for assessing the ecological status of surface water bodies is being developed by the CIS WGs 2.3 (REFCOND) in WFD CIS Guidance Document No. 10 and WG 2.4 in WFD CIS Guidance Document No. 5 (COAST). The WFD CIS Guidance Document No. 3 of WG 2.1 IMPRESS will give more explicit Guidance for carrying out the "characterisation" and the "risk assessment". The Monitoring Working Group WG 2.7 (WFD CIS Guidance Document No. 7) will set the monitoring requirements for water bodies "at risk" as well as for all other water bodies.

5.7 IS THE WATER BODY SUBSTANTIALLY CHANGED IN CHARACTER DUE TO PHYSICAL ALTERATIONS BY HUMAN ACTIVITY (step 6)? PROVISIONAL IDENTIFICATION OF HMWB

If it is likely that the water body will fail to achieve good ecological status due to hydromorphological changes then a range of options exist for objective setting. In some cases, restoration measures can be taken before 2015, which will allow the water body to reach GES. In other circumstances, an extension of the deadline by the application of the Article 4(4) derogation will allow the water body to achieve GES later.[15] Clearly, less stringent environmental objectives can also be set if an Article 4(5) derogation is appropriate. These approaches will be required in those circumstances where a water body is subject to significant changes in hydromorphology but is not substantially changed in character.

If a water body is to be provisionally identified as heavily modified (Examples in the toolbox) the following criteria apply:

1. The failure to achieve good status results from **physical alterations** to the hydromorphological characteristics of a water body. It must not be due to other impacts, such as physico-chemical impacts (pollution);

2. The water body must be **substantially changed in character**. This is the case when there is a major change in the appearance of the water body. It is clearly a partly subjective decision as to whether a water body is (a) only significantly changed in character (e.g. water abstraction without morphological alterations) or (b) substantially changed in character when provisional identification as HMWB may be appropriate (e.g. long-term hydromorphological changes caused by a weir). Both may be likely not to achieve GES. However, the following considerations should be borne in mind:

    - When visiting a water body that is substantially changed in character, it should be very obvious that the water body is substantially changed from its natural condition;

15 According to Article 4(4) the maximum extension of the deadline is 2027.

- The change in character must be extensive/widespread or profound. Typically this should involve substantial change to both the hydrology and morphology of the water body;
- The change in character must be permanent and not temporary or intermittent;
- Many alterations to the hydrological characteristics of water bodies, such as abstractions and discharges, are not associated with morphological changes, and may therefore often be easily reversible, temporary or short-term. Consequently, such alterations would not constitute substantial changes in the character of water bodies and hence the application of HMWB designation would not be considered;
- The modification must be consistent with the scale of change that results from the activities listed in Article 4(3)(a): a canalised river, a harbour, a river constrained for flood protection or a dammed river or lake.

3. The substantial change in character must be the result of the **specified uses**. It must have been created by uses listed in Article 4(3) or uses which represent equally important sustainable human development activities (either singly or in combination).

In Table 1, an overview of the main specified uses and the connected physical alterations and impacts on hydromorphology as well as on biology is given. A more extensive list of physical alterations and impacts on hydromorphology and biology can be found in the HMWB synthesis report (Hansen *et al*., 2002).

Table 1: Overview of the main specified uses, physical alterations and impacts

Specified Uses	**Naviga-tion**	**Flood protection**	**Hydro-power generation**	**Agriculture/ Forestry/ Fish farms**	**Water supply**	**Recreation**	**Urbani-sation[16]**
Physical Alterations (pressures)							
Dams & weirs	X	X	X	X	X	X	
Channel maintenance/dredging/ removal of material	X	X	X	X		X	
Shipping channels	X						
Channelisation/straightening	X	X	X	X	X		X
Bank reinforcement/fixation/ embankments	X	X	X		X		X
Land drainage				X			X
Land claim				X			X

16 Urbanisation is not mentioned in Article 4(3)(a), but has been identified as an important use in the HMWB case studies. Therefore it presumes that it is an important sustainable human development activity.

Specified Uses	Naviga-tion	Flood protection	Hydro-power generation	Agriculture/ Forestry/ Fish farms	Water supply	Recreation	Urbani-sation[16]
Creation of back waters through embankments	X					X	X
Impacts on hydromorphology and biology							
Disruption in river continuum & sediment transport	X	X	X	X	X	X	
Change in river profile	X	X	X	X			X
Detachment of ox-bow lakes/wetlands	X	X	X	X	X		X
Restriction/Loss of flood plains		X	X				X
Low/reduced flows			X	X	X		
Direct mechanical damage to fauna/flora	X		X			X	
Artificial discharge regime		X	X	X	X		
Change in groundwater level			X	X			X
Soil erosion/silting	X		X	X			X

If a water body is not designated and it becomes apparent later on that it probably is heavily modified, provisional identification as HMWB and application of the designation tests is still possible after 2004. Similarly if a water body is provisionally identified as HMWB, Member States do not have to complete designation. They can at any time consider it as a non-heavily modified water body and set appropriate objectives under Article 4(1)(a)(ii), 4(4) or 4(5).

5.7.1 Scope, scale and extent of provisional identification

Within the provisional HMWB identification, the scale, scope and extent of water body identification should be considered. It may be necessary to adapt the boundaries of the initially identified water bodies (step 1) according to the substantial changes in hydromorphology. More specifically, where the hydromorphogical changes do not coincide with the boundaries of a surface water body, it may be appropriate to subdivide the water body in order to separate heavily modified stretches from the unaffected areas of the water body.

The following three examples may be helpful for the decision on whether to subdivide water bodies or not under different circumstances (Figure 3 - Figure 5):

- In Figure 3, two physically altered areas cover a major percentage of the absolute length/area of the original water body (8 km out of 10 km). The water body is, to a large extent, impacted by the same pressure and it would therefore be suggested **not to split** the original water body, but to apply provisional HMWB identification to the whole water body;
- In Figure 4, the original water body is modified by a physically altered area (6 km) covering a major percentage of the entire length/area of the original water body. In

this case it would be recommended **to split** the original water body into two distinct water bodies (1a & 1b). Water body 1b, impacted by the physical alteration, would be provisionally identified as heavily modified. The water body 1a would be regarded as a natural water body;

- In Figure 5, a series of small physically altered areas each covering < 1 km are present at a small stretch of the entire water body length. Here the question occurs, whether those < 1 km stretches should be identified as distinct water bodies and be provisionally identified as HMWB, or whether the overall impact is low and therefore the whole water body should be regarded as a natural water body. It is suggested **not to split** the water body and regard the entire water body as natural.

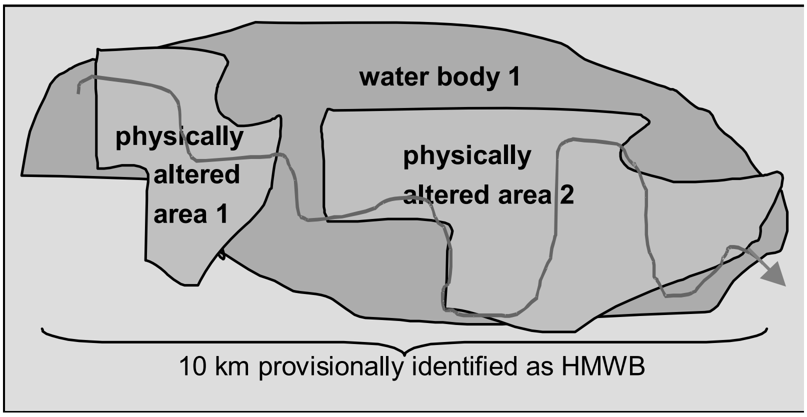


Figure 3: Example 1, no subdivision of the water body

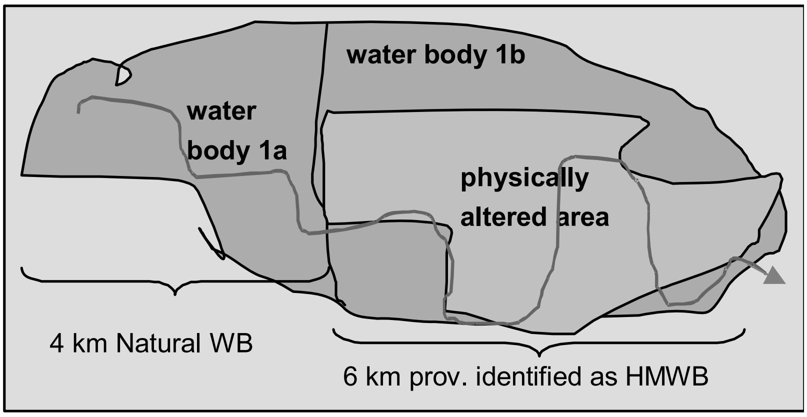

Figure 4: Example 2, subdivision of the water body

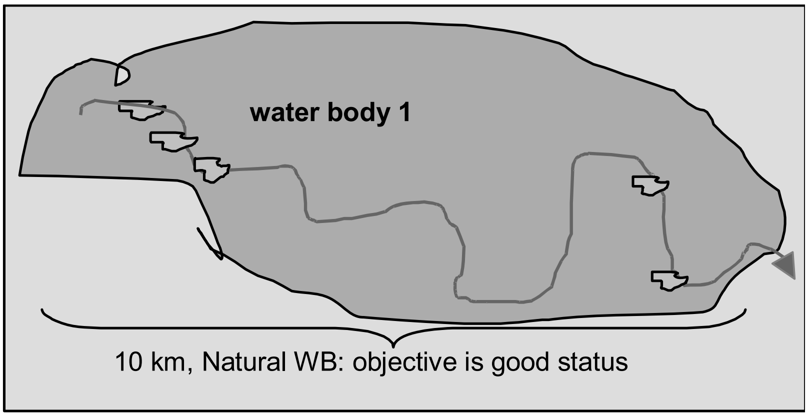

Figure 5: Example 3, no division of water body

Note: The provisional identification of HMWB refers to river stretches and not to the catchments or sub-catchments. In the three figures above the catchments are marked because it is difficult to only mark river stretches; the latter would be more appropriate.

Another important issue is that only water bodies which are substantially changed in character (due to physical alterations) themselves, may be provisionally identified as HMWB. If a physical alteration (e.g. dam) impacts the biological quality elements in the upstream part of a river system (for example fish migration is hindered), this upstream part may not be considered for provisional HMWB identification. If the GES cannot be achieved in this water body upstream of a physical alteration, the environmental objective may be less stringent.

6 TESTS LEADING TO THE DESIGNATION OF HMWB (Steps 7 - 9)

6.1 TIMING FOR DESIGNATION TESTS

Water bodies that have been provisionally identified as heavily modified (cf. Section 5) may be considered for designation.[17] The designation process must be completed in time for the consultation of the draft RBMP in 2008 and final publication of the RBMP in 2009. The designation process should be undertaken as soon as possible after the provisional identification. In addition it will be important to co-ordinate the designation process with the other requirements of the RBM planning process. In particular, the links to the following requirements should be considered:

- The designation process helps to identify which "restoration measures" or "other means" may be required to meet the environmental quality objective. Additionally, "mitigation measures" will be identified in the reference condition and objective setting process (cf. Section 7). These "mitigation measures" must be identified in time to allow for the assessment of the most cost effective programmes of measures for the draft RBMP in 2008 and for ensuring that the programmes of measures are operational by 2012 [Art. 11(7)];

- It may be efficient to undertake the designation process at the same time as the setting of less-stringent environmental objectives [Art. 4(5)] for both natural and HMWB which include similar tests (e.g. consideration of disproportionate costs).

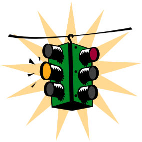
6.2 DESIGNATION IS OPTIONAL AND ITERATIVE

It is stressed that Member States **may** designate a water body as artificial or heavily modified.

Provisionally identified HMWB do not, therefore, necessarily have to be considered for the designation tests, in this Section 6. Member States may decide not to proceed with the designation process at any stage, and may decide to consider the water body as natural, having to achieve GES. This decision may be influenced by additional information that may have become available since the identification process was performed.

---

[17] Also other water bodies that have not been provisionally identified as HMWB may additionally be considered if evidence shows that they are at risk to fail the GES due to physical alterations (see Section 6.2).



Look out! Designation is optional!

The designation of HMWB and AWB is optional. Member States can choose not to designate a water body as a AWB or HMWB. The designation tests can be stopped at any point in the process. In this case the water body would be treated as a natural water body and the environmental quality objective would be GES.

For several reasons, water bodies designated as heavily modified in the first cycle may be regarded as natural water bodies in future cycles and vice-versa (Section 8). Designation is hence an iterative process. It should also be pointed out that new data or information may reveal water bodies, which have not been provisionally identified (in steps 1-6), as heavily modified, that should be considered for the designation tests. In future RBMP cycles, the designation of HMWB must be reviewed (cf. Section 8).

6.3 THE DESIGNATION TESTS

A water body may be designated as heavily modified if it has passed through the designation procedure involving both designation tests as specified under Article 4(3)(a) & (b) (steps 7 and 8). In some cases both tests do not have to be carried out entirely, see Figure 6.

For AWB only the designation test 4(3)(b) applies (see Section 6.8).

The designation tests are designed to ensure that HMWB are only designated where there are no reasonable opportunities for achieving good status within a water body. They are therefore water body specific. However, where the designation tests are applied at a regional or national scale it may be appropriate to apply the test to groups of water bodies, to reduce the overall work load involved in the designation tests. For example, if the main stem of a river was being considered for designation as a series of HMWB because it is used for navigation, it should be possible to consider the tests for groups of water bodies within the affected stretch. If water bodies are grouped, there must be no differences in the characteristics of the water bodies or the specified uses which could affect the outcome of the designation tests. Justification for grouping water bodies should be provided.

A step-wise approach for the identification and designation of HMWB and AWB which includes the designation tests is presented in Section 4. Figure 6 is based on Figure 1 but identifies more detail on the "Designation test 4(3)(a)" (step 7) and "Designation test 4(3)(b)" (step 8), which consist of several sub-steps.

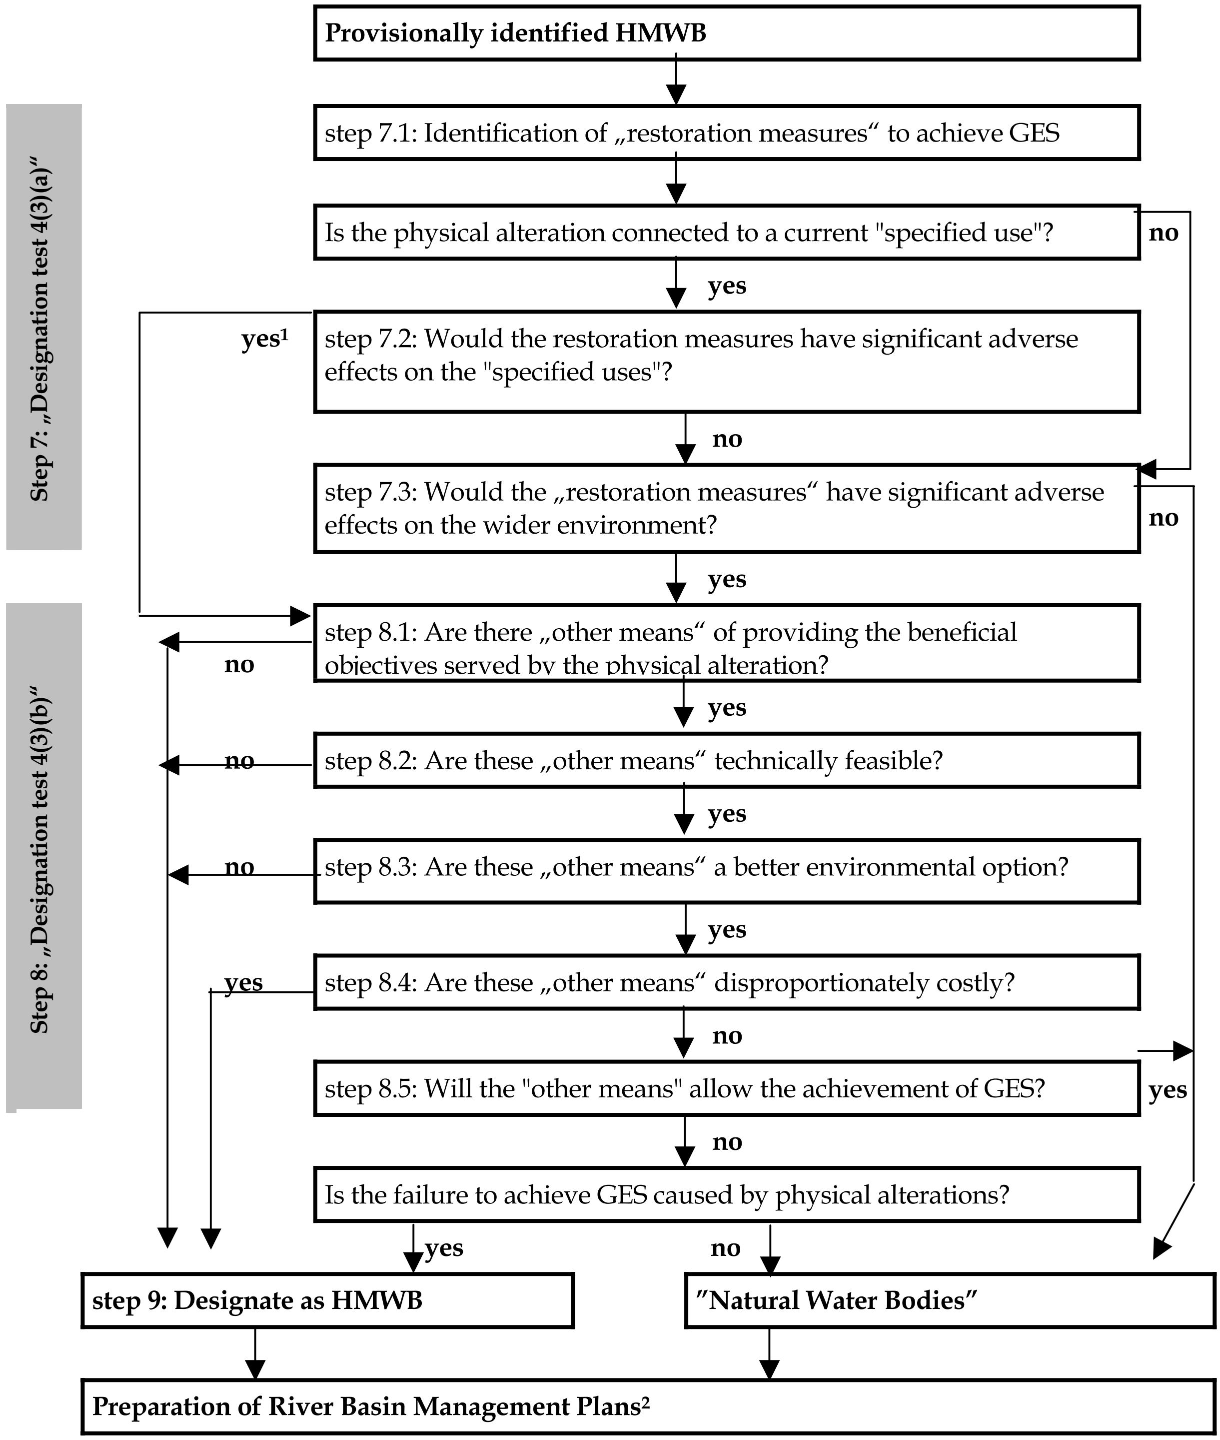


Figure 6: Steps leading to the designation of HMWB (steps 7-9)

Note 1: Step 7.2: If the restoration measures would have significant adverse effects on the "specified uses" you could directly proceed to the "Designation test 4(3)(b)", step 8.1. But for a better justification for designation you may also want to apply step 7.3.

Note 2: Preparation of River Basin Management Plans including: identifying objectives, identifying programmes of measures (POM), cost effectiveness analysis, derogation for an extended timetable and less stringent objective, consideration of Article 4(8), to ensure no deterioration of other water bodies.

6.4 DESIGNATION TEST 4(3)(a) (Step 7)

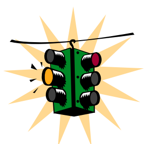
The designation test 4(3)(a) has three components, and is divided into sub-steps 7.1-7.3, accordingly (see Figure 6):

- First, the "restoration measures" for achieving GES are to be identified (step 7.1, see Section 6.4.1);
- Then, the adverse effects of these restoration measures on the specified uses have to be assessed (step 7.2, see Section 6.4.2); if the adverse effects on the specified uses **are significant**, you may go directly to step 8 (see Section 6.5), but you could also proceed to step 7.3 (see Note 1 to Figure 6). If they are **not significant** you proceed with:
- step 7.3 and assess whether the application of restoration measures would have significant adverse effects on the wider environment (see Section 5.4.3).

6.4.1 Identification of "restoration measures" to achieve GES (Step 7.1)

The first sub-step 7.1 of the designation test 4(3)(a) is to identify the hydromorphological changes which could lead to the achievement of GES. This process is complicated by the fact that water bodies will frequently be impacted by different pressures. Consequently, it will be necessary (but not always possible) to separate:

- measures to change hydromorphology;
- measures to improve the physico-chemical status; and
- direct measures to improve the biological status (such as manipulation of fish population or planting macrophytes).[18]



Look out! Hydromorphological conditions!

The Guidance Document for HMWB and AWB is dealing with hydromorphological conditions that result from physical alterations and with "restoration measures" which improve these hydromorphological conditions. The non-hydromorphological measures will <u>not</u> be considered in this Guidance Document but will be part of the programmes of measures (POM) to be set up for the RBMP.

The hydromorphological changes for achieving GES (hereafter called restoration measures) may range from measures aimed at reducing the environmental impact of

[18] All measures (including hydromorphological and physico-chemical improvements) ultimately aim to improve the biological status.

the physical alteration (e.g. increased compensation flows or fish passages) to measures resulting in the complete removal of the physical alteration. Measures can be directly related to the physical alteration (e.g. changing the physical alteration) or enhance the general ecological conditions (e.g. creation of habitats). In this sub-step the contribution that an individual measure could make towards achieving GES needs to be predicted. It should also be assessed whether an overall package of proposed restoration measures could lead to GES (Examples in the toolbox).

The measures should be well-defined (e.g. exact percentage of compensation flow) and should include an assessment of whether GES status will be delivered (full or partial delivery) (Example in the toolbox). Combinations of "partial" measures may allow GES to be achieved. The identification of suitable measures can be difficult, because information on the cause-effect relationship of measures is often not sufficient.

The costs of restoration measures are not considered here (see substep 7.2 and Section 8.1).

A list of examples for restoration measures for different specified uses ("navigation" and "hydropower") is given in the toolbox. This list can be used as an initial check list.

6.4.2 Significant adverse effects on specified uses (Step 7.2)

The second sub-step 7.2 of the designation test 4(3)(a) requires an assessment of whether the necessary "restoration measures" to achieve GES will have significant adverse effects on the specified uses (e.g. on navigation, on hydropower, on recreation, or on other specified uses).

It should be emphasised that the application of the test should consider the full range of possible restoration measures. For example, in a river, which has been modified for navigation that has artificial vertical embankments, it may be possible to create more natural banks which may allow GES to be achieved without causing significant adverse effects upon the use.

This sub-step 7.2 can only be applied to water bodies that have a current specified use-related physical alteration. If the physical alteration to the water body is due to a historic specified use which no longer exists, then you may directly proceed to step 7.3 (see Figure 6 and Section 6.4.7). Clearly, the specified uses of a water body may also change over time. For example, an abandoned drinking water supply reservoir may develop an important new specified use as a recreational resource (e.g. sailing). Then, the possible adverse effects on this changed specified use should be assessed in this sub-step 7.2.

6.4.3 What effects are to be considered?

Adverse effects on the specified uses are losses of/in important services (e.g. flood protection, recreation or navigation) or production losses (e.g. hydropower or agricultural goods) (Examples in the toolbox). In assessing "significant adverse effects" on the specified uses, economic effects will play an important role, but also social aspects may need to be considered (e.g. removal of flood defences may lead to displacement of population).

6.4.4 What aspects are not relevant in this sub-step?

In assessing whether the restoration measures have "significant adverse effects" on the specified use not all aspects are relevant. For example, when considering an estuary used for navigation, the focus of the test should be on the effect of restoration measures upon the movement of ships. The ability of the user to pay is not relevant at this stage as this would potentially discriminate against efficient and profitable enterprises. Similarly, at this stage disproportionate costs cannot be used as an additional consideration beyond the assessment of significant adverse effects on the specified use (see Section 8.1).

6.4.5 What is significant?

It is not considered possible to derive a standard definition for "significant" adverse effect. "Significance" will vary between sectors and will be influenced by the socio-economic priorities of Member States.

It is possible to give an indication of the difference between "significant adverse effect" and "adverse effect". A significant adverse effect on the specified use should not be small or unnoticeable but should make a notable difference to the use. For example, an effect should not normally be considered significant, where the effect on the specified use is smaller than the normal short-term variability in performance (e.g. output per kilowatt hour, level of flood protection, quantity of drinking water provided). However, the effect would clearly be significant if it compromised the long-term viability of the specified use by significantly reducing its performance. It is important to undertake this assessment at the appropriate scale. Effects can be determined at the level of a water body, a group of water bodies, a region, a RBD or at national scale. The appropriate scale will vary according to the situation and the type of specified use or sector. It will depend on the key spatial characteristics of the adverse effects. In some cases it may be appropriate to consider effects at more than one scale in order to ensure the most appropriate assessment. The starting point will usually be the assessment of local effects (Examples in the toolbox).

If the adverse effects are considered to be significant, the water body should be considered for the designation test 4(3)(b) (cf. Section 6.5). If there was no significant adverse effect on specified uses, the measures have to be checked as to whether they would have significant adverse effects on the wider environment (see Section 6.4.7, step 7.3).

6.4.6 If there is no specified use

Although the use for which the physical alteration was intended might not be there any more, in almost all cases the modified characteristics of the water body serve a specified use of some form (e.g. a dam originally built for water supply might alternatively be used for recreation).

In the rare cases where no uses whatsoever are served by the modified characteristics of the water body any more, step 7.2 of the designation test 4(3)(a) does not apply, since no specified uses exist upon which a restoration measure could have a significant adverse effect.

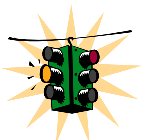
Proceeding to step 7.3, the possibility of the significant adverse effects of restoration measures on the wider environment needs to be assessed. If the restoration measures have a significant adverse effect on the environment, then the water body normally should be considered for the "designation test 4(3)(b)". However, without a specified use, “other means” for delivering the beneficial objectives of the specified use cannot be defined. Consequently, under these circumstances, if the wider environment is significantly affected by the restoration measures, the steps 8.2-8.5 are of no relevance and the water body can directly be designated as a HMWB.

6.4.7 Significant adverse effect on the wider environment (step 7.3)

The intent of this sub-step 7.3 of the designation test 4(3)(a) is to ensure that restoration measures required to achieve GES do not deliver environmental improvements for the water body whilst creating environmental problems elsewhere (Example in the toolbox).

6.4.8 What is the wider environment?

Article 4(3)(a) refers to the <u>wider</u> environment. Consequently a restricted definition of environment would not be appropriate and the environment is considered to include the natural environment and the human environment including archaeology, heritage, landscape and geomorphology.



Look out!

In general, a significant adverse effect on the wider environment would exist, if the damage to the wider environment caused by restoration measures exceeds the benefits for the improved water status itself (such as significantly increased $C0_2$ emissions or the generation and disposal of large quantities of demolition waste).

6.4.9 Examples of "restoration measures" that have an adverse effect on the wider environment

- Normally the restoration of flood plains increases the biodiversity of the environment. However, there may be some limited circumstances where the restoration of flood plains threatens a specific landscape and biodiversity that has developed over the years as a result of the elimination of the floods in riparian zones and former floodplains;
- The removal of a dam may lead to the elimination of wetlands that have developed in connection to the water storage;
- Building a channel around a physical obstacle to improve ecological continuum (see Section 7.2 MEP) to allow fish migration, may use considerable energy, damage an archaeological site and produce waste materials. It may therefore, in some circumstances, not be appropriate in relation to the benefit;
- A historical modification, such as a mill or a weir which no longer has a current specified use, may now have aesthetic or historical value. This feature should not necessarily be removed and some may wish to designate the affected water body as HMWB.

In general it has to be prevented that such adverse effects on the wider environment are significant.

This test also has links to Article 4(8) and 4(9) that require measures under the WFD to be consistent with the requirements of existing Community Environmental legislation. For example, where the modified water body or its floodplain is (or is to be) designated under another directive such as the Fauna Flora Habitat or the Birds Directive, the requirements for these directives must be taken into account. "Restoration measures" that would result in conflicts with these directives should be considered as having a "significant effect on the environment".

The importance of the improvement which would be delivered by the restoration measures relative to the impact on the wider environment has to be considered here. It would, for example, not be appropriate if a large environmental improvement programme was prevented because of a significant adverse effect on a small component of the wider environment (e.g. a reservoir that serves no current purpose which results in a valuable (local) wetland; removing the dam would result in losing the wetland, but it would allow fish migration for a large river length (region). In this example, the fish migration would probably represent a larger improvement to the environment than the loss of wetland, but it strongly depends on the circumstances).

If there are no significant adverse effects upon the specified use or the wider environment, the provisional HMWB should be regarded as a natural water body and restoration measures should be undertaken to ensure that the GES can be reached. In some circumstances, Article 4(4) or 4(5) derogations will be appropriate and less stringent environmental objectives may be set.

If there are significant adverse effects on either the specified use or on the wider environment then the water body should proceed to designation test 4(3)(b).

6.4.10 Significant adverse effect and timing

The WFD requires Member States to achieve good status by 2015. Timing is therefore a relevant consideration in the Art.4(3)(a) test. The selection of measures should allow for the achievement of GES by 2015, or if derogations under Art. 4(4) apply, by 2021 or 2027. The assessment should therefore first consider whether there is a significant adverse effect on the specified use or environment up to 2015. If there is a significant adverse effect then the time period up to 2021 and then 2027 should be considered.

6.5 DESIGNATION TEST ACCORDING TO ARTICLE 4(3)(b) (Step 8)

The designation test 4(3)(b) considers whether the beneficial objectives served by the modified characteristics of the water body can reasonably be achieved by "other means" (step 8.1), which are:

- technically feasible (cf. Section 6.5.2, step 8.2);
- significantly better environmental options (cf. Section 6.5.3, step 8.3); and
- not disproportionately costly (cf. Section 6.5.4, step 8.4).

Water bodies for which "other means" can be found that fulfil these three criteria and can achieve the beneficial objectives of the modified characteristics of the water body may not be designated as HMWB. The existing specified use may, in some cases, be abandoned and the physical alterations removed so that good status can be achieved.

6.5.1 Identification of "other means" for achieving the beneficial objectives (Step 8.1)

In considering the Article 4(3)(b) test it is important to distinguish between:

- "restoration measures", which are covered under the "designation test 4(3)(a)" (step 7), and involve changes to the existing specified use in order to achieve GES; and
- "other means" which will deliver the beneficial objectives of the modified characteristics of the water body and involve the replacement or displacement of the existing specified use.

The Article 4(3)(b) test should only consider the potential for "other means" of delivering the beneficial objectives of the modified characteristics of the water body, including the benefits of specified uses and the wider environment. Other means may include the following options:

- Displacement of the specified use to another water body. For example, the replacement of a hydropower station with a new one (in another water body) where it causes less environmental damage. Another example would be stopping navigation in one river because a canal connection would provide alternative transport links (Example in the toolbox);

- Replacement of the existing specified use with an alternative option to deliver the beneficial objectives. For example, replacing hydropower with other energy sources, or replacing navigation with rail and road transport at lower environmental costs, alternative flood defence strategies such as restoration of upstream flood-plains to remove flood defence hard engineering downstream, i.e. soft-engineering as opposed to hard-engineering solutions (Example in the toolbox).

The partial replacement or displacement of the beneficial objectives of the specified use should also be considered, while not necessarily allowing the achievement of GES.

6.5.2 Assessment of "technical feasibility" of "other means" (Step 8.2)

It then has to be assessed whether these "other means" are technically feasible. Technical feasibility is put here as the first check as it represents a relatively simple test and there is clearly no value in assessing the environmental impact of options that are not technically feasible.

"Technical feasibility" considerations include the practical, technical and engineering aspects of implementing the "other means". It addresses the question of whether “other means” of delivering the beneficial objectives of an existing specified use exist. It should not include consideration of disproportionate costs; these will be assessed as part of the later component of the test (step 8.4) (Example in the toolbox).

There may be some circumstances where it is appropriate to consider social issues which constrain the development of “other means”. The use of such social constraints should be fully explained within the RBMP.

6.5.3 Assessment of whether “other means” are better environmental options (Step 8.3)

The purpose of this sub-section 8.3 of the Article 4(3)(b) test is to ensure that proposed “other means” do represent a better environmental option and that one environmental problem is not replaced with another. The test is, therefore, similar in concept to the earlier Article 4(3)(a) test, which assessed whether possible measures have a “significant adverse effect on the wider environment” (step 7.3).

When assessing other means as better environmental options, the following issues should be considered:

- <u>Scope of "environment" in better environmental option:</u> It is suggested that in order to ensure a consistent approach with the Article 4(3)(a) test, the assessment should include - where appropriate - consideration of the “wider environment” such as archaeology and urban and other landscapes;
- <u>Issue of scale:</u> There is a range of scales at which the question of “better environmental options” can be assessed: local, regional, RBD, national or

international level. Clearly it may be appropriate to consider the impacts and benefits just on the water environment or on the wider environment (water, land, air). In the first instance it is suggested that the assessment should focus on local options. Further considerations should then be considered where appropriate.

An example for this is the possible replacement of navigation on a large river system. In this instance it may be appropriate to include an assessment at a regional, national or international level taking into account increased road or rail traffic and the potential impact on $C0_2$ emissions.

It is clear that the most appropriate scale used to assess "better environmental option" will depend on the kind of "other means" under consideration. Where there is uncertainty about the appropriate scale an assessment should be carried out at different scales (Examples in the toolbox).

6.5.4 Assessment of disproportionate costs of "other means" (Step 8.4)

Those "other means" which are considered to be "technically feasible" and which represent a "significantly better environmental option" should be subject to an assessment of whether they are "disproportionately costly".

This assessment is likely to focus on financial/economic costs. However, there may be some circumstances where it may be appropriate to consider social issues as part of the assessment of disproportionality of costs.

In undertaking this assessment it is important to take account of likely or planned capital expenditures associated with the existing specified use; this should include planned expenditures up to 2027, where appropriate. This is particularly appropriate (and important) in cases where the existing specified use is associated with large scale engineering works which are subject to regular maintenance, replacement or upgrading.

This represents a key baseline, against which the incremental costs and benefits of the alternative 'other means' are to be analysed and presented.

The following two options are recommended for assessing disproportionate cost :

6.5.5 a) Comparison of cost alternatives

Disproportionate costs can be determined by assessing the incremental costs and environmental impacts of the "other means". The benefits of the existing specified use and the alternative are assumed to be the same. The main cost elements to be considered are:

- For the existing situation: operational and maintenance costs, and capital costs for necessary replacements (including investment and interest costs);
- For each option/alternative ("other means"): capital costs (including investment and interest costs), operational and maintenance costs, and possible foregone benefits from changes in economic activities (e.g. reduction in agricultural

production resulting from the development of a retention area as an alternative to dikes for preventing floods).

6.5.6 b) Comparison of overall costs and benefits

Disproportionate costs can be determined by comparing the overall costs and benefits of the existing modification and the alternative ("other means"). In this assessment the overall net benefit to society of the modification and of the alternative are compared. The main elements that are to be considered include:

- Costs as listed in a);
- benefits of the existing specified use; and
- benefits of the alternative, especially benefits gained from the higher ecological status (e.g. angling, recreation).

In order to ensure that the environmental impacts of the existing specified use are properly compared with the "other means", it is recommended to consider the:

- existing specified use; and
- "other means", subject to typical sector-specific best environmental practice.

It will be important to ensure that the economic and environmental appraisal of the "other means" are in line with the best practice techniques customarily used for each type of modification (e.g. flood defence, navigation etc.) to ensure that the "other means" thereby identified can actually be financed and implemented.

After having assessed the costs (and in case b) also the benefits) of the existing specified use and the "other means" it has to be decided whether the costs are disproportionate. To pass this test it is not sufficient to demonstrate that the costs exceed the benefits. The costs must be disproportionately greater than the benefits. Clearly it is not possible to define by how much the costs must exceed the benefits before they become disproportionate (Example in the toolbox).

In the context of economic assessments, the WFD CIS Guidance Document No. 1 produced by the CIS-WG 2.6 on WATECO should be considered.

Examples on the assessment of disproportionate costs are provided within the toolbox.

6.5.7 Will the "other means" allow the achievement of GES? (Step 8.5)

Under some circumstances the "other means" may represent only a **partial** replacement/displacement of the use. In these cases "other means" would fulfil all relevant criteria (steps 8.2 - 8.4) but GES still cannot be achieved due to physical alterations. This will result in those circumstances where a "better environmental option" should be realised, but GES still cannot be achieved. In the following, some examples are given:

- Example (a) If a water body is modified by two uses and it is possible to find "other means" of delivering the beneficial objective of one of the uses. The second use may still require physical alterations that prevent the water body from achieving GES;
- Example (b) If a water body is modified by a single use and it is possible to find "other means" of delivering a proportion of the beneficial objective of the use. For example, if "other means" are available that would supply 50% of the drinking water (for example from groundwater) then the variation in water levels will be reduced. This may still not allow the water body to achieve GES but it may represent a "significantly better environmental option". The result may be an improvement in the environmental quality of the reservoir and the river downstream and it may allow new additional uses of the reservoir for example recreation. Such "other means" which offer "better environmental options" but do not achieve GES should be undertaken as part of the programme of measures.

If GES is not achieved by the other means, and this is caused by the physical alterations, the water body may be designated as HMWB.

If GES can be achieved by the other means, the water body must be regarded as natural.

6.5.8 "Other means" and timing

The WFD requires Member States to achieve good status by 2015. Timing is also a relevant consideration in step 8 [the Article 4(3)(b) test]. The selection of "other means" (i.e. alternative options in the sense of displacement or replacement) should allow for the restoration of the site by 2015, or, if derogations under Article 4(4) apply, by 2021 or 2027. In particular, the time constraint may influence the decision as to whether the "other means" are technically feasible or disproportionately expensive as part of this step 8 [Article 4(3)(b) test].

The assessment should therefore firstly consider, whether the "other means" are technically feasible and not disproportionately expensive during the period up to 2015. If this is not the case, then it should be considered until 2021 or 2027.

6.6 DESIGNATION OF HMWB IN 2008 (Step 9)

A water body may be designated as HMWB if it has passed through the designation procedure involving, if applicable, both designation tests (steps 7 & 8).

After applying the designation tests, Member States may still decide that they do not wish to designate the water body as a HMWB.

If there are no significant adverse effects neither on the specified uses nor on the wider environment, or there are "other means" of delivering the beneficial objectives then the water body should be regarded as natural.

6.7 GUIDANCE ON METHODS FOR APPLYING THE DESIGNATION TESTS 4(3)(a) & (b) (for Steps 7 and 8)

A very large number of water bodies will have to be assessed for possible designation as HMWB until 2008/9. Consequently, the methods used to comply with the requirements of the designation tests must be proportionate and pragmatic. The purpose of this Section is to identify appropriate methodological options so that the complexity of the assessment methodology can be made proportionate to the circumstances.

In order to reduce the workload for the designation tests, the possibility exists to group the water bodies for the assessment (see Section 6.3). It should be stressed that water bodies should only be grouped if they require similar levels of assessment, for example, if purely descriptive methods are to be used because the water body is obviously substantially changed in character. However, it would be entirely inappropriate to group water bodies which are obviously substantially changed in character with others where a more detailed assessment would be necessary to decide whether they are HMWB.

The designation of HMWB will be undertaken as part of the RBM planning process and is therefore subject to the requirements for the provision of public information and consultation as defined by Article 14. Information provided by the assessment methods must be sufficient to ensure that the process of decision-making associated with the Article 4(3) designation tests is transparent allowing for the active participation of the public in the planning process based on the provision of necessary appropriate information. In addition it is clearly important that the information is sufficient to demonstrate compliance.

Four potentially complementary types of appraisal methods are suggested.

1. **Descriptive (qualitative) methods** - can be applied where the position is clear-cut and detailed analysis is unnecessary. Descriptive methods may also be necessary where environmental or social impacts cannot be quantified;

2. **Simple quantitative measures for assessing the impact or benefit** – involves the description of relative change. For example, the percentage reduction in the beneficial output of a specified use. This can be expressed as a function of the output (for example kilowatt/hours for hydropower or tonnes transported p.a. for navigation). However, the preferred output is percentage change expressed in terms of EUROs as this allows a comparison between different sectors as well as temporal comparison within sectors. Ideally the absolute value of the output should also be included so that the scale of the change can be put into context;

3. **Benchmarking information** – where standard costs and/or benefits can be derived for individual sectors or types of measures. In some cases the benchmark will most

appropriately be considered in terms of the measure[19], in other cases it can be expressed in terms of cost-effectiveness (i.e. as a cost per unit of benefit achieved)[20];

4. **More in-depth economic assessment methods** – includes a range of tools of varying complexity. These may be used for marginal cases and for situations requiring high levels of investment.

The extent to which it will be necessary to move down this list of methods will depend on the costs and contentiousness of the options in question. It is considered that the first two types of methods will be most frequently used.

6.7.1 Methods for determining significant adverse effects (for Step 7)

Table 2 provides guidance on the type of analyses that may be considered. Simple qualitative descriptive methods are appropriate where the following situations apply:

- The adverse effects on specified uses are relatively small in relation to the specified use (clearly not significant); or
- The adverse effects on specified uses are very large and prejudice their viability (clearly significant). This is particularly relevant when the necessary "measures" imply the cessation of specified uses, functions and related human activities. For example, where the removal of flood defences would lead to widespread flooding of an urban area.

Where the situation is not clear-cut, a simple quantitative assessment should be carried out using relative assessment of impact.

Table 2: Preliminary guidance on the selection of methods for Article 4(3)(a) test.

INCREASING COMPLEXITY (move in this direction only when necessary, i.e. when a decision cannot easily be made with methods on the left of the table).

Test	Descriptive (qualitative) methods	Simple quantification	Benchmarking information	Economic assessment
Significant adverse effect on specified use (step 7.2)	If abandonment of, or very major change in, specified use/function/activity If very limited change in specified use /function/activity	When partial change in specified use/ function		Where significance of change in specified use/function is uncertain
Significant adverse effect on environment (step 7.3)	Description of scale of impacts relative to benefits provided by restoration measures		National / local scale benchmarking may be of assistance	

[19] e.g. annualised costs of a fish ladder in X Euros pa.

[20] Y Euros per fish passing etc.

It may be appropriate to consider the adverse effects at a local level, or at a local level in relation to regional or national significance. A locally significant adverse effect may become insignificant when considered in a regional or national context.[21] But it could also be vice versa. [22]

It is difficult to assess the "significance" of adverse effects on the environment, because there is a lack of methods to quantify or cost such effects. It may be appropriate to list the environmental impacts/benefits of the restoration measures together with a subjective estimate of the scale (e.g. large, moderate, small) (Example in Section 3.1.3 of the toolbox is of relevance).

To assist the assessment of the "significance" of adverse effects, a standard format is provided in the toolbox. This table lists the range of issues and information that may be considered.

6.7.2 Methods for evaluating "other means" (Step 8)

Table 3 indicates that technical feasibility and better environmental option would normally be dealt with the use of descriptive methods. In the case of "better environmental options" a simple table may be prepared comparing the existing specified use and the proposed alternatives with regards to their environmental impacts. In some cases, the quantification of the physical impacts of the existing specified use and alternatives may be possible.

Table 3: Preliminary guidance on the selection of methods for Article 4(3)(b) test.

INCREASING COMPLEXITY (move in this direction only when necessary, i.e. when a decision cannot easily be made with methods on the left of the table).

Test	Descriptive (qualitative) methods	Simple quantification	Benchmarking information	Economic assessment
Technically feasible (step 8.2)	Description of practical difficulties			
Better environ-mental options (step 8.3)	Qualitative assessment for impact on different media if conclusion is clear	If uncertain about which option is best	National / local scale benchmarking may be of assistance	
Dispropor-tionate costs (step 8.4)	Description of scale of costs and also benefits if conclusion is clear	N.A.	National / local scale benchmarking may provide sufficient clarity for good judgement	Where local situation significantly different from benchmark case or where other reasons for uncertainty exist

21 The reduction of power production within one particular hydropower station might be regarded as significant but on a regional scale it might be negligible.

22 If the power production of a hydropower plant is reduced by a small percentage, it might be regarded as not significant locally; but if the energy supply of a region depends mainly on hydropower and the production is reduced in each hydropower plant, it might be regarded as significant.

In many cases, the assessment of disproportionate costs may be quite straightforward and the qualitative description of the specified use and the consequences of its removal are sufficient to decide on whether the "other means" are disproportionately costly or not.

Where this is not the case, an economic assessment of the costs and benefits (listed in Section 6.5.4) should be undertaken.

To ensure that data on costs can be compared between existing modifications and "other means", and because of likely different life-times and temporal distribution of costs, all costs have to be annualised using standard discounted cash flow analysis and appropriate discount rates (Example in the toolbox).

6.7.3 Consultative mechanisms

Many of the designation tests may involve a subjective process involving a descriptive approach to the tests. In order to ensure a transparent approach and improve decision making it may be appropriate to use formal consultative mechanisms for decision making.

- Consultative for a - involving a participatory approach to identify whether the foreseen impacts on uses are considered as significant. This approach should take social issues and cultural/local perceptions into account[23] These fora would operate within the wider RBM stakeholder engagement and public participation process;
- Representative committees – involving the authorities responsible for water management;
- Expert group panels - technical assessment of the options by a multi-disciplinary team of experts. The selection of this "expert group" is subjective but should be well-justified and transparent. The group should include stakeholder experts.

6.8 DESIGNATION OF ARTIFICIAL WATER BODIES (Step 9)

The designation process, in relation to artificial water bodies, is difficult to understand. Therefore this Section has been introduced to consider how to operate the designation process for AWB. The suggested approach should be applied to AWB (see Figure 1). It aims to:

- minimise the amount of work involved in the designation of AWB; and
- ensure that the purpose of the WFD in protecting and enhancing the water environment is delivered.

---

23 It is clearly in line with the requirements of Article 14 of the WFD to involve all interested parties.

6.8.1 Do all artificial water bodies have to be designated?

Article 4(3) states that Member States may designate a water body as artificial. This suggests that it may not always be necessary to consider designating waters which have been created by man as artificial. There may be some circumstances where long established water bodies, which are subject to little or no pressures, are indistinguishable from natural waters. Under such circumstances it may be appropriate to consider their current biological condition as HES or GES.

6.8.2 Application of "Designation test 4(3)(a)"

It is clear from the text of the Directive that the designation tests of Article 4(3) apply to AWB as well as to HMWB. However, the interpretation of Article 4(3)(a) in relation to AWB is problematic.

Article 4(3)(a)

the changes to the hydromorphological characteristics of that body which would be necessary for achieving good ecological status would have significant adverse effects on:….

In order to undertake the Article 4(3)(a) designation test, the restoration measures necessary to deliver GES must be identified. This is not possible for AWB because they were created in a location where no significant water existed before and therefore the HES natural condition would be "dry land" and a sensible GES could not be derived. Consequently, it should be assumed that test 4.3(a) does not apply to AWB. However, it is considered that the intent of Article 4.3(a) should apply to the process of AWB designation. This requires that restoration measures which result from the application of the designation process should not have a significant adverse effect on the specified use or on the wider environment.

6.8.3 Application of Article 4.3(b) test

The second "designation test 4(3)(b)" does not impose interpretation difficulties when applied to most AWB and should be used as a designation test. Consequently, when designating AWB, it should be considered whether there are “other means” which can deliver the beneficial objectives of the AWB.

It should be noted that the application of the "designation test 4(3)(b)" for AWB does not aim at considering whether water bodies are artificial or natural (or HMWB). The designation test is applied in order to see whether there are "other means" to achieve a significantly better environmental option for example resulting in an improvement of the condition of the water body.

7 REFERENCE CONDITIONS AND ENVIRONMENTAL OBJECTIVES FOR HMWB & AWB (Steps 10 & 11)

7.1 INTRODUCTION

In the HMWB and AWB identification and designation process it is necessary to identify the appropriate reference conditions and environmental objectives for AWB and HMWB (see steps 10 and 11 in Figure 1).

For HMWB and AWB the reference conditions on which status classification is based are called "Maximum Ecological Potential (MEP)". The MEP represents the maximum ecological quality that could be achieved for a HMWB or AWB once all mitigation measures, that do not have significant adverse effects on its specified use or on the wider environment, have been applied. HMWB and AWB are required to achieve "good ecological potential" (GEP) and good surface water chemical status. GEP accommodates "slight" changes in the values of the relevant biological quality elements at MEP. Member States must prevent deterioration from one status class to another, and aim to achieve GEP by 22nd December 2015 unless grounds for derogation to a less stringent objective under Article 4(5) or to an extended timescale under Article 4(4) are demonstrated. For the timing of establishing MEP and GEP see Sections 8.2 and 8.3.

7.2 ESTABLISHING THE MAXIMUM ECOLOGICAL POTENTIAL - MEP (Step 10)

A series of sub-steps are required to establish appropriate values for the quality elements at MEP (see Figure 7). In this process it is important to differentiate between "closest comparable surface water category" and "closest comparable surface water body type". The appropriate quality elements are chosen from the closest comparable categories, whereas closest comparable water body types are used to help determine the value of these elements for HMWB and AWB.

Step 10 - substep 1 (s 10.1): Choose the appropriate **quality elements** for MEP. Identify the closest comparable natural surface water category. This will either be a "river", "lake", "transitional water" or "coastal water". The appropriate quality elements are those of the closest comparable natural surface water category and are identified in Annex V No. 1.1.1- 1.1.4.

Step 10 - substep 2 (s 10.2): Establish the **hydromorphological conditions** required for MEP. The values for the biological and general physico-chemical quality elements at MEP depend on the MEP hydromorphological conditions. Establishing the MEP hydromorphological conditions is one of the first steps in defining MEP since it is these conditions which are impacted by the physical alterations and which will, primarily, dictate the ecological potential of a HMWB or AWB.

Step 10 - substep 3 (s 10.3): Establish the MEP **physico-chemical conditions**. Identify the closest comparable surface water body type. Physico-chemical conditions at MEP should be based on the conditions of this comparable type taking account of the MEP hydromorphological conditions. The physico-chemical conditions will be an important influence on the values for the biological quality elements at MEP.

Step 10 - substep 4 (s 10.4): Establish the MEP **biological conditions** that shall reflect, as far as possible, those associated with the closest comparable water body type (cf. S 10.3 above). The biological conditions at MEP will be influenced by the MEP hydromorphological and physico-chemical conditions.

step 10.1:

Choose quality elements for MEP (and GEP) based on comparable water category.

↓

step 10.2:

Establish MEP hydromorphological conditions, applying all hydromorphological mitigation measures which do not have significant adverse effects on the specified use or the wider environment.

↓

step 10.3:

Establish MEP physico-chemical conditions based on comparable water type and results of step 10.2.

↓

step 10.4:

Establish MEP biological conditions based on comparable water type and results of steps 10.2. and 10.3.

Figure 7: **Process for defining MEP (Steps 10.1 – 10.4)**

The following example shows how the establishment of MEP can be achieved according to Figure 7.

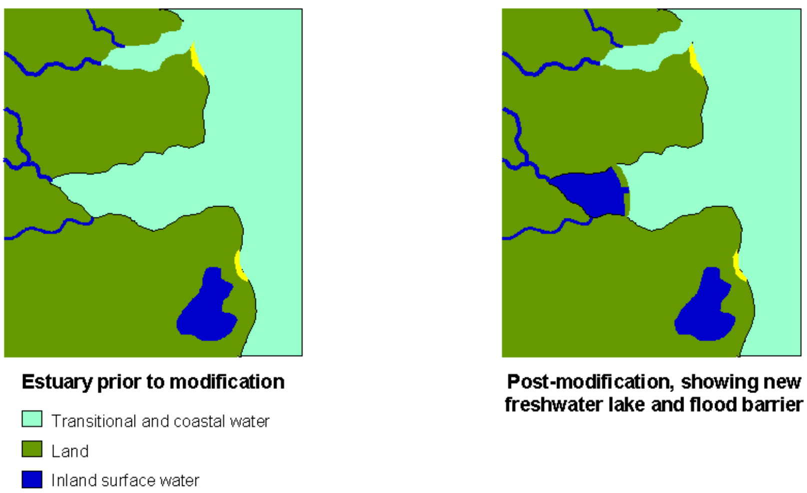


Figure 8: **Example showing an estuary turned into a freshwater lake**

The estuary was altered for flood protection (see Figure 8). It is clearly a substantial change in the character of the water body due to physical alterations. It is also an Article 4(3) specified use (flood defence).

Substep 10.1: The closest comparable natural water category in the present situation is a lake. The relevant biological, hydromorphological and physico-chemical elements of the lake category should be used to establish MEP (see Section 7.2.1

Substep 10.2: It is clear that the hydromorphological elements required for MEP **do <u>not</u> reflect the historical situation (estuary)** but should reflect the theoretical improvements which could be undertaken by hydromorphological mitigation measures (which have no significant adverse effect upon the use (flood protection)). The closest comparable lake type should be used to choose the values for those elements as far as possible (see Section 7.2.2).

Substep 10.3: The MEP physico-chemical conditions are those values found under the given circumstances of step 10.2 but reflect in general the condition at high ecological status for the most comparable lake water bodies (see Section 7.2.3).

Substep 10.4: The MEP biological conditions are those values found under the given circumstances of step 10.2 and 10.3 (see Section 7.2.4).

7.2.1 Choosing the appropriate quality elements for MEP (Step 10.1)

<u>Annex V No. 1.1.5</u>

"The quality elements applicable to artificial and heavily modified surface water bodies shall be those applicable to whichever of the four natural surface water categories above most closely resembles the heavily modified or artificial water body concerned".

The relevant hydromorphological, biological and physico-chemical quality elements are those for the most closely comparable water <u>category</u> (River, Lake, Transitional Water or Coastal Water) [cf. Annex V No. 1.1.1-1.1.4]. For example, if a river has been modified (e.g. impounded) to closely resemble a lake, the relevant quality elements will be those specified in the Directive for lakes [Annex V No. 1.1.2], rather than those for rivers [Annex V No. 1.1.1] (see Figure 9).

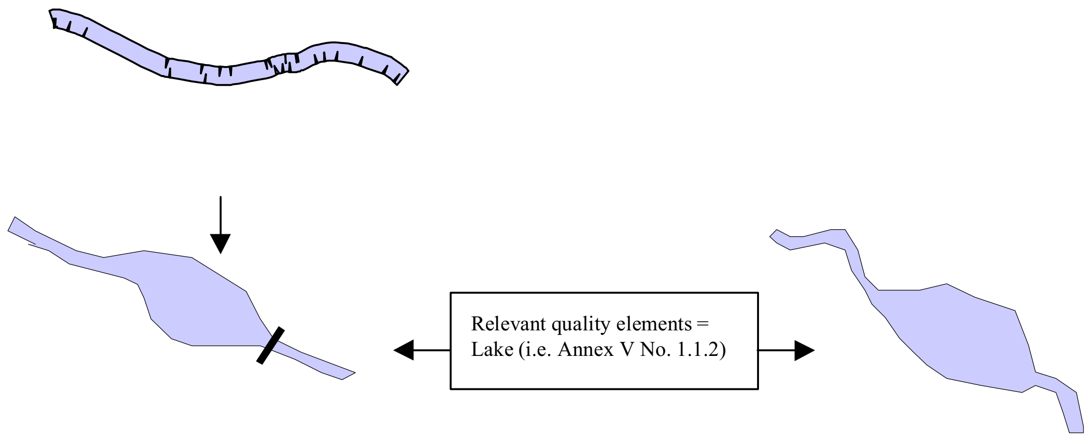

Figure 9: Example for choosing quality elements for MEP (s 10.1)

7.2.2 Establishing MEP hydromorphological conditions (Step 10.2)

Annex V No. 1.2.5

"The hydromorphological conditions [of a HMWB or AWB at MEP] are consistent with the only impacts on the surface water body being those resulting from the artificial or heavily modified characteristics of the water body once all mitigation measures have been taken to ensure the best approximation to ecological continuum, in particular with respect to migration of fauna and appropriate spawning and breeding grounds."

The hydromorphological conditions at MEP are the conditions that would exist if all hydromorphological mitigation measures were taken to ensure the best approximation to the ecological continuum. The mitigation measures for defining MEP should:

(a) not have a significant adverse effect on the specified use (including maintenance and operation of the specified use; see Section 6.4.2). This consideration includes an assessment of possible economic effects incurred by mitigation measures but not an assessment of disproportionate cost of the measures themselves or on the wider environment (see Section 6.4.7); and

(b) ensure the best approximation to ecological continuum, in particular with respect to migration of fauna and appropriate spawning and breeding grounds (Examples in the toolbox).

For the purpose of this guidance 'best approximation to ecological continuum, in particular with respect to migration of fauna and appropriate spawning and breeding grounds' is interpreted as having the following requirements:

(a) An adequate quantity and quality of usable habitat to ensure that the structure and function of the ecosystem is maintained over space and time;

(b) Longitudinal and lateral continuity/connectivity of water bodies (e.g. river continuity, aquatic – semi-aquatic - terrestrial habitat connectivity) to enable biota access to the habitats on which they depend.

The best approximation to ecological continuum therefore requires consideration of all hydromorphological mitigation measures that could reduce any obstacles to migration and improve the quality, quantity and range of habitats affected by the physical alterations. This could include connectivity to groundwater and to riparian, shore and intertidal zones. However, the WFD emphasises migration in particular. Priority should therefore be given to reducing any obstacles that significantly inhibit longitudinal and lateral migration of biota.

The technical feasibility and the financial costs (i.e. capital costs) that would be incurred if the mitigation measures were implemented is not a consideration in setting the standards for the hydromorphological quality elements at MEP. Such cost considerations are relevant when deciding whether the achievement of GEP or a less stringent objective under Article 4(5) is appropriate for the HMWB or AWB. However, the mitigation measures should not have a significant adverse effect on the specified use (including economic effects), or the wider environment according to the designation test 4(3)(a). This can include an assessment of the economic effects on the specified use or the wider environment. Although all mitigation measures should be identified, it would not be useful to further consider measures that were impractical. Such impractical measures should be excluded from any detailed assessment.

The combination of considering only measures which do not have a significant adverse effect upon the use/environment and of excluding clearly impractical measures will result in the definition of reasonable values for MEP.

In designating and setting objectives for HMWB and AWB, Member States must ensure consistency with the implementation of other Community legislation [cf. Art. 4(8)], such as the Fauna Flora Habitat Directive (FFH) Directive (92/43/EEC) and the Birds Directive (79/409/EEC). At the same time, the requirements of the WFD need to be respected in the implementation of these directives. The definition of MEP must ensure that the achievement of GEP is compatible with the achievement of the objectives established under such legislation. In the case of the FFH and Birds Directives, the mitigation measures used to define MEP hydromorphological conditions must consider the needs of those flora, fauna and habitats for which the Directives have set objectives.

7.2.3 Establishing MEP physico-chemical conditions (Step 10.3)

Annex V No. 1.2.5

"The [general] physico-chemical quality elements correspond totally or nearly totally to the undisturbed conditions associated with the surface water body type most closely comparable to the artificial or heavily modified water body concerned.

Concentrations [of specific non-synthetic pollutants] remain within the range normally associated with undisturbed conditions found in the surface water body type most closely comparable to the artificial or heavily modified body concerned. (background levels = bgl)".

The general physico-chemical conditions and the values for specific non-synthetic pollutants should correspond to those of the most closely comparable water body type, given the MEP hydromorphological conditions (see above) (Example in the toolbox).

For some AWB and HMWB, the values for some of the physico-chemical quality elements in the closest comparable water body type may be significantly different from the values that could be achieved in the HMWB or AWB, given the MEP hydromorphogical characteristics (see above). The following examples illustrate how HMWB may have different physico-chemical conditions than the nearest equivalent natural water body:

- The hydromorphological characteristics of impoundment created for hydropower and water supply can dictate the oxygen and temperature conditions in the impounded water and in the downstream river. These may be different from those in a natural water body;
- The hydromorphological characteristics of a freshwater impoundment created from a dammed estuary may result in different levels of turbidity. These may be different from those in a natural water body.

These differences can be taken into account when defining MEP.

Since the values for these physico-chemical quality elements would not correspond "totally or even nearly totally to those for the closest comparable water body type" at high ecological status (HES), such AWB and HMWB would never achieve MEP. In some cases they would also be unable to achieve GEP and therefore would require derogation to a less stringent objective under Article 4(5). Where these physico-chemical conditions are directly connected to physical alterations necessary to sustain the specified use, it is suggested that these differences be taken into account when setting MEP. These considerations are only applicable to certain physico-chemical elements such as oxygenation, temperature and turbidity, and should not be applied to general pollutants which are not connected to the hydromophological alterations.

The requirements for specific synthetic pollutants at MEP are the same as those for unmodified, non-artificial water bodies with "concentrations close to zero and at least below the limits of detection of the advanced analytical techniques in general use" [cf. Annex V No. 1.2.5]. CIS WG 2.3 REFCOND and CIS WG 2.4 COAST will provide further guidance.

7.2.4 Establishing MEP biological requirements (Step 10.4)

Annex V No. 1.2.5

[Maximum Ecological Potential (MEP) is defined as the state where] "the values of the relevant biological quality elements reflect, as far as possible, those associated with the closest comparable surface water body type, given the physical conditions which result from the artificial or heavily modified characteristics of the water body."

MEP is intended to describe the best approximation to a natural aquatic ecosystem that could be achieved given the hydromorphological characteristics that cannot be changed without significant adverse effects on the specified use or the wider environment. Accordingly, MEP biological conditions should reflect, as far as possible, those associated with the closest comparable water body type given the hydromorphological and resulting physico-chemical conditions at high ecological status to those established for MEP (see steps 10.2 and 10.3).

The Directive allows a number of methods to be used in establishing MEP values for the biological quality elements. The range of methods should also be used in establishing MEP values for the general physico-chemical quality elements and specific non-synthetic pollutants (see above). The methods are the same as those permitted in establishing the values for quality elements at HES.

They consist of:

(i) Spatial networks of sites meeting MEP criteria (Example in the toolbox);

(ii) Modelling approaches (Example in the toolbox);

(iii) A combination of (i) and (ii); or

(iv) Where it is not possible to use the above methods, expert judgement (Example in the toolbox).

7.2.5 Most comparable water body

A "comparable water body" can be one or more similar water body(s) that is/are, amongst other things, most similar in terms of category, type and other characteristics to the modified water body and from which spatial or temporal (i.e. hindcasting) data can be derived to support the establishment of MEP. The "comparable water body" helps to:

- choose quality elements to be regarded (derived from most comparable water body category); and

- set values for physico-chemical and biological quality elements regarded (derived from most comparable water body type).

The first priority is to look for a comparable natural water body (or a modelled or historical situation) (Example in the toolbox).

In many cases, the HES hydromorphological and sometimes also the physico-chemical conditions in the closest comparable water body type will be significantly different from the MEP hydromorphological and physico-chemical conditions. In establishing the MEP biological values, it will therefore be necessary to adjust the HES biological values of the closest comparable water body type to take account of the heavily modified or artificial characteristics.

In special cases, comparable natural water bodies will not be available. In these cases, which have to be justified, information from closely comparable HMWB and AWB at MEP (i.e. best possible rather than best available) should be used where it is available (Example in the toolbox). Information from best available sites could be used as long as best possible conditions can be extrapolated through modelling or expert judgement.

The following example shows how MEP can be established by reference to another HMWB.

If a series of large reservoirs were created in a mountainous region where large natural lakes did not exist, it may not be possible to identify a comparable natural water body within the ecoregion. Under these circumstances, it may be possible to identify a reservoir which is already close to MEP. A reservoir would be close to MEP if "all mitigation measures" to improve the hydromorphological characteristics of the reservoir had been undertaken. If "all mitigation measures" had not been undertaken, then the effect of undertaking "all mitigation measures" could be modelled and then used as the definition of MEP.

7.3 ESTABLISHING THE GOOD ECOLOGICAL POTENTIAL – GEP (Step 11)

Annex V No. 1.2.5

[The good ecological potential (GEP) is defined as the state where] "There are slight changes in the values of the relevant biological quality elements as compared to the values found at maximum ecological potential".

The good ecological potential (GEP) is the environmental quality objective for HMWB and AWB. Risk of failure of the ecological objective for AWB and HMWB is assessed against GEP (see Annex II No. 1.4).

The hydromorphological conditions at GEP must be such as to support the achievement of the GEP biological values. The values for the general physico-chemical quality elements at GEP also need to support the achievement of the GEP biological values. However, it is also required that the values for the general physico-chemical quality elements at GEP are such as to ensure the functioning of the ecosystem. The role of physico-chemical elements in the classification of water bodies is defined within the WFD CIS Guidance Documents No.'s 10, provided by the WG 2.3 (REFCOND) and No. 5, WG 2.4 (COAST). GEP also requires compliance with environmental quality standards established for the specific synthetic and non-synthetic pollutant quality elements in accordance with the procedure set out in Annex V No. 1.2.6 of the Directive.

The following substeps (s 11.1 – s 11.4) are necessary to establish GEP:

Step 11 - substep 1 (s 11.1): The establishment of the good ecological potential for HMWB and AWB is principally based on the **biological quality** elements (derived from MEP). GEP accommodates "slight changes" in the values of the biological elements from the MEP (Examples in the toolbox). The meaning and interpretation of the term "slight changes" is dealt with in the WFD CIS Guidance Document No. 10 - REFCOND and WFD CIS Guidance Document No. 6 - Intercalibration.

Step 11 - substep 2 (s 11.2): The **hydromorphological conditions** at GEP must be such as to support the achievement of the GEP biological values (Example in the toolbox).This will require the identification of the hydromorphological conditions necessary to support the achievement of the GEP values for the biological quality elements, and in particular the achievement of the values for those biological quality elements that are sensitive to hydromorphological alterations.

Step 11 - substep 3 (s 11.3): The values for the **general physico-chemical** quality elements at GEP are such as to support the achievement of the GEP biological values (Example in the toolbox). It is also required that the values for the general physico-chemical quality elements at GEP are such as to ensure the functioning of the ecosystem [Annex V No. 1.2.5]. The role of physico-chemical elements in the classification of water bodies is defined within the WFD CIS Guidance Document No.'s 10 and 5 provided by the WG 2.3 (REFCOND) and WG 2.4 (COAST).

Step 11 - substep 4 (s 11.4): GEP also requires compliance with environmental quality standards established for the **specific synthetic and non-synthetic pollutant** quality elements in accordance with the procedure set out in Annex V No. 1.2.6 (Example in the toolbox).

7.4 REPORTING AND MAPPING FOR HMWB AND AWB

The classification of HMWB and AWB requires the development of monitoring systems capable of estimating the values of the biological quality elements in AWB and HMWB and comparing those estimates with the values established for those elements at MEP. The ratio of the measured values of the biological parameters and the values for these parameters at MEP [the "ecological quality ratio"; cf. Annex V No. 1.4] will be used in classifying the status. Member States must establish values of the environmental quality ratio that correspond to the boundaries between the status classes. Some of the work of the EU Common Implementation Strategy working groups 2.3 (REFCOND) and 2.4 (COAST) may possibly help in establishing boundaries between ecological potential classes.

The classification of the ecological potential of HMWB and AWB is principally based on the degree of anthropogenic alteration away from the MEP values for the biological quality elements (see Section 7.2.4). For reporting purposes and mapping, MEP and GEP are combined in a single class [Annex V No. 1.4.2 (ii)], see following Figure 10.

Good and above Ecological Potential

1. Slight changes to the MEP values for the biological elements.

2. General physico-chemical quality elements within ranges established to ensure the functioning of the ecosystem.

3. Specific synthetic and non-synthetic pollutants do not exceed environmental quality standards set in accordance with the Annex V 1.2.6 procedure.

Moderate Ecological Potential

Moderate changes to MEP values for the biological quality elements.

Poor Ecological Potential

Major changes to the MEP values for the biological quality elements.

Bad Ecological Potential

Severe changes to the MEP values for the biological quality elements (i.e. large portions of the MEP biological community are absent).

Figure 10: **Reporting System**

7.4.1 Programme of measures

HMWB and AWB are required to achieve "good ecological potential" (GEP) and good surface water chemical status. Member States must prevent deterioration from one status class to another, and aim to achieve GEP by 22nd December 2015 unless grounds for derogation are demonstrated.

Where the results of the monitoring programmes achieved on the Annex II risk assessments indicate that a HMWB or AWB is likely to fail to achieve GEP, Member States must establish an appropriate set of measures to improve the ecological potential of a water body with the aim of achieving GEP by 2015 (Examples in the toolbox).

This requires a good understanding of how measures will improve the ecological potential of the water body. For example, the identification of the relevant GEP hydromorphological conditions will require an understanding of the relationships between hydromorphological and biological elements; this knowledge is still relatively limited. It would also be advantageous to understand biological response lag times within any particular water body.

For the design of effective and efficient programmes of measures (POMs), better information is likely to be collected over time. In the meantime, Member States will have to base the design of POMs on the best available knowledge and judgements.

If it is technically infeasible or disproportionately expensive to achieve GEP by 2015, Member States may extend the deadline for achieving GEP in accordance with Article 4(4) or establish a less stringent objective for the water body under Article 4(5). In this context the WFD CIS Guidance Document No. 10 produced by the CIS-Working Group WATECO for the assessment of disproportionate costs should be considered.

8 CROSS-CUTTING ISSUES AND OUTLOOK

8.1 OVERVIEW OF MEASURES AND THEIR COSTS IN THE HMWB AND AWB PROCESS

There are some issues within the designation process that are not particularly unique to one single step of the identification and designation process. These are summarised below.

Different kinds of **measures** are to be considered at different stages (steps) of the process. These include restoration measures in the designation test 4(3)(a) and mitigation measures for establishing MEP and GEP. For reaching the environmental quality objectives, a programme of measures needs to be set up for each RBD. This includes not only (mitigation) measures for AWB or HMWB, but also measures for natural water bodies.

When (restoration or mitigation) measures are being identified and their impacts assessed, the scale becomes important. It has to be taken into account that measures upstream might influence the conditions downstream and vice-versa. The identification of suitable measures can be difficult, because information on the cause-effect relationship of measures is often insufficient. Related to the identification (and at some points realisation) of different measures, considerations of **costs** and benefits as well as technical feasibility are relevant at several stages of the process to different extents, as shown in Table 4.

The following Table 4 gives an overview of the types of measures (second column) that are to be considered in the different steps (first column) of the designation and objective setting processes for HMWB and AWB. In the third column the related cost (and benefit) considerations are listed, and it is indicated where the consideration of technical feasibility is relevant.

Table 4: Overview of measures and cost considerations in the overall HMWB and AWB identification and designation process

Step	Measures to be considered	Costs (and benefits) related to measures /other means
1-6: Up to provisional identification	None.	Not considered.
7: Designation test 4(3)(a)	**Restoration measures** necessary to achieve GES.	• When assessing the adverse effects on the specified uses and on the wider environment, **costs** need to be considered. • The **benefits** of achieving GES must be considered, other benefits may be considered. • Costs of restoration measures (including disproportionality of costs) are **NOT** considered.
8: Designation test 4(3)(b)	Not "measures" but "**other means**" are considered.	• Comparison of current benefits with benefits of **other means**. • Disproportionality of costs of other means should be considered. • Technical feasibility of other means should be considered.
9: Designation	None.	Not considered.
10: Establishing MEP	All **mitigation measures**[24] that: • do not significantly adversely affect the specified uses or the wider environment; and • ensure the best approximation to ecological continuum.	• When assessing the adverse effects on the specified uses and on the wider environment, **costs** need to be considered. • The benefits to the water body of applying the mitigation measures should be considered. • Costs of mitigation measures (including disproportionality of costs) are **NOT** considered. • Technical feasibility of mitigation measures **NOT** to be considered.
11: Establishing GEP	**Mitigation measures** that: • do not significantly adversely affect the specified uses or the wider environment; and • improve water body to slight deviation of MEP.	• When assessing the adverse effects on the specified uses and on the wider environment, **costs** need to be considered. • The benefits to the water body of applying the mitigation measures should be considered. • Costs of mitigation measures (including disproportionality of costs) are **NOT** considered. • Technical feasibility of mitigation measures **NOT** to be considered.
For all water bodies (natural, artificial and heavily modified):		
POM for reaching the environmental quality objectives (EQO)	All **measures** according to Article 11 WFD (including other means and mitigation measures considered in the designation process)..	• Costs of measures (including disproportionality of costs) should be considered. • Select the most cost-effective combination of measures to achieve the EQO. • Technical feasibility of the measures should be considered.

24 According to Annex V 1.2.5 WFD, all hydromorphological mitigation measures should be theoretically considered in order to define the MEP. However, it would not be useful to consider impractical measures. For further explanation please see Section 7.2.2.

Within the first steps up to provisional HMWB identification (steps 1-6), no measures or cost and feasibility estimations are considered.

In the first designation test (step 7) all "restoration measures" necessary to achieve the GES are to be considered, regardless of their costs or technical feasibility. In this test it has to be assessed whether these restoration measures have a significant adverse effect on the specified uses or the wider environment. In assessing this, cost considerations are relevant (e.g. loss of revenue). In the second designation test (step 8), no measures are considered but "other means" (including displacement or replacement of current specified use),[25] that serve the same beneficial objective, are considered. These other means have to be assessed with regard to their technical feasibility and their disproportionality of costs.

In defining MEP (step 10) and GEP (step 11) conditions, all mitigation measures that do not have significant adverse effects neither on the specified uses nor on the wider environment are to be considered. The capital costs that would be incurred if the mitigation measures were implemented and disproportionality of costs are not relevant considerations in this context. The mitigation measures only define the reference conditions for the classification of HMWB and AWB. Setting this standard does not require the measures to be implemented. Again only cost in the context of impact on specified uses is relevant. When setting up the RBMP, the feasibility and costs play a major role and might lead to derogations.

8.2 TIMING IN THE FIRST RIVER BASIN PLANNING CYCLE

The first draft RBMP should be available for public consultation by December 2008 [Article14(1)(c)], while the final version is due one year later, in December 2009 [Article13(6)]. The RBMP shall be reviewed and updated at the latest in December 2015 and every 6 years thereafter [Article13(7)].

This Guidance Document provides advice on how the HMWB and AWB identification and designation process should be undertaken during the first RBMP cycle. An overview of the step-wise identification and designation process for the first planning cycle is given in Section 4. In this Section we describe the timetable for when particular process activities have to be completed within this first cycle. It will be important that the timing of these activities is considered within other relevant WFD Common Implementation Strategy working group Guidance Documents. Figure 11 identifies the major deadlines in the timetable of the HMWB and AWB identification and designation process in the first planning cycle.

As identified in Section 5.7 the provisional identification of HMWB and AWB will be complete by Dec 2004. For physically modified water bodies an assessment of the likelihood of failing to meet the "GES" objective (step 5) must be complete by Dec 2004 to determine whether a water body is to be provisionally identified as HMWB (step 6).

---

25 For example: replacing a particular hydropower station with a new hydropower station in a different water body, or replacing hydropower with wind power.

For AWB an assessment of the likelihood of failing to meet a "GEP" objective must be complete by Dec 2004. Determination of "GES" and "GEP" prior to the Dec 2004 deadline will only be first estimations of these objectives based on available knowledge, data and tools. It is expected that further refinement of these objectives will be made later in the planning process as new tools and data become available, particularly as a result of further monitoring.

For provisionally identified HMWB, designation (or not; step 7-9), determination of GEP (step 10-11) and an assessment of the risk of failing to meet the "GEP" objective must be complete by Dec 2008. For identified AWB it is expected that between 2004-8 the water body will be designated as AWB, the estimate of GEP will be refined and the risk of failing to meet the refined GEP will be reassessed. If a designated HMWB or AWB does not meet the GEP objective, then a programme of measures or a case for derogation has to be developed by Dec 2008. This allows one year for consultation of the draft RBMP before publication of the final RBMP in 2009.

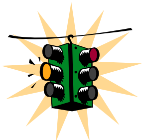
For some provisionally identified HMWB, Member States may wish to move the designation steps (steps 7-9), the first estimation of GEP and the assessment of the likelihood of failing the GEP objective forward. This may be particularly appropriate for modified water bodies that have changed category (e.g. river to reservoir). Here the assessment of the likelihood of failing the GES objective will be straightforward (comparing a reservoir with a river) as there will be little uncertainty over the identification of the water body as a provisional HMWB. Consequently, steps 5 & 6 should not involve complex assessments and steps 7-11 can start sooner.

As a general rule steps 7-11 and the assessment of the risk of failing the GEP objective should occur as soon as possible before Dec 2008.

By when?	What major task?	What needs to be done for HMWB and AWB?
2004	Characterisation of river basin district [Art. 5]	steps 1-6: Including: identification of water bodies (step 1); identification of AWB (step 2); description of hydromorphological changes (step 3); description of significant changes in hydromorphology (step 4); estimation of GES (non-AWB); likelihood of failing GES objective (Step 5; non-AWB); estimation of GEP (AWB); likelihood of failing GEP (AWB); and provisional HMWB identification (step 6).
2008/9	River basin management plan & public consultation [Art. 13 & 14]	steps 7-11: Including designation tests (steps 7 and 8), designation (step 9), identification of reference conditions (step 10) and environmental quality objective (step 11) for HMWB and AWB.

Figure 11: Major deadlines in the timetable for the identification and designation of HMWB and AWB in the first planning cycle

8.3 HMWB & AWB IN FUTURE RBMP CYCLES



Look out! The view of future RBMP cycles has some implications for the first process of designation

It is important to appreciate that the identification and designation of HMWB and AWB is not a "one off" process and the Directive provides for the flexibility to modify designations to take account of changes over time in environmental, social and economic circumstances.

The designation process in the second RBMP cycle will be different in several important aspects. Clearly it is not appropriate to give a detailed assessment of the designation process for future cycles here as it is likely to change as a result of experiences during the first planning cycle. We can, however, give an indication of the key differences that will be encountered.

8.3.1 Characterisation in the second cycle

The second characterisation of River Basin District (RBD) in the second RBMP cycle (first review) has to be finished by 2013 [Article5(2)]. The main difference with the first characterisation will be that water bodies (natural, HMWB & AWB) will already have been identified and a fully compliant monitoring programme should be in place.

Characterisation is likely to start with a review of monitoring data which will define the current (ca 2013) status of waters. On the basis of this information, water body definitions could be at least partly changed. This will ensure that water bodies can be used to correctly describe the status of surface waters. For example, if monitoring has demonstrated that the status of half a water body has changed, then the water body could be split in two, whereas if the status of two adjacent water bodies were now the same then they could be combined into a single water body.

The risk assessment process in the second RBMP cycle will be based on a better understanding of GES and GEP. Consequently, the risk assessment process will identify the risks of failure of good status for natural water bodies and GEP for HMWB and AWB.

8.3.2 Designation tests in the second cycle

In the second RBMP cycle the Article 4(3) designation tests will be applied in three circumstances: (i) (ii) and (iii) below:

(i) Suspected HMWB and AWB which were, possibly, mistakenly not designated in the first RBMP. For instance water bodies which were historically modified but which were mistakenly not identified and designated during the previous planning cycle (they have not deteriorated);

(ii) Newly modified water bodies. For instance water bodies that have become substantially changed in character as a result of the application of the Article 4(7) derogation.

Water bodies from situations (i) and (ii) will in general proceed in the same manner as in the first RBMP cycle, but without provisional identification of HMWB.

(iii) As part of the review of existing HMWB and AWB. The designations of HMWB and AWB must be reviewed every six years. It is assumed that these reviews will be undertaken as part of the production of the RBMP which will be complete in 2015. It is assumed that a review of HMWB and AWB will involve a reconsideration of the designation tests. This is likely to include a screening process which will assess whether the situation has changed since the original designation [Annex VII (B)]. Only where changes have occurred will the water body be considered for the designation tests in the second cycle. A review may be necessary if there has been a change in the:

- technical circumstances of the use (including operation and maintenance) or the disappearance of the use;
- use itself;
- available restoration measures, so that they may no longer have a significant adverse effect on the use or the environment;
- "other means" available to deliver the same beneficial objective of the use, so that they may no longer be disproportionately expensive or technically infeasible.

In future planning cycles existing HMWB and AWB may be "de-designated" and new HMWB and AWB being designated.

8.3.3 Review of MEP (and GEP) values in the second cycle

The values established for MEP in step 10, sub-steps 10.1-10.4, must be reviewed every six years (Annex II No. 1.3(ii)). This will mean that GEP also has to be revised every six years, as GEP is a "slight deviation" from MEP. This would involve a similar screening process as for the review of the designation tests.

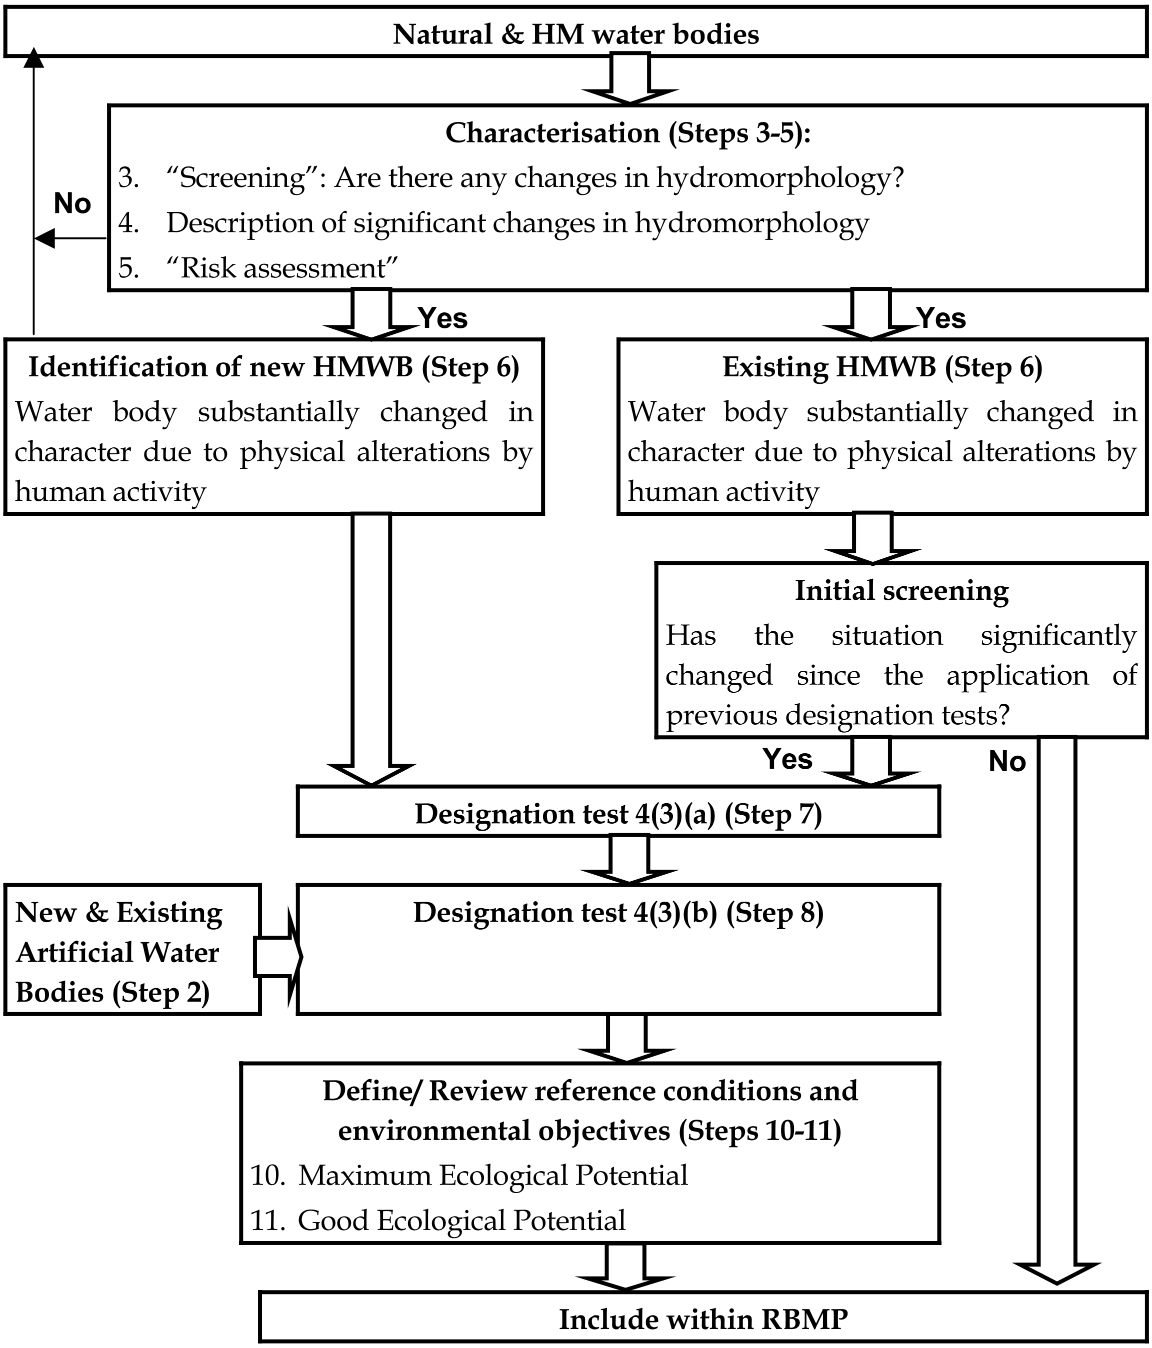


Figure 12: Consideration of HMWB during the second River Basin Management Plan

8.4 CONCLUSION AND OUTLOOK

This Guidance Document provides advice on how the HMWB and AWB identification and designation process should be undertaken during the first RBMP cycle (2008/2009). The designation process in the second and in subsequent RBMP cycles will be different in several aspects. It is important to appreciate that the identification and designation of HMWB and AWB is not a "one off" process and that the WFD provides for the flexibility to modify designations to take account of changes over time in environmental, social and economic circumstances.

This Guidance Document is based on the experiences of thirty-four case studies. It should, therefore, be applicable to most circumstances. However, further experiences in implementing the provisions relevant to HMWB and AWB in Member States will shed new light on the interpretation of the HMWB and AWB requirements of the Directive and the approach suggested in the Guidance and the accompanying toolbox. In the pilot river basins as well as in other river basins across Europe the Guidance will be applied in the coming months and years. This HMWB and AWB Guidance Document will require adaptations as a result of these new experiences and, as all other CIS Guidance Documents, the HMWB and AWB Guidance will remain a "living document".

ANNEX I - GLOSSARY

Terms used within the Guidance (excluding terms already defined in Article 2 of the Directive).

Term	Definition
Beneficial objectives	The benefits that result from the artificial or heavily modified characteristics of a water body. These can include "specified use"-related or environmental benefits.
Common Implementation Strategy	The Common Implementation Strategy for the Water Framework Directive (known as the CIS) was agreed by the European Commission, Member States and Norway in May 2001. The main aim of the CIS is to provide support in the implementation of the WFD, by developing a common understanding and guidance on key elements of this Directive. Experts from the above countries and candidate countries as well as stakeholders from the water community are all involved in the CIS to: • Raise awareness an exchange information; • Develop Guidance Documents on various technical issues; and, • Carry out integrated testing in pilot river basins. A series of working groups and joint activities has been developed to help carry out the activities listed above. A Strategic Co-ordination Group (or SCG) oversees these working groups and reports directly to the Water Directors of the European Union, Norway, Switzerland, the Candidate Countries and Commission, the engine of the CIS. For more information refer to the following website: http://europa.eu.int/comm/environment/water/water-framework/index_en.html.
Impact	The environmental effect of a pressure (e.g. fish killed, ecosystem modified).
Modification	Change (or changes) made to the surface water body by human activity (which may result in failing to meet good ecological status). Each modification will have a current or historical "specified use" (such as straightening for navigation, or construction of flood banks for flood defence).

Term	Definition
Physical alterations	Modifications of the hydromorphology of a water body by human activity.
Pressure[26]	The direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry of surface and groundwater bodies.
Restoration measures	Necessary hydromorphological changes to achieve GES (e.g. re-meandering of a straightened channel and introduction of "natural" pool-riffle sequences using references to historical channel form). Associated with "Designation test 4(3)(a)".
Specified use	Water uses as described in Article 4(3)(a)(ii)-(v).
WFD, The Directive	Directive 2000/60/EC establishing a framework for Community action in the field of water policy.
Wider environment	The natural environment and the human environment including archaeology, heritage, landscape and geomorphology.

[26] Interim working definition. Discussions in the context of the WFD implementation are ongoing

ANNEX II - HMWB AND RIVER BASIN MANAGEMENT PLANS (FIRST CYCLE)

The RBMP must be produced for each river basin district [Article 13(1)], covering the information detailed in Annex VII [Article 13(4)]. The information detailed in Annex VII relevant for HMWB and AWB in the first cycle concern at least the following points A1, A2, A4 and A7 of Annex VII:

A1 requires a general description of the characteristics of the river basin district [Article 5 and Annex II No. 1.1/2/3], i.e. the identification of boundaries of water bodies, a mapping of types and an identification of reference conditions. Guidance on the identification of HMWB and AWB as well as the identification of the maximum ecological potential (MEP) have to be given by this HMWB and AWB Guidance Document. The process should be in line with the general identification of water bodies and the identification of reference conditions (REFCOND and COAST Guidance Documents).

A2 requires a summary of significant pressures and impacts of human activity [Article 5 and Annex II No. 1.4/5], i.e. an overall description of significant pressures such as important hydromorphological changes and an assessment of those surface waters being at risk of failing the environmental objectives. Guidance on the overall description of significant pressures and the assessment of impacts will be provided by the IMPRESS Guidance, the identification of significant physical pressures and their impact on hydromorphology and biology as well as the designated HMWB and AWB being at risk of failing the environmental quality objective (GEP) should be covered by the HMWB & AWB Guidance. The process of HMWB and AWB identification and designation should be in line with the general approach of IMPRESS.

A4 requires a map of the monitoring networks and a presentation, in a mapped format, of the results of the monitoring programmes [Article 8 and Annex V]. It is assumed that the Guidance on the monitoring requirements for HMWB and AWB will be provided by the Monitoring Working Group. Some advice for the selection of the most sensitive indicators for the operational monitoring of HMWB and AWB identified as being at risk will be provided by this HMWB Guidance Document.

A7 requires a summary of the programmes of measures [Article 11], including information on how the established environmental quality objectives [Article 4] are to be achieved. The HMWB & AWB Guidance and toolbox should assist in identifying those measures which could improve the status of HMWB and AWB resulting from physical impacts. Not only measures for the designation tests [Article 4(3)] will be provided, i.e. examples for restoration measures to achieve GES, but also mitigation measures - which have no adverse effects on "specified uses" or the wider environment - to identify MEP and to achieve GEP. The measures will consider all important specified uses and focus on the improvement of the hydromorphological circumstances.

ANNEX III - ELEMENTS OF HMWB IN THE WFD (ORIGINAL TEXT)

Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy

Title	Specification	Provision
Article 2	**Definitions**	
	4.	'River' means a body of inland water flowing for the most part on the surface of the land but which may flow underground for part of its course.
	8.	'Artificial water body' means a body of surface water created by human activity.
	9.	'Heavily modified water body' means a body of surface water which as a result of physical alterations by human activity is substantially changed in character, as designated by the Member State in accordance with the provisions of Annex II.
	10.	'Body of surface water' means a discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.
	23.	'Good ecological potential' is the status of a heavily modified or an artificial body of water, so classified in accordance with the relevant provisions of Annex V.
Article 4	**Environmental objectives**	
	1.	In making operational the programmes of measures specified in the river basin management plans: (a) for surface waters (i) Member States shall implement the necessary measures to prevent deterioration of the status of all bodies of surface water, subject to the application of paragraphs 6 and 7 and without prejudice to paragraph 8;

Article 4 Environmental objectives

(ii) Member States shall protect, enhance and restore all bodies of surface water, subject to the application of subparagraph (iii) for artificial and heavily modified bodies of water, with the aim of achieving good surface water status at the latest 15 years after the date of entry into force of this Directive, in accordance with the provisions laid down in Annex V, subject to the application of extensions determined in accordance with paragraph 4 and to the application of paragraphs 5, 6 and 7 without prejudice to paragraph 8;

(iii) Member States shall protect and enhance all artificial and heavily modified bodies of water, with the aim of achieving good ecological potential and good surface water chemical status at the latest 15 years from the date of entry into force of this Directive, in accordance with the provisions laid down in Annex V, subject to the application of extensions determined in accordance with paragraph 4 and to the application of paragraphs 5, 6 and 7 without prejudice to paragraph 8;

(iv) Member States shall implement the necessary measures in accordance with Article 16(1) and (8), with the aim of progressively reducing pollution from priority substances and ceasing or phasing out emissions, discharges and losses of priority hazardous substances;

without prejudice to the relevant international agreements referred to in Article 1 for the parties concerned.

3. Member States may designate a body of surface water as artificial or heavily modified, when:

(a) the changes to the hydromorphological characteristics of that body which would be necessary for achieving good ecological status would have significant adverse effects on:

(i) the wider environment;

(ii) navigation, including port facilities, or recreation;

(iii) activities for the purposes of which water is stored, such as drinking-water supply, power generation or irrigation;

(iv) water regulation, flood protection, land drainage; or

(v) other equally important sustainable human development activities.

(b) the beneficial objectives served by the artificial or modified characteristics of the water body cannot, for reasons of technical feasibility or disproportionate costs, reasonably be achieved by other means, which are a significantly better environmental option.

Article 4 Environmental objectives

Such designation and the reasons for it shall be specifically mentioned in the river basin management plans required under Article 13 and reviewed every six years.

4. The deadlines established under paragraph 1 may be extended for the purposes of phased achievement of the objectives for bodies of water, provided that no further deterioration occurs in the status of the affected body of water when all of the following conditions are met:

(a) Member States determine that all necessary improvements in the status of bodies of water cannot reasonably be achieved within the timescales set out in that paragraph for at least one of the following reasons:

(i) the scale of improvements required can only be achieved in phases exceeding the timescale, for reasons of technical feasibility;

(ii) completing the improvements within the timescale would be disproportionately expensive;

(iii) natural conditions do not allow timely improvement in the status of the body of water.

(b) Extension of the deadline, and the reasons for it, are specifically set out and explained in the river basin management plan required under Article 13.

(c) Extensions shall be limited to a maximum of two further updates of the river basin management plan except in cases where the natural conditions are such that the objectives cannot be achieved within this period.

(d) A summary of the measures required under Article 11 which are envisaged as necessary to bring the bodies of water progressively to the required status by the extended deadline, the reasons for any significant delay in making these measures operational, and the expected timetable for their implementation are set out in the river basin management plan. A review of the implementation of these measures and a summary of any additional measures shall be included in updates of the river basin management plan.

5. Member States may aim to achieve less stringent environmental objectives than those required under paragraph 1 for specific bodies of water when they are so affected by human activity, as determined in accordance with Article 5(1), or their natural condition is such that the achievement of these objectives would be infeasible or disproportionately expensive, and all the following conditions are met:

(a) the environmental and socioeconomic needs served by such human activity cannot be achieved by other means, which are a significantly better environmental option not entailing disproportionate costs;

Article 4 Environmental objectives

(b) Member States ensure:

- for surface water, the highest ecological and chemical status possible is achieved, given impacts that could not reasonably have been avoided due to the nature of the human activity or pollution.

8. When applying paragraphs 3, 4, 5, 6 and 7, a Member State shall ensure that the application does not permanently exclude or compromise the achievement of the objectives of this Directive in other bodies of water within the same river basin district and is consistent with the implementation of other Community environmental legislation.

Article 5 Characteristics of the river basin district, review of the environmental impact of human activity and economic analysis of water use

1. Each Member State shall ensure that for each river basin district or for the portion of an international river basin district falling within its territory:

- an analysis of its characteristics;
- a review of the impact of human activity on the status of surface waters and on groundwater; and
- an economic analysis of water use.

is undertaken according to the technical specifications set out in Annexes II and III and that it is completed at the latest four years after the date of entry into force of this Directive.

2. The analyses and reviews mentioned under paragraph 1 shall be reviewed, and if necessary updated at the latest 13 years after the date of entry into force of this Directive and every six years thereafter.

Article 8 Monitoring of surface water status, groundwater status and protected areas

1. Member States shall ensure the establishment of programmes for the monitoring of water status in order to establish a coherent and comprehensive overview of water status within each river basin district:

- for surface waters such programmes shall cover:

(i) the volume and level or rate of flow to the extent relevant for ecological and chemical status and ecological potential, and

(ii) the ecological and chemical status and ecological potential.

2. These programmes shall be operational at the latest six years after the date of entry into force of this Directive unless otherwise specified in the legislation concerned. Such monitoring shall be in accordance with the requirements of Annex V.

Article 11 Programme of measures

3. 'Basic measures' are the minimum requirements to be complied with and shall consist of:

(i) for any other significant adverse impacts on the status of water identified under Article 5 and Annex II, in particular measures to ensure that the hydromorphological conditions of the bodies of water are consistent with the achievement of the required ecological status or good ecological potential for bodies of water designated as artificial or heavily modified. Controls for this purpose may take the form of a requirement for prior authorisation or registration based on general binding rules where such a requirement is not otherwise provided for under Community legislation. Such controls shall be periodically reviewed and, where necessary, updated.

7. The programmes of measures shall be established at the latest nine years after the date of entry into force of this Directive and all the measures shall be made operational at the latest 12 years after that date.

Article 13 River basin management plans

4. The river basin management plan shall include the information detailed in Annex VII.

6. River basin management plans shall be published at the latest nine years after the date of entry into force of this Directive.

7. River basin management plans shall be reviewed and updated at the latest 15 years after the date of entry into force of this Directive and every six years thereafter.

Article 14 Public information and consultation

1. Member States shall encourage the active involvement of all interested parties in the implementation of this Directive, in particular in the production, review and updating of the river basin management plans. Member States shall ensure that, for each river basin district, they publish and make available for comments to the public, including users:

   (c) draft copies of the river basin management plan, at least one year before the beginning of the period to which the plan refers.

Annex II

1. Surface Waters

1.1. Characterisation of surface water body types

Member States shall identify the location and boundaries of bodies of surface water and shall carry out an initial characterisation of all such bodies in accordance with the following methodology. Member States may group surface water bodies together for the purposes of this initial characterisation.

(i) The surface water bodies within the river basin district shall be identified as falling within either one of the following surface water categories - rivers, lakes, transitional waters or coastal waters - or as artificial surface water bodies or heavily modified surface water bodies.

(v) For artificial and heavily modified surface water bodies the differentiation shall be undertaken in accordance with the descriptors for whichever of the surface water categories most closely resembles the heavily modified or artificial water body concerned.

1.3. Establishment of type-specific reference conditions for surface water body types

(ii) In applying the procedures set out in this Section to heavily modified or artificial surface water bodies references to high ecological status shall be construed as references to maximum ecological potential as defined in table 1.2.5 of Annex V. The values for maximum ecological potential for a water body shall be reviewed every six years.

1.4. Identification of Pressures

Member States shall collect and maintain information on the type and magnitude of the significant anthropogenic pressures to which the surface water bodies in each river basin district are liable to be subject, in particular the following.

Estimation and identification of significant point source pollution, in particular by substances listed in Annex VIII, from urban, industrial, agricultural and other installations and activities, based, *inter alia*, on information gathered under:

(i) Articles 15 and 17 of Directive 91/271/EEC;

(ii) Articles 9 and 15 of Directive 96/61/EC;

and for the purposes of the initial river basin management plan:

(iii) Article 11 of Directive 76/464/EEC; and

(iv) Directives 75/440/EC, 76/160/EEC, 78/659/EEC and 79/923/EEC.

Estimation and identification of significant diffuse source pollution, in particular by substances listed in Annex VIII, from urban, industrial, agricultural and other installations and activities; based, inter alia, on information gathered under:

(i) Articles 3, 5 and 6 of Directive 91/676/EEC;

(ii) Articles 7 and 17 of Directive 91/414/EEC;

(iii) Directive 98/8/EC;

and for the purposes of the first river basin management plan:

(iv) Directives 75/440/EEC, 76/160/EEC, 76/464/EEC, 78/659/EEC and 79/923/EEC.

Estimation and identification of significant water abstraction for urban, industrial, agricultural and other uses, including seasonal variations and total annual demand, and of loss of water in distribution systems.

Estimation and identification of the impact of significant water flow regulation, including water transfer and diversion, on overall flow characteristics and water balances.

Identification of significant morphological alterations to water bodies.

Estimation and identification of other significant anthropogenic impacts on the status of surface waters.

Estimation of land use patterns, including identification of the main urban, industrial and agricultural areas and, where relevant, fisheries and forests.

1.5. Assessment of Impact

Member States shall carry out an assessment of the susceptibility of the surface water status of bodies to the pressures identified above.

Member States shall use the information collected above, and any other relevant information including existing environmental monitoring data, to carry out an assessment of the likelihood that surface waters bodies within the river basin district will fail to meet the environmental quality objectives set for the bodies under Article 4. Member States may utilise modelling techniques to assist in such an assessment.

For those bodies identified as being at risk of failing the environmental quality objectives, further characterisation shall, where relevant, be carried out to optimise the design of both the monitoring programmes required under Article 8, and the programmes of measures required under Article 11.

Annex V

1.1. Quality elements for the classification of ecological status

1.1.5. The quality elements applicable to artificial and heavily modified surface water bodies shall be those applicable to whichever of the four natural surface water categories above most closely resembles the heavily modified or artificial water body concerned.

1.2. Normative definitions of ecological status classifications

1.2.5. Definitions for maximum, good and moderate ecological potential for heavily modified or artificial water bodies

Element	Maximum ecological potential	Good ecological potential	Moderate ecological potential
Biological quality elements	The values of the relevant biological quality elements reflect, as far as possible, those associated with the closest comparable surface water body type, given the physical conditions which result from the artificial or heavily modified characteristics of the water body.	There are slight changes in the values of the relevant biological quality elements as compared to the values found at maximum ecological potential.	There are moderate changes in the values of the relevant biological quality elements as compared to the values found at maximum ecological potential. These values are significantly more distorted than those found under good quality.

Element	**Maximum ecological potential**	**Good ecological potential**	**Moderate ecological potential**
Hydromorpho-logical elements	The hydromorphological conditions are consistent with the only impacts on the surface water body being those resulting from the artificial or heavily modified characteristics of the water body once all mitigation measures have been taken to ensure the best approximation to ecological continuum, in particular with respect to migration of fauna and appropriate spawning and breeding grounds.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Physico-chemical elements			
General conditions	Physico-chemical elements correspond totally or nearly totally to the undisturbed conditions associated with the surface water body type most closely comparable to the artificial or heavily modified body concerned. Nutrient concentrations remain within the range normally associated with such undisturbed conditions. The levels of temperature, oxygen balance and pH are consistent with those found in the most closely comparable surface water body types under undisturbed conditions.	The values for physico-chemical elements are within the ranges established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements. Temperature and pH do not reach levels outside the ranges established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements. Nutrient concentrations do not exceed the levels established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.

Element	Maximum ecological potential	Good ecological potential	Moderate ecological potential
Specific synthetic pollutants	Concentrations close to zero and at least below the limits of detection of the most advanced analytical techniques in general use.	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 without prejudice to Directive 91/414/EC and Directive 98/8/EC. (< EQS)	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Specific non-synthetic pollutants	Concentrations remain within the range normally associated with the undisturbed conditions found in the surface water body type most closely comparable to the artificial or heavily modified body concerned (background levels = bgl).	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 (1) without prejudice to Directive 91/414/EC and Directive 98/8/EC. (< EQS)	Conditions consistent with the achievement of the values specified above for the biological quality elements.

1.4. Classification and presentation of ecological status

1.4.1. Comparability of biological monitoring results

(i) Member States shall establish monitoring systems for the purpose of estimating the values of the biological quality elements specified for each surface water category or for heavily modified and artificial bodies of surface water. In applying the procedure set out below to heavily modified or artificial water bodies, references to ecological status should be construed as references to ecological potential. Such systems may utilise particular species or groups of species which are representative of the quality element as a whole.

1.4.2. Presentation of monitoring results and classification of ecological status and ecological potential

(i) For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below. Member States shall provide a map for each river basin district illustrating the classification of the ecological status for each body of water, colour-coded in accordance with the second column of the table set out below to reflect the ecological status classification of the body of water:

Ecological status classification	Colour Code
High	Blue
Good	Green
Moderate	Yellow
Poor	Orange
Bad	Red

(ii) For heavily modified and artificial water bodies, the ecological potential classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below. Member States shall provide a map for each river basin district illustrating the classification of the ecological potential for each body of water, colour-coded, in respect of artificial water bodies in accordance with the second column of the table set out below, and in respect of heavily modified water bodies in accordance with the third column of that table:

Ecological potential classification	Colour code	
	Artificial Water Bodies	Heavily Modified
Good and above	Equal green and light grey stripes	Equal green and dark grey stripes
Moderate	Equal yellow and light grey stripes	Equal yellow and dark grey stripes
Poor	Equal orange and light grey stripes	Equal orange and dark grey stripes
Bad	Equal red and light grey stripes	Equal red and dark grey stripes

(iii) Member States shall also indicate, by a black dot on the map, those bodies of water where failure to achieve good status or good ecological potential is due to non-compliance with one or more environmental quality standards which have been established for that body of water in respect of specific synthetic and non-synthetic pollutants (in accordance with the compliance regime established by the Member State).

Annex VII River basin management plans

A. River basin management plans shall cover the following elements:

1. a general description of the characteristics of the river basin district required under Article 5 and Annex II. This shall include:

1.1. for surface waters:

- mapping of the location and boundaries of water bodies;
- mapping of the ecoregions and surface water body types within the river basin;
- identification of reference conditions for the surface water body types.

2. a summary of significant pressures and impact of human activity on the status of surface water and groundwater, including:

- estimation of point source pollution;
- estimation of diffuse source pollution, including a summary of land use;
- estimation of pressures on the quantitative status of water including abstractions;
- analysis of other impacts of human activity on the status of water.

4. a map of the monitoring networks established for the purposes of Article 8 and Annex V, and a presentation in map form of the results of the monitoring programmes carried out under those provisions for the status of:

4.1 surface water (ecological and chemical);

4.2 groundwater (chemical and quantitative);

4.3 protected areas;

7. a summary of the programme or programmes of measures adopted under Article 11, including the ways in which the objectives established under Article 4 are thereby to be achieved.

Executive Summary

In May 2001 the Common Implementation Strategy was established. The objective of the Strategy has been to provide support to the implementation of the Water Framework Directive by developing coherent common understanding and guidance on key elements of the Directive.

The COAST working group was one of the working groups established within the Strategy. The remit of the group has been to develop a non-legally binding document providing Guidance on the implementation of Annexes II and V in relation to transitional and coastal waters.

This Guidance Document has been written over a relatively short period of time. A series of working group meetings were held and attended by technical experts and regulators from European Union Member States, Norway and some Accession States as well as experts representing Non-Governmental Organisations and Stakeholder organisations associated with water and environmental policy.

The Guidance is not prescriptive and will need to be adapted to fit local circumstances. It is also recognised that further work is required on the development of classification schemes as classification tools are tested and class boundaries are set.

The importance of continued communication between experts from different Member States is emphasised throughout the Guidance especially with respect to typology, reference conditions and classification.

Acknowledgements

The project has been funded and supported by the following organisations:

- Scotland and Northern Ireland Forum for Environmental Research (SNIFFER);
- Environment and Heritage Service (EHS), Northern Ireland;
- Scottish Environment Protection Agency (SEPA);
- Environment Agency of England and Wales;
- Bundesamt fuer Seeschifffahrt und Hydrographie (BSH), Germany;
- Umweltbundesamt (UBA), Germany;
- European Environment Agency;
- Ministry of Ecology and Sustainable Development, France;
- Seine-Normandie Water Agency, France;
- Swedish Environment Protection Agency;
- National Environmental Protection Agency (ANPA);

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology are therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

A working group referred to as COAST was established to produce a practical Guidance Document for the implementation of the Directive for transitional and coastal waters. The working group was established in summer 2001 and was led by the UK with France, Germany, Sweden and the EEA forming the steering group. The working group included representatives from each Member State as well as some candidate countries and non-governmental organisations (NGOs) and stakeholder organisations.

This Guidance is the outcome of COAST. It synthesises COAST activities and discussions since summer 2001. It builds on the input and feedback from a wide range of experts and stakeholders in EU Member States and candidate countries who were involved in the development of the Guidance through meetings, workshops, conferences and electronic communication, without binding them in any way to its content.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders, Claire Vincent and the steering group, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a *living document* that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

Table of Contents

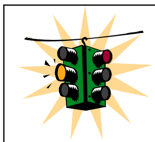
Introduction - A Guidance Document: What For?

This document aims to guide experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the key requirements for implementation of the Directive in relation to coastal and transitional waters.

TO WHOM IS THIS GUIDANCE DOCUMENT ADDRESSED?

If this is your task, we believe the Guidance will help you in *doing the job,* if you or your team are:

- **Developing typology, producing descriptions of reference conditions or developing classification schemes for coastal and transitional waters;**
- **Reporting the status of coastal and transitional waters to the European Union as required by the Directive;**
- **Using the results of the classification of coastal and transitional waters to develop policy**;
- **Implementing related parts of the Directive such as the Intercalibration or Pilot River Basin Studies exercises.**



Look out! The methodology from this Guidance Document can be adapted to regional and national circumstances.

The Guidance Document proposes a European approach. Because of the diversity of coastal and transitional waters across Europe the document has been kept as general as possible whilst still trying to provide a practical level of guidance.

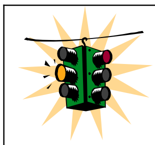
WHAT CAN YOU FIND IN THIS GUIDANCE DOCUMENT?

The Common Understanding of Terms

Typology

Reference Conditions

Classification



Look out! What you will <u>not</u> find in this Guidance Document:

- Guidance for coastal and transitional waters that are designated as Heavily Modified water bodies;
- A definitive typology for coastal and transitional waters;
- A set of reference conditions;
- A definitive classification tool or scheme;
- Guidance relating to lakes, rivers (WG 2.3) groundwaters and heavily modified water bodies (WG 2.2).

Historically there has been only limited classification in the transitional and coastal waters of Europe. Existing classification tools have relied heavily on expert judgement. Therefore this Guidance Document makes suggestions of schemes, tools and best practice which will have to be tested and developed over the next few years.

Section 1 – Introduction – Implementing the Directive.

This Section introduces you to the overall context for the implementation of the Water Framework Directive (WFD) and informs you of the initiatives that led to the production of this Guidance Document.

1.1. DECEMBER 2000: A MILESTONE FOR WATER POLICY

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the WFD (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the WFD.

1.2. THE WATER FRAMEWORK DIRECTIVE: NEW CHALLENGES IN EU WATER POLICY

What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancement, protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution;
- Contributes to mitigating the effects of floods and droughts.

…and what is the key objective?

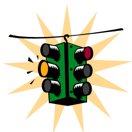
Overall, the Directive aims at achieving *good water status* for all waters by 2015.

1.3. WHAT ARE THE KEY ACTIONS THAT MEMBER STATES NEED TO TAKE?

- To identify the individual river basins lying within their national territory and assign them to River Basin Districts (RBDs) and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);
- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (*Article 2 (22), Annex V*);
- To make operational the monitoring networks by 2006 (*Article 8*);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving cost-effectively the environmental objectives of the WFD (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).

Table 1.1. Timetable of Implementation of the Water Framework Directive.

Year	Requirements
2000	Directive Adopted
2003	Transpose into National law Identify River Basin Districts and Competent Authorities Identify draft register of intercalibration sites
2004	Characterisation of water bodies, including Heavily Modified water bodies Review pressures and impacts and identify sites at risk of not meeting the environmental objective of 'good status' Establish register of Protected Areas Undertake economic analysis of water use Final register of intercalibration sites
2006	Comprehensive monitoring programmes operational
2007	Repeal some Directives
2008	Publish Draft River Basin Management Plans which will include a first draft of the classification of water bodies
2009	River Basin Management Plans produced to include final classification of the ecological status of water bodies Programme of measures for each RBD
2010	Water pricing policies contribute to environmental objectives
2013	Repeal some Directives
2015	"Good" Status to be achieved



Look Out!

Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such circumstances that will be specifically explained in the RBMPs, the WFD offers the opportunity to Member States to engage in two further six- year cycles of planning and implementation of measures.

1.4. CHANGING THE MANAGEMENT PROCESS – INFORMATION, CONSULTATION AND PARTICIPATION

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

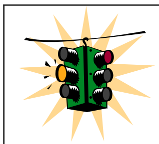
- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

1.5. INTEGRATION: A KEY CONCEPT UNDERLYING THE WATER FRAMEWORK DIRECTIVE

The concept central to the WFD is *integration* which is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Freshwater Fish Directive) have been reformulated in the WFD to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;

- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** whether local, regional or national, for effective management of all waters;
- **Integration of water management from different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.



Look out! A number of international marine conventions deal with the protection of large maritime areas such as the North East Atlantic (OSPAR), the Baltic (HELCOM) and the Mediterranean (BARCOM). These Conventions deal with many marine environmental protection issues including the issue of transboundary pollution. Throughout the drafting of this Guidance the COAST working group has tried to ensure good linkages with these Conventions and to build on the sound science that has already been developed. It is the intention to continue to improve the linkages between the Marine Conventions and the EU under the imminent EU Marine Strategy.

1.6. WHAT IS BEING DONE TO SUPPORT IMPLEMENTATION?

Activities to support the implementation of the WFD are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilots for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the WFD.

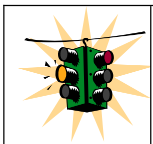
May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the WFD by developing a coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities has been launched to develop and test non-legally binding Guidance (see *Annex A of this Guidance Document*). A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision body for the Common Implementation Strategy.

1.7. THE COAST WORKING GROUP (CIS WG 2.4)

The COAST working group was created specifically to deal with the issues relating to transitional and coastal waters and to produce a non-legally binding document of practical advice for implementing the WFD, specifically Annexes II and V, in relation to these waters. The members of the working group included technical experts and regulators from European Union Member States, Norway and some Accession States as well as experts representing NGOs and Stakeholders organisations associated with water and environmental policy.



Look out! You can contact the experts involved in the COAST activities

A complete list of COAST members with full contact details is in *Annex B* of this Guidance Document. If you need input into your own activities, please contact a member from COAST in your country. If you want more information on specific pilot studies (Annex C), or classification tools and schemes and tools presented in the toolbox (Section 6) you may directly contact those people from the relevant Member State.

To ensure adequate input and feedback from a wide audience during the drafting of this document, the COAST group organised a series of working group meetings and workshops as well as widely circulating draft documents for comments.

Development of this Guidance Document was an interactive process. Between September 2001 and September 2002 a large number of experts and stakeholders have been involved in the development of this Guidance. The process has included the following activities:

- **Regular meetings** of the 40 or more experts and stakeholder members of COAST;
- A series of **meetings of the Steering Group** (representatives from UK (lead), France, Germany, Sweden and EEA). These meetings guided the project and agreed on the final structure and format;
- Organisation of **three eco-region workshops** (Baltic, Mediterranean and North-East Atlantic) on typology;
- The **collation of draft coastal and transitional types** from Member States. The purpose of this exercise was four-fold:
    - to determine the approximate number of coastal and transitional types;
    - to prevent Member States assigning different names to the same types and *vice versa*;

    - to identify where Member States have the same type and may therefore be able to share reference conditions;
    - to assist in the identification of suitable types for intercalibration.
- A series of **reference condition pilot studies** were carried out by several Member States and the lessons learnt from these have contributed to the Guidance Document;
- Invitation of **experts from other working groups to attend *COAST* meetings**;
- **Experts from COAST attending the meetings of other working groups**;
- Regular **interactions with experts from other working groups of the Common Implementation Strategy**:
    - WG 2.1 (Assessment of pressures and impacts);
    - WG 2.2 (Designation of heavily modified water bodies);
    - WG 2.3 (Reference conditions and classification for freshwater);
    - WG 2.5 (Intercalibration);
    - WG 2.7 (Monitoring).

  The links established with these working groups have resolved some of the issues encountered by COAST and also highlighted areas that needed consideration and discussion (Figure 1);
- The **working group leader, Claire Vincent, attended regular meetings of the Strategic Co-ordination Group and Working Group Leaders** in Brussels throughout the development of the Guidance.

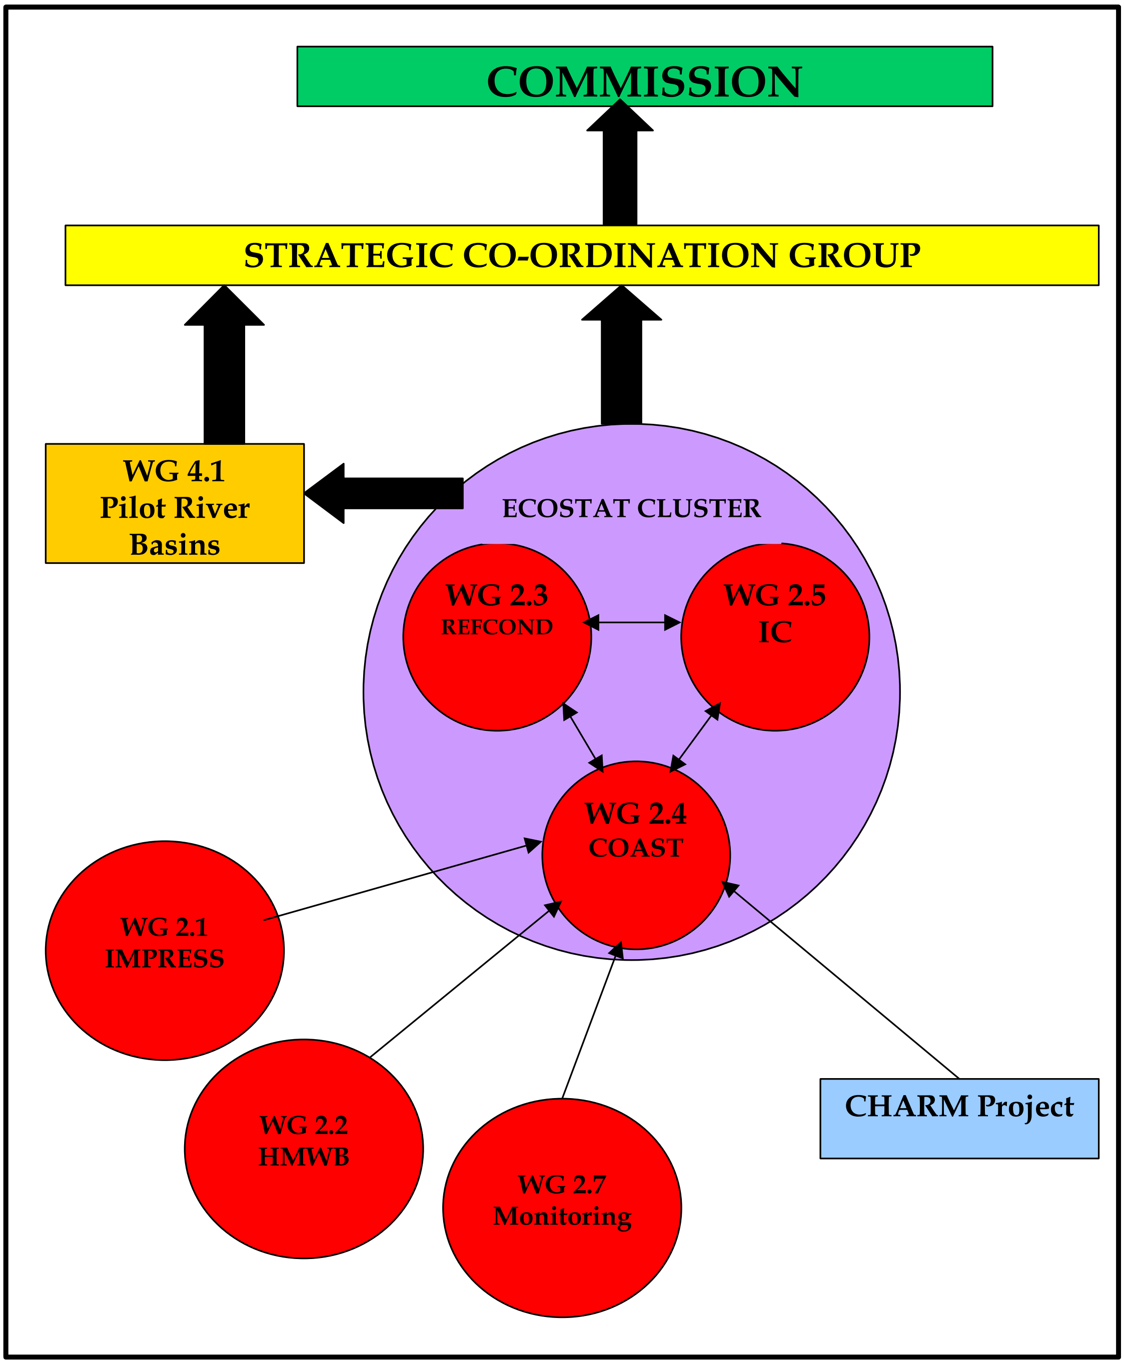


Figure 1.1. **Links between COAST, the Commission, other CIS working groups and European funded projects.**

Section 2 – The Common Understanding of Terms related to Transitional and Coastal Waters.

This Section provides guidance on the language used in the Directive for transitional and coastal waters.

2.1. DEFINITIONS OF TRANSITIONAL AND COASTAL WATERS

2.1.1. The Directive defines **transitional waters** as:

> **Article 2 (6)**
> *"'Transitional waters' are bodies of surface water in the vicinity of river mouths which are partly saline in character as a result of their proximity to coastal waters but which are substantially influenced by freshwater flows."*

2.1.2. Further guidance is given in Section 2.3 on defining transitional waters.

2.1.3. The Directive defines **coastal waters** as:

> **Article 2 (7)**
> *"'Coastal water' means surface water on the landward side of a line, every point of which is at a distance of one nautical mile on the seaward side from the nearest point of the baseline from which the breadth of territorial waters is measured, extending where appropriate up to the outer limit of transitional waters."*

2.1.4. The ecological status of coastal waters should be classified from the landward extent of either the coastal or transitional waters out to one nautical mile from the baseline. According to the United Nations Convention on the Law of the Sea (UNCLOS) the baseline is measured as the low-water line except along the mouths of estuaries and heads of bays where it cuts across open water. Along highly indented coastlines, bays, mouths of estuaries or coastlines with islands, the baseline can be drawn as a straight line. Each Member State has a legislative baseline associated with this definition.

2.1.5. The Directive gives no indication of the landward extent of either transitional or coastal waters. One of the hydromorphological quality elements for both transitional and coastal waters is the structure of the intertidal zone. Since it is likely that some of the quality elements may be monitored within the intertidal area, it is recommended that transitional and coastal water bodies include the intertidal area from the highest to the lowest astronomical tide.

2.2. DEFINING SURFACE WATER BODIES WITHIN TRANSITIONAL AND COASTAL WATERS

Annex II 1.1
"Member States shall identify the location and boundaries of bodies of surface water and shall carry out an initial characterisation of all such bodies".

2.2.1. The Directive requires surface waters within the River Basin District to be split into water bodies (Figure 2.1). Water bodies represent the classification and management unit of the Directive. A range of factors will determine the identification of water bodies. Some of these will be determined by the requirements of the Directive and others by practical water management considerations.

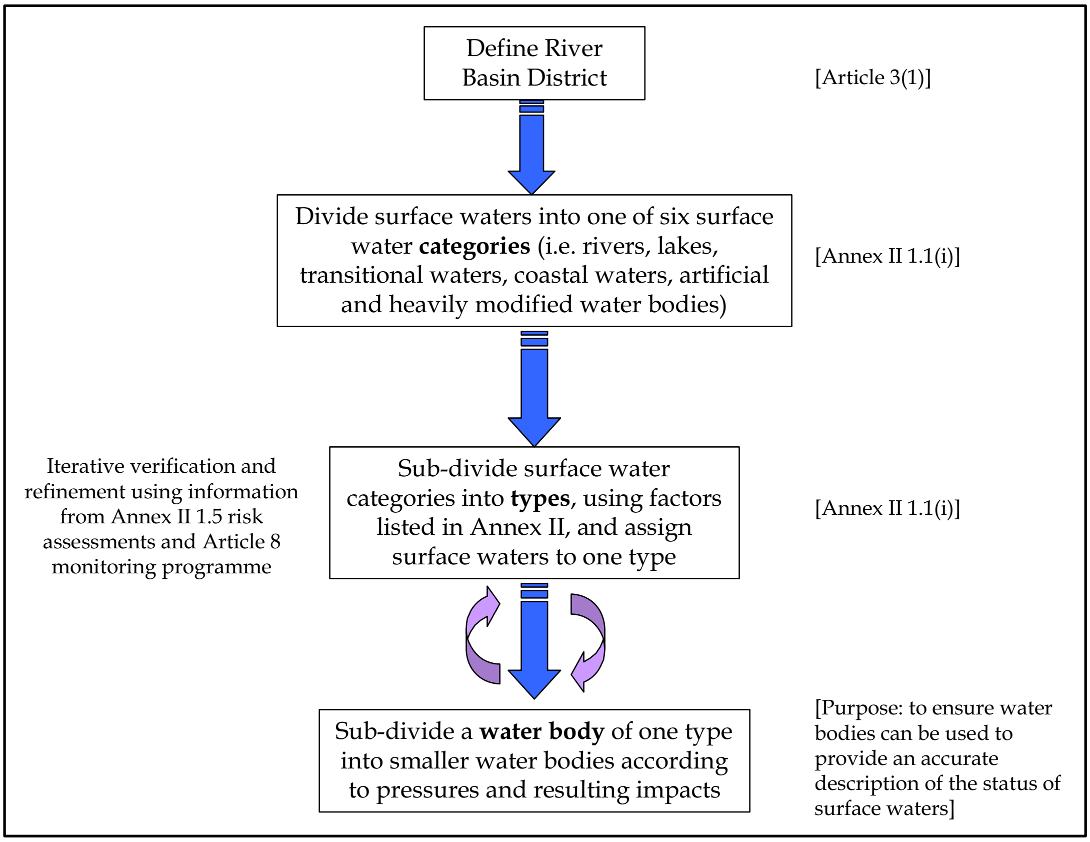

Figure 2.1. Summary of suggested hierarchical approach to the identification of surface water bodies.

2.2.2. This paper provides guidance on defining water bodies specific to coastal and transitional waters. A separate horizontal Guidance Document is available which specifically gives guidance on the term 'water body' and the identification of water bodies (WFD CIS Guidance Document No 2.).

Surface Water Categories

Annex II 1.1(i)
"The surface water bodies within the river basin district shall be identified as falling within either one of the following surface water categories – rivers, lakes, transitional waters or coastal waters – or as artificial surface water bodies or heavily modified surface water bodies."

2.2.3. The first stage in describing surface water bodies is to assign all surface waters to a surface water category – rivers, lakes, transitional waters or coastal waters – or to artificial surface water bodies or heavily modified surface water bodies (Figure 2.2).

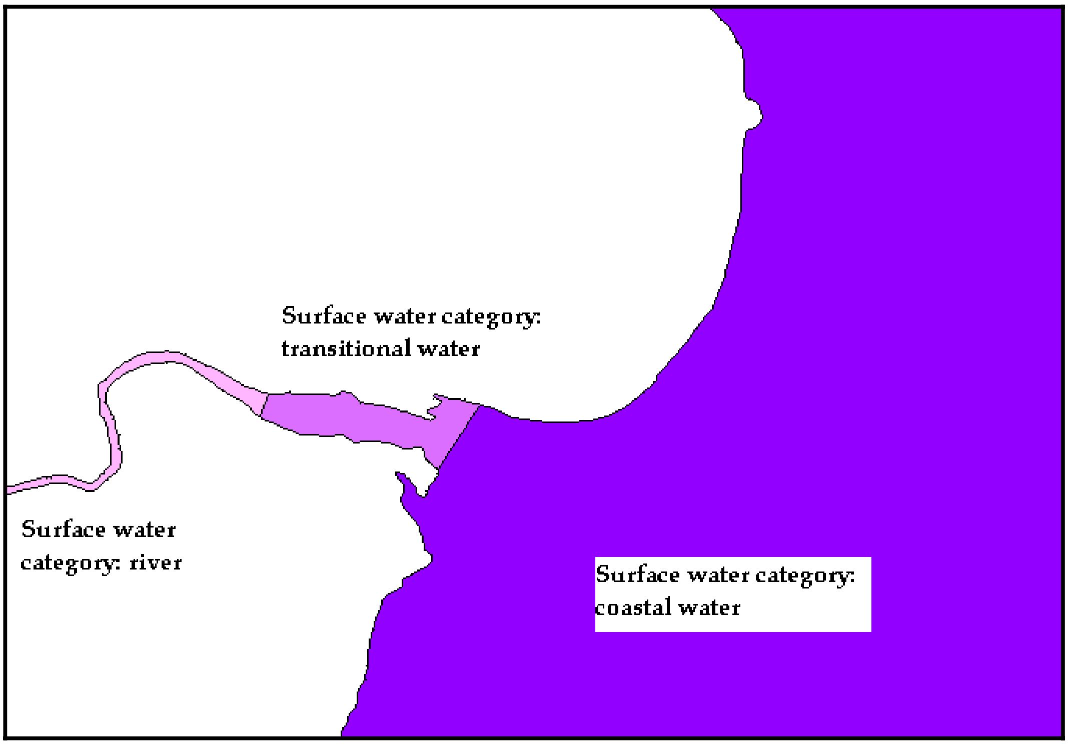

Figure 2.2. Surface Water Categories.

Surface Water Types

Annex II 1.1(ii)
"For each surface water category, the relevant surface water bodies within the river basin district shall be differentiated according to type. These types are those defined using either 'system A' or 'system B'."

2.2.4. The Directive recognises that the ecological character of surface waters will vary according to their different physical regimes. For example, a marine scientist expects to find different biological communities on an exposed Atlantic rocky shore compared to a fjord, a bay in the Baltic or a Mediterranean coastal lagoon. Examples of surface water types are shown in Figure 2.3. The purpose of assigning water bodies to a physical type is to ensure that valid comparisons of its ecological status can be made. For each type reference conditions must also be described, as these form the 'anchor' for classification of the water bodies status or quality. Guidance on how to type surface water bodies is given in Section 3.

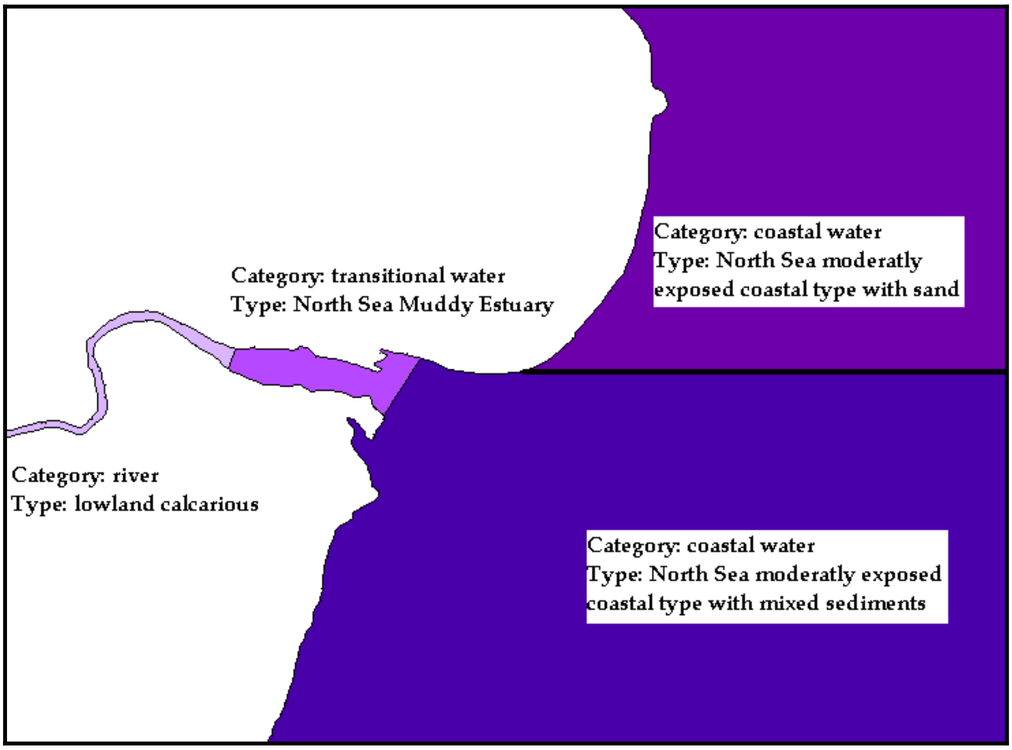

Figure 2.3. Types of surface water.

Surface Water Bodies

> **Article 2(10)**
> *"Body of surface water" means a discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.*

2.2.5. The water body is the management unit of the Directive.

2.2.6. Water bodies may be identified for all surface waters (natural, heavily modified and artificial waters). This step is of major importance for the implementation process because water bodies represent the units that will be used for reporting and assessing compliance with the Directive's principal environmental objectives.

2.2.7. To assign a single classification and effective environmental objectives to a water body it may be necessary to divide an area which is of one type further into two or more separate water bodies (Figure 2.4.). Water bodies may not spread over two types because reference conditions and hence environmental objectives are type specific.

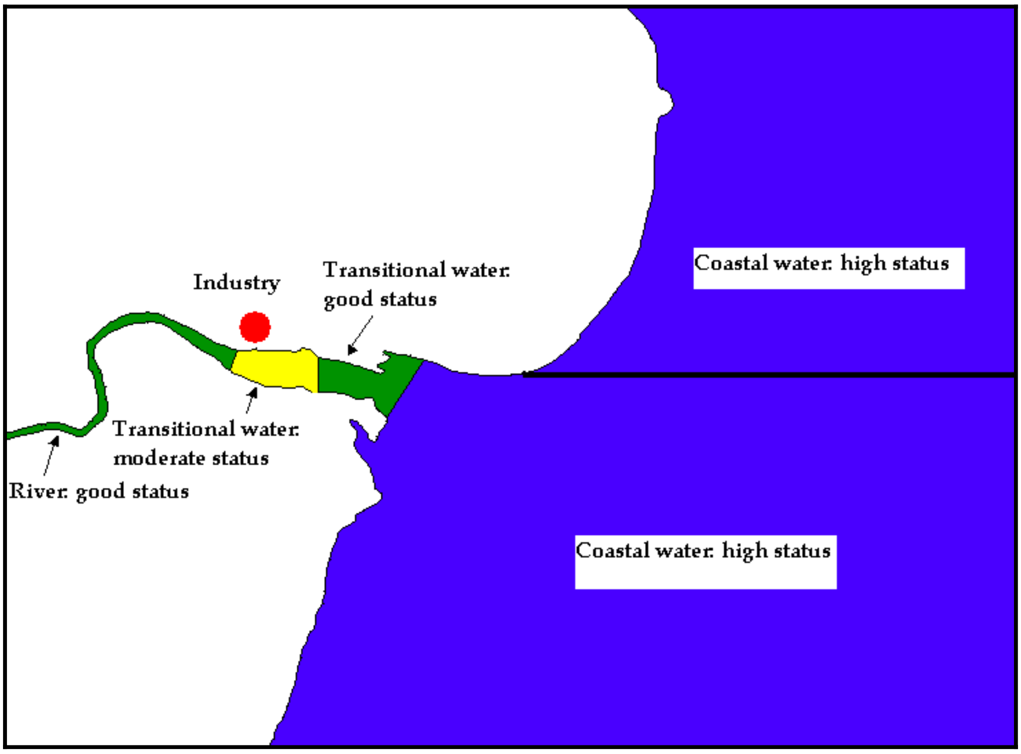

Figure 2.4. Surface water bodies. The colours used relate to those stated in Annex V 1.4.2 for reporting.

2.2.8. According to the definition in the Directive, water bodies must be "discrete and significant". This means that they must not be arbitrary sub-divisions of river basin districts, that they must not overlap with each other, nor be composed of elements of surface water that are not contiguous.

2.2.9. The Directive specifies that rivers and coastal waters may be sub-divided. It is assumed that transitional waters may also be sub-divided as long as the resulting water bodies are discrete and significant (Figure 2.5). In the case of coastal waters, stretches of open coast are often continuous (unless divided by transitional waters); here subdivisions may follow significant changes in substratum, topographies or aspect.

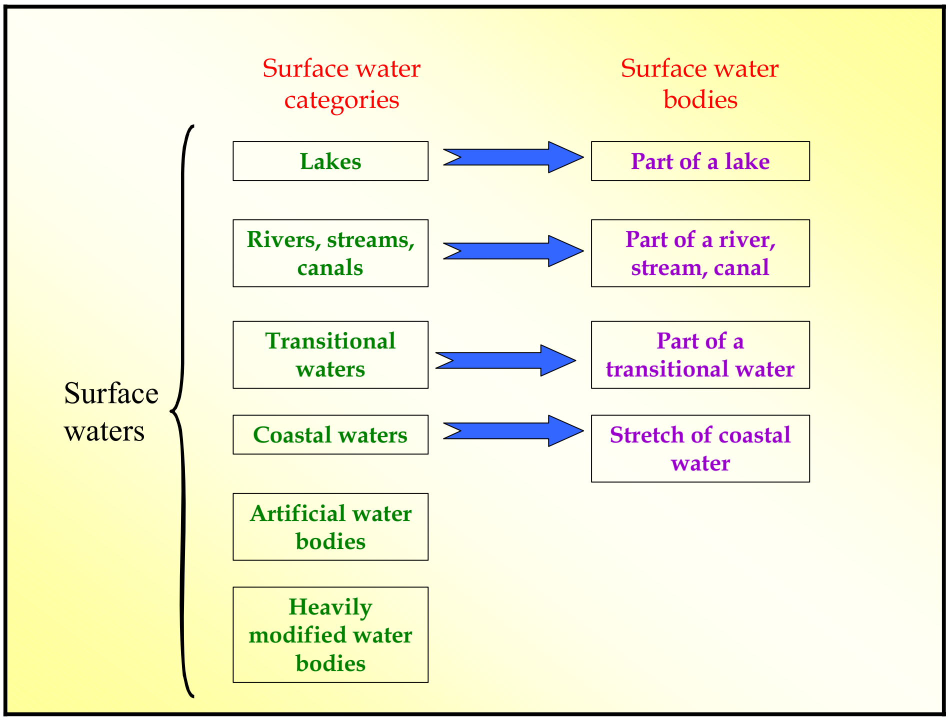

Figure 2.5. The splitting of surface water categories into surface water bodies.

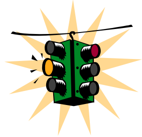
2.2.10. The need to keep separate two or more contiguous water bodies of the same type depends upon the pressures and resulting impacts. For example, a discharge may cause organic enrichment in one water body but not in the other. Such an area of one type could therefore be divided into two separate water bodies with different classifications. If there were no impact from the discharge it would not be necessary to divide the area into two water bodies as it would have the same classification and should be managed as one entity.



Look out! The Directive only requires sub-divisions of surface water that are necessary for the clear, consistent and effective application of its objectives. Sub-divisions of coastal and transitional waters into smaller and smaller water bodies that do not support this purpose should be avoided.

2.2.11. Every six years from 2013, Member States must review the characterisation of water bodies, including the type-specific reference conditions, so as to reflect greater understanding and knowledge of the systems and natural variability including climate change. In this review, water bodies whose status changes may be merged with adjacent water bodies of the same status **and** the same type.

> **Article 5(2)**
> *"The analyses and reviews mentioned under"* [Article 5] *"paragraph 1 shall be reviewed, and if necessary updated at the latest 13 years after the date of entry into force of this Directive and every six years thereafter."*

2.3. DEFINING TRANSITIONAL WATERS

2.3.1. The Directive defines transitional waters as:

> **Article 2 (6)**
> *"'Transitional waters' are bodies of surface water in the vicinity of river mouths which are partly saline in character as a result of their proximity to coastal waters but which are substantially influenced by freshwater flows."*

2.3.2. When defining transitional waters for the purposes of the WFD, it is clear that the setting of boundaries between transitional waters, freshwaters and coastal waters must be ecologically relevant.

2.3.3. Transitional waters are:
(1) "...in the vicinity of a river mouth" meaning close to the end of a river where it mixes with coastal waters;
(2)"...partly saline in character" meaning that the salinity is generally lower than in the adjacent coastal water;
(3)"...substantially influenced by freshwater flow" meaning that there is a change to salinity or flow.

2.3.4. If riverine dynamics occur in a plume outside the coastline because of high and strong freshwater discharge, the transitional water may extend into the sea area (allowed in definition 1).

2.3.5. For the purposes of the Directive, the main difference between transitional and coastal waters is the inclusion of the abundance and composition of fish fauna in the list of biological quality elements for the classification assessment of transitional waters.

2.3.6. Transitional waters are usually characterised by their morphological and chemical features in relation to the size and nature of the inflowing rivers. Many different methods might be used to define them but the method should be relevant ecologically. This will ensure reliable derivation of type-specific biological reference conditions.

2.3.7. In certain areas of the Baltic Sea, such as the Bothnian Bay, the salinity of coastal water is similar to that of fresh water. As a result riverine fresh water life may extend into the adjacent coastal water. However, because of the different physical characteristics (flow dynamics) of a river and coastal water (Article 2(6)), the same biological community falls into two different categories of surface waters (river - coastal) and hence must be separated into two different water bodies, as required by the Directive. In such cases the delimitation of a transitional water might be superfluous.

Defining the seaward boundary of transitional waters

2.3.8. To assist Member States in defining the seaward boundary of transitional waters, four methods are proposed.

1. The use of boundaries defined under other European and national legislation such as the Urban Waste Water Treatment Directive;
2. Salinity gradient;
3. Physiographic features;
4. Modelling.

2.3.9. Member States should select the most ecologically relevant method for their own situation. The use of one or more of these approaches will allow comparisons across all Member States.

The use of boundaries defined under other European and National legislation

2.3.10. Where boundaries of transitional waters were defined for the purposes of existing legislation, they may be used to define transitional waters under the WFD as long as they are consistent with the WFD categories.

2.3.11. Article 17(1) and (2) of the Urban Waste Water Treatment Directive (91/271/EC) gave Member States the task of establishing an implementation programme to include information on discharges into different types of water bodies, which might have implicated defining the outer (seaward) limit of estuaries. Each Member State used its own individual method. These boundaries are likely to have been drawn for most sizeable estuaries and could be used to define transitional waters for the purposes of the WFD.

Salinity gradient

2.3.12. If salinity measurements exist, the outer boundary should be drawn where the salinity of the transitional water is usually substantially lower than the salinity of the adjacent coastal water. By definition, the transitional water must also be substantially influenced by freshwater flows.

2.3.13. For larger rivers the influence of freshwater is likely to extend into coastal waters (Figure 2.6).

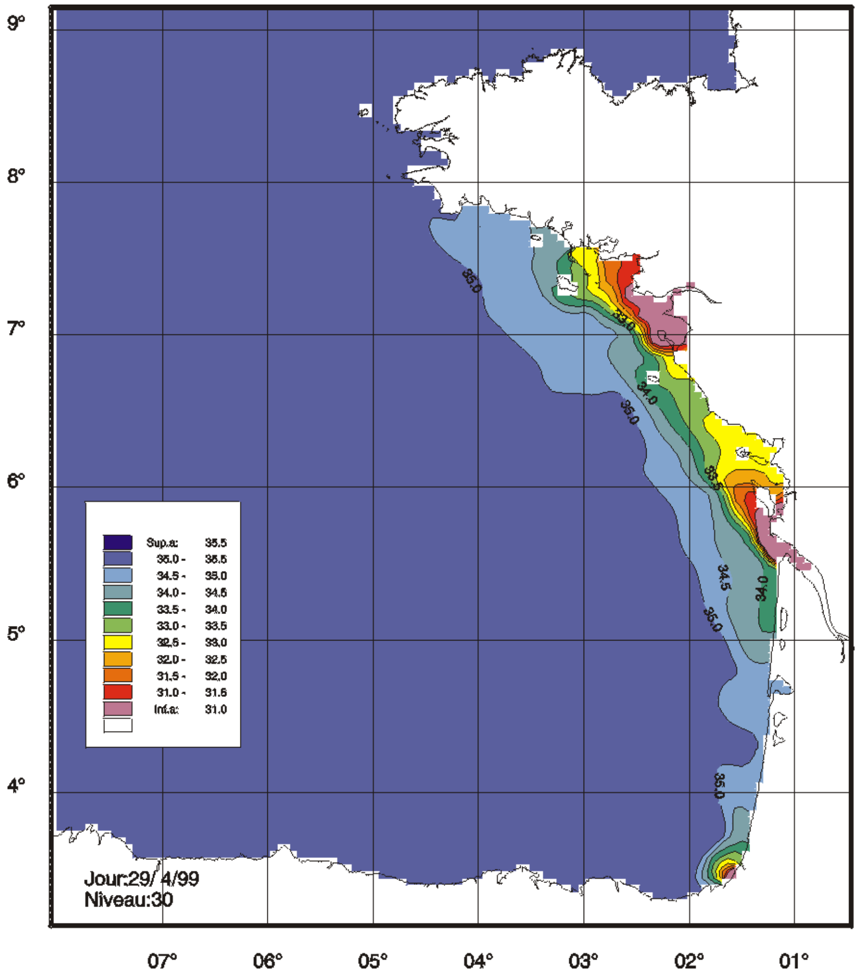


Figure 2.6. **Examples of the plumes of the Loire and Gironde estuaries on the French Atlantic coast. The extension of the plume (salinity gradient) varies according to freshwater flow and tide conditions.**

Physiographic features

2.3.14. Where morphological boundaries lie close to enclosing geographic features such as headlands and islands, such features may be used to define the boundary.

This is acceptable in some cases such as bar-built estuaries (Figure 2.7) whose morphological features may also coincide with biological boundaries.

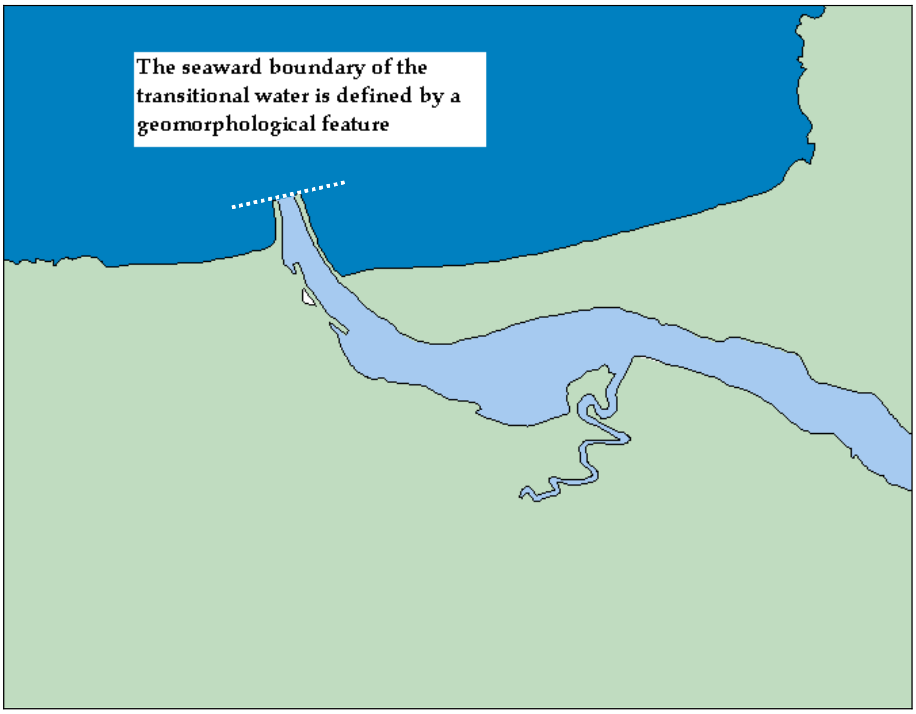

Figure 2.7. Bar-built estuary showing that geomorphological and biological limits of transitional waters can coincide.

Modelling

2.3.15 Models may be designed to predict the size of transitional waters. This method may be applicable where no estuary boundary has been defined for the purpose of existing legislation and where no suitable salinity data are available. Models may be used to estimate the area of water of a salinity substantially less than the salinity of the adjacent coastal water.

Defining the freshwater boundary of transitional waters

2.3.16. Annex II 1.2.3. and 1.2.4 of the Directive defines freshwater as less than 0.5 salinity.

2.3.17. There are two main methods for defining the freshwater boundary of transitional waters: the fresh/salt water boundary or the tidal limit (Figure 2.8). In some large estuaries, the tidal limit can be several tens of kilometres further inland than the freshwater/salt water boundary.

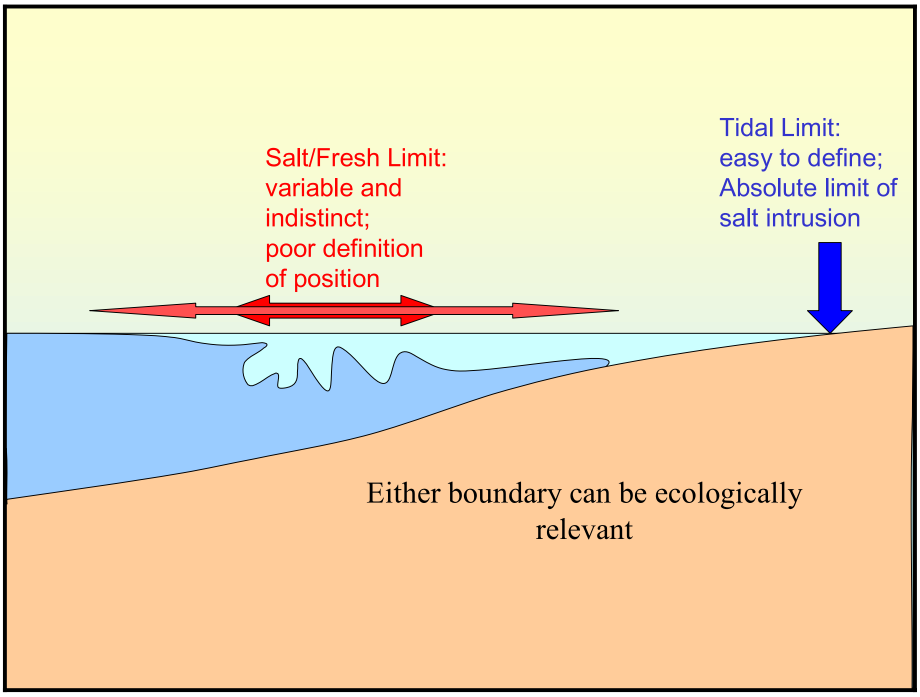

Figure 2.8. Methods for defining the freshwater boundary of transitional waters.

2.3.18. It is suggested that either the fresh /salt boundary or the tidal limit be used to define the freshwater boundary of transitional waters depending upon which method is most suitable to local circumstances. Whichever method is used, it is clear that all transitional waters must abut freshwater, leaving no section of the system unassigned to a surface water category.

The Minimum Size of Transitional Waters

2.3.19. The Directive gives no indication of the minimum size of transitional waters to be identified as separate water bodies. Although catchment size may be used as a guideline for the size of identified transitional waters, it should be considered with other factors such as the size, length, volume, river, discharge and the nature of the mixing zone. Most importantly it must meet the water body definition (Article 2.10) of being a 'discrete and significant' element of surface water. Significant could mean in terms of size or risk of failing to meet good ecological status.

2.3.20. The horizontal Guidance on water bodies (WFD CIS Guidance Document No. 2) gives no guidance on the minimum size for transitional or coastal water bodies. It does however state that Member States have the flexibility to decide whether the purposes of the Directive, which apply to all surface waters, can be achieved without the identification of every minor but discrete element of surface water as a water body**.**

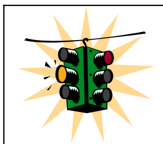
2.4. ASSIGNING COASTAL WATERS WITHIN THE RIVER BASIN DISTRICT

Article 3.1
"Coastal waters shall be identified and assigned to the nearest or most appropriate river basin district or districts."

3.4.1. The free exchange of substances from river basin districts to the open sea takes place in coastal waters. Coastal waters must be assigned to a River Basin District. This may involve the splitting of stretches of coastal water that might otherwise be considered as single water bodies.

2.4.2. When assigning a stretch of coastal water to a River Basin District the objective is to ensure that coastal waters are assigned to the closest possible or the most appropriate natural management unit and to minimise any unnecessary splitting of coastal stretches. To ensure consistency in the approach, the following principles should be applied:

- Where possible, existing administrative boundaries could be used. Examples are, ecoregions defined within the Directive and regions defined in the Marine Conventions;
- The boundaries between two adjacent types should be used wherever possible to minimise unnecessary splitting of the coastline;
- In the general case, the coastline should be split at open coast areas rather than through natural management units such as bays or inlets. However, specific situations may exist where the splitting of natural units for management purposes can not be avoided.



Look out! Further details on assigning coastal stretches to River Basin Districts are given in the Guidance Document "Identification of River Basin Districts in Member States. Overview, criteria and current state of play" produced by working group 2.9.

2.4.3. When managing coastal water bodies it must be recognized that water bodies in different river basin districts may interact to affect water quality in adjacent water bodies or even further away. In this case, the management plans of both river basins should acknowledge the problem and work together to resolve any issues. Where possible the coastal water body should be assigned to the River Basin District most likely to influence its quality, particularly taking into account long-shore influences of any contaminants.

2.5. TERRITORIAL WATERS

Article 2. 1
"'Surface water' means inland waters, except groundwater; transitional and coastal waters, except in respect of chemical status for which it shall also include territorial waters."

2.5.1. The definition of surface waters includes territorial waters. The Directive requires the achievement of good surface water chemical status for all surface water up to 12 nautical miles seaward from the baseline from which territorial waters are measured (i.e. territorial waters).

2.5.2. However, Member States are only required to identify water bodies in coastal waters, not in territorial waters.

Article 2. 10
"'Body of surface water' means a discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.'"

2.5.3. By protecting these inland surface waters, transitional waters, coastal waters and groundwaters, the Directive *contributes* to the protection of territorial and marine waters.

2.5.4. It is intended that the daughter directives that must be proposed by the Commission for substances on the Priority List by 20 November 2003 will clarify the compliance, assessment and reporting requirements relevant to the classification of good surface water chemical status.

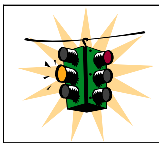
2.5.5. One option for reporting any failures to achieve good surface water chemical status in territorial waters would be to identify territorial water bodies only where needed to delineate contiguous stretches of water in which the required environmental quality standards for good chemical status are not being met.

2.6. MARINE LAGOONS

2.6.1. Coastal lagoons may be either coastal waters or transitional waters, depending on whether the lagoon fits the definition of transitional waters in the Directive *"in the vicinity of river mouths"* and *"substantially influenced by freshwater flows"* *(Article 2(6)).*

2.6.2. All surface waters are covered by the Directive. The minimum size of lagoons to be covered by the Directive is here suggested to be the same as the minimum size of lakes. Within Annex II of the Directive, the smallest size of lakes included in System A is a surface area of 0.5 to 1 km^2. This must not be considered as an absolute value and Member States may wish to include lagoons smaller than 0.5 km^2, particularly if they are at risk of failing to meet good status or are at high status and require a high level of protection. Further information on significant water bodies is given in the horizontal Guidance on water bodies (WFD CIS Guidance Document No. 2).

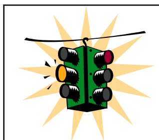
2.7. WETLANDS



Look out! A horizontal Guidance paper (currently under preparation) deals with the role of wetlands in the WFD and should be referred to for more detailed discussion.

Article 1
"The purpose of this Directive is to establish a framework for the protection of inland surface waters, transitional waters, coastal waters and groundwater which:
(a) prevents further deterioration and protects and enhances the status of aquatic ecosystems, and with regard to their water needs, terrestrial ecosystems and wetlands directly dependent on aquatic ecosystems."

2.7.1. It is clear from Article 1 of the Directive that one of the primary objectives of the WFD is to protect and enhance aquatic ecosystems including wetlands directly dependent on aquatic ecosystems. The major strength of the WFD as a management tool is that these interdependencies are recognised, in contrast to previous water pollution control or nature conservation directives.



Look out! Although specific Guidance on marine wetlands is not covered within this Guidance Document, the importance of wetlands associated with coastal and transitional waters, in particular salt marshes, is recognised.

2.7.2. Wetland ecosystems are ecologically and functionally significant elements of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in CIS horizontal Guidance Documents water bodies (WFD CIS Guidance Document No. 2) and further considered in the Guidance Document on wetlands (currently under preparation).

2.7.3. Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

2.7.4. Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal Guidance paper on wetlands (currently under preparation).

Section 3 – Guidance for Typology in Transitional and Coastal Waters.

This Section interprets the requirements of the WFD to define typology as one of the supporting factors in determining ecological status.

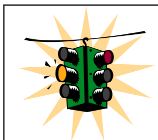
3.1. INTRODUCTION TO TYPOLOGY

Article 5(1).
"Each Member State shall ensure that for each river basin district or for the portion of an international river basin district falling within its territory:
- an analysis of its characteristics"…
…"is undertaken according to the technical specifications set out in Annexes II and III and that it is completed at the latest four years after the date of entry into force of this Directive."

3.1.1. Article 5 of the Directive requires Member States to carry out a characterisation of all water bodies. This exercise is referred to as typology. It is one of the first stages in the implementation of the WFD.

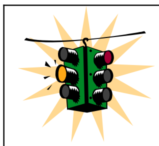
3.1.2. Annex II of the Directive gives instructions on how typology should be carried out and the obligatory and optional factors that can be used.

3.1.3. The purpose of typology is to enable type specific reference conditions to be established. These then become the anchor for classification systems. Typology has consequences for all subsequent operational aspects of the implementation of the Directive including monitoring, assessment and reporting.



Look out! Typology should be completed as soon as possible because all successive steps of Annexes II and V build on typology. In addition, the selection of types and sites for the draft register to form the intercalibration network is needed in 2003.

3.1.4. When carrying out typology Member States should focus on the overall purpose of the Directive outlined in Article 1; to establish a framework for the protection of both water quality and water resources preventing further deterioration and protecting and enhancing ecosystems. Typology is simply a tool to assist this process by comparing like with like.



Look out! The aim of typology is to produce as simple a physical typology as possible that is both ecologically relevant and practical to implement. It is recognised that a simple typology system needs to be complemented by more complex reference conditions that cover ranges of biological conditions.

3.1.5. The final typology should be submitted to the Commission in the form of GIS map(s) by 2004.

Annex II 1.1(vi)
"Member States shall submit to the Commission a map or maps (in a GIS format) of the geographical location of the types".

3.2. THE PROCESS OF TYPING

3.2.1. According to Annex II, Member States shall assign surface water bodies to one of the following categories: rivers, lakes, transitional, coastal, artificial or heavily modified surface water bodies. These categories must then be further divided into types.

Annex II 1.1(ii)
"For each surface water category, the relevant surface water bodies within the river basin district shall be differentiated according to type. These types are those defined using either 'system A' or 'system B'"

3.2.2. Water bodies within each surface water category are differentiated according to type using a system of typology as defined in Annex II of the Directive. Member States may choose to use either System A or System B.

3.2.3. If system A is used the type must first be assigned to an Ecoregion as shown in Map B of the Directive (Figure 3.1). In transitional waters the surface water type is then described according to mean annual salinity and mean tidal range. In coastal waters mean annual salinity and mean depth are used to describe the type. The COAST working group held the opinion that the class limits defined for the various descriptors by system A are not always ecologically relevant for the local environmental conditions.

Annex II 1.1(iv)
"If system B is used, Member States must achieve at least the same degree of differentiation as would be achieved using System A. Accordinly, the surface water bodies within the river basin district shall be differentiated into types using the values for the obligatory descriptors and such optional descriptors, or combinations of descriptors, as are required to ensure that type specific biological reference conditions can be reliably derived."

3.2.4. The Directive states that if Member States choose to use system B at least the same degree of differentiation must be achieved as if system A were used. System B uses a series of obligatory (e.g. tidal range and salinity) and optional factors (e.g. mean substratum composition, current velocity) in order to classify surface waters into types.

3.2.5. Most Member States have expressed the opinion that system B will be applied. This is because the differences in biological compositions and community structures normally depend on more descriptors than those in system A.

3.3. THE DEVELOPMENT OF TYPOLOGY GUIDANCE

3.3.1. The Directive does not prescribe a scientific methodology as to how Member States should type their surface waters.

3.3.2. The ecological approach to assessing the quality of Europe's transitional and coastal waters takes into account biological differences caused by land-ocean interactions and climatic zones. Therefore, the starting point for managing the scientific development of types of water bodies is a separation into broad ecoregions based on accepted marine biological provinces.

3.3.3. On the basis of the 'Obligatory Factors' in system B (latitude, longitude, tidal range and salinity), it is possible to split the maritime area into three basic Ecoregions/Ecoregion Complexes:

- **Atlantic/North Sea Ecoregion Complex** comprises North Atlantic Ocean, North Sea, Norwegian Sea and the Barents Sea Ecoregions. A general physical description shows mostly full salinity regimes and moderate to higher hydrodynamic properties;
- **Baltic Sea Ecoregion** with brackish waters and mostly low hydrodynamic properties;
- **Mediterranean Sea Ecoregion** with euhaline waters and moderate hydrodynamic properties.

3.3.4. These Ecoregions are shown on Map B in the Directive (Figure 3.1).

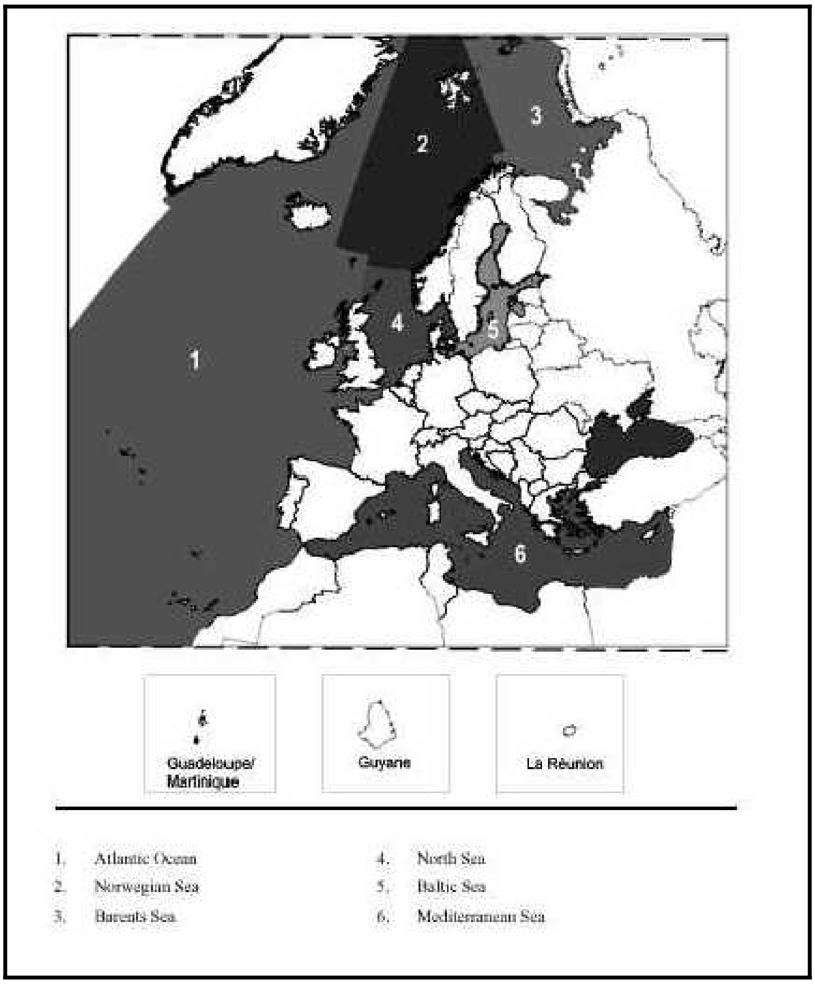


Figure 3.1. Map B from the Directive. System A: Ecoregions for transitional and coastal waters. The North-East Atlantic eco-region complex referred to in this Guidance Document includes the Atlantic Ocean, Norwegian Sea, Barents Sea and North Sea.

3.3.5. The Guidance was developed at three Ecoregion workshops by investigating:

- the common key optional factors within each Ecoregion;
- the order in which optional factors could be used to achieve the appropriate level of differentiation;
- the way in which the optional factors could be used.

3.4. COMMON FRAMEWORK FOR THE USE OF FACTORS FOR SYSTEM B

3.4.1. The factors listed in Annex II for coastal and transitional waters under System B are as follows:

Annex II 1.2.3. Transitional Waters
System B

Alternative Characterisation	***Physical and chemical factors that determine the characteristics of the transitional water and hence the biological population structure and composition***
Obligatory factors	*latitude* *longitude* *tidal range* *salinity*
Optional factors	*depth* *current velocity* *wave exposure* *residence time* *mean water temperature* *mixing characteristics* *turbidity* *mean substratum composition* *shape* *water temperature range*

Annex II 1.2.4. Coastal Waters
System B

Alternative Characterisation	***Physical and chemical factors that determine the characteristics of the coastal water and hence the biological population structure and composition***
Obligatory factors	*latitude* *longitude* *tidal range* *salinity*
Optional factors	*current velocity* *wave exposure* *mean water temperature* *mixing characteristics* *turbidity* *retention time (of enclosed bays)* *mean substratum composition* *water temperature range*

3.4.2. From the set of factors listed in Annex II of the Directive, Member States should use the obligatory factors followed by the optional factors that are most applicable to their own ecological situation.

3.4.3. It is suggested that a hierarchical approach is used for use of the optional factors when using System B.

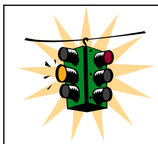
- First use obligatory factors
  - Latitude/Longitude - Ecoregion (c.f. Annex 11 of the Directive, Map B) (Figure 3.1 above);
  - Tidal Range;
  - Salinity.

3.4.4. If ecological separation to define the type specific reference conditions can be achieved by using only the obligatory factors, the use of optional factors is unnecessary.

3.4.5. If ecological separation to define the type specific reference conditions according to types cannot be achieved by using only the obligatory factors, then optional factors should also be used.

3.4.6. In **transitional waters**, the optional factors may be used in the following order if possible:
- Mixing;
- Intertidal Area (as an integrator of depth, tidal range and shape);
- Residence time;
- Other factors until an ecologically relevant type of water body is achieved.

3.4.7. In **coastal waters**, the optional factors may be used in the following order if possible:
- Wave exposure;
- Depth (*not in Annex II list);*
- Other factors until an ecologically relevant type of water body is achieved.

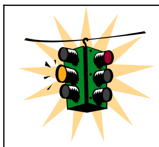


Look out! Even if only several factors are used to describe a type, it is suggested that Member States describe each water body using all factors in order to allow comparison of types between Member States. This will also aid the intercalibration exercise.

3.5. HOW COULD THE FACTORS BE USED?

3.5.1. Each factor has been split into several ranges on the basis of the ecological relevance across the three ecoregions.

3.5.2. Working within the agreed ranges will
- ensure true comparability between Member States on types;
- enable the identification of common types which could be used for intercalibration.



Look out! The Guidance was agreed on the understanding that:
- Member States may further split descriptors within these ranges if this is necessary to achieve an ecologically relevant type;
- Member States may aggregate descriptors within these ranges if there is no biological difference.

3.5.3. **Salinity**
In defining types the ranges of the broadly in line with system A of the Directive should be used.

freshwater	< 0.5 (‰)
oligohaline	0.5 to 5 - 6 (‰)
mesohaline	5 - 6 to 18 - 20 (‰)
polyhaline	18 – 20 to 30 (‰)
euhaline	>higher than 30 (‰)

3.5.4. **Mean Spring Tidal Range** (astronomical)

micro tidal	< 1 m
meso tidal	1 m to 5 m
macro tidal	> 5 m

Tidal Range is irrelevant for the Baltic Sea and the Mediterranean Sea because they have negligible tides. These whole areas are therefore defined as microtidal.

3.5.5. **Exposure (wave)**
It has been agreed that a pan-European scale should be used.

Extremely exposed open coastlines which face into prevailing wind and receive oceanic swell without any offshore breaks (such as islands or shallows) for more than 1000 km and where deep water is close to the shore (50 m depth contour within about 300 m).

Very exposed open coasts which face into prevailing winds and receive oceanic swell without any offshore breaks such as islands, or shallows for at least several hundred kilometres. Shallow water less than 50 m is not within about 300 m of the shore. In some areas exposed sites may also be found

	along open coasts facing away from prevailing winds but where strong winds with a long fetch are frequent.
Exposed	the prevailing wind is onshore although there is a degree of shelter because of extensive shallow areas offshore, offshore obstructions, or a restricted (<90°) window to open water. These stretches of coast are not generally exposed to strong or regular swell. Coasts may also face away from prevailing winds if strong winds with a long fetch are frequent.
Moderately exposed	these sites generally include open coasts facing away from prevailing winds and without a long fetch but where strong winds can be frequent.
Sheltered	at these sites there is a restricted fetch and/or open water window. Coasts can face prevailing winds but with a short fetch e.g. 20 km or extensive shallow areas offshore or may face away from the prevailing winds.
Very sheltered	these sites are unlikely to have a fetch greater than 20 km (the exception being through a narrow channel) and may face away from prevailing winds or have obstructions such as reefs offshore or be fully enclosed.

3.5.6. **Depth**

shallow	< 30 m
intermediate	30 m to 50 m
deep	> 50 m

3.5.7. **Mixing**

permanently fully mixed
partially stratified
permanently stratified

3.5.8. **Proportion of Intertidal Area**

small	< 50%
large	> 50%

The intertidal area integrates other Annex II factors such as depth, tidal range, residence time and shape.

3.5.9. **Residence Time**

short	days
moderate	weeks
long	months to years

3.5.10. **Substratum**

hard (rock, boulders, cobble)
sand-gravel
mud
mixed sediments

In many cases different seabed substrata will occur within one water body type. The dominant substratum should be selected.

3.5.11. **Current Velocity**

weak	<1 knot
moderate	1 knot to 3 knots
strong	>3 knots

Average current velocities should be used from measurements, tidal atlases or modelling. Current velocities throughout the Mediterranean Sea are expected to be <1 knot. Member States may further divide this class into < 0.5 knots and 0.5 – 1 knot.

3.5.12. **Duration of Ice Coverage**

irregular	
short	< 90 days
medium	90 to 150 days
long	> 150 days

In parts of the Baltic Sea ice coverage has an important influence on the ecosystem. It was the expert's advice to include this factor in the set of optional descriptors.

Section 4 – Guidance on the Development of Biological Reference Conditions for Coastal and Transitional Waters.

This Section of the Guidance explains the concepts of biological reference conditions and presents a way to use these concepts in practice.

4.1. INTRODUCTION

4.1.1. The reference condition is a description of the biological quality elements that exist, or would exist, at high status. That is, with no, or very minor disturbance from human activities. The objective of setting reference condition standards is to enable the assessment of ecological quality against these standards.

4.1.2. Within the Directive, reference conditions are described as follows:

> **Annex II 1.3 (i)**
> *"Type specific biological reference conditions shall be established, representing the values of the biological quality elements" … "for that surface water body type at high ecological status".*

4.1.3. In defining biological reference conditions, criteria for the physico-chemical and hydromorphological quality elements at high status must also be established. The reference condition is a description of the **biological** quality elements only. High **ecological status** incorporates the biological, physico-chemical and hydromorphological elements.

> **Annex II 1.3 (i)**
> *"For each surface water body type"….."type-specific hydromorphological and physicochemical conditions shall be established representing the values of the hydromorphological and physico chemical elements"….."for that surface water body type at high ecological status".*

4.1.4. 'Type specific' means that reference conditions are specific to a type as described under Annex II, System A or B (Section 3.2.).

4.1.5. It is recognised that some Member States may have few or no water bodies at high status and may need to use reference conditions established in another Member State for the same type.

4.1.6. Pressures such as diffuse pollution and land-use patterns are indirect pressures that Member States are required to control under the WFD. However, it is unrealistic to base reference conditions upon historic landscapes that no longer exist in modern Europe.

4.1.7. High status provides the direction, not the target, for restoration.

> **Article 4.1 a (ii)**
> *"Member States shall protect, enhance and restore all bodies of surface water" with the aim of achieving good surface water status at the latest 15 years after the date of entry into force of this Directive."*

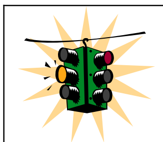
4.1.8. Qualitative and quantitative aspects of reference conditions should be published as part of the River Basin Management Plan and be available to the public.

> **Annex VII, A 1.1.**
> *"River basin management plans shall cover the following elements:*
> *1.1. …for surface waters….identification of reference conditions for the surface water body types;"*

4.1.9. Member States may wish to engage in a consultation process on any reference network of high status sites in the spirit of Article 14. Further Guidance on the Public Participation Process is given in the WFD CIS Technical Report No. 2Identification of river basin districts in Member States, Overview, Criteria and State of play.

4.2. REFERENCE CONDITIONS AND THE RANGE OF NATURAL VARIATION

4.2.1. Reference conditions must summarise the range of possibilities and values for the biological quality elements over periods of time and across the geographical extent of the type. The reference conditions represent part of nature's continuum and must reflect natural variability (Figure 4.1).



Look out! Reference conditions are type specific, and therefore the typology must lead to the reliable derivation of biological reference conditions.

4.2.2. Because reference conditions must incorporate natural variability, in most instances they will be expressed as ranges. Reference conditions should be derived with a view to distinguishing between very minor, slight, and moderate disturbance. 'Very minor' disturbance could be defined as just detectable in the sense that the disturbance is more likely to be anthropogenic than not. Slight disturbance could be defined as anthropogenic at a prescribed level of confidence.

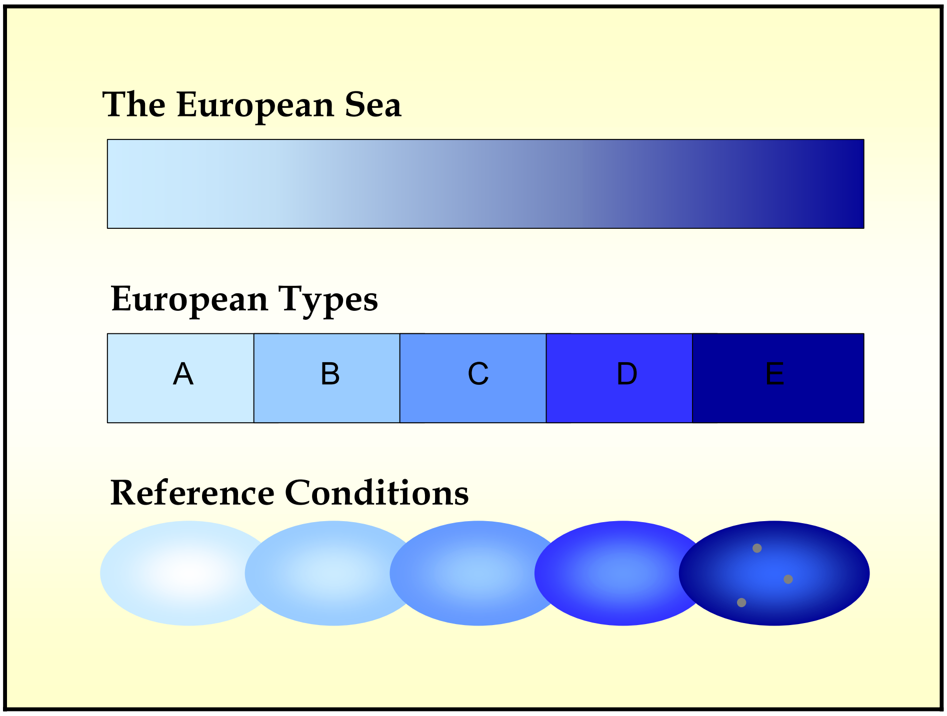


Figure 4.1. **The relationship between all the seas in Europe (the European Sea), typology and type-specific reference conditions. The European sea is a continuum. Typology falsely compartmentalises this continuum into a number of physical types. The reference conditions for a specific water body type must then describe all possible natural variation within that type. In type E, sites are shown. This shows how sites within a type may be used to establish the natural variability within the type.**

4.2.3. It is likely that the natural variability of a quality element within a type may be as large as the natural variability between types. Member States should adopt the spirit of the Directive and attempt to minimise variability by making valid comparisons between biological communities (i.e. compare 'like with like' by selecting comparable parts of the biological communities with the comparable part of the reference condition).

4.3. THE RELATIONSHIP BETWEEN REFERENCE CONDITIONS, HIGH STATUS AND THE ECOLOGICAL QUALITY RATIO

4.3.1. Type specific reference conditions are to be established for the **biological** quality elements for that type of surface water at high status. **Reference conditions are a description of the biological quality elements at high status.**

> **Annex V 1.4.1. (ii)**
> *"the results of the (classification) systems"…"shall be expressed as ecological quality ratios for the purposes of classification of ecological status. These ratios shall represent the relationship between the values of the biological parameters observed for a given body of surface water and the values for these parameters in the reference conditions applicable to that body. The ratio shall be expressed as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero."*

4.3.2. The description of the biological reference conditions must permit the comparison of monitoring results with the reference conditions in order to derive an Ecological Quality Ratio (EQR). The values of the EQR set for each status class must mean that the water body meets the normative definition for that status class given in Annex V Table 1.2. and each biological quality element meets the relevant definition in Annex V Tables 1.2.3. or 1.2.4. The EQRs must be defined in such a way that allows the comparison of high status sites between Member States.

4.3.4. The EQR is not necessarily a simple ratio of two numbers but 'represents the relationship between the values of the biological parameters' in a given water body.

4.3.5. The EQR expresses the relationship between observed values and reference condition values. Its numerical value lies between 0 and 1. At high status, the reference condition may be regarded as an optimum where the EQR is close to, and including one.

4.3.6. Outside the reference condition range, the method of conversion of measurements to a numerical EQR will depend on the quality element and on classification schemes within individual Member States.

4.4. BIOLOGICAL QUALITY ELEMENTS REQUIRING REFERENCE CONDITIONS

4.4.1. Reference conditions should be described according to the definitions of the biological quality elements at high status in Annex V Table 1.2.3 and Table 1.2.4.

Definitions of the biological elements at high status in transitional waters taken from Annex V Table 1.2.3.

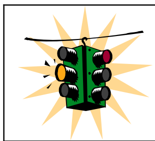
Element	High Status
Biological Quality Elements	
Phytoplankton	*The composition and abundance of the phytoplanktonic taxa are consistent with undisturbed conditions.* *The average phytoplankton biomass is consistent with the type-specific physico-chemical conditions and is not such as to significantly alter the type-specific transparency conditions.* *Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physico-chemical conditions.*
Macroalgae	*The composition of macroalgal taxa is consistent with undisturbed conditions.* *There are no detectable changes in macroalgal cover due to anthropogenic activities.*
Angiosperms	*The taxonomic composition corresponds totally or nearly totally to undisturbed conditions.* *There are no detectable changes in angiosperm abundance due to anthropogenic activities*
Benthic Invertebrate Fauna	*The level of diversity and abundance of invertebrate taxa is within the range normally associated with undisturbed conditions.* *All the disturbance-sensitive taxa associated with undisturbed conditions are present.*
Fish Fauna	*Species composition and abundance is consistent with undisturbed conditions.*

Definitions of the biological elements at high status in coastal waters taken from Annex V Table 1.2.4.

Element	High Status
Biological Quality Elements	
Phytoplankton	*The composition and abundance of the phytoplanktonic taxa are consistent with undisturbed conditions.* *The average phytoplankton biomass is consistent with the type-specific physico-chemical conditions and is not such as to significantly alter the type-specific transparency conditions.* *Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physico-chemical conditions.*
Macroalgae and Angiosperms	*All disturbance-sensitive macroalgal and angiosperm taxa associated with undisturbed conditions are present.* *The levels of macroalgal cover and angiosperm abundance are consistent with undisturbed conditions.*
Benthic Invertebrate Fauna	*The level of diversity and abundance of invertebrate taxa is within the range normally associated with undisturbed conditions.* *All the disturbance-sensitive taxa associated with undisturbed conditions are present.*

4.4.2. There is an urgent need to collect new data to ensure that reference conditions which incorporate natural variability can be derived. The development of reference conditions is likely to be an iterative process until adequate data sets are available. This urgent need is reflected in Annex V 1.3.1. The impact assessment has to be completed by 2004 and reference conditions will be required in order to undertake the intercalibration exercise.

Annex V 1.3.1
"Member States shall establish surveillance monitoring programmes to provide information for:
- supplementing and validating the impact assessment procedure detailed in Annex II."

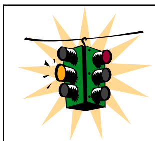


Look out! It is likely that the complete descriptions of reference conditions for transitional and coastal waters will not be possible at this stage as there are few or no data for some of the biological quality elements.

4.5. METHODS FOR DETERMINING REFERENCE CONDITIONS

4.5.1 The WFD identifies four options for deriving reference conditions.

Annex II, 1.3 (iii)
Reference conditions may be *"either spatially based or based on modelling, or may be derived using a combination of these methods. Where it is not possible to use these methods, Member States may use expert judgement to establish such conditions."*



Look out! A hierarchical approach for defining reference conditions is suggested using the various methods in the following order:

1. An existing undisturbed site or a site with only very minor disturbance; or
2. historical data and information; or
3. models; or
4. expert judgement.

4.5.2. Models are generally not well developed or validated for the marine environment and given the problems with using historical data, the reference network of high status sites is the preferred approach for deriving reference conditions for transitional and coastal waters.

Spatial Data

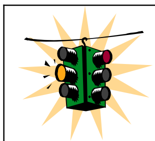
4.5.3. With regard to spatial data, Annex II, 1.3 (iv) states that:

> **Annex II 1.3 (iv)**
> *"Member States shall develop a reference network for each surface water body type. The network shall contain a sufficient number of sites of high status to provide a sufficient level of confidence about the values for the reference conditions, given the variability in the values of the quality elements corresponding to high ecological status for that surface water body type".*

4.5.4. Where a site with 'very minor disturbance' is used to derive reference conditions it should be validated to ensure that it meets the definitions of high status given in Annex V.

4.5.5. It may be possible to use a site to derive biological reference conditions for a biological quality element, even though not all other quality elements at the site are at high status. In this case it must be demonstrated that this biological quality element is not disturbed.

4.5.6. A site with hydromorphological modification may be used to derive biological reference conditions for the quality elements which are not disturbed by the modification (e.g. a slipway or a small jetty will not disturb the phytoplankton community). Although this water body as a whole may not qualify for high status, given the hydromorphological modification, it may be possible to derive biological reference conditions from this site.



Look out! At present there are no reference networks of high status sites for coastal and transitional waters. In addition, there are few reliable models for predicting marine biological communities. The few existing tools which are in existence have generally not been tested outside individual Member States.

Historical data and information

4.5.7. It may be possible to use historical information to derive reference conditions if the historical data are of assured quality. If reference conditions are derived from historical conditions, these should be based upon the condition of water bodies at times of no or very minor anthropogenic influence. No single date can be used to determine the reference conditions, for example, in urbanised estuaries a historical period of low nutrient inputs from agriculture may have corresponded to high industrial discharges and the release of untreated sewage.

4.5.8. A site at which there are historic pressures may still be used to derive biological reference conditions if the pressures are not causing current ecological disturbance to that quality element.

Modelling

4.5.9. A number of different modelling techniques may be used to derive reference conditions.

> **Annex V 1.3 (v)**
> *"Type-specific biological reference conditions based on modelling may be derived using either predictive models or hindcasting methods. The methods shall use historical, palaeological and other available data and shall provide a sufficient level of confidence about the values for the reference conditions to ensure that the conditions so derived are consistent and valid for each surface water body type."*

Expert Judgement

4.5.10. It is emphasised that expert judgement is required with all the above techniques: for example, use of historical data will require expert judgement in deciding which data are appropriate. In addition, robust predictive models can only be developed using data plus expert judgement. In the early stages of implementation of the Directive, expert judgement will be used alongside the development of classification tools outlined in Section 6 to derive reference conditions consistent with the normative definitions.

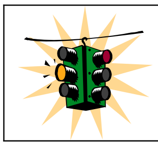
4.6. THE SELECTION OF A REFERENCE NETWORK OF HIGH STATUS SITES

4.6.1. The Directive requires Member States to establish a reference network of high status sites.

4.6.2. A possible starting point for this process is to screen for unimpacted areas using pressure criteria. It is clear that pressure criteria alone cannot be used to define high status areas because something which would be a minor pressure in one water body e.g. a sewage works of 250 population equivalent discharging to the Atlantic Ocean may have a significant impact if discharged to a small lagoon with poor water exchange. However, screening for areas with a lack of pressures is a useful starting point in identifying a reference network of high status sites.

4.6.3. The screening process starts with the identification of areas with no or very minor morphological changes. These areas can be identified from examining sea charts and from obtaining licensing information on the disposal of dredged material, extraction of oil, gas, aggregates or other marine resources. More information would be required to ensure that these areas are not subject to a fishing pressure which would constitute more than a 'very minor disturbance'.

4.6.4. The next step is to identify areas of no or very minor pressures from land based activity (i.e. areas which have no or low intensity agricultural practises and no or few point sources of pollution).



Look out! A German screening tool for identifying significant pressures and evaluating their impacts is included in WFD CIS Guidance Document No. 3 – Analysis of pressures and impacts (Section 4.2)

4.6.5. A detailed examination of the biological status of these areas is required alongside expert judgement to establish if these sites are at high status. In many cases it may be unacceptable to base reference conditions on current land management practice.

4.7. EXCLUSION OF QUALITY ELEMENTS WITH HIGH NATURAL VARIABILITY

Annex II 1.3 (vi)
"Where it is not possible to establish reliable type-specific reference conditions for a quality element in a surface water body type due to high degrees of natural variability in that element, not just as a result of seasonal variations, then that element may be excluded from the assessment of ecological status for that surface water type. In such circumstances Member States shall state the reasons for this exclusion in the river basin management plan".

4.7.1. The WFD allows Member States to exclude a quality element from the assessment of ecological status if its natural variability, other than seasonal, is too high to allow the derivation of reliable reference conditions. In this case reference conditions need not be formulated but the reason for the exclusion along with supporting evidence must be stated in the river basin management plan.

4.7.2. No specific guidance is given within the Directive on the level of natural variability that justifies such exclusion. It is recommended that sufficient reason for exclusion may exist if the range of natural variability within a type overlaps with the range expected in disturbed conditions resulting in a high risk of mis-classification.

4.7.3. When formulating reference conditions it is important to express natural variability as explicitly as possible (e.g. the specific seasonal (spring or summer) range of phytoplankton biomass).

4.8. REFERENCE CONDITIONS AND OTHER SIGNIFICANT ANTHROPOGENIC IMPACTS

Non-indigenous species

4.8.1. The biological quality of water bodies may be impacted by pressures such as the introduction of non-indigenous species or disease-causing organisms. The WFD does not identify them explicitly as pressures but includes them as "*other significant anthropogenic impacts*" (Annex II 1.4.). Such pressures may affect some biological quality elements and must be taken into account when deriving reference conditions.

4.8.2. The mere presence of a non-indigenous species in a water body of high status is acceptable if it does not unduly influence the overall structure and function of the ecosystem and if the normative definitions of high status are not compromised.

Fishing

4.8.3. Where a fishing operation constitutes more than 'a very minor disturbance' on one or more of the biological quality elements, that water body cannot be considered to be at high status (e.g. benthic trawling has a direct impact on the benthic invertebrate fauna). In addition, fishing activities may compromise high hydromorphological status in transitional or coastal waters.

Definitions of the hydromorphological elements at high status in transitional waters taken from Annex V Table 1.2.3.

Element	*High Status*
Hydromorphological Quality Elements	
Morphological	*Depth variation, substrate conditions and both the structure and condition of the intertidal zones correspond totally or nearly totally to undisturbed conditions.*

Definitions of the hydromorphological elements at high status in coastal waters taken from Annex V Table 1.2.4.

Element	*High Status*
Hydromorphological Quality Elements	
Morphological	*Depth variation, structure and substrate of the coastal bed conditions and both the structure and condition of the intertidal zones correspond totally or nearly totally to undisturbed conditions.*

4.8.4. The specification for fish fauna in transitional waters at good status includes impacts due to the physico-chemical or hydromorphological quality elements but does not explicitly include the effects of fishing. Therefore a water body within which fishing takes place can be considered to be at good status if the effects of, for example benthic trawling, lead only to slight disturbance of the quality elements from high status.

Annex V 1.2.3.
Description of fish fauna at high status
"Species composition and abundance is consistent with undisturbed conditions".
Description of fish fauna at good status

"The abundance of the disturbance-sensitive (fish) species shows slight signs of distortion from type specific conditions attributable to anthropogenic impacts on physico-chemical or hydromorphological quality elements".

4.9. UPDATING REFERENCE CONDITIONS

4.9.1. Reference conditions are not permanent. Climate, land cover and marine ecosystems vary naturally over many periods relevant to the WFD. Every six years from 2013, Member States must review the characterisation of water bodies, including reference conditions.

4.9.2. Reference conditions must therefore be formulated so as to include natural variability over a period of at least six years, and other factors directly out of the control of Member States. It is accepted that many of these variables are not fully understood in the marine environment.

4.9.3. Over the forthcoming years as understanding increases it may be possible to develop sound predictive models, thus reducing the degree of expert judgement in the process.

4.10. REFERENCE CONDITIONS / HIGH STATUS STUDIES

4.10.1. Through the COAST working group, a number of Member States completed reference condition pilot studies for areas which may be in high status. It cannot be confirmed that these areas are in high status until classification tools are developed and the intercalibration exercise has been completed. Some Members States with no sites considered to be at high status completed 'best of type' studies for types that may be in good or moderate status.

4.10.2. The papers were discussed by the working group and the main lessons learnt through the exercise are listed below:

- It is likely that there will be very few sites across the whole of Europe at high status because of human pressures and impacts.
- The IMPRESS Guidance Document gives guidance on what constitutes a specific pollutant (WFD CIS Guidance Document No. 3). This Guidance will need to be tested to see if the strict requirements for specific pollutants discount sites which are **biologically** in high status.
- In the marine environment there is a lack of biological and chemical data for high status sites as the focus for monitoring programmes has historically been centred on polluted areas.

- At present Member States do not have a full set of data for each quality element. This is particularly true for macroalgae, angiosperms and fish. It is clear that additional studies may be required in order to derive reference conditions.
- Where possible reference conditions should be quantitative rather than qualitative. However it is appreciated that this may not be possible initially, if at all, for all quality elements.
- At least in the short term, expert judgement is essential because of the lack of good data sets. Over the forthcoming years as understanding increases it may be possible to develop sound predictive models, thus reducing the degree of expert judgement.

4.10.3. A table can be found in Annex C which lists the pilot studies that were carried out by various Member States.

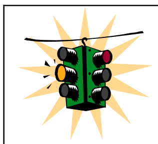
Section 5 – General Guidance on the Classification of Ecological Status within Transitional and Coastal Waters.

This Section of the Guidance introduces the principles underlying classification and the requirements of classification tools and schemes for the purposes of the WFD.

5.1. INTRODUCTION TO CLASSIFICATION

5.1.1. The WFD requires Member States to assess the ecological status of water bodies and then ensure that the appropriate environmental objectives are set for these water bodies through the river basin management process.

5.1.2. At present, there are a limited number of coastal and transitional water classification schemes in Europe. None of the existing schemes meet all the requirements of the WFD. Existing classification schemes do not generally include all of the quality elements given in Annex V 1.2.3 and 1.2.4. Each of the existing schemes has different strengths and weaknesses in relation to WFD implementation.



Look out!
A **classification scheme** is what is used for the overall classification and includes a measure of all appropriate quality elements.
Classification tools are used for assessing the status of each individual quality element against high status.

5.1.3. WFD classification schemes and tools must assess status against the biological reference conditions.

5.1.4. The classification of ecological status is based upon the status of the biological, hydromorphological and physico-chemical quality elements (Figure 5.1). The quality elements to be included in classification are listed in Annex V 1.1.3. and 1.1.4. The hydromorphological and physico-chemical elements are also referred to as the supporting elements.

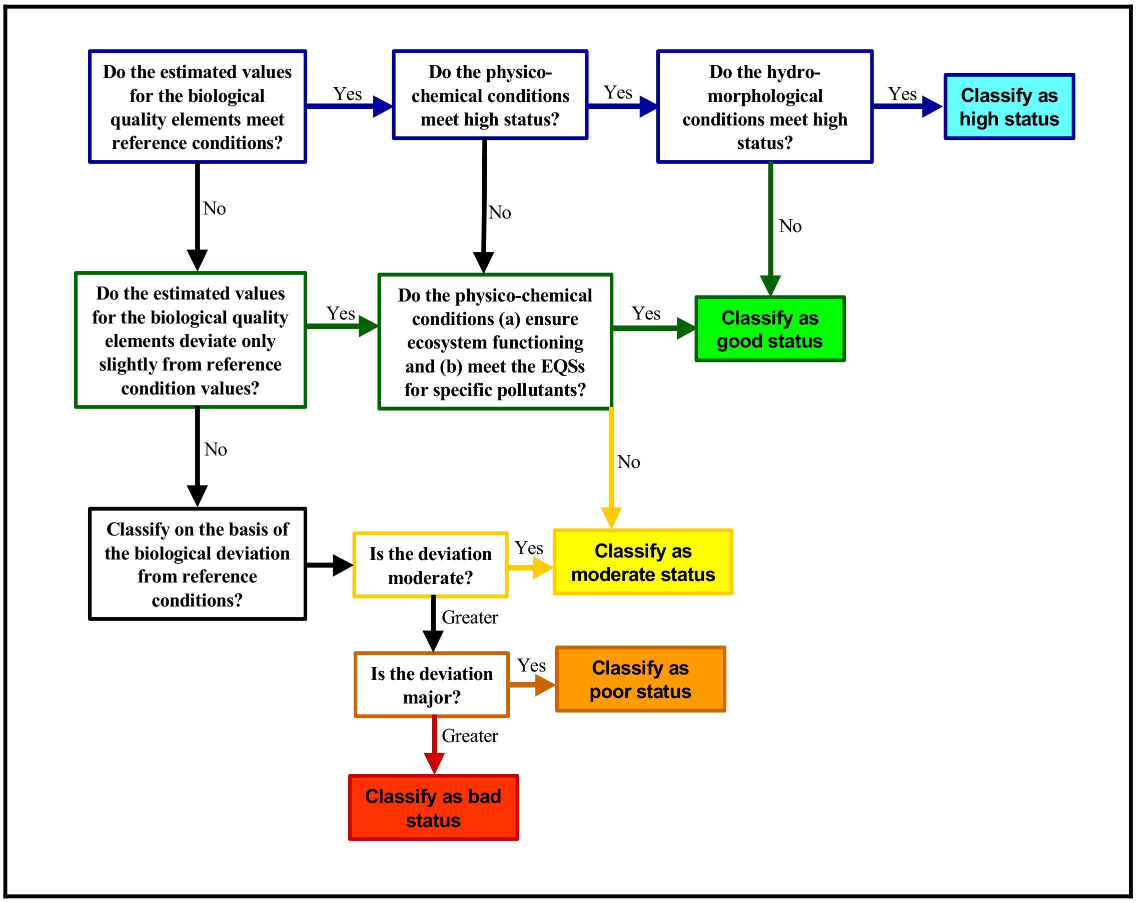


Figure 5.1. **Indication of the relative roles of biological, hydromorphological and physico-chemical quality elements in ecological status classification according to the normative definitions in Annex V 1.2. A more detailed understanding of the role of physico-chemical parameters in the classification of the ecological status will be developed in specific Guidance on this issue during 2003.**

Annex V 1.1.3. Transitional Waters	**Annex V 1.1.4. Coastal Waters**
Biological elements	
• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora* • *Composition and abundance of benthic invertebrate fauna* • *Composition and abundance of fish fauna*	• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora* • *Composition and abundance of benthic invertebrate fauna*
Hydromorphological elements supporting the biological elements:	
Morphological conditions: • *depth variation* • *quantity, structure and substrate of the bed* • *structure of the inter-tidal zone* *Tidal regime:* • *freshwater flow* • *wave exposure*	*Morphological conditions:* • *depth variation* • *structure and substrate of the coastal bed* • *structure of the inter-tidal zone* *Tidal regime:* • *direction of dominant currents* • *wave exposure*
Chemical and physio-chemical elements supporting the biological elements:	
General: • *Transparency* • *Thermal conditions* • *Salinity* • *Oxygenation conditions* • *Nutrient conditions* *Specific Pollutants:* • *Pollution by all priority substances identified as being discharged into the body of water* • *Pollution of other substances identified as being discharged in significant quantities into the body of water.*	*General:* • *Transparency* • *Thermal conditions* • *Salinity* • *Oxygenation conditions* • *Nutrient conditions* *Specific Pollutants:* • *Pollution by all priority substances identified as being discharged into the body of water* • *Pollution of other substances identified as being discharged in significant quantities into the body of water.*

5.2. ECOLOGICAL STATUS CLASSES AND THE ECOLOGICAL QUALITY RATIO

5.2.1. Definitions of the five ecological status classes are given in Annex V Table 1.2. These are referred to as the **normative definitions**.

Annex V Table 1.2. General definition for rivers, lakes, transitional waters and coastal waters

High status

"There are no, or only very minor, anthropogenic alterations to the values of the physicochemical and hydromorphological quality elements for the surface water body type from those normally associated with that type under undisturbed conditions.

The values of the biological quality elements for the surface water body reflect those normally associated with that type under undisturbed conditions, and show no, or only very minor, evidence of distortion.

These are the type specific conditions and communities."

Good status

"The values of the biological quality elements for the surface water body type show low levels of distortion resulting from human activity, but deviate only slightly from those normally associated with the surface water body type under undisturbed conditions."

Moderate status

"The values of the biological quality elements for the surface water body type deviate moderately from those normally associated with the surface water body type under undisturbed conditions. The values show moderate signs of distortion resulting from human activity and are significantly more disturbed than under conditions of good status."

Poor status

"Water showing evidence of major alterations to the values of the biological quality elements for the surface water body type and in which the relevant biological communities deviate substantially from those normally associated with the surface water body type under undisturbed conditions, shall be classified as poor."

Bad status

"Water showing evidence of severe alterations to the values of the biological quality elements for the surface water body type and in which large portions of the relevant biological communities normally associated with the surface water body type under undisturbed conditions are absent, shall be classified as bad."

5.2.2. The observed results from the monitoring of the biological quality elements should be compared against the reference conditions for that type and expressed as an Ecological Quality Ratio (Figure 5.2).

Annex V, 1.4.1 (ii)

"In order to ensure comparability of such monitoring systems, the results of the systems operated by each Member State shall be expressed as ecological quality ratios for the purposes of classification of ecological status. These ratios shall represent the relationship between the values of the biological parameters observed for a given body of surface water and the values for these parameters in the reference conditions applicable to that body. The ratio shall be expressed as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero."

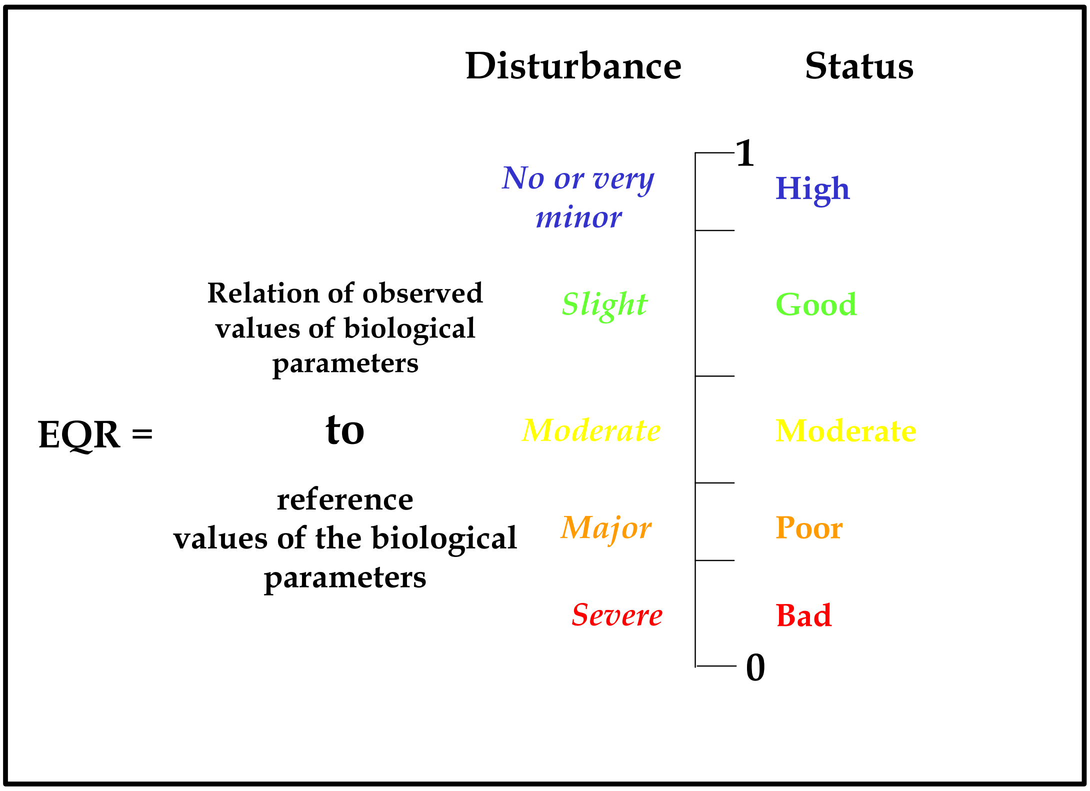

Figure 5.2. **Suggested Ecological Quality Ratio according to Annex V, 1.4.1. The size of the bands differ because the boundaries between classes must align with the normative definitions, not a simple percentage. Note that all the deviations are measured from the reference condition.**

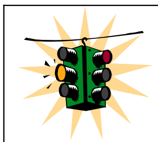
5.2.3. A most critical issue in implementing the WFD will be setting the borders between the high, good and moderate classes, as this determines whether management action is necessary.

Annex V 1.4.1.(iii)
"The value for the boundary between the classes of high and good status, and the value for the boundary between good and moderate status shall be established through the intercalibration exercise…"



Look out! The borders between high and good status and good and moderate status will be set as part of the Intercalibration exercise to be carried out by the Member States. The role of the Commission is to facilitate the information exchange between the Member States. More information on intercalibration can be found in the Intercalibration Guidance (WFD CIS Guidance Document No. 6).

5.2.4. Definitions are given for each of the quality elements at high, good and moderate status in Annex V Tables 1.2.3 and 1.2.4. These definitions can therefore be used to help determine whether a quality element is affected by very minor, slight or moderate anthropogenic influences. The preliminary description of high and good ecological status will, to a large extent, have to rely on existing monitoring data and pressure information in combination with risk assessments. It will be extremely difficult to define the difference between very minor and slight disturbance before the results of monitoring programmes are available.

5.2.5. Environmental objectives are set for water bodies as laid out in Article 4 of the Directive. These are summarised below:

Article 4(1)(a)(i) No Deterioration
"… to prevent deterioration of the status of all bodies of surface water…"

Article 4(1)(a)(ii) Good Status – Default Objective
"Member States shall protect, enhance and restore all bodies of surface water"…"with the aim of achieving good surface water status at the latest 15 years after the date of entry into force of this Directive…"

Article 4(1)(a)(iii) Good Ecological Potential
"Member states shall protect and enhance all artificial and heavily modified bodies of water, with the aim of achieving good ecological potential and good surface water chemical status at the latest 15 years from the date of entry into force of this Directive….."

Article 4(1)(c) Protected Areas
"for protected areas
Member States shall achieve compliance with any standards and objectives at the latest 15 years after the date of entry into force of the Directive, unless otherwise specified in the Community legislation under which the individual protected areas have been established."

Article 4(4) Good Status with an Extended Deadline Derogation
"The deadlines"…"may be extended for the purposes of phased achieved of the objectives for bodies of water, provided that no further deterioration occurs in the status of the affected body of water when all of the following conditions are met…"

Article 4(5) Less Stringent Environmental Objectives Derogation
"Member States shall aim to achieve less stringent environmental objectives"…"when they are so affected by human activity"…"or their natural condition is such that the achievement of these objectives would be infeasible or disproportionately expensive and all of the following objectives are met…"

5.2.6. The results of classification will be used alongside the requirements of Annex II to evaluate the risk of a water body failing its objectives (Figure 5.3).

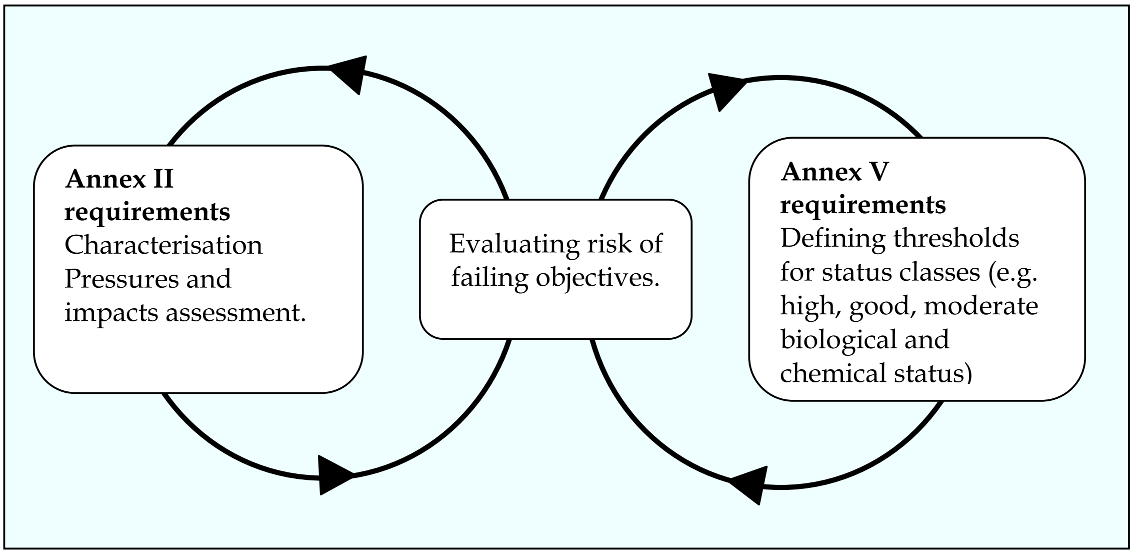


Figure 5.3. The iterative evaluation of the risk of failing objectives.

5.3. BASIC PRINCIPLES UNDERPINNING CLASSIFICATION

Precautionary Principle

> **Preamble (11)**
> *As set out in Article 174 of the Treaty, the Community policy on the environment is to contribute to pursuit of the objectives of preserving, protecting and improving the quality of the environment, in prudent and rational utilisation of natural resources, and to be based on the precautionary principle and on the principles that preventive action should be taken, environmental damage should, as a priority, be rectified at source and that the polluter should pay.*

5.3.1. The EC Treaty sets out the general principles of environmental policy including the precautionary principle. The precautionary principle underpins all environmental legislation.

One Out, All Out Principle

5.3.2. The classification scheme must apply the one-out all-out principle. This means that the ecological status of the water body equates to the lower status of either the biological quality elements or the physico- chemical elements

> **Annex V 1.4.2.(i)**
> *"For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified".*

5.4. QUALITY ASSURANCE AND EXPERT JUDGEMENT

5.4.1. The sources of uncertainty in the classification of ecological status fall into the following categories:

- **Natural Spatial Variability** Within each water body there will be spatial heterogeneity in the microhabitats. This means that, for example, taxonomic richness and composition or the concentration of a contaminant within sediments can vary within the sampling location;
- **Natural Temporal Variability** The taxa present or contaminant in biota at a site will vary naturally over time;
- **Biological Sampling and Analytical Errors.** When e.g. sorting the material in a new macro invertebrate sample and identifying the taxa, some taxa may be missed or misidentified;
- **Chemical Sampling and Analytical Errors.** For chemical quality elements the errors associated with different analytical techniques may vary for the same substance.

5.4.2. Any of these errors or variability may lead to misclassification.

5.4.3. Confidence in the overall classification requires confidence in the

- sampling process;
- analysis; and
- classification.

The Directive gives a clear message on the importance of quality assurance at all stages in the classification process.

Sampling and Analysis

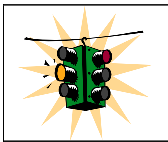
5.4.4. In recognition that different sampling methods and analysis can produce incomparable results, the Directive also specifies the use of ISO/CEN standards, or other national or international standards, where available.

Annex V 1.3.6. Standards for the Monitoring of Quality Elements
"Methods used for the monitoring of type parameters shall conform to the international standards listed below or such other national or international standards which will ensure the provision of data of an equivalent scientific quality and comparability."

5.4.5. To date there are few ISO/CEN standards applicable to the marine environment. However, there is a wealth of international standards, monitoring methods and guidelines available that have been developed by the marine conventions (OSPAR, HELCOM, AMAP, UNEPMAP), or ICES. More information on this is given in the WFD CIS Guidance Document No 7 - Monitoring under the Water Framework Directive.

5.4.6. Quality assurance systems are well developed for some of the marine chemistry determinands through the QUASIMEME Scheme, though not all of the WFD priority substances are covered at present.

5.4.7. BEQUALM is a Europe wide scheme for quality assurance in marine biological effects measurement. The scope of this scheme is being developed further.



Look out! Given the difficulties and expense involved in sampling the marine environment, Member States need to ensure excellent quality assurance and control throughout the sampling and analysis process.

Expert Judgement

5.4.8. In addition to good quality assurance in sampling and analysis, expert judgement will be extremely important in the development of classification tools and in the preliminary 2004 assessment (Figure 5.4).

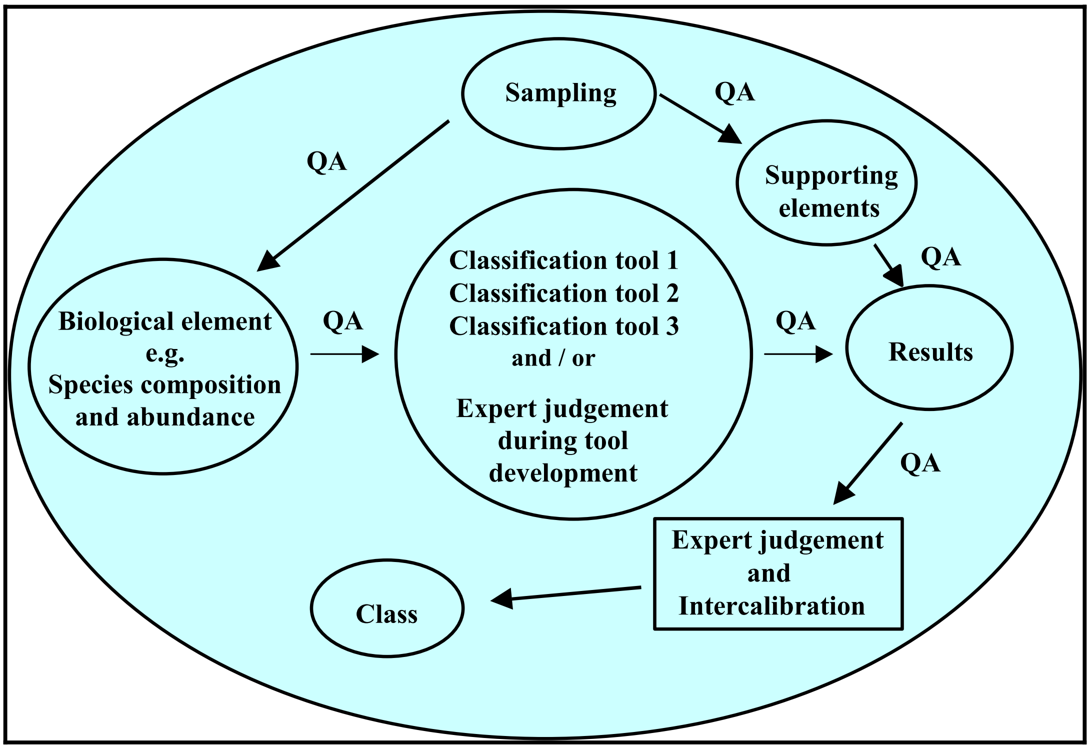


Figure 5.4. The importance of quality assurance and the use of expert judgement through the whole classification process.

Annex V 1.3.4 Frequency of Monitoring
"Frequencies shall be chosen to achieve an acceptable level of confidence and precision. Estimates of confidence and precision attained by the monitoring system shall be stated in the river basin management plan."

5.4.9. In order to quantify the level of confidence, the errors associated with each classification method must be quantified. For some of the biological quality elements there is no or little information on spatial or temporal variability.

5.4.10. Until there is a better understanding of spatial and temporal variability in the marine environment along with adequate marine biological quality control schemes, expert judgement will play an important role in classification.

5.5. CLASSIFICATION OF THE BIOLOGICAL QUALITY ELEMENTS

Phytoplankton

5.5.1. The classification of phytoplankton in transitional and coastal waters must be based upon:
- composition
- abundance
- biomass.

The Directive also mentions transparency conditions and frequency and intensity of blooms.

5.5.2. The WFD presents definitions of phytoplankton at high, good and moderate status.

Transitional Waters Annex V, 1.2.3.

High status	***Good status***	***Moderate Status***
The composition and abundance of the phytoplanktonic taxa are consistent with undisturbed conditions. *The average phytoplankton biomass is consistent with the type-specific physico-chemical conditions and is not such as to significantly alter the type specific transparency conditions.* *Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physicochemical conditions.*	*There are slight changes in the composition and abundance of phytoplanktonic taxa.* *There are slight changes in biomass compared to the type-specific conditions. Such changes do not indicate any accelerated growth of algae resulting in undesirable disturbance to the balance of organisms present in the water body or to the physico-chemical quality of the water.* *A slight increase in the frequency and intensity of the type specific planktonic blooms may occur.*	*The composition and abundance of phytoplanktonic taxa differ moderately from type specific conditions.* *Biomass is moderately disturbed and may be such as to produce a significant undesirable disturbance in the condition of other biological quality elements.* *A moderate increase in the frequency and intensity of planktonic blooms may occur. Persistent blooms may occur during summer months.*

Coastal Waters Annex V, 1.2.4.

High status	*Good status*	*Moderate Status*
The composition and abundance of the phytoplanktonic taxa are consistent with undisturbed conditions. *The average phytoplankton biomass is consistent with the type-specific physico-chemical conditions and is not such as to significantly alter the type specific transparency conditions.* *Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physico-chemical conditions.*	*The composition and abundance of planktonic taxa show slight signs of disturbance.* *There are slight changes in biomass compared to the type-specific conditions. Such changes do not indicate any accelerated growth of algae resulting in undesirable disturbance to the balance of organisms present in the water body or to the quality of the water.* *A slight increase in the frequency and intensity of the type specific planktonic blooms may occur.*	*The composition and abundance of phytoplanktonic taxa show signs of moderate disturbance.* *Algal biomass is substantially outside the range associated with type-specific conditions, and is such as to impact upon other biological quality elements.* *A moderate increase in the frequency and intensity of planktonic blooms may occur. Persistent blooms may occur during summer months.*

Other aquatic flora:

5.5.3. The classification of aquatic fauna in transitional and coastal waters must be based upon:

- composition
- abundance.

The Directive also mentions the presence and absence of disturbance sensitive taxa.

5.5.4. The Directive separates transitional and coastal waters for plants.

5.5.5. The WFD presents separate normative definitions for macroalgae and angiosperms at high, good and moderate status in transitional waters.

Annex V, 1.2.3.

High status	*Good status*	*Moderate status*
Macroalgae:		
The composition of macroalgal taxa is consistent with undisturbed conditions. *There are no detectable changes in macroalgal cover due to anthropogenic activities.*	*There are slight changes in the composition and abundance of macroalgal taxa compared to the type-specific communities. Such changes do not indicate any accelerated growth of phytobenthos or higher forms of plant life resulting in undesirable disturbance to the balance of organisms present in the water body or to the physico-chemical quality of the water.*	*The composition of macroalgal taxa differs moderately from type-specific conditions and is significantly more distorted than at good quality.* *Moderate changes in the average macroalgal abundance are evident and may be such as to result in an undesirable disturbance to the balance of organisms present in the water body.*
Angiosperms:		
The taxonomic composition corresponds totally or nearly totally to undisturbed conditions. *There are no detectable changes in angiosperm abundance due to anthropogenic activities.*	*There are slight changes in the composition of angiosperm taxa compared to the type-specific communities.* *Angiosperm abundance shows slight signs of disturbance.*	*The composition of the angiosperm taxa differs moderately from the type-specific communities and is significantly more distorted than at good quality.* *There are moderate distortions in the abundance of angiosperm taxa.*

5.5.6. The WFD presents joint normative definitions for macroalgae and angiosperms in coastal waters at high, good and moderate status.

Annex V 1.2.4.

High status	*Good status*	*Moderate status*
All disturbance sensitive macroalgal and angiosperm taxa associated with undisturbed conditions are present. *The levels of macroalgal cover and angiosperm abundance are consistent with undisturbed conditions.*	*Most disturbance sensitive macroalgal and angiosperm taxa associated with undisturbed conditions are present.* *The level of macroalgal cover and angiosperm abundance shows slight signs of disturbance.*	*A moderate number of the disturbance sensitive macroalgal and angiosperm taxa associated with undisturbed conditions are absent.* *Macroalgal cover and angiosperm abundance is moderately disturbed and may be such as to result in an undesirable disturbance to the balance of organisms present in the water body.*

Benthic invertebrate fauna

5.5.7. The classification of benthic invertebrate fauna in transitional and coastal waters must be based upon:
- composition;
- abundance.

It also mentions both disturbance sensitive taxa and taxa indicative of pollution.

5.5.8. The WFD presents normative definitions of benthic invertebrate fauna at high, good and moderate status.

Annex V 1.2.3. & 1.2.4.

High status	*Good status*	*Moderate status*
The level of diversity and abundance of invertebrate taxa is within the range normally associated with undisturbed conditions. *All the disturbance-sensitive taxa associated with undisturbed conditions are present.*	*The level of diversity and abundance of invertebrate taxa is slightly outside the range associated with the type-specific conditions.* *Most of the sensitive taxa of the type-specific communities are present.*	*The level of diversity and abundance of invertebrate taxa is moderately outside the range associated with the type-specific conditions.* *Taxa indicative of pollution are present* *Many of the sensitive taxa of the type specific communities are absent.*

Fish fauna

5.5.9. The classification of fish fauna is only required in transitional waters and must be based upon:
- composition
- abundance.

It also mentions disturbance sensitive specie.

5.5.10. The WFD presents normative definitions of the fish fauna at high, good and moderate status for **transitional waters** (Annex V, 1.2.3, 1.2.4).

Annex V 1.2.3.

High status	*Good status*	*Moderate status*
Species composition and abundance is consistent with undisturbed conditions.	*The abundance of the disturbance-sensitive species shows slight signs of distortion from type specific conditions attributable to anthropogenic impacts on physico-chemical or hydromorphological quality elements.*	*A moderate proportion of the type-specific disturbance-sensitive species are absent as a result of anthropogenic impacts on physicochemical or hydromorphological quality elements.*

5.6. CLASSIFICATION OF THE HYDROMORPHOLOGICAL AND PHYSICO-CHEMICAL SUPPORTING ELEMENTS

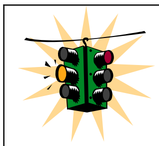
5.6.1. The hydromorphological and physico-chemical elements are supporting elements for the classification of ecological status.

Hydromorphological Elements

5.6.2. The classification of hydromorphological quality elements in transitional and coastal waters must be based upon:

Annex V, 1.1.3. **Annex V,1.1.4.**

Transitional waters (Annex V, 1.1.3)	***Coastal waters (Annex V, 1.1.4)***
Morphological conditions: *depth variation* *quantity, structure and substrate of the bed* *structure of the inter-tidal zone* *Tidal regime:* *freshwater flow* *wave exposure*	*Morphological conditions:* *depth variation* *structure and substrate of the coastal bed* *structure of the inter-tidal zone* *Tidal regime:* *direction of dominant currents* *wave exposure*



Look out! Hydromorphological elements are only included in the classification of high ecological status. For a waterbody to be at high status the biological, hydromorphological and physico-chemical quality elements must be at high status (Figure 5.1).

5.6.3. The WFD presents definitions of the hydromorphological quality elements at high, good and moderate status for **transitional waters** (Annex V, 1.2.3.):

Annex V 1.2.3.

High status	*Good status*	*Moderate status*
Morphological conditions:		
Depth variations, substrate conditions, and both the structure and condition of the inter-tidal zones correspond totally or nearly totally to undisturbed conditions.	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*
Tidal regime:		
The freshwater flow regime corresponds totally or nearly totally to undisturbed conditions.	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*

5.6.4. The WFD presents definitions of the hydrological quality elements at high, good and moderate status for **coastal waters** (Annex V, 1.2.4):

Annex V 1.2.4.

High status	***Good status***	***Moderate status***
Morphological conditions:		
The depth variation, structure and substrate of the coastal bed, and both the structure and condition of the inter-tidal zones correspond totally or nearly totally to the undisturbed conditions.	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*
Tidal regime:		
The freshwater flow regime and the direction and speed of dominant currents correspond totally or nearly totally to undisturbed conditions.	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*

Physico-Chemical Elements

5.6.5. The WFD presents normative definitions of ecological status classifications (Annex V, 1.1.3, 1.1.4). For the purposes of classification of the physico-chemical quality elements in transitional and coastal waters, the following is to be included:

Annex V 1.1.3. and 1.1.4.
General:
- *Transparency*
- *Thermal conditions*
- *Oxygenation conditions*
- *Salinity*
- *Nutrient conditions*

Specific Pollutants:
- *Pollution by all priority substances identified as being discharged into the body of water*
- *Pollution of other substances identified as being discharged in significant quantities into the body of water*

5.6.6. The WFD presents normative definitions of the physico-chemical elements at high, good and moderate status for **transitional** and **coastal waters** (Annex V, 1.2.3, 1.2.4).

Annex V 1.2.3. and 1.2.4.

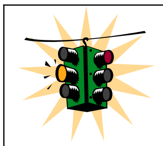
High status	***Good status***	***Moderate status***
General conditions:		
The physico-chemical elements correspond totally or nearly totally to undisturbed conditions. *Nutrient concentrations remain within the range normally associated with undisturbed conditions.* *Temperature, oxygen balance and transparency do not show signs of anthropogenic disturbance and remain within the ranges normally associated with undisturbed conditions.*	*Temperature, oxygenation conditions and transparency do not reach levels outside the ranges established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.* *Nutrient concentrations do not exceed the levels established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*
Specific synthetic pollutants:		
Concentrations close to zero and at least below the limits of detection of the most advanced analytical techniques in general use.	*Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<environmental quality standard).*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*
Specific non synthetic pollutants:		
Concentrations remain within the range normally associated with undisturbed conditions (background levels).	*Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6. without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<environmental quality standard).*	*Conditions consistent with the achievement of the values specified above for the biological quality elements.*

Specific Pollutants

5.6.7. Under 'Chemical and physico-chemical elements supporting the biological elements', the Directive refers to specific pollutants. These are understood to mean substances not included in the chemical status assessment i.e. priority substances for which European EQSs have not yet been agreed or other substance identified as being discharged in significant quantities into the body of water. These may be described as:

a) Specific synthetic pollutants.
b) Specific non-synthetic pollutants.

5.6.8. The word "specific" indicates that not all pollutants listed in Annex VIII, points 1-9. (or any others) must be considered.



Look out! The IMPRESS Guidance Document produced by CIS working group 2.1 (WFD CIS Guidance Document No. 3) provides guidance on how specific pollutants are to be identified in the pressures and impacts analysis.

5.6.9. Specific pollutants are included in ecological status and accordingly there are five class categories. The definitions for specific pollutants at high status are stringent (Annex V Tables 1.2.3. and 1.2.4.).

5.6.10. This definition has been subject to a long political debate (*cf.* OSPAR) and it is clear that no scientific specification can be given for terms such as "close to zero". These issues are being examined by a sub-group of the Expert Advisory Forum on Priority Substances (EAF PS) dealing with Analysis and Monitoring (AMPS). It is recommended that the approach adopted by the EAF PS, AMPS group, be adopted for substances for which national detection limits and background concentrations are to be set.

5.7. THE RELATIONSHIP BETWEEN CHEMICAL AND ECOLOGICAL STATUS

5.7.1. Chemical status refers only to those priority substances for which Environmental Quality Standards (EQSs) are set at the European level.

Annex V, 1.4.3
"Where a body of water achieves compliance with all the environmental quality standards established in Annex IX (existing List I substances, Dangerous Substances Directive), Article 16 (Priority Substances, Annex X) and under other relevant Community legislation setting environmental quality standards it shall be recorded as achieving good chemical status. If not, the body shall be recorded as failing to achieve good chemical status."

5.7.2. Chemical status is only divided into 2 classes; good status and bad status and good status is defined as being less than the EQS.

Relationship between Chemical Status and Ecological Status

5.7.3. Once European EQSs have been established, those substances are **NOT** included in ecological status. There are currently 18 of these from the existing Dangerous Substance Directive. More will be added to this list by the end of 2003 for the Annex X. These EQSs are to be agreed by the Expert Advisory Forum on Priority Substances. Until European EQSs have been agreed, priority substances are part of the ecological status.

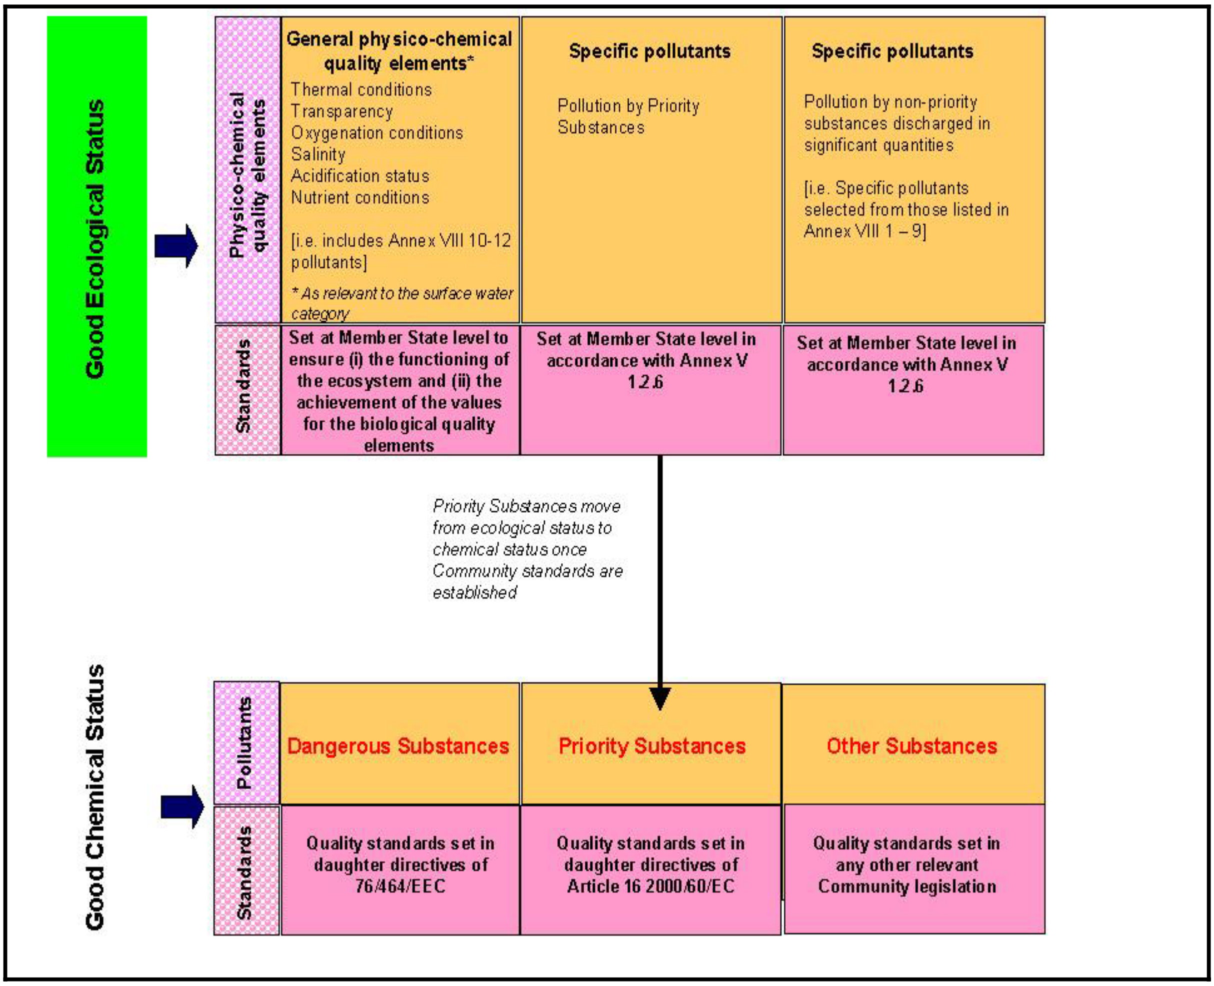


Figure 5.5. The relationship between good ecological status and good chemical status.

Section 6 - Toolbox

6.1. INTRODUCTION

6.1.1. This toolbox contains examples of existing classification schemes and tools for transitional and coastal waters that may be suitable for testing by Member States.

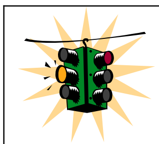
6.1.2. It must be stressed that very little testing of these tools for the purposes of the WFD has been completed yet. Member States are encouraged to test existing classification schemes and tools in their ecoregion and share the results and knowledge gained with experts from other Member States.

6.2. PHYTOPLANKTON

Tools currently available in Member States to assess the ecological status of phytoplankton:

6.2.1. Several tools for classifying the ecological status of phytoplankton in transitional and coastal waters are presented here although no single suggested tool meets all the requirements of the Directive.

6.2.2. **OSPAR – Comprehensive Procedure**
The OSPAR Comprehensive Procedure provides a framework for classifying the trophic status of marine waters into three classes; non-problem, problem and potential problem areas. The criteria include the maximum and mean chlorophyll *a* concentrations (a surrogate for algal biomass) and the presence / concentration of nuisance / toxic algae species, providing some measure of composition and abundance.



Look out! The OSPAR Common Assessment Criteria is an area of study that is still evolving. An example of the agreed criteria at the time of publishing can be found in Section 6.6 of the toolbox. Member States must endeavour to use the latest version of the criteria which at the time of publication of this Guidance Document could be found on the OSPAR website at www.ospar.org/ see Measures, Agreements, Agreement 2002-20.

6.2.3. **Tentative classification tool for phytoplankton under development in France by IFREMER.**

As part of a global classification tool for transitional and coastal waters, France is currently developing a classification tool for phytoplankton, building on the work undertaken for the Shellfish Hygiene Directive.

6.2.4. **EC Shellfish Hygiene Directive: (Council Directive 91/492/EEC of 15 July 1991 laying down the health conditions for the production and the placing on the market of live bivalve molluscs.)**

The purpose of this Directive is to protect public health and includes a requirement to monitor the presence of plankton containing marine biotoxins. Periodic sampling is required to detect changes in the composition and distribution of specific plankton that produce biotoxins. When threshold values are reached, more intensive sampling is undertaken.

<u>Do the available tools available fulfill the requirements of the Directive?</u>

6.2.5. **OSPAR Comprehensive Procedure**

The Comprehensive Procedure is not fully compatible with the requirements of the Directive, but there is the potential to develop the criteria further to fit the Directive's requirements. The procedure includes algae composition but focuses on nuisance and toxic algae rather than the whole community. It also includes a measure of biomass in terms of chlorophyll *a*, which may not be sensitive enough in many areas. The Comprehensive Procedure may have to be adapted for region-specific circumstances, but clearly could be used as a framework for further development of classification tools under the WFD.

6.2.6. **Tentative classification scheme for phytoplankton under development in France by IFREMER**

The threshold values for nuisance/toxic algal species are strongly associated with detecting diarrhetic and paralytic shellfish poisoning species, rather than any measure of ecological status. The links between the two have been the subject of debate among marine scientists for many years. It is clear that the links will need to be further explored. This French classification tool, which is under development, takes into account the abundance of phytoplankton species that are toxic for both human health and flora and fauna as well as those species that are used as an eutrophication indicator. The tool does not include measures of biomass of the population.

6.2.7. Summary of the **tentative classification tool for phytoplankton under development in France by IFREMER**.

1. Phytoplankton species toxic for human health

Species: those species producing DSP, PSP and ASP toxins. *Dinophysis* spp., *Alexandrium minutum, Gymnodinium catenatum, Gymnodinium breve, Prorocentrum minimum.*

Thresholds: DSP negative results of biological tests
PSP 80 µg.100g^{-1}
ASP 20 g. g^{-1} domoic acid

Indicator: Number of weeks of positive results over a 5-year moving period.

Classification:

Table 6.1. Classification of number of positive results of DSP and PSP over a 5 year moving period.

High (blue)	Good (green)	Moderate (yellow)	Poor (orange)	Bad (red)
0	1-5	6-15	16-25	>25

Table 6.2. Classification of number of positive results of ASP over a 5 year moving period.

High (blue)	Good (green)	Moderate (yellow)	Poor (orange)	Bad (red)
0	1	2-3	4-5	>5

2. Phytoplankton species toxic for the flora or the fauna:

Species: *Gymnodinium* cf. *nagasakiense (= G. nagasakiense, G. aureolus, G. mikimotoi), G. splendens (=G. sanguineum), G. breve (=Ptychodiscus brevis), Gyrodinium spirale, Prorocentrum micans (= P. arcuatum = P gibbosum)* (main species) + *P. minimum (= P. balticum = P. cordatum)* (high proportion species), *P. gracile, P. lima (=P marinum); P. triestum (=P. redfieldii)* (low proportion species) + *P. compressum, P. mexicanum* (sporadic species), *Dictyocha* sp., *Heterosigma carterae, Fibrocapsa japonica, Chrysochromulina* spp.

Thresholds: A bloom occurrence means >10^{6} cell.l^{-1}

Indicator: Total number of bloom occurrences over a 5 years moving period.

Classification:

Table 6.3. Classification of the number of blooms of phytoplankton species toxic for the flora or fauna over a 5 year moving period.

High (Blue)	Good (Green)	Moderate (yellow)	Poor (Orange)	Bad (red)
0	1-2	3-5	6-10	>10

3. Phytoplankton species used as a eutrophication indicator

Species: All species

Thresholds: A bloom occurrence means >10^{5} cell.l^{-1}

Indicator: Total number of bloom occurrences over a 5 years moving period.

Classification:

Table 6.4. Classification of the number of blooms of phytoplankton species used as an eutrophication indicator over a five year moving period.

High (Blue)	Good (Green)	Moderate (yellow)	Poor (Orange)	Bad (red)
0-10		11-20	21-40	>40

6.3. OTHER AQUATIC FLORA

Tools currently available in Member States to classify other aquatic flora:

6.3.1. The **OSPAR Comprehensive Procedure** has criteria for macrophytes which are region specific and include a shift from long-lived to short-lived nuisance species. These regional criteria have still to be developed.

6.3.2. **Sweden** has a classification system covering both chemical elements as well as biota. Below is presented some examples from the Swedish classification scheme (angiosperms and rocky shore communities).

6.3.3. **Greece** is developing a classification tool for seaweed and seagrasses.

6.3.4. **Spain** has developed a classification tool for rocky shore communities using multivariate methods.

Do the tools available fulfill the requirements of the Directive?

6.3.5. The OSPAR Criteria for macrophytes could be developed further on a regional basis to take into account WFD requirements.

6.3.6. The Swedish classification tool does not fulfill all the criteria in the WFD, but the tool is being adjusted at the moment and could be tested for the relevant ecoregions.

6.3.7. The Greek tool compares composition and abundance of sensitive and non-sensitive species and could be tested in more areas.

6.3.8. The Spanish tool fulfils the criteria and could be tested in more areas.

6.3.9. Summary of the **Swedish Classification Tool for Angiosperms and Rocky Shore Communities** (Swedish Environmental Protection Agency 2000)**.** A full presentation can be downloaded at: www.environ.se

The term "macrovegetation" refers to plants that are large enough to be readily visible to the naked eye. The species composition of vegetation is affected by two aspects of eutrophication – an increased supply of nutrients, and increased turbidity (increasing number of particles). In some cases, the distribution and species composition of the vegetation can also be influenced by thick layers of ice, other pollutants, wave actions from heavy boat traffic, etc.

The correct interpretation of macrovegetation characteristics requires knowledge of natural variations in the flora associated with various parts of a coast. These variations depend to a large extent on differences in salinity. Also, there are usually important differences between the vegetation of hard bottoms (rocks, boulders, etc.) and that of soft bottoms (sand, clay, mud, etc.). Furthermore, the vegetation of exposed bottoms in outer archipelagos and along open coasts often has a different character from that of more sheltered areas.

The examples below are from the Skagerrak/Kattegat area. The scheme also covers the Baltic proper and the Bothnian Sea.

No special reference values are provided, but the conditions described in class 1 can in most cases be used as a basis for comparisons. Class 1, which is based on data from historical sources and more-or-less pristine areas, is intended to represent natural conditions.

Assessments of the macrovegetation's current conditions should be based on data gathered during the summer.

For the Skagerrak/Kattegat, there are three classifications, which can be used separately or together. A basic precondition for all three is that the salinity of the water must be greater than five parts per thousand.

Table 6.5. Classification of common eelgrass (Zostera marina) beds on soft bottoms in the Skagerrak / Kattegat.

Class	Level	Description
1	Little or none	Dense growth of common eelgrass *(Zostera marina)*, which occurs at depths greater than 6 metres.
2	Moderate	Abundant growth of common eelgrass down to depths of 3 metres, sparse growth to depths of 6 metres.
3	Significant	Common eelgrasses present to depths of 3 metres; loose filamentous algae also common.
4	Serious	Isolated specimens of common eelgrass; loose filamentous algae dominate.
5	Eradication	"Dead" bottom areas, or absence of stationary vegetation. Possibly masses of loose algae and/or bottom layer of luminous white sulphurous bacteria (thread-like or downy substance).

Table 6.6. Classification of sheltered to moderately exposed hard bottom communities in the Skagerrak / Kattegat.

Class	Level	Description
1	Little or none	Dense stands of bladder wrack *(Fucus vesiculosus)* and/or *Ascophyllum nodosum*, (Knobbed or knotted wrack). Epiphytes consist primarily of brown and red algae, and only to a limited extent of green algae or the odd filter feeders. (Green algae may grow more abundantly on cliffs with large quantities of bird droppings.) The undervegetation is varied. In exposed areas, the bladder wrack may lack bladders and may thus be confused with *Fucus evanescens*.
2	Moderate	Dense stands of *Fucus vesiculosus* and/or *Ascophyllum nodosum*, which are partly covered with epiphytic green algae. Also present are *Fucus evanescens* and the red alga *Porphyra purpurea*.
3	Significant	Sparse stands of bladder wrack. *Fucus evanescens* often more abundant, together with belts of green algae. *Porphyra purpurea* may also be common. The bladder wrack is covered with thick growths of green algae and/or filtering animal species.
4	Serious	Sparsely distributed specimens of *Fucus vesiculosus* or *Fucus evanescens*, often covered with thick growths of green algae and/or filtering animal species. Loose drifting algae may also be common.
5	Eradication	Perennial brown algae such as bladder wrack are lacking entirely. Vegetation is dominated by stands of green algae or drifting carpets of algae, usually of the genera *Enteromorpha* (grass kelp) and *Blidingia*, but also *Cladophora*. Alternatively, no algae larger than 1 cm are present; instead, there are "blue-green algae" (cyanobacteria) and other bacteria.

This classification applies to the vegetation of rocky bottoms to depths of 0–1 metre. Inventories should be made during the period 1 June–31 August. Areas affected by heavy layers of ice or intensive boat traffic should not be used.

Table 6.7. Classification of exposed hard bottom communities in the Skagerrak / Kattegat.

Class	Level	Description
1	Little or none	Macroalgae grow at depths greater than 25 metres
2	Moderate	Macroalgae grow at depths of at least 20 metres.
3	Significant	Macroalgae grow at depths of up to 10–25 metres
4	Serious	Macroalgae grow at depths of up to 5 metres. Perennial species are present, but short-lived species dominate.
5	Eradication	Macroalgae grow at maximum depths of up to 1–2 metres. Perennial species are completely lacking.

This classification applies to the vegetation of hard bottoms to depths of 0–20 metres. Inventories require diving, and should be taken during the period 1 April–31 October. Class 1 requires sites that are at least 25 metres deep or have well-developed vegetation at 20 metres.

6.3.10. Summary of the **Greek classification tool for seaweed and seagrasses** (Orfanidis *et al.*, 2002)**.**

A model to estimate the ecological status and identify restoration targets of transitional and coastal waters was developed. Marine benthic macrophytic species (seaweeds, seagrasses) were used to indicate shifts in the aquatic ecosystem from the pristine state with late-successional species (Ecological State Group (ESG) I) to the degraded state with opportunistic (ESG II) species. The first group comprises species with a thick or calcareous thallus, low growth rates and long life cycles (perennials) whereas the second group includes sheet-like and filamentous species with high growth rates and short life cycles (annuals). Seagrasses were included in the first group, whereas Cyanophyceae and species with a coarsely branched thallus were included in the second group.

The evaluation of ecological status into five categories from high to bad includes a cross comparison in a matrix of the ESG and a numerical scoring system. The model could allow comparisons, ranking and setting of priorities at regional and national levels fulfilling the requirements of the WFD. A successful application of the model was realised in selected lagoons of the Macedonian & Thrace region (North Greece) and in the Saronikos coastal ecosystems (Central Greece).

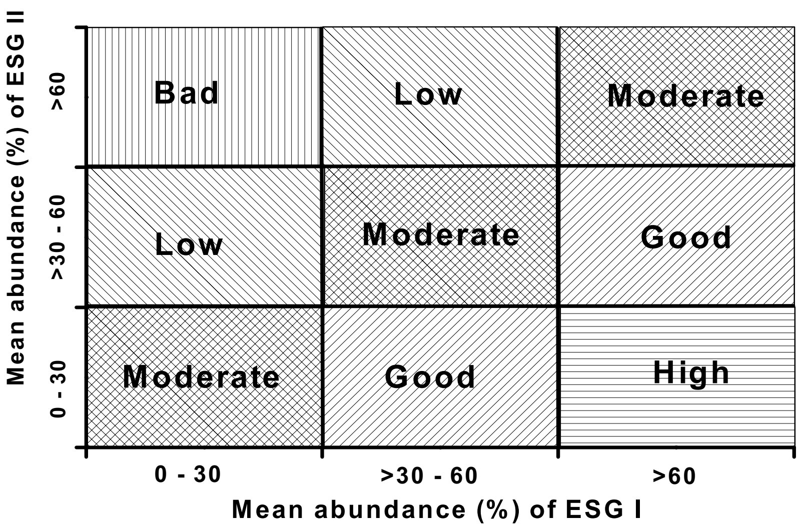


Figure 6.1. A matrix based on the mean abundance (%) of ESGs to determine the ecological status of transitional and coastal waters.

6.3.11. Summary of the **Spanish classification tool for littoral benthic communities using multivariate analysis (**Agència Catalana de l'Aigua and Centre d'Estudis Avançats de Blanes 2002)**.**

A combination of sampling information, the species-coverage and species-biomass data matrices are developed, prior to carrying out the two- or three-dimensional cluster aggregation ordering analyses. Numerous multivariate analyses and hierarchical classification systems can be used. Each of them has advantages and weaknesses and it is up to each researcher to select the method that can best help to interpret the data. One of the multivariate analyses is the PCA (Principal Components Analysis), which uses the Euclidean metric distance, giving too much importance to the abundance/biomass of the species and is useful only if the samples are very similar. The AC (Analysis of Correspondences) uses the X^2 distance, which solves the problem since it gives relatively greater importance to the species with little representation. But it has a double weakness. On one side, the species that appear in very few samples but are very abundant distort the representation, and, on the other, if the samples are located along a strong gradient, the second axis is often a function of the first and then the samples are distributed in the factorial space in the form of an arc (Guttman effect). The DCA (Detrended Correspondence Analysis) has the advantages of the AC (uses the X^2 distance) but avoids the relationship between the second and the first axes, avoiding the Guttman effect. Hence, we have considered that it is the method that best suits our data. Another of the methods in use is the MDS (Multidimensional Scaling) and, more specifically, the non-parametric MDS, recently applied to biological data. One of the advantages of this method is that it requires very few assumptions about the data and the interrelation among samples to apply it effectively. It is a very flexible method that uses ranges of similarity among samples. This new method has not yet been applied to the environmental quality data on the Catalan coast.

The statistics packages that can be used to apply the various multivariate analyses are the CANOCO (Ter Braak, 1988) and the PRIMER (Clark & Warwick, 1994). The objective of hierarchical classification systems is to group the objects in classes or homogenous groups, so that each group is differentiated from the rest with measurements of similarity or of distance among samples. The process builds up increasingly larger groups that include some classes within others. It is presented in the form of a classification tree or dendrogram. The statistical package that will be used to apply this type of classification system will be the PRIMER (Clark & Warwick, 1994). All the analyses have considered the overall set of species (flora and fauna) and have eliminated all those species that appear in less than 2% of the samples, considering that they are hardly representative of the community.

6.4. BENTHIC INVERTEBRATE FAUNA

Tools currently available in Member States to classify benthic invertebrate fauna

6.4.1. **Norway has** a classification tool covering both chemical elements as well as biota.

6.4.2. **Greece** is developing a classification tool for benthic invertebrate fauna.

6.4.3. **Spain** has developed a biotic index to establish the ecological quality of soft bottom benthos. The index has been designed for use with in European estuarine and coastal environments.

6.4.4. The **UK** has started to test the Spanish classification tool within a number of estuaries and this work is to be continued over the forthcoming year.

6.4.5. The **OSPAR Comprehensive Procedure** includes benthic invertebrate fauna as a possible indirect effect of eutrophication in relation to zoobenthos kills from oxygen depletion and / or long-term changes in zoo-benthos biomass and species composition due to nutrient enrichment (see Section 6.6).

Do the tools available fulfill the requirements of the Directive?

6.4.6. All of the existing methods either have limitations to areas they can be used or are not yet widely tested. Methods combining composition, abundance and sensitivity may be the most promising.

6.4.7. Summary of the **Norwegian Classification tool for soft bottom macrofauna and chemical elements (Molvær *et al.*, 1997).**

This Norwegian classification tool uses the faunal diversity of soft bottom macrofauna to assess ecological status. The present form of the system has been used since 1997 and a former version was used from 1993. The system also includes chemical elements and harmful substances in biota and will be adjusted to fit the requirements of the WFD.

The faunal diversity is measured by the Shannon-Wiener index (H') (Shannon and Weaver 1963) and the Hurlbert rarefaction method (Hurlbert 1971). Samples must be quantitative, usually taken with a 0.1 m^2 grab and the samples are sieved on 1 mm screens. Calculations are carried out using four or five pooled samples representing 0.4-0.5 m^2 bottom surface, but is also used for single samples as well.

In addition to fauna the organic content of the sediment is measured in terms of total organic carbon (TOC) using an elemental analyser. The measured values are adjusted for the content of silt and clay (fine fraction) in the sediments. This part of the tool has to be developed further as it does not fit in all areas.

The classification is shown in Table 6.8. The class limits have been set using a large number of samples (> 500) from Norwegian waters taken under different environmental conditions as a reference basis. The limit between class II (good conditions) and class III (fair conditions) has been set at the median value for the indices, i.e. such that classes I and II encompass 50 % of the samples and classes III, IV and V the other 50 %. The further separation between classes has been based on the calculation of percentiles. In addition, expert judgement is used to adjust the values according to the environmental conditions.

Table 6.8. The Norwegian system for classification of environmental status with regard to fauna and total organic content (TOC) of soft sediments.

		Classes				
	Parameters	**I Very Good**	**II Good**	**III Fair**	**IV Bad**	**V Very bad**
Diversity of soft-bottom fauna	Shannon-Wiener index (H'_{log2})					
	Hurlbert's index $ES_{n=100}$					
Sediments	TOC (mg/g)					

6.4.8. Summary of the **Greek classification tool for benthic invertebrate fauna** (Simboura and Zenetos 2002).

The general scheme proposed for the implementation of WFD requirements into Greek coastal waters with the use of macrozoobenthic quality element, comprises three steps leading to the typological justification of water body types and the classification of ecological quality (Simboura & Zenetos, 2002). These steps are briefly described bellow:

a) Definition of habitat types. The outline of the major benthic habitat types occurring in the Mediterranean is essential for linking water body types and benthic habitat types and also for the implementation of classical classification tools as the diversity indices.

b) Definition of benthic indicator species. These are species which according to the literature are either sensitive and characterise a given habitat type by their dominance or exclusive presence in the specific habitat, or are tolerant and indicate instability or pollution. Linking sensitive indicator species to a habitat type serves as a biological justification of the typological definition of a given water body.

c) Development of a new Biotic index (BENTIX). The new index was developed on the basis of former indices which combine the relative percentages of five ecological groups of species with varying degree of sensitivity to disturbance factors, into a single formula. The innovation of the new index lies in the reduction of the ecological groups from five to three and finally to two as described below. Reducing the number of groups has the advantage of avoiding uncertainty regarding the grouping (two groups instead of five) and also of increasing the simplicity of its calculation.

Ecological groups:

Group 1 (GI). Species belonging to this group are very sensitive to disturbance conditions in general. This group correspond to the k-strategy species, with relatively long life, slow growth and high biomass. Also species indifferent to disturbance always present in low densities with non-significant variations with time are included in this group, as they cannot be considered as tolerant by any degree.

Group 2 (GII). This group includes species tolerant to disturbance or stress whose populations may respond to enrichment or other sources of pollution by an increase in density (slightly unbalanced situations). This group also includes second-order opportunistic species, or late successional colonisers with r-strategy: species with short life span, fast growth, early sexual maturation and larvae throughout the year.

Group 3 (GIII). First order opportunistic species (pronounced unbalanced situations), pioneers, colonisers, species tolerant to hypoxia.

The derived formula gives a series of continuous values from 2 to 6, being 0 when the sediment is azoic. By assigning the factor 2 to both groups GII and GIII, the ecological groups are finally reduced to two: the sensitive and the tolerant.

Bentix Index = {6 X %GI + 2 X (% GII + % GIII)}/100

A classification system appears as a function of the Bentix Index including five levels of ecological quality. The Bentix Index is independent from the habitat type and the sample size, does not require exhaustive taxonomic effort and is easy in its calculation and use.

Table 6.9. Pollution Classification, Bentix Index and Ecological Status.

Pollution Classification	BC	Ecological Status
Normal	$4.5 \leq BC < 6$	High
Slightly polluted, transitional	$3.5 \leq BC < 4.5$	Good
Moderately polluted	$2.5 \leq BC < 3.5$	Moderate
Heavily polluted	$2 \leq BC < 2.5$	Poor
Azoic	0	Bad

6.4.9. Summary of the **Spanish marine Biotic Index to establish the ecological quality of soft-bottom benthos within European estuarine and coastal environments** (Borja *et al.*, 2000).

The index developed is based on that first used by Glémarec and Hily (1981) and then by Hily (1984), which utilises soft-bottom benthos to construct a biotic index. Hily (1984) and Glémarec (1986) stated that the soft-bottom macrofauna could be ordered in five groups, according to their sensitivity to an increasing stress gradient (i.e. increasing organic matter enrichment). These groups have been summarized by Grall and Glémarec (1997), as outlined below.

Group I: Species very sensitive to organic enrichment and present under unpolluted conditions (initial state).
Group II: Species indifferent to enrichment, always present in low densities with non-significant variations with time (from initial state, to slight unbalance).
Group III: Species tolerant to excess organic matter enrichment. These species may occur under normal conditions, but their populations are stimulated by organic enrichment (slight unbalance situations).
Group IV: Second-order opportunistic species (slight to pronounced unbalanced situations). Mainly small sized polychaetes: subsurface deposit-feeders, such as cirratulids.
Group V: First-order opportunistic species (pronounced unbalanced situations). These are deposit-feeders, which proliferate in reduced sediments.

The distribution of these ecological groups, according to their sensitivity to pollution stress, provides a biotic index with eight levels, from 0 to 7 (Hily, 1984, Hily *et al.*, 1986; Majeed, 1987). Based upon Hily's model (Hily, 1984; Hily *et al.*, 1986, Majeed, 1987), and in order to improve the index, a single formula was proposed. This is based upon the percentages of abundance of each ecological group, within each sample, to obtain a continuous index (the Biotic Coefficient, BC), where:

$$BC = \{(0 \times \%GI) + (1.5 \times \%GII) + (3 \times \%GIII) + (4.5 \times \%GIV) + (6 \times \%GV)\}/100$$

In this way, use of the Biotic Coefficient can derive a series of continuous values, from 0 to 6, being 7 when the sediment is azoic. The result obtained is a "pollution classification" of a site which is a function of the Biotic Coefficient. Consequently, this represents the benthic community "health", represented by the entire numbers of the Biotic Index.

Table 6.10. Site Pollution classes derived from the Biotic Coefficient.

Site Pollution Classification	Biotic Coefficient	Biotic Index	Dominating Ecological Group	Benthic Community Health
Unpolluted	$0.0 < BC \leq 0.2$	0	I	Normal
Unpolluted	$0.2 < BC \leq 1.2$	1		Impoverished
Slightly Polluted	$1.2 < BC \leq 3.3$	2	III	Unbalanced
Meanly Polluted	$3.3 < BC \leq 4.3$	3		Transitional to pollution
Meanly Polluted	$4.3 < BC \leq 5.0$	4	IV-V	Polluted
Heavily Polluted	$5.0 < BC \leq 5.5$	5		Transitional to heavy pollution
Heavily Polluted	$5.5 < BC \leq 6.0$	6	V	Heavy polluted
Extremely Polluted	Azoic	7	Azoic	Azoic

The index has been validated and has been shown to be able to detect differences between control and contaminated stations (based on the oxygenation at bottom waters, and organic matter and heavy metal content of the sediments). The results were published in Marine Pollution Bulletin (Borja *et al.*, 2000). This index could comply with the requirements of the WFD if combined with measures of abundance and diversity.

6.5. FISH

Tools currently available in Member States to classify fish fauna

6.5.1. No tools are commonly used at the moment in Europe.

6.5.2. Within the **UK** a fish classification tool that was developed for assessing the status of fish communities in estuaries within South Africa is currently being tested.

6.5.3. **Belgium** has developed an estuarine fish index for the Scheldt estuary in Flanders.

Do the available tools fulfill the requirements of the Directive?

6.5.4. The **South African tool being tested by the UK**: includes a measure of both the composition and abundance of the fish fauna.

6.5.5. The **Belgium** classification tool considers the composition of the fish community. The tool does not include a direct measure of abundance.

6.5.6. Summary of the **South African Fish Classification System currently being tested within the UK.**

Introduction
The UK is currently testing a fish classification system developed in South Africa. It is believed that although this approach was developed to assess the status of fish communities in estuaries in South Africa, it could also be applied to European estuaries. Until adequate datasets are available, full testing and refinement of the categories in Table 6.11 to ensure alignment with the normative definitions in the Directive will not be possible.

The approach described below was developed in order to provide a state of the environment indicator and monitoring tool within South Africa. Research was based on a 7-year intensive field sampling program during which 257 estuaries were visited. Using fisheries data and typological classification, biogeographic regions were identified and characterised in order to form six basic estuary types (Harrison et al., 2000).
The fish community structure within each estuary type was investigated, with each estuary type being found to contain a fairly distinctive fish assemblage. From this an Estuarine Classification Scheme was developed. The fish community structure (species richness, composition & relative abundance) of each estuary type within a biogeographic region is described and used as a reference against which each estuary is assessed.

Methods
A multi-method sampling approach was used including seine netting and gill netting. Sampling was generally carried out until no new species were encountered or until all representative habitats within the estuary had been sampled.

The fisheries data was then analysed using the Bray-Curtis similarity co-efficient which was essential for standardisation of sampling effort. The Bray-Curtis coefficient reflects the differences between two samples due to differing community composition and/or differing total abundance. Standardisation removes any effect of the latter.

These results showed that estuarine fish communities within each geomorphological type formed groups which were related to their geographical position & biogeography.

Classification
Having determined the biogeographic boundaries along the South African coast the fish community structure was investigated in relation to estuary type. Data analysis used a combination of hierarchical agglomerative clustering and non-metric multi-dimensional scaling (MDS) using PRIMER (Clark and Warwick 1994).

The concept of biological community health (in relation to the ecosystem) was used and termed 'Fish Community Status (Health)'. It uses the 'Community Degradation Index (CDI)' which measures the degree of dissimilarity (degradation) between a potential fish assemblage and the actual measured fish assemblages. This was then modified into the 'Biological Health Index' (BHI) to provide a measure of the similarity between the potential and actual fish assemblages (Cooper *et al.*, 1994). The index ranges from 0 (poor) to 10 (good). Although the BHI is a useful tool in condensing information on estuarine fish assemblages into a single value (the index is based on presence/absence data) it does not take into account the relative proportions of the species present.

Whitfield and Elliott (2002) give examples of indexes which can be used to condense biological community data and suggest how these parameters could be used to determine the degree of human induced change within an estuary (Table 6.11).

Table 6.11. Fish-based parameters that could be used in a single or composite scoring system (the higher the score, the more natural the system) for monitoring human induced changes within an estuary. Some of the indicators are subjective and qualitative whereas others are more objective and quantitative.

Level	Indicator	Value	Score
1. Fish species	1(a). Species abundance/ biomass	Artificially low	1
		Medium/high	3
	1(b). Keystone/indicator species	Present	3
		Absent	1
	1(c). Alien/introduced species	Presence of alien/introduced species	1
		Absence of alien/introduced species	3
	1(d). Fish species health	Toxic accumulations present	1
		Toxic accumulations absent	3
2. Fish community	2(a). Harrison et al. (2000) Species richness index	Similarity with mean number of taxa:	
		>95% upper confidence interval	5
		Within 95% confidence intervals	3
		<95% lower confidence interval	1
	2(b). Harrison et al. (2000) Bray-Curtis presence/absence similarity index	Similarity with reference condition:	
		>50th percentile similarity	5
		10th – 50th percentile similarity	3
		<10th percentile similarity	1
	2(c). Harrison et al. (2000) Bray-Curtis percentage abundance similarity index	Similarity with reference condition:	
		>50th percentile similarity	5
		10th – 50th percentile similarity	3
		<10th percentile similarity	1
	2(d). Deegan et al. (1997) Estuarine Biotic Integrity Index (number and/or biomass)	EBI value (eight metrics used):	
		Score 31 – 40	5
		Score 21 – 30	3
		Score 0 – 20	1

6.5.7. Summary of the **of an estuarine fish index (EFI) for the Scheldt estuary in Flanders (Belgium)** (Goethals *et al.*, 2002, Adriaenssens *et al.*, 2002a, Adriaenssens *et al.*, 2002b).

The Estuarine Fish Index consists of seven metrics, which each aim to assess a different functional aspect of the estuarine fish assemblages and the integrated quality of the ecosystem.

Description of the score system

Application area: Schelde estuary between Burcht and the Dutch Belgian border, based on salinity measurements

Description of reference conditions: a combination of historical data, data from similar European Estuaries (e.g. Eems-Dollard), expert knowledge and recent data collections.

Data collection: double fykes (type 120/80). Fykes were emptied every three days. Data were based on averaging data collected during one month, recalculated as average catch per day per fyke for a particular month.

Table 6.12. Metrics, variables and scoring system:

Parameter	**Score**				
	1	2	3	4	5
Total number of species	>=4	5-14	15-19	20-24	>24
Type species*					
% Flounder	<=5	>5-10 >50-80			>10-50
% Smelt	<=5	>5-10 >50-80			>10-50
Trophic composition*					
% omnivores	<=1 >80	>1-2.5 >20-80			>2.5-20
% piscivores	<=5 >80	>5-10 >50-80			>10-50
♦**Tolerance**	<1.20	1.20-1.59	1.60-1.99	2-3	>3
Estuarine resident species*					
Number E.R.S.	<2	2	3	4	>4
% E.R.S.	<5 >50	5-10 40-50			>10-<40
% diadromous species	<=5 >80	5-10 >70-80			>10-70
% marine juvenile migrating species	<=10 >90	5-10 >80-90	>20-30 >70-80		>30-70

*adding missing scores 3, 4 (and 5) would be of no ecological relevance, presence of extremely low as well as extreme high number reflect deterioration
♦A tolerance score was attributed to each fish species present.

Overall classification of the estuarine fish index, is the average of the seven metric sores as shown in Table 6.13.

Table 6.13. Estuarine Fish Index quality classes.

colorcode	EFI-value	Classification
	>4,5	excellent
	4-<4,5	good
	3-<4	moderate
	2-<3	bad
	<2	very bad

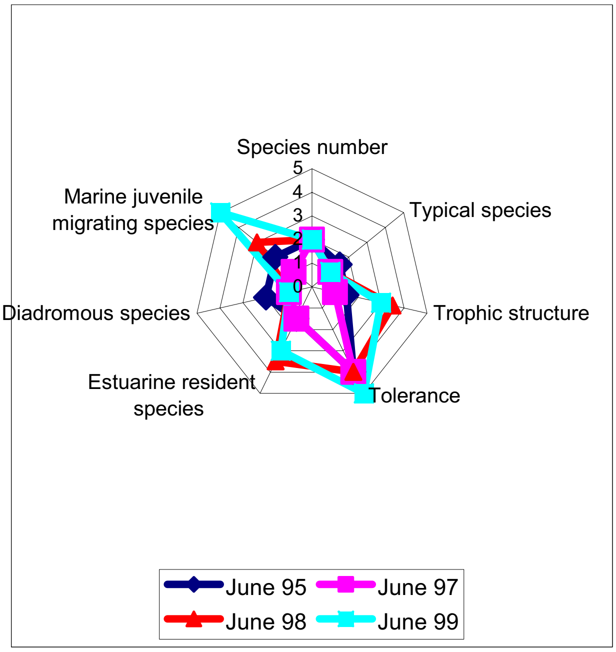

Figure 6.2. Visual presentation of the evolution for the 7 metric scores at Bath.

6.6. CLASSIFICATION SCHEMES FOR BIOLOGICAL QUALITY ELEMENTS

The OSPAR Comprehensive Procedure.

6.6.1. Marine eutrophication is one of the main issues that has been dealt with for over 10 years in the context of the North Sea Conferences (Declarations of London 1987, den Hague 1990, Esbjerg 1995) and OSPAR. Consequently, PARCOM Recommendation 88/2 recommends that OSPAR Contracting Parties:

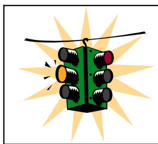
(i) take effective national steps in order to reduce nutrient inputs into areas where these inputs are likely, directly or indirectly, to cause pollution;

(ii) aim to achieve a substantial reduction (in the order of 50 %) in the inputs of phosphorus and nitrogen into these areas between 1985 and 1995, or earlier if possible.

6.6.2. The Comprehensive Procedure for the Identification of the Eutrophication Status of the Maritime Area is a main element of that strategy. The Strategy has the aim of identifying the eutrophication status of all parts of the maritime area by the year 2002 and asks for every effort to be made to combat eutrophication in order to achieve, by the year 2010, a healthy marine environment where eutrophication does not occur.

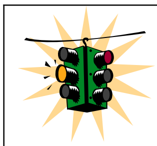
6.6.3. The Comprehensive Procedure consists of a set of assessment criteria that may be linked to form a holistic and common assessment of the eutrophication status of the maritime area. Through this process the OSPAR maritime area is classified into areas which are considered to be problem, potential problem, or non-problem areas with regard to eutrophication. Repeated application of the Comprehensive Procedure should identify any change in the eutrophication status of a particular area.

6.6.4. The Comprehensive Procedure comprises two steps. The first step is the screening procedure which is a broad-brush process to identify obvious non-problem areas with regard to eutrophication. Following that step, all areas not identified as non-problem areas shall be subject to the Comprehensive Procedure.



The Comprehensive Procedure is specifically designed to assess the effects of eutrophication within the North-East Atlantic. This is just one of the pressures that a classification scheme for the WFD should be able to detect.

6.6.5. The following is a summary of the **Comprehensive Procedure** (OSPAR 1997).



Look out! The OSPAR Common Assessment Criteria is an area of study that is still evolving. An example of the agreed criteria at the time of publishing can be found in Section 6.6 of the toolbox. Member States must endeavour to use the latest version of the criteria which at the time of publication of this Guidance Document could be found on the OSPAR website at www.ospar.org/ see Measures, Agreements, Agreement 2002-20.

Assessment criteria and their assessment levels within the Comprehensive Procedure

In order to enable Contracting Parties to undertake a harmonised assessment of their waters subject to the Comprehensive Procedure it was necessary to develop a number of the qualitative assessment criteria into quantitative criteria that could be applied in a harmonised way. On the basis of common denominators within a wide range of qualitative and quantitative information provided by Contracting Parties on the criteria and assessment levels already used, a set of assessment criteria were selected and further developed into quantitative criteria for use in a harmonised assessment. It should also be noted that, although the levels against which assessment is made may be region-specific, the methodology for applying these assessment criteria is based on a common approach.

The assessment criteria selected for further development fall into the following categories (Table 6.14):

Category I ***Degree of nutrient enrichment;***
Category II ***Direct effects of nutrient enrichment;***
Category III ***Indirect effects of nutrient enrichment;***
Category IV ***Other possible effects of nutrient enrichment.***

The main interrelationships between the assessment parameters and their categories are shown in Figure 6.3.

Agreed harmonised assessment criteria and their assessment levels

For each criterion an assessment level has been derived (based on a level of elevation) with the exception of nutrient inputs for which there should also be an examination of trends. The level of elevation is defined, in general terms, as a certain percentage above a background concentration. The background concentration is, in general terms, defined as a salinity related and/or region specific derived spatial (offshore) and/or historical background concentration.

In order to allow for natural variability in the assessment, the level of elevation is generally defined as the concentration of more than 50 % above the salinity related and/or region specific background level (e.g. DIN and DIP concentrations).

Table 6.14. The agreed Harmonised Assessment Criteria and their respective assessment levels of the Comprehensive Procedure.

Assessment parameters		
Category I	**Degree of Nutrient Enrichment**	
	1	**Riverine total N and total P inputs and direct discharges (RID)** Elevated inputs and/or increased trends (compared with previous years)
	2	**Winter DIN- and/or DIP concentrations**[1] Elevated level(s) (defined as concentration > 50% above[2] salinity related and/or region specific natural background concentration)
	3	**Increased winter N/P ratio (Redfield N/P = 16)** Elevated cf. Redfield (> 25)
Category II	**Direct Effects of Nutrient Enrichment (during growing season)**	
	1	**Maximum and mean Chlorophyll a concentration** Elevated level (defined as concentration > 50% above[2] spatial (offshore) / historical background concentrations)
	2	**Region/area specific phytoplankton indicator species** Elevated levels (and increased duration)
	3	**Macrophytes including macroalgae (region specific)** Shift from long-lived to short-lived nuisance species (e.g. *Ulva*)
Category III	**Indirect Effects of Nutrient Enrichment (during growing season)**	
	1	**Degree of oxygen deficiency** Decreased levels (< 2 mg/l: acute toxicity; 2 - 6 mg/l: deficiency)
	2	**Changes/kills in Zoobenthos and fish kills** Kills (in relation to oxygen deficiency and/or toxic algae) Long term changes in zoobenthos biomass and species composition
	3	**Organic Carbon/Organic Matter** Elevated levels (in relation to III.1) (relevant in sedimentation areas)
Category IV	**Other Possible Effects of Nutrient Enrichment (during growing season)**	
	1	**Algal toxins (DSP/PSP mussel infection events)** Incidence (related to II.2)

[1] *Maps, figures and mixing diagrams are available in OSPAR EUC 01/11/1 Annex 5 Appendix 4*
[2] *Other values less than 50 % can be used if justified*

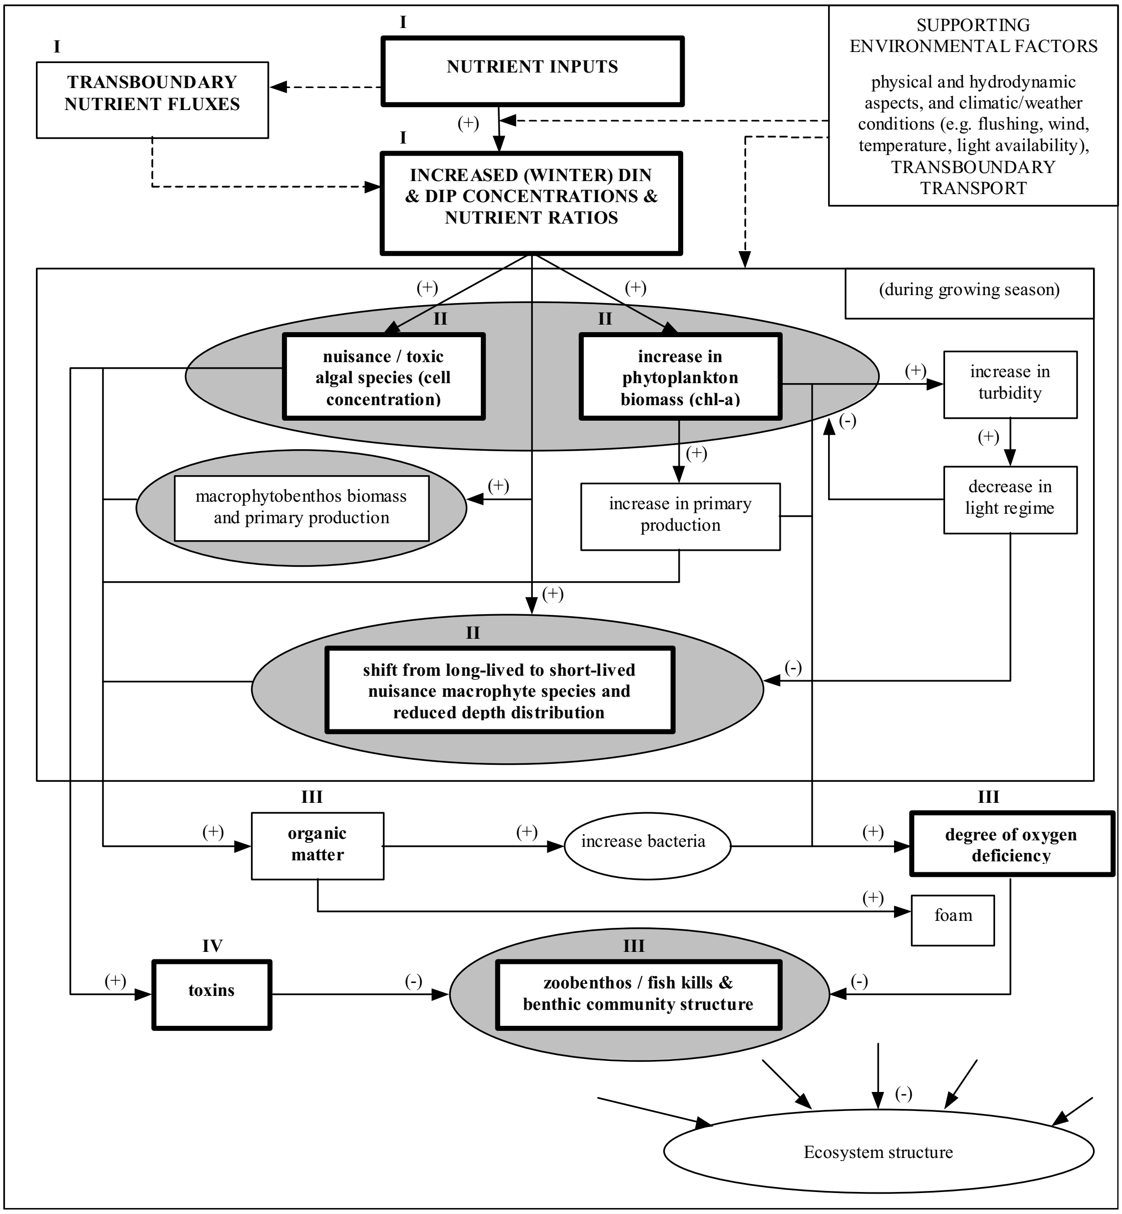


Figure 6.3. Main Interrelationships between the Assessment Parameters (in bold) of the OSPAR Comprehensive Procedure (COMPP).

Parameters for which Assessment Criteria and their assessment levels are identified are shown in boxes with bold lines. Biological elements are shaded. Continuous arrow lines with (+) and (-) indicate 'having stimulating effect upon', and 'having inhibiting effect upon', respectively. Dashed arrow lines indicate 'having influence upon'.

Key:	I	=	Category I	Degree of Nutrient Enrichment (Causative factors)
	II	=	Category II	Direct Effects of Nutrient Enrichment
	III	=	Category III	Indirect Effects of Nutrient Enrichment
	IV	=	Category IV	Other Possible Effects of Nutrient Enrichment

Classification on the basis of the harmonised assessment criteria and their respective assessment levels

For a harmonised holistic assessment of eutrophication status of an area one needs at least to address the common assessment parameters listed in the four categories of the assessment procedure.

To carry out the classification of the eutrophication status of areas of the maritime region each Contracting Party should undertake a number of steps, which are outlined below. The first step is to provide a score for each of the harmonised assessment criteria being applied according to Table 6.14. The second step will bring these scores together according to Table 6.15 to provide a classification of the area. The third step is to make an appraisal of all relevant information (concerning the harmonised assessment criteria their respective assessment levels and the supporting environmental factors), to provide a transparent and sound account of the reasons for establishing a particular status for the area.

Finally this process should enable the classification of the maritime area in terms of problem areas, potential problem areas, and non-problem areas.

Integration of Categorised Assessment Parameters for Classification

The assessment levels of the agreed harmonised assessment criteria form the basis of the first step of the classification.

The next step is the integration of the categorised assessment parameters mentioned in Table 6.14 to obtain a more coherent classification. For each assessment parameter of Categories I, II, III and IV mentioned in Table 6.14 it can be indicated whether its measured concentration relates to a problem area, a potential problem area or a non-problem area as defined in the OSPAR Strategy to Combat Eutrophication. The results of this step are summarised in Table 6.15 and explained below:

a. Areas showing an increased degree of nutrient enrichment accompanied by direct and/or indirect/other possible effects are regarded as **'problem areas**;
b. Areas may show direct effects and/or indirect or other possible effects when there is no evident increased nutrient enrichment, e.g. as a result of transboundary transport of (toxic) algae and/or organic matter arising from adjacent/remote areas. These areas could be classified as **'problem areas'**;
c. Areas with an increased degree of nutrient enrichment, but without showing direct, indirect/ other possible effects, are initially classified as **'potential problem areas'**;
d. Areas without nutrient enrichment and related (in) direct/other possible effects are considered to be **'non-problem areas'**.

Table 6.15. Integration of Categorised Assessment Parameters for Classification (see also Table 6.14.)

	Category I Degree of nutrient enrichment	Category II Direct Effects	Category III and IV Indirect effects/ other possible effects	Classification
A	+	+ and/or	+	problem area
B	-	+ and/or	+	problem area[3]
C	+	-	-	potential problem area
D	-	-	-	non-problem area

(+) = Increased trends, elevated levels, shifts or changes in the respective assessment parameters in Table 6.14.
(-) = Neither increased trends nor elevated levels nor shifts nor changes in the respective assessment parameters in Table 6.14.

Note: Categories I, II and/or III/IV are scored '+' in cases where one or more of its respective assessment parameters is showing an increased trend, elevated level, shift or change.

Supporting Environmental Factors

3.6 Region specific characteristics should be taken into account, such as physical and hydrodynamical aspects, and weather/climate conditions (see Figure 6.3.). These region specific characteristics may play a role in explaining the results of the classification.

[3] *Caused by transport from other parts of the maritime area.*

6.7. SUPPORTING ELEMENTS (HYDROMORPHOLOGICAL AND PHYSICO-CHEMICAL)

Tools currently available in Member States to classify the general elements:

6.7.1. A number of Member States have or are developing classification tools for all or most of the general supporting elements.

6.7.2. In the context of the Marine Strategy, the Commission will initiate action to prepare in collaboration with the regional marine conventions by 2006 a comprehensive assessment of the extent of marine eutrophication on the basis of a harmonised classification tool.

6.7.3. The OSPAR Common Procedure includes nutrients and could be tested by non-OSPAR Contracting Parties. One challenge is how to handle nutrients because the Comprehensive Procedure only handles winter values and has been developed for open seas.

Section 7 – Summary and Conclusions

7.1. Typology

7.1.1. Many Member States have started to develop a typology for transitional and coastal waters. This Guidance Document promotes the development of a harmonised European typology for transitional and coastal waters through the use of the factors for system B.

7.1.2. It is important to establish good links between typing experts in Member States with similar types. Collaboration is the most important process in reaching a harmonised elaboration of a pan-European basis for the implementation of the Water Framework Directive with regard to monitoring and assessment. Communication between experts in different Member States at the typology stage could aid with the implementation of the successive stages of the Directive such as the establishment of reference conditions and the intercalibration exercise.

7.1.3. In cases where Member States of an Ecoregion have similar coastlines experts should work together to develop a common set of surface water body types where possible. This process should result in a smaller number of water body types than if Member States work independently.

7.1.4. In addition, harmonisation of types between Member States should be encouraged to avoid:

- the same surface water body type having different names; or
- different surface water body types having the same name.

Such collaboration should also prevent disharmony in water body types at the borders between neighbouring Member States.

7.2. Reference conditions

7.2.1. At present no reference networks of high status sites for transitional and coastal waters are known to exist within Europe that meet the requirements of the WFD.

7.2.2. To date the majority of monitoring within transitional and coastal waters has concentrated upon polluted areas rather than areas that will meet the definition of high status for the WFD. Data are not always available for all quality elements. Therefore, there is a need to start collecting data as soon as possible for the purposes of deriving biological reference conditions.

7.2.3. It should be emphasised that the derivation of reference conditions that encompass the full natural variability found within a water body type is likely to take many years. It will be an iterative process and will be assisted by the collection of monitoring data for the purposes of the Directive over the forthcoming years.

7.2.4. Member States with similar types should work together where possible in order to enable the sharing of reference conditions.

7.2.5. Member States should collaborate as soon as possible to start developing a European reference network of high status sites.

7.3. CLASSIFICATION

7.3.1. Section 6 of this Guidance is a toolbox which contains existing classification schemes and tools that may be suitable for testing by Member States. Those classification tools which currently exist have generally not been tested against the normative definitions (Annex V Tables 1.2.) and descriptions of high, good and moderate status for each of the quality elements in transitional and coastal waters (Annex V Tables 1.2.3. and 1.2.4.).

7.3.2. As classification tools are developed within Member States, experts are encouraged to exchange information and knowledge gained from testing. It is likely that Member States with similar types may find that they can use the same classification tools.

7.3.3. Once classification tools have been developed and tested it will be possible to develop further guidance on the setting of EQRs and the boundaries between high/good, and good/moderate status.

7.3.4. It is recognised that this Guidance does not give specific advice on setting EQR values and on the statistical issues surrounding classification. It is suggested that this work needs to be taken further. The development of classification tools will require the gathering of data from a wide range of sites at different status. It should be noted that robust classification tools require many years of data, for example, the South African Fish Classification tool in Section 6.5.6. was developed after seven years of intensive data collection.

7.4. THE PROMOTION OF COMMUNICATION

7.4.1. The establishment of the COAST working group has brought together experts from across Europe who are involved in the implementation of the WFD with regard to transitional and coastal waters.

7.4.2. The establishment of the COAST working group has highlighted that communication and collaboration between experts from different Member States is an important and integral part in the implementation of all parts of the Directive. Communication and collaboration between those people who are implementing the Directive both within and between Member States is essential to ensure the effective and integrated implementation of the Directive both within Member States and across Europe and to exchange knowledge and experience.

Annex A – Key Activities and the Working Groups of the Common Implementation Strategy

Key Activity 1: Information Sharing

1.1. Tools for Information sharing
1.2. Raising Awareness

Key Activity 2: Develop Guidance on Technical Issues

2.1. Guidance on the analysis of pressures and impacts
2.2. Guidance on the designation of heavily modified bodies of water
2.3. Guidance on classification of inland surface water status and identification of reference conditions
2.4. Guidance on the development of typology and classification systems of transitional and coastal waters
2.5. Guidance for establishing the intercalibration network and intercalibration exercise
2.6. Guidance on economic analysis
2.7. Guidance on monitoring
2.8. Guidance on tools on assessment and classification of groundwater
2.9. Guidance on best practices in river basin management planning

Key Activity 3: Information and Data Management

3.1. Development of a shared Geographical Information System

Key Activity 4: Application, testing and validation

4.1. Integrated testing of guidelines in pilot river basins

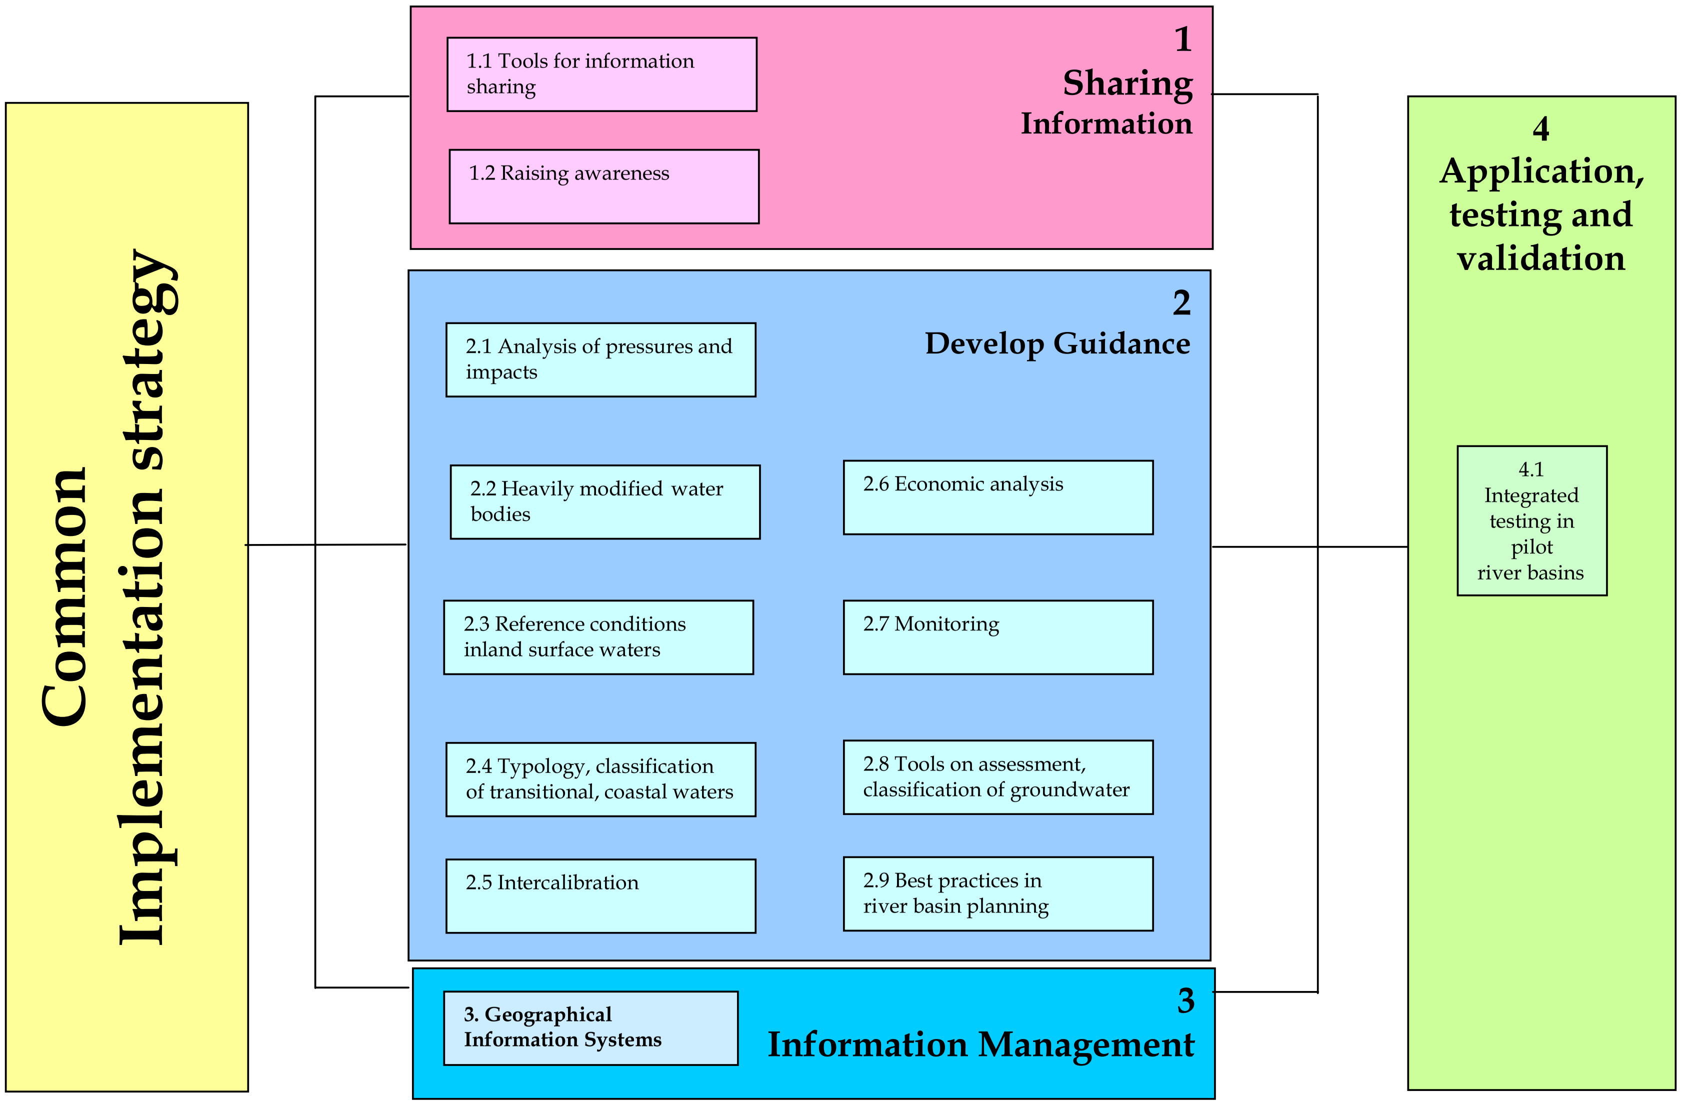

Figure A.1. Overall structure of the Common Implementation Strategy.

Annex B – Members of the COAST Working Group

This list is by no means exhaustive. There were many other people who had an input to the writing of the Guidance Document.

Annex C – List of Reference Conditions Studies

The following table lists all the pilot studies that were carried out within the COAST working group. It is recognised that not all of these areas are in high status. Some are 'best of type' and may equate to good status.

For further information regarding these pilot studies please contact one of the COAST representatives from the respective Member State.

Table C.1. List of Pilot Studies.

Site	Member State	Coastal or Transitional
Randers Fjord	Denmark	Coastal
Rio Formosa, (mesotidal shallow ria)	Portugal	Coastal
Mira Estuary, (Mesotidal torrential estuary)	Portugal	Transitional
Loch Creran and Loch Ardbhair, Scotland	United Kingdom	Coastal
Strangford Lough, Northern Ireland	United Kingdom	Coastal
Northern part of South Evvoikos Gulf	Greece	Coastal
Southern part of South Evvoikos Gulf	Greece	Coastal
Tsoukalio, Rhodia and Tsopeli lagoon complex	Greece	Transitional
North Sea Skagerrak Open Rocky Coast	Norway	Coastal

Annex D - Glossary

Term	Definition
AMAP	Arctic Monitoring and Assessment Programme established in 1991 to implement certain components of the Arctic Environmental Protection Strategy.
Angiosperm	Flowering plant.
Bar-built estuary	An estuary characterised by a bar across the mouth. Usually associated with the availability of large volumes of sediment and a restricted tidal range.
Barcelona Convention	Convention for the Protection of the Mediterranean Sea against Pollution adopted in Barcelona on 16 February 1976.
Baseline for Territorial Waters	According to the United Nations Convention on the Law of the Sea the baseline is measured as the low-water line except along the mouths of estuaries and heads of bays where it cuts across open water. Along highly indented coastlines, bays, mouths of estuaries or coastlines with islands, the baseline can be drawn as a straight line. Each Member State has a legislative baseline associated with this definition.
Benthic Invertebrate Fauna	Invertebrate animals living at least for part of their lifecycles on or in the benthic substrates of rivers, lakes, transitional waters or coastal waters
BEQUALM	Biological Effects Quality Assurance in Monitoring Programmes.
Birds Directive	Council Directive 79/409/EEC of 2 April 1979 on the conservation of wild birds
Catchment	Refer to definition of 'River Basin' in Article 2 of the WFD (2000/60/EC)
Deterioration	A reduction in quality of one or more of the quality elements.
Diffuse Source Pollution[4]	Pollution which originates from various activities, and which cannot be traced to a single source and originates from a spatially extensive land use (e.g. agriculture, settlements, transport, industry). Examples for diffuse source pollution are atmospheric deposition, run-off from agriculture, erosion, drainage and groundwater flow.
Discharge[5]	The release of polluting substances from individual or diffuse sources in the installation through effluent directly or indirectly into water bodies as defined under Article 2 (1) of Directive 2000/60/EC.
Diurnal tidal cycle	Tide which has a period or cycle of approximately one tidal day (about 25 hours). Diurnal tides usually have one high and one low tide each day.

[4] *Interim working definition. Discussions in the context of the WFD implementation are ongoing.*
[5] *Interim working definition. Discussions in the context of the WFD implementation are ongoing.*

Term	Definition
Ecological Quality Ratio	Ratio representing the relationship between the values of the biological parameters observed for a given body of surface water and values for these parameters in the reference conditions applicable to that body. The ratio shall be represented as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero (Annex V 1.4(ii)).
Eco-region	The geographical areas illustrated in Annex XI Maps A (rivers and lakes) and B (transitional waters and coastal waters).
EU Marine Strategy	Part of the 6th Environment Plan in order to develop a strategy for the marine environment in collaboration with all major stakeholders. The aim is for a joint Europe wide assessment to be published by 2010.
Habitats Directive	Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora.
HELCOM Convention	Convention on the Protection of the Marine Environment of the Baltic Sea Area, 1992 which entered into force on 17 January 2000 (otherwise known as the Helsinki Convention).
Hydromorphology	The physical characteristics of the shape, the boundaries and the content of a water body. The hydromorphological quality elements for classification of ecological status are listed in Annex V.1.1 and are further defined in Annex V.1.2 of the Water Framework Directive.
ICES	International Council for the Exploration of the Sea which coordinates and promotes marine research in the North Atlantic.
Impact	The environmental effect of a pressure (e.g. fish killed, ecosystem modified).
Intercalibration	An exercise facilitated by the Commission to ensure that the high/good and good/moderate class boundaries are consistent with the normative definitions in Annex V Section 1.2 of the Directive and are comparable between Member States (see Guidance produced by WG 2.5) (Annex V 1.4. (iv)).
Isohaline	A line connecting points of equal salinity (OSPAR QSR 2000 North Sea).
Lagoon	Isolated saline water. Enclosed bodies of water, separated or partially separated from the sea.
Macrophyte[6]	All aquatic higher plants, mosses and characean algae, but excluding single celled phytoplankton or diatoms.
Non-Indigenous Species	An introduced species that would not naturally occur in that water body.
OSPAR Common Procedure	The Common Procedure for the Identification of the Eutrophication Status of the OSPAR Maritime Area.
OSPAR Convention	The Convention for the Protection of the Marine Environment of the North-East Atlantic which replaces the former Oslo and Paris Conventions. The Convention entered into force on 25 March 1998.

[6] *Interim working definition. Discussions in the context of the WFD implementation are ongoing.*

Term	Definition
Phytoplankton	Unicellular algae and cyanobacteria, both solitary and colonial, that live, at least for part of their lifecycle, in the water column of surface water bodies.
Point source pollution	Pollution arising from a discrete source , e.g. the discharge from a sewage treatment works
Pressure[7]	The direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry of surface and groundwater bodies.
QUASIMEME	Quality Assurance in Marine Environmental Monitoring in Europe.
RAMSAR Convention	The Convention on Wetlands, signed in Ramsar, Iran, in 1971, is an intergovernmental treaty which provides the framework for national action and international cooperation for the conservation and wise use of wetlands and their resources.
RDM – INSPIRE	Reference Data and Metadata - Inspire Working Group
Reference conditions	For any surface water body type reference conditions or high ecological status is a state in the present or in the past where there are no, or only very minor, changes to the values of the hydromorphological, physico-chemical, and biological quality elements which would be found in the absence of anthropogenic disturbance. Reference conditions should be represented by values of the biological quality elements in calculation of ecological quality ratios and the subsequent classification of ecological status.
Register of Protected Areas	A register of areas lying within the river basin district which have been designated as requiring special protection under specific Community legislation for the protection of their surface water and groundwater, or for the conservation of habitats and species directly depending on water (see Annex IV). This register must be completed by December 2004 (Art 6, 7 and Annex IV).
River Basin Management Plan	A plan that must be produced for each River Basin District within a Member State in accordance with Article 13. The plan shall include the information detailed in Annex VIII.
Salt marsh	An area of coastal grassland that is regularly flooded by seawater.
Shellfish Waters Directive	Council Directive of 30 October 1979 on the quality required of shellfish waters (79/923/EEC).
Specific Pollutants	Pollution by all priority substances defined as being discharged into the body of water; and pollution by other substances identified as being discharged in significant quantities into the body of water (Annex V, 1.1)
Specific Non-Synthetic Pollutants	Naturally occurring priority substances identified as being discharged into the body of water and other substances identified as being discharged in significant quantities into the body of water (Annex V 1.1).

[7] *Interim working definition. Discussions in the context of the WFD implementation are ongoing.*

Term	Definition
Specific Synthetic Pollutants	Man-made priority substances identified as being discharged into the body of water and other substances identified as being discharged in significant quantities into the body of water (Annex V 1.1)
Strategic Co-ordination Group	A group led by the Commission with participants from all Member States which was established to co-ordinate the work of the different working groups of the Common Implementation Strategy.
Taxa	Taxonomic groups of any rank.
Territorial waters	The breadth of waters extending out to 12 nautical miles from the baseline defined under the United Nations Convention on the Law of the Sea, 1982.
Toxic Algae	Species of algae that produce harmful toxins.
Transboundary	Crossing the boundary between Member States, River Basin Districts etc.
UNEPMAP	United Nations Environment Programme Mediterranean Action Plan.
Unit cost	The cost of producing one unit of a product.**
Urban Waste Water Treatment Directive	Council Directive of 21 May 1991 concerning urban waste water treatment (91/271/EEC).
Wetland	Refer to Guidance on wetlands currently under preparation.

ISSN 1725-1087

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

In the context of this strategy, an informal working group dedicated to prepare guidance for the technical protocol of the Intercalibration required in the Directive has been set up. The main (short-term) objective of this working group, launched in June 2001, was the development of a non-legally binding and practical Guidance Document on the technical protocol for the establishment of the intercalibration network and the intercalibration exercise of the Water Framework Directive. The Commission's Directorate General, Joint Research Centre (Institute of Environment and Sustainability) has the responsibility of the leadership and co-ordination of the working group that is composed of technical experts from governmental and non-governmental organisations.

The present Guidance Document is the outcome of this working group. It contains the synthesis of the output of the INTERCALIBRATION working group activities and discussions that have taken place since June 2001. It builds on the input and feedback from a wide range of experts and stakeholders from both EU Member States and candidate countries that have been involved throughout the process of guidance development through meetings, workshops, conferences or electronic communication media, without binding them in any way to its content.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined this guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders of the Joint Research Centre, for preparing this high quality document.

We recognise that the Guidance Document represents a significant first step towards the elaboration of a comprehensive approach for intercalibration as required under the directive.

The Water Directors agreed that the document must be developed further during 2003 and beyond. It was stressed that the elaboration of an intercalibration system in line with the requirements of the Water Framework Directive was a major challenge. Pragmatic solutions need to be developed which bridge the gap between the technical and scientific possibilities and the formal requirements. As expressed in the guidance, a step-wise approach should be developed with improvements and refinements being introduced in the light of experience and new information.

The Water Directors highlighted that the status of the document is as an interim product, still under active development.

We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work. Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the guidance is applicable in practice. We also invite the Working Group to come forward with a further developed document by the end of 2003 taking account of the above comments.

Table of Contents

Introduction - A Guidance Document: What for?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the guidance for the procedure of establishment of the intercalibration network and the execution of the intercalibration exercise ensuring comparability of biological monitoring results between the Member States, as required by the Directive.

To whom is this Guidance Document addressed?

If this is your task, we believe the guidance will help you in doing the job, whether you are:

- **Carrying out the analysis for ecological quality classification of surface waters yourself;**
- **Leading and managing experts undertaking the ecological quality classification;**
- **Using the results of the classification for selection of the intercalibration sites**, **or**
- **Reporting on the results of the classification of the ecological quality of the intercalibration sites to the European Union, as required by the Directive.**

What can you find in this Guidance Document?

- **Common understanding of Water Framework Directive intercalibration requirements**
- Extraction and description of the relevant text concerning intercalibration from the Directive, Annex V;
- Agreement on what this text means in practical terms.

- **Synthesis of the intercalibration process: problems and possible solution**
- Description of the timetable of the intercalibration process;
- Description of practical problems in requirements of the Directive in relation to the implementation timetable in Member States;
- Possible solutions to these problems on short-term and long term basis;
- Possible implications of limited intercalibration.

- **Description of a practical procedure of the intercalibration process (Figure 1)**

- **Practical organization for the selection of intercalibration sites**
- Roles of Member States and the Commission in the site selection process;
- Procedure, timetable, and criteria for the selection of water body types for intercalibration;
- Procedure, timetable and criteria for the selection of intercalibration sites;
- Deliverables and milestones of the intercalibration process;
- Artificial and heavily modified water bodies and the intercalibration network;
- Criteria for the selection of intercalibration sites.

- **Preliminary technical protocol for the intercalibation exercise**
- Stepwise description of the intercalibration exercise and the tasks of the participants;
- Guidance on data collection and data exchange;
- Reporting of the classification results;
- Expected outcome of the intercalibration exercise.

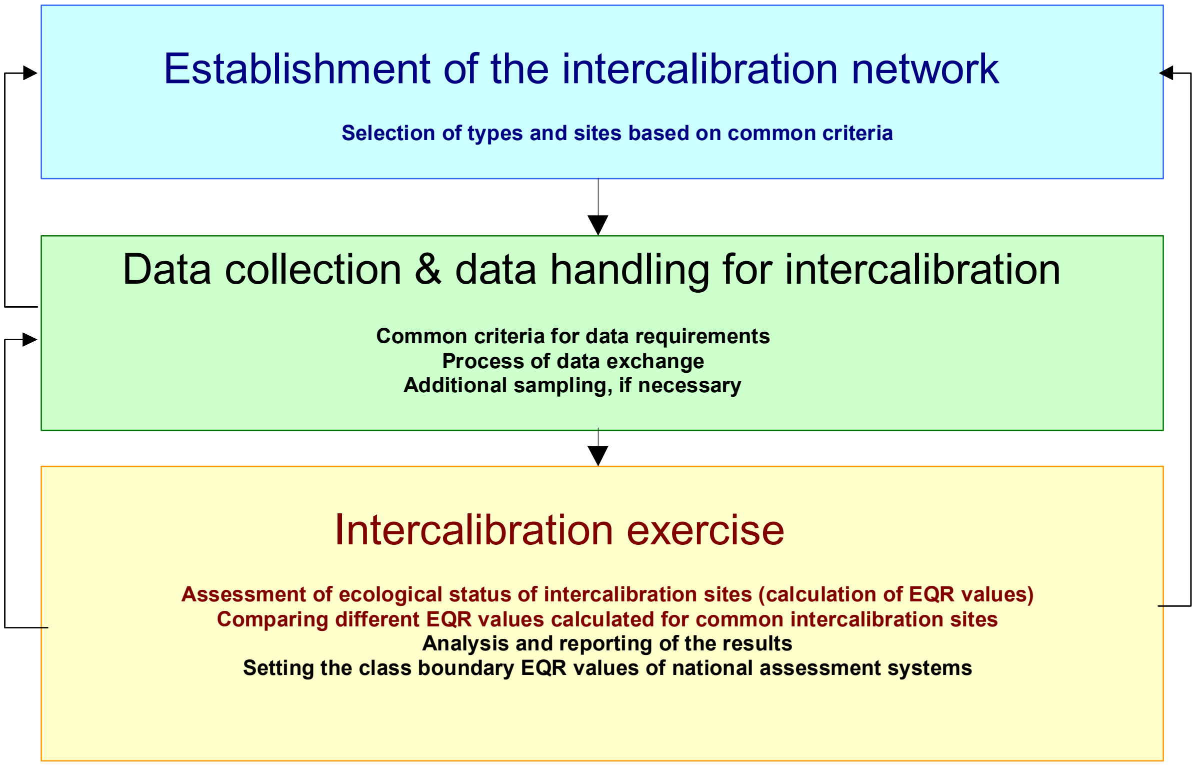

Figure 1 Structure of the guidance for the process of Intercalibration

	***Look out! The methodology from this Guidance Document must be adapted to regional and surface water category specific circumstances*** *The Guidance Document describes an overall approach for the selection of intercalibration sites and the intercalibration process. Because of the diversity of the surface waters and their natural conditions in the European Union, the intercalibration process needs to be tailored for the different ecoregions and surface water categories. To achieve this, a procedure is proposed involving experts from all Member States.*

	***Look out! What you will not find in this Guidance Document*** • *Guidance on how to calculate Ecological Quality Ratios for different quality elements is not included, because:* - *This will depend on the assessment method and metrics that each MS chooses for the assessment of their surface water quality (this is addressed in the WFD CIS Guidance Document No. 7 - Monitoring);* - *This will depend on the method that each MS chooses for establishing reference conditions (this is addressed in the WFD CIS Guidance Document No.s 10 and 5 - REFCOND and COAST).* • *Guidance on a common understanding and more specific interpretations of the normative definitions of the quality classes given in the Directive is not included, because:* - *The REFCOND and COAST working groups have started to address these issues, and (to a certain extent) will address these in their Guidance Documents (WFD CIS Guidance Documents No. 10 and 5 respectively).*

	- *It is proposed that water category and type specific criteria for the normative definitions of the high-good and good-moderate class boundaries will be developed by expert groups as a part of the continuation of the ECOSTAT cluster (REFCOND, COAST, and Intercalibration WGs), building on the present Guidance Documents.*

Section 1 – Implementing the Directive: Setting the scene

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

December 2000: A milestone for water policy

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the Water Framework Directive.

The Water Framework Directive: New challenges in EU water policy

What is the purpose of the Directive?

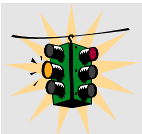
The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);
- To carry out intercalibration of the surface water ecological quality status assessment systems by 2006 (*Annex V*);
- To make operational the monitoring networks by 2006 (*Article 8*);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).



Look out!
Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin management including those which are beyond the scope of the Water Framework Directive such as flood protection and flood prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** be local, regional or national, for an effective management of all waters;
- **Integration of water management from different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.

What is being done to support implementation?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include public consultation , development of national guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding guidance (see *Annex A*). A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision body for the Common Implementation Strategy.

The working group 2.5. Guidance for establishing the intercalibration network and intercalibration exercise

A working group was created for dealing specifically with the issue of the intercalibration process. The main short-term objective of this working group (named shortly: Intercalibration) has been the development of a non-legally binding and practical guidance for the process of intercalibration of the surface water ecological quality assessment systems required by the Water Framework Directive. The members of the working group are environmental officers, technical experts, and researchers from European Union Member States, from a limited number of candidate countries to the European Union and from organisations involved in the standardisation, assessment and reporting of the ecological status of surface waters (European Environment Agency, European Water Topic Centre, and CEN).

To ensure an adequate input and feedback during the guidance development phase and to evaluate earlier versions of the Guidance Document, interaction with other working groups and relevant research projects has been an integral part of the activities (Fig. 2). The Intercalibration working group has organised three workshops, including a joint workshop with REFCOND[1],. Representatives from the working groups COAST[2], IMPRESS[3], MONITORING[4], HMWB[5], and Pilot River Basins[6], participated in the workshops.

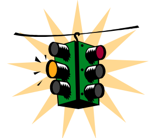
[2] *Working group 2.4 Guidance on the development of typology and classification systems of transitional and coastal waters*
[3] *Working group 2.1 Guidance on the analysis of pressures and impacts*
[4] *Working group 2.7 Guidance on monitoring*
[5] *Working group 2.2 Guidance on designation of heavily modified bodies of water*
[6] *Working group 4.1 Integrated testing of guidelines in pilot river basins*

Additionally, expert drafting group meetings were held with the aim to draft and define criteria of selection of types and sites for the intercalibration network for rivers, lakes, and coastal & transitional waters.



Look out! You can contact the experts involved in the planning and execution of the Intercalibration process
*The list of Intercalibration Working Group members with full contact details can be found in Annex **B**, if you want to know the status is the intercalibration process in your country.*

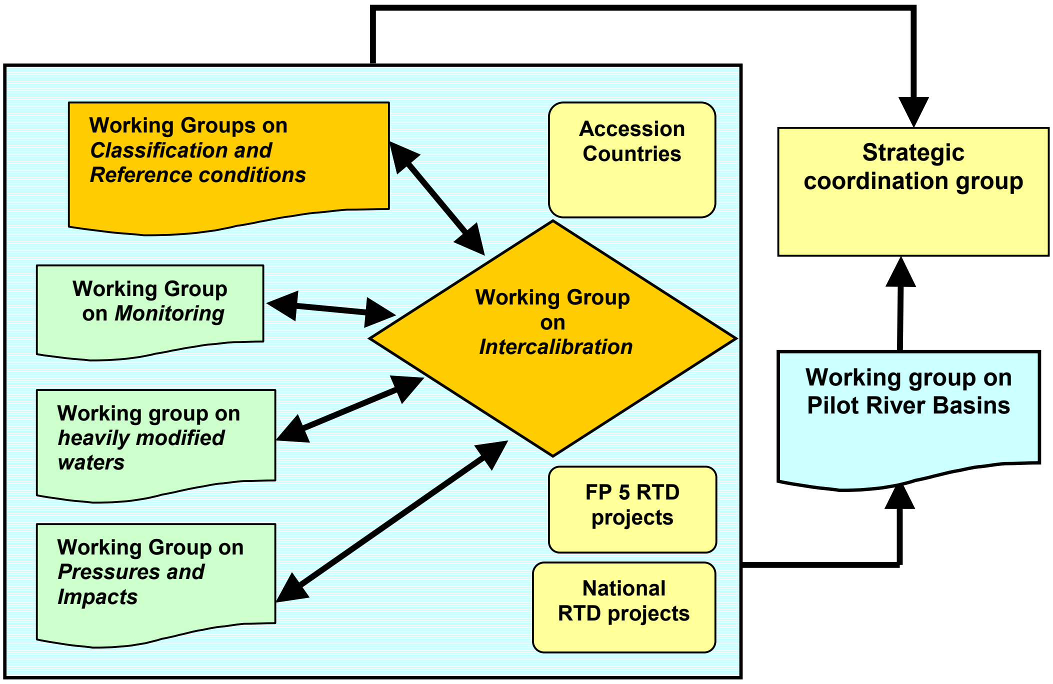


Figure 2 *Links between Common Implementation Strategy Working Groups and other research activities, relevant for the information needs of the Working Group on Intercalibration.*

Developing the Guidance Document: an interactive process

Within a very short time period, a large number of experts have been involved in the different stages of the development of this Guidance Document. The process has included the following activities:

- **Regular communication through internet and emails** of the 30+ members of the Intercalibration Working Group;
- Organisation of **three workshops** to present and discuss the intermediate draft documents and activities:
  - Kick-off meeting with participation of REFCOND, IMPRESS, and HMWB working groups (June 2001, JRC-Ispra, Italy);
  - Jointly with the REFCOND, with participation of COAST working group and WWF representatives (December 2001 – JRC, Ispra, Italy);
  - Workshop for discussing and evaluating the draft Guidance Document, including experts from interested candidate countries (June 2002 – JRC, Ispra, Italy).
- A series of three **expert drafting group meetings** to establish more specific criteria for selection of types and sites for the intercalibration network for rivers, lakes and coastal and transitional waters, and discussion of obstacles and potential solutions of the intercalibration process (March and April 2002 – JRC, Ispra, Italy); you can find the papers produced by the expert drafting groups on CIRCA[7];
- Interactions with relevant **5th Framework Programme RTD-projects**; participation of their experts in workshops and expert drafting group meetings, and presentations of WFD Intercalibration issues in the meetings of research projects (AQUEM[8], STAR[9], FAME[10], CHARM[11]);
- Regular **interactions with experts from other working groups of the Common Implementation Strategy**, including joint drafting of documents, regular email exchange of documents and participation in relevant workshops of the other working groups (mainly with REFCOND & COAST, IMPRESS, HMWB, Monitoring and Integrated testing of guidance in pilot river basins). In spring 2002, an Ecological Status Cluster was formed of the three working groups closely linked to each other (Intercalibration, REFCOND and COAST).

Section 2 – Common understanding of the text and terms related to intercalibration requirements

In this Section the common understanding and the implications of the relevant parts of the Annex V and Article 21 of the Directive, concerning Intercalibration, and other relevant legal texts[12] are presented and briefly discussed.

Water Framework Directive, Annex V:

1.4. Classification and presentation of ecological status

1.4.1. Comparability of biological monitoring results

WFD Annex V, 1.4.1 only deals with **biological** monitoring results, implying that the intercalibration exercise described below includes only the biological quality elements, not ecological status as a whole.

(i) Member States shall establish monitoring systems for the purpose of estimating the values of the biological quality elements specified for each surface water category or for heavily modified and artificial bodies of surface water.

Monitoring systems should estimate "values" for the category-specific **biological** quality elements (example: aquatic flora, benthos, and fish for rivers). For artificial and heavily modified water bodies biological quality elements to be monitored should be those used in the most applicable category (example: lake quality elements for reservoirs).

In applying the procedure set out below to heavily modified or artificial water bodies, references to ecological status should be construed as references to ecological potential.

"Applying the procedure set out below" implies that **artificial or heavily modified water bodies should be considered in the intercalibration (but not as a separate category)**, using maximum ecological potential as reference (see Section 4.3).

Such systems may utilise particular species or groups of species which are representative of the quality element as a whole.

In order to assess which particular species or groups are "representative" for the quality element as a whole one should take into account the definitions for high, good and moderate status for the different quality elements (WFD Annex V, 1.2.1). (Example: benthic invertebrate fauna indicators in rivers must be able to show changes in composition/abundance, the ratio of disturbance sensitive taxa to insensitive taxa, and diversity).

Monitoring systems should be able to detect anthropogenic impact from different kinds of pressures (Example: a saprobic index that is very sensitive to eutrophication pressures could be insensitive to heavy metal pollution).

[12] *Decision 1999/468/EC, Article 205(2) of the Treaty (see Annex C).*

(ii) In order to ensure comparability of such monitoring systems, the results of the systems operated by each Member State shall be expressed as ecological quality ratios for the purposes of classification of ecological status.

These ratios shall represent the relationship between the values of the biological parameters observed for a given body of surface water and the values for these parameters in the reference conditions applicable to that body. The ratio shall be expressed as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero.

> The monitoring results for the biological quality elements are expressed as EQRs - ratios derived from observed values and reference values.
>
> Intercalibration of individual parameters is difficult because different Member States may measure different parameters for a given biological quality element. ***The biological quality elements should be the level for intercalibration***.

(iii) Each Member State shall divide the ecological quality ratio scale for their monitoring system for each surface water category into five classes ranging from high to bad ecological status, as defined in Section 1.2, by assigning a numerical value to each of the boundaries between the classes. The value for the boundary between the classes of high and good status, and the value for the boundary between good and moderate status shall be established through the intercalibration exercise described below.

> The results of the intercalibration exercise will determine the numerical (EQR) values for the high-good and the good-moderate boundaries in each Member State's classification system. Values for the other two class boundaries are established by the Member States themselves.

	What will be intercalibrated is ***not*** ecological status, but the outcome (as status classes) of the numerical (EQR) values for the biological quality elements in Member State's assessment systems. The ecological status is determined by the lower of the values (high/good/moderate/poor/bad) of the relevant biological and physico-chemical monitoring results for the relevant quality elements[13].

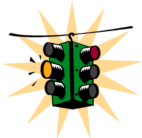
(iv) The Commission shall facilitate this intercalibration exercise in order to ensure that these class boundaries are established consistent with the normative definitions in Section 1.2 and are comparable between Member States.

(v) As part of this exercise the Commission shall facilitate an exchange of information between Members States leading to the identification of a range of sites in each ecoregion in the Community; these sites will form an intercalibration network.

> As a first step in this information exchange it should be decided **what information (including biological and other data) is needed to identify intercalibration sites**.

[13] *WFD Annex V, Article 1.4.2 (i)*

The network shall consist of sites selected from a range of surface water body types present within each ecoregion.

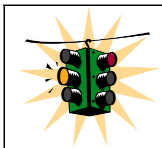


'Sites' for the intercalibration network refer to whole water bodies, because the water body is the unit of ecological status classification (i.e. each water body has only one classification status)[14].

Not all types distinguished by member States (and shared by other Member States) need to be included in the intercalibration network, but a subset of common types will be selected. For intercalibration purposes, common types between Member States sharing same ecoregion(s) need to be agreed.

Criteria and a process for the selection of water body types for the intercalibration network are presented in Section 4.2.

For each surface water body type selected, the network shall consist of at least two sites corresponding to the boundary between the normative definitions of high and good status, and at least two sites corresponding to the boundary between the normative definitions of good and moderate status.



In the opinion of the Intercalibration working group, the sites included in the intercalibration network should be selected by the Member States, representing the interpretations by the respective Member States of the normative class boundary definitions. Harmonised class boundaries should be the outcome of the intercalibration exercise – not the starting point.

More than 2 sites per boundary can be selected for each surface water type included in the intercalibration network (number of sites recommended is presented in Section 4.7).

The normative definitions of the different quality classes are formulated in terms of the biological quality elements; the values of these should not deviate too much from reference conditions (i.e. the least "*slight deviations*" within the good status range, and the least "*moderate deviations*" within the moderate status range).

The information required for the selection of intercalibration sites is presented in Section 4.6.

The sites shall be selected by expert judgement based on joint inspections and all other available information.

Regional expert groups will evaluate the information from the sites proposed by the Member States and make recommendations for the Commission.

The process to carry out the selection of intercalibration sites is presented in Section 4.1 of this guidance.

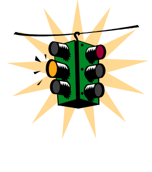
[14] See "WFD CIS Guidance Document No. 2 on the application of the term "water body" in the context of the Water Framework Directive".

(vi) Each Member State monitoring system shall be applied to those sites in the intercalibration network which are both in the ecoregion and of a surface water body type to which the system will be applied pursuant to the requirements of this Directive.

For each Member State monitoring system it must be determined to which ecoregion(s) and water body type(s) the system will be applied.

If the ecoregions presented in Annex XI (as a part the System-A typology) are used as the sole basis for intercalibration there will be limited possibilities for comparison of monitoring and assessment systems of inland waters for many Member States (example: ES-P, IRL-GB), or even no possibility at all (I, GR).

The directive does not prescribe the use of the Annex XI ecoregions. The intercalibration would benefit from using larger ecoregions, as long as the same surface water body types are found within those regions. This would better enable intercalibration between larger numbers of Member States.



"Ecoregions" for intercalibration are not necessarily the ecoregions for System A typology presented in Annex XI, but should be as large as possible to enable intercalibration between a maximum number of Member States. Preliminary proposals for intercalibration ecoregions are presented in Section 4.5 of this Guidance Document.

The results of this application shall be used to set the numerical values for the relevant class boundaries in each Member State monitoring system.

The EQR values of the boundaries will be established through the intercalibration exercise.

Member States define the numerical values for the relevant class boundaries using their monitoring systems. Intercalibration compares the outcome (as status classes) of the numerical values "measured" according to the methodology adopted by Member States.

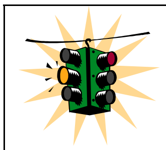
In order to allow comparison of Member States' classification results from the same intercalibration sites, information of data and assessment methods will need to be brought together.

Guidance how to translate the results of the intercalibration exercise into numerical values for the class boundaries will be developed in the next phase of the Common Implementation Strategy when there will be metadata (information about the availability of data) available from the potential intercalibration sites (i.e. during 2003; see Section 5.7.

(vii) Within three years of the date of entry into force of the Directive, the Commission shall prepare a draft register of sites to form the intercalibration network which may be adapted in accordance with the procedures laid down in Article 21. The final register of sites shall be established within four years of the date of entry into force of the Directive and shall be published by the Commission.

The procedures laid down in Article 21[15] concern the regulatory committee, referring to Decision 1999/468/EC[16]. The regulatory committee consists of representatives of the Member States and is chaired by the Commission.

The Commission shall submit to the committee a draft of the measures to be taken (in this case the draft register of intercalibration sites together with a plan how to finalise it). The committee shall deliver its opinion on the draft, by qualified majority (Article 205(2) of the Treaty[17]). The Commission shall adopt the measures if they are in accordance with the opinion of the committee. If this is not the case, the Commission shall submit to the Council a proposal relating to the measures to be taken and inform the European Parliament.



This procedure should allow for the amendment of the draft register of the intercalibration network after it has been proposed by the Commission (December 2003 at the latest) and before the final register is published (December 2004).

(viii) The Commission and Member States shall complete the intercalibration exercise within 18 months of the date on which the finalised register is published.

(ix) The results of the intercalibration exercise and the values established for the Member State monitoring system classifications shall be published by the Commission within six months of the completion of the intercalibration exercise.

[15] *WFD art. 21: Regulatory committee.(1) A committee, hereinafter referred to as "the Committee", shall assist the Commission; (2) Where reference is made to this Article, Articles 5 and 7 of Decision 1999/468/EC shall apply, having regard to the provisions of Article 8 thereof. The period laid down in Article 5(6) of Decision 1999/468/EC shall be set at three month; (3) The Committee shall adopt its rules of procedure.*
[16] *See Annex C of this document.*
[17] *See Annex C of this document.*

Section 3 – Synthesis of the intercalibration process: problems and possible solution

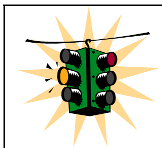
In this Section a synthesis of the intercalibration process is presented, key steps of the critical path and the bottlenecks in the fulfilment of the requirements of the Directive are presented and discussed. The potential implications of a limited intercalibration and the possible short and long-term solutions are also presented.

3.1. Formal requirements and the timetable of intercalibration

The Directive requires that the boundaries between the ecological quality classes high - good and good - moderate will be established through an intercalibration exercise (WFD Annex V, 1.4.1, iii). An intercalibration network, consisting of selected sites, will be established representing Member States' interpretations of the normative definitions of surface water status (defined in WFD Annex V, Section 1.2) in relation to reference conditions.

The purpose of the Intercalibration exercise is to ensure comparable ecological quality assessment systems and harmonised ecological quality criteria for surface waters in the Member States. This ensures a harmonised approach to define one of the main environmental objectives of the WFD, the "***good ecological status***", by establishing:

- Agreed ecological quality criteria for good quality sites, setting the targets for protection and restoration;
- Agreed numerical Ecological Quality Ratio (EQR) values for two quality class boundaries (high/good and good/moderate).



This means that the normative definitions for the high and good surface water quality need to be interpreted equally regardless of differences in ecological quality assessment systems between Member States (i.e. good ecological quality should have the same meaning all over the EU).

Intercalibration is carried out by the Member States. The role of the Commission is to facilitate the information exchange between the Member States.

An intercalibration exercise shall be carried out in 2005 and 2006 between the Member States to ensure the comparability of the biological monitoring results. Prior to this an intercalibration network should be established by the end of 2004 (Figure 3). The draft register of the Intercalibration network, published by the Commission may be adapted in accordance with the procedures laid down in Article 21 of the Directive.

The intercalibration network will be established for a limited number of water body types with two or more sites corresponding to both boundaries between quality classes *High-Good* and *Good-Moderate* according to each Member States' classification. The selection of water body types and intercalibration sites needs to be carried out using expert judgement based on joint inspections and all available information. In the intercalibration exercise, Member State's ecological quality assessment systems are then applied to classify these sites in the ecoregions where their classification systems are applicable. The results are used to set the boundary '*Ecological Quality Ratio*' (EQR) values of the classification systems and published by the Commission.

The Directive requires the following timetable for the intercalibration:

- establishment of draft register of the intercalibration network – December 2003;
- establishment of final register of intercalibration network – December 2004;
- Intercalibration exercise completed – June 2006;
- Results of intercalibration exercise published by Commission – December 2006;

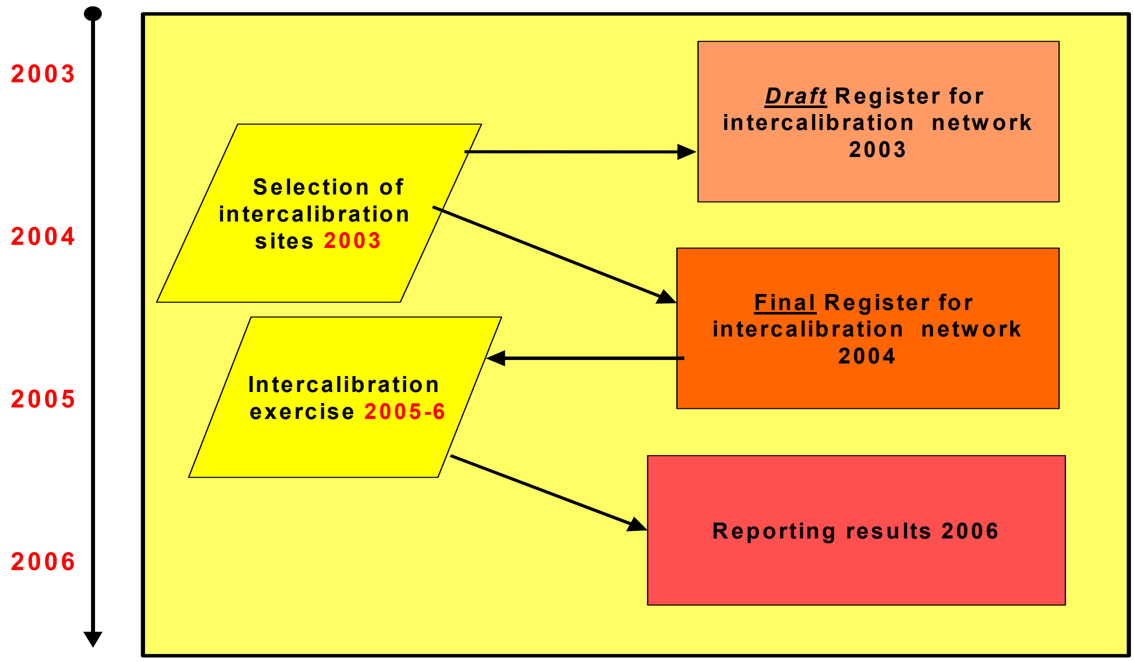


Figure 3 *Task phases and time-table of the formal Intercalibration exercise.*

3.2. Obstacles in the timetable of the intercalibration process

In the fulfillment of the formal requirements of the intercalibration exercise, as described in Annex V of the Directive, certain difficulties are foreseen. The main reason is that the intercalibration timetable does not completely match with the implementation timetable in the Member States. As a consequence, crucial information for the intercalibration will only be available during the progress in implementation (Table 1).

Table 1 Comparison of the Member States' implementation timetable and the intercalibration timetable, as required by Annex V of the Directive.

Year	MS implementation timetable	Intercalibration timetable
2003		Draft register of the Intercalibration network
2004	Analysis of characteristics (typology and reference conditions) and pressures & impacts	Final register of the Intercalibration network
2005		Intercalibration exercise
2006	Monitoring programs operational	Intercalibration exercise completed: harmonized class boundaries

The major obstacles for the intercalibration process due to the differences in timetables are presented below.

3.3. *Problem of typology incompatibility*

It will be difficult to select intercalibration types that are compliant with water body types differentiated by the Member States, because:

- Different Member States may use different typology systems;
- Member States do not need to differentiate surface water body types (needed for the 'analysis of the characteristics' of each River Basin District) before December 2004[18] (cf. Table 1);
- Before that (in 2003) the sites for the draft register of the intercalibration network should already be selected and the draft register submitted to the Article 21 Committee for adoption. In absence of a common typology, this selection can only be made on an *ad hoc* basis and using expert judgement.

Implications:

- Water body types selected for the intercalibration network on an *ad hoc* basis in 2003 may not be compliant with water body types that will be differentiated by the Member States when their typologies are completed in 2004;
- It will be difficult to select and agree upon intercalibration sites representing class boundaries, since type-specific reference conditions are needed for classification of the ecological quality.

Potential solutions on a short term basis:

- Member States should start to carry out implementation of typology and reference conditions as soon as possible;
- Member States should agree on compatible typology systems (still allowing regional refinements) and, if possible, a common basis for reference conditions

[18] *WFD, Art. 5, Annex II, 1.1. (i-vi)*

within (eco)regional intercalibration groups as soon as possible or latest in early 2003;

- If the solutions above are not practically possible, the *ad hoc* selection of common types using expert judgement in 2003 should be designed so that it would allow further division into ecologically relevant subtypes that will be later differentiated by Member States.

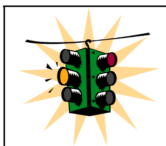
3.4. *Problem of data availability*

The selection of sites for the intercalibration network by the Member States requires that they have adequate and reliable information on all relevant pressures and impacts. Furthermore, reference conditions must be specified for the intercalibration types. At present it is foreseen that this information will only partially be available at the time when the sites have to be selected (in 2003 and 2004), because:

- At present **no** Member States have monitoring systems that are compliant with the requirements of WFD. Data from the on-going monitoring systems are in many cases incomplete or not applicable for the intercalibration;
- There is practically no possibility to collect new data to be available for the site selection in 2003 and 2004. Thus the site selection (i.e. the setting of the ecological quality class boundaries *high-good* and *good-moderate*) can only be based on data presently available;
- The monitoring systems of the Member States do not need be operational before December 2006[19]. By that time the intercalibration exercise should be already completed and the results should be published (Table 1).

Implications:

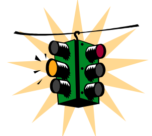
- Site selection can only be based on limited data, not covering all biological quality elements, meaning that the intercalibration network will reflect impacts of pressures on some quality elements only[20];
- Establishment of the class boundaries (*high-good* and *good-moderate*) will be based mostly on expert judgement;
- Limited data availability will limit the number of water body types that can be included in the intercalibration network;
- Once new monitoring data, including other biological quality elements, is available (i.e. after 2006), the intercalibration network may no longer adequately represent the ecological quality class boundaries (i.e. *high-good*, and *good-moderate*) presumed during the site selection in 2003 and 2004.



The WFD foresees a single intercalibration exercise in 2005 and 2006. It is inevitable that this exercise will be based on results from monitoring systems that are still under development, with limited data available and practically no possibility to collect additional data.

[19] *WFD, Art. 8, Annex V, 1.3.*

[20] *For example, the intercalibration of rivers would mainly have to use data on macroinvertebrates, because for the other quality elements there is not sufficient data available at this stage.*



The objectives of the intercalibration exercise – agreement on class boundaries and harmonised classification systems – can be only partially met in the single intercalibration exercise that is required by the WFD.

Potential solutions on a short term basis:

A number of potential solutions on a short term basis exist, including:

- The site selection in 2003 and 2004 should be targeted for water body types where most data is available, recognising that the intercalibration network established will not reflect the impacts of all pressures, and all biological quality elements;
- Member States should voluntarily start WFD compatible monitoring programs as soon as possible, in order to obtain as much as possible of the data required to carry out the intercalibration exercise;
- The intercalibration exercise in 2005 and 2006 could be limited to comparison of classification methods on sites where most data concerning selected pressures would be available.

WFD-req. Submit Draft Register of Intercalibration Network

WFD-req. Final establishment of Register

Bottleneck 1-3. Typology, reference conditions and class boundaries not available. Draft register based on expert judgement and (little available data)

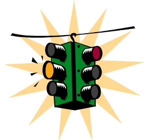
Bottleneck 4. Need to start monitoring potential Reference condition and Intercalibration sites before monitoring programmes are operational

Bottleneck 5. Finishing intercalibration exercise and setting EQR values for good-high, good-moderate borders before monitoring programmes are operational

WFD-req. Intercalibration exercise completed, reporting of results

3.5. *Problems of 'limited' intercalibration*

Member States select intercalibration sites using information on pressures and the impact of these pressures on the biological quality elements (compared with reference conditions). Intercalibration sites represent their judgement of what is a "slight" or a "moderate" impact.



There is no guarantee that different Member States will have the same views on how the normative definitions of the quality class boundaries should be interpreted. Differences in interpretation will be reflected in the draft intercalibration network.

Member States may, or may not, have monitoring data on biological quality elements sensitive to the pressures identified as the most significant for the water bodies proposed for the intercalibration network.

Since EQR values will be established based on biological quality data (using relevant quality elements), sites where there is no biological data collected and available before 2005, cannot be used in the intercalibration exercise (Fig. 4).

The prerequisite to use any site in the intercalibration exercise requires that there will be **biological monitoring data** (of relevant quality elements) available latest in 2005.

An intercalibration network including only sites impacted by the most widespread pressures (such as eutrophication in lakes and coastal waters), as proposed in Section 4.4, would imply that:

- Only those parts of the classification systems targeted to detect impacts of such pressures on the selected quality elements would be intercalibrated (Fig. 4);
- Agreed ecological quality criteria for good quality sites, setting the targets for protection and restoration of water bodies would be set only for most widespread pressures, while impacts of other pressures would not be considered;
- In 2006, there will be no verified and comparable targets for 'good ecological status' as a whole.

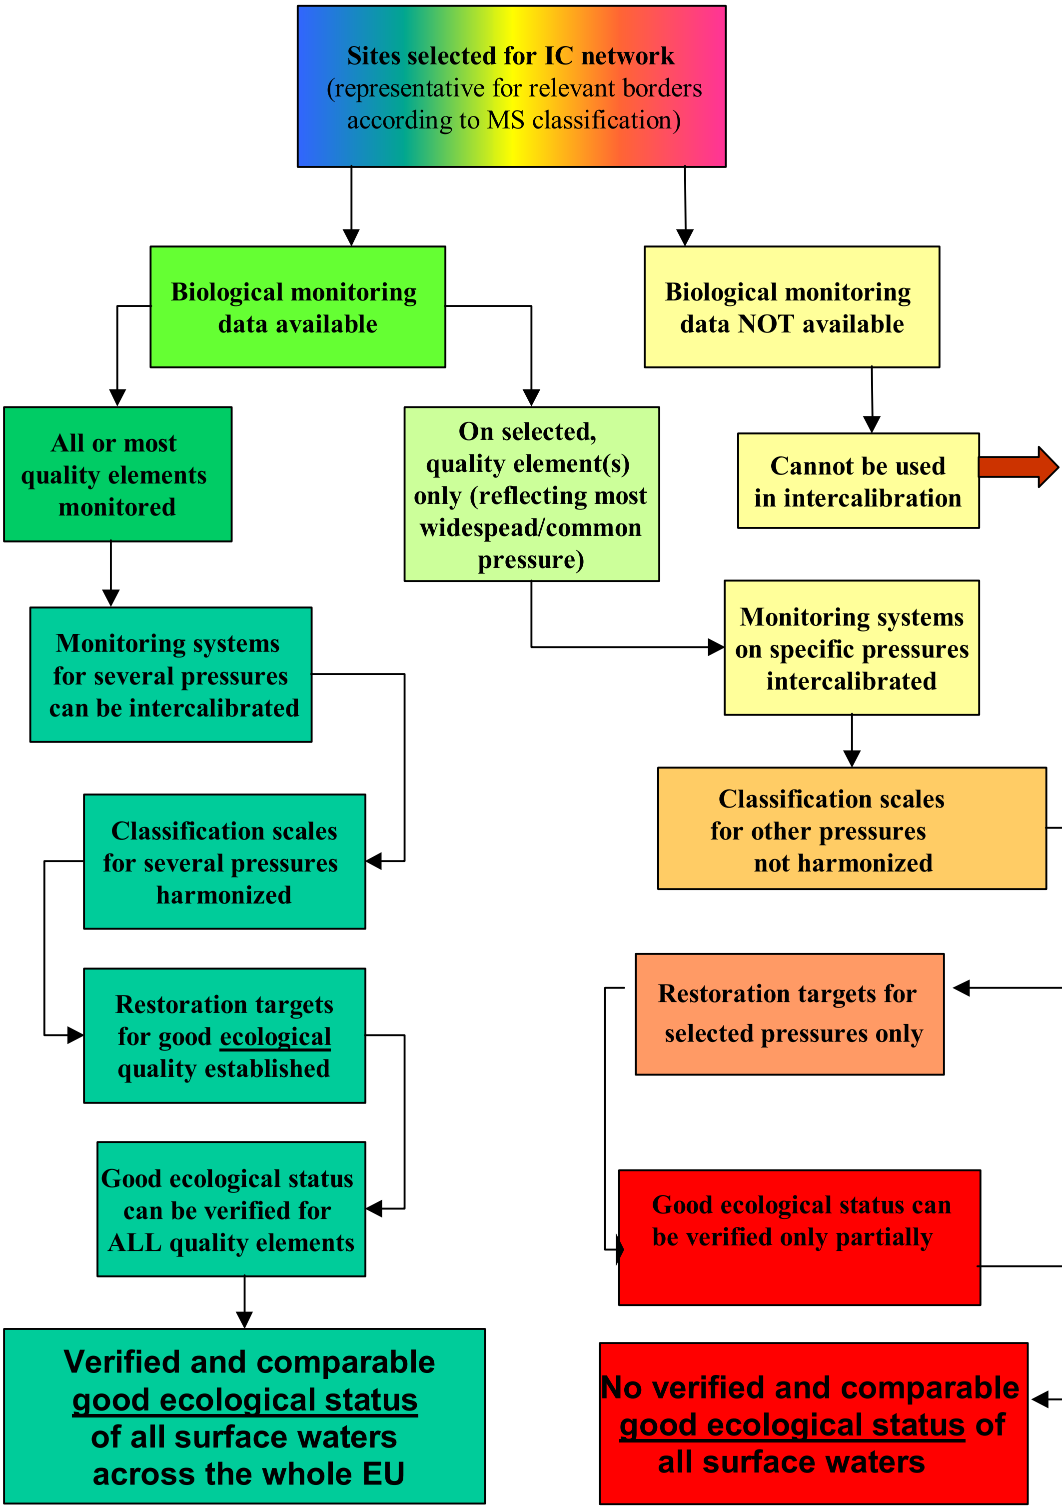


Figure 4 *Flow chart of the benefits of complete intercalibration (not possible in present implementation time schedule) vs. risks of limited intercalibration that will be carried out during 2005 and 2006.*

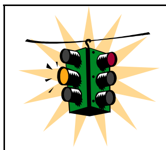
3.6. Long-term strategy to overcome the problems of intercalibration

It is anticipated that a voluntary commitment of the Member States could improve the outcome of the intercalibration exercise in 2003-2006. However, due to practical problems in establishing WFD compatible monitoring systems in time it is anticipated that the objectives of the intercalibration exercise – agreement on class boundaries and harmonised classification systems – can be only partially met in the single intercalibration exercise that is required by the WFD. In order to establish reliable and comparable ecological quality class boundaries, a review mechanism for the intercalibration network at a time when more data with better quality and compatible with WFD requirements will be available (i.e. after 2006) is strongly recommended. In principle, a revision of the intercalibration network is implicit due to the timetable for revision of the analysis of river basin district characterisation – including typology and reference conditions – provided for in Article 5 of the WFD.



A long-term strategy allowing a mechanism for the revision of the intercalibration network after 2006 is strongly recommended by the Intercalibration working group. The practical implications[21] and the legal possibilities[22] for such revisions should be clarified as soon as possible in the continuation of the Common Implementation Strategy.

The establishment of a long-term strategy and a review mechanism for the intercalibration register in specific guidelines would allow:

- Assessment of the possible changes in the quality of the intercalibration sites;
- Intercalibration and harmonisation of new assessment methods (i.e. development of new indicators, new assessment tools, approval of new standards, etc.);
- Addition of new sites impacted by other significant pressures (which were not represented in the intercalibration network in 2004);
- Addition of further water body types in the intercalibration network as a consequence of verification of the typology systems in Member States when new biological monitoring data is available;
- Intercalibration and harmonisation of the monitoring and classification systems of the new Member States.

[21] *Taking into account the consequences for preparing programmes of measures, river basin management plans and establishing classification systems*
[22] *Taking into account the possibilities given in WFD Art. 19, 20 and 21*

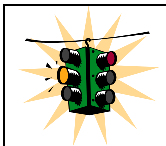
Section 4 – Guidance for the establishment of the intercalibration network

This Section provides practical guidance for the establishment of the intercalibration network:

1) How to carry out site selection process for the intercalibration network in practise;
2) Criteria for selection of types for the intercalibration network;
3) Criteria for selection of sites for the intercalibration network.

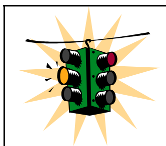
The guidance is based on the common understanding of the Directive's requirements concerning intercalibration (*Section 2*) and the Synthesis of the intercalibration process (*Section 3*). It is to a large extent the result of the work of three temporary expert drafting groups that were established by the Working Group on Intercalibration to address issues specific to the major categories of water bodies – rivers, lakes, and coastal and transitional waters.

The WFD intercalibration will harmonise results of the biological assessment systems implemented by the Member States. All obligatory quality elements and all relevant pressures should be taken into account to completely accomplish this task.



The intercalibration working group concludes that **the intercalibration has to be limited** to water body types and quality elements where sufficient data will be available in time.

The intercalibration working group concludes that the **Member States select intercalibration sites** using information on selected pressures and the impact of these pressures on the biological quality elements (compared with reference conditions).



Thus **the sites of the Intercalibration network represent the respective Member State's interpretations of the normative definitions of Annex V (1.2.)** including their judgement what is a "slight" or a "moderate" impact.

4.1. *Procedure for the establishment of the intercalibration network*

The selection of intercalibration sites for the intercalibration network needs to be carried out in two steps.

1. Firstly, selection of the surface water body types for each of the surface water categories (rivers, lakes, transitional and coastal waters), and possibly the artificial and heavily modified waters in each ecoregion, which will be included in the intercalibration network;
2. Secondly, within these types a minimum number of intercalibration sites have to be selected by the Member States following the requirements described in the Annex V of

the Directive (Fig. 5). The intercalibration network must consist of sites selected from a range of surface water body types present within each ecoregion (WFD Annex V).

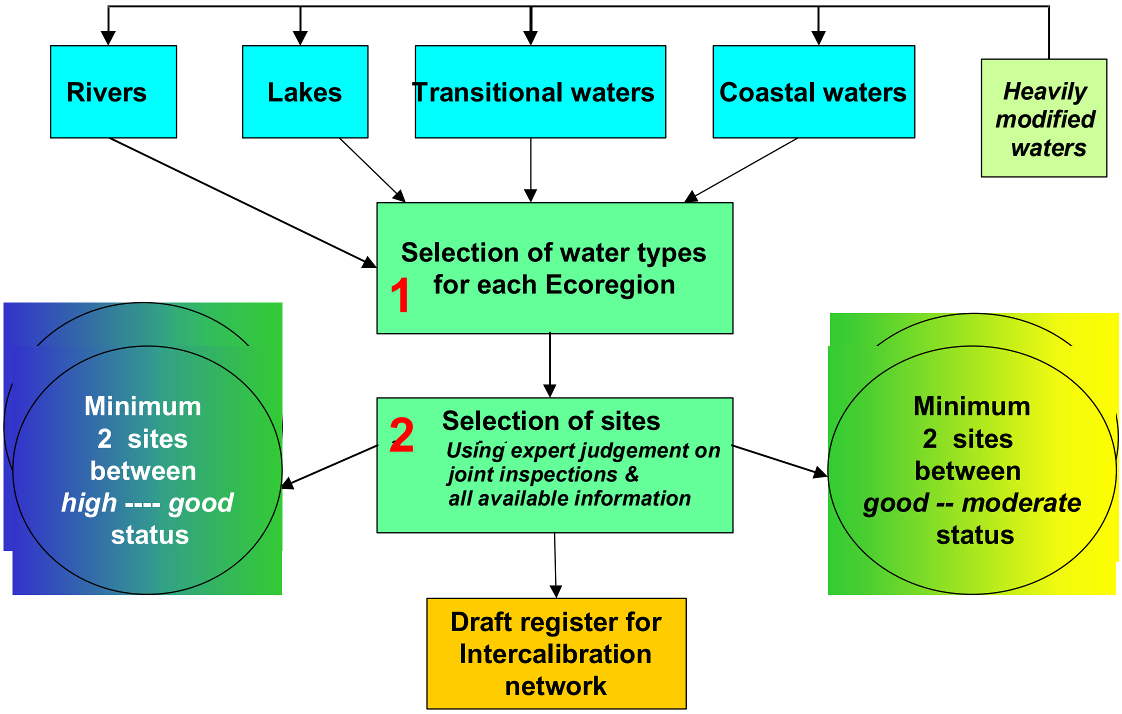


Figure 5 *Selection of intercalibration sites for the intercalibration network.*

	Intercalibration is carried out by the Member States. The role of the Commission is to facilitate the information exchange between the Member States.

The technical work of the Commission is carried out by the ***European Centre of Ecological Water Quality & Intercalibration – EEWAI*** *(hosted by EC-JRC)* which is the organisation responsible for facilitating the intercalibration exercise and organising the work of the expert groups. The Ecological Status Cluster will co-ordinate the work of the expert groups.

4.1.1 *How to carry out the site selection process for the intercalibration network in practice*

The following is a stepwise description of the proposed procedure for the selection of sites for the intercalibration network. Flowcharts of the process are presented in Figure 6a and 6b.

Step 1. Establishment of the Expert groups:

- Expert groups will be established for all main water body categories (rivers, lakes, and transitional and coastal waters);
- The experts are proposed and selected by the Member States. Their work will be co-ordinated through the Ecological Status Cluster;
- Each Member State should be represented in the expert groups relevant for their surface waters;
- Expert groups can be subdivided into (eco)regional groups, or further into geographical intercalibration groups (*Section 4.5.*) when necessary;
- A platform for the communication within/between the expert groups (information exchange, meetings, www-page, etc.) will be organised by the Commission.

Step 2. Proposal of water body types:

- The expert groups will propose the ***water body types*** for each surface water category and (eco)region included in the intercalibration network, taking into account the output of working groups REFCOND and COAST (refer to WFD CIS Guidance Documents No.s 10 and 5, respectively). Preliminary proposals of common intercalibration types for each surface water category have been prepared by the expert drafting groups[23].

Step 3. Proposal of pressures and biological quality elements:

- For each selected intercalibration type, the expert groups need to agree on the pressures and the biological quality elements, where the intercalibration exercise should focus on, taking into account guidance from the IMPRESS and MONITORING working groups (WFD CIS Guidance Document No.s 3 and 7, respectively). Preliminary proposals for the focus and information requirements for the site selection have been prepared by the expert drafting groups[22].

Step 4. Selection of types, pressures, and quality elements for the intercalibration network:

- The proposals of the expert groups will be discussed and finalised by the Intercalibration working group.

Step 5. Selection of sites for the draft intercalibration register:

- Each Member State will select sites for the draft intercalibration register;
- The sites selected should represent high-good and good-moderate class boundaries according to each Member States' interpretation of the

[23]*drafting expert group reports are available on CIRCA: http://forum.europa.eu.int/Members/irc/env/wfd/library?l=/working_groups/intercalibration/drafts/expert_drafting&vm=detailed&sb=Title*

normative definitions, taking into account the Guidance Documents of REFCOND and COAST (WFD Guidance document No.s 10 and 5);

The selection process should follow these steps:

i. Member States identify which types in the Member State's typology system correspond to the intercalibration types relevant for the Member State, and identify the reference conditions for those types;

ii. Bring together all available information necessary for the site selection (pressures, impacts, biological data for the sites that will be considered for the sites selection - ranging from high to moderate status);

iii. If there is not sufficient biological data, site selection should be partially based on pressure criteria, and the Member State should plan to acquire biological data to be available for the intercalibration exercise in 2005-6;

iv. Based on the available information, Member States select sites representing the high-good and good-moderate boundary, according to their interpretation of the normative definitions specified in Annex V (1.2.) of the Directive, motivating their choice.

Step 6. Metadata analysis:

- The Commission will set up a database holding metadata (information about the availability of data) for all intercalibration sites as selected by the Member States;
- Member States will provide metadata on typology, reference conditions and biological and physico-chemical monitoring results (step 5.1-5.3 above). If essential information is lacking at the time of the site selection, they should indicate if, when and in what form the data will become available;
- Additionally, information should be provided on the criteria for classification of the sites (step 5(iv) above). This information is necessary for the evaluation of the choices of the Member States by the expert groups in the next step;
- The metadata analysis will be the basis for the compilation of the draft register for the intercalibration network providing an overview of the information available for each intercalibration site;
- The metadata analysis will be the basis for a realistic planning for the intercalibration exercise and for the preparation of the database for this purpose.

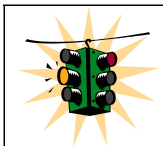
Step 7. Evaluation of the proposed intercalibration sites by expert groups:

- The Commission will compile the results of the metadata analysis and make them available to the expert groups;

- The expert groups evaluate the selection by the Member States and point out possible inconsistencies (including differences in Member State's interpretations of the normative definitions);
- The expert groups review the metadata and propose what data should be collected / made available for the intercalibration exercise – allowing Member States to start collecting data which is still not available.

Step 8. Finalisation of the draft register:

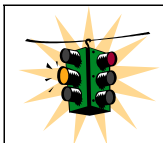
- The evaluation of the different expert groups of the proposed selections of the Member States will be presented, discussed and approved by the Intercalibration working group;
- The draft register of the intercalibration network will be discussed in a joint workshop of Member State representatives (Intercalibration WG) and the Commission, to evaluate consistency with the normative definitions of the class boundaries and comparability between Member States[24]. Where possible, proposals are made how inconsistencies should be resolved;
- The draft register will be the list of sites selected by the Member States, together with the approved summary of the metadata analysis including information of the criteria for the quality classification of those sites.



The sites selected for the draft intercalibration register represent high-good and good-moderate class boundaries according to each Member State's interpretation of the normative definitions in the WFD Annex V (1.2.).

Step 9. Presentation of the draft register to the Article 21 Committee:

- The Commission will finalise the draft register of the Intercalibration network, and submit it to the Article 21 Committee before 22 December, 2003;
- Together with the draft register, the Commission will submit the results of the evaluation made in step 8.



The procedure for revising the draft intercalibration register will depend on the decisions of the Article 21 Committee.

Step 10. Revision of the draft intercalibration register:

- If a revision of the draft intercalibration is decided, ***Member States should reconsider and possibly expand their selection*** (based on the decisions of the Article 21 Committee);

[24] *WFD Annex V, 1.4.1 (iv)*

- If new sites are selected by the Member States they should be included in the metadata analysis;
- For the final register, it is recommended to follow the same procedure should be followed as for the draft intercalibration register (see steps 7-9 above):
  - Evaluation of the proposed intercalibration sites by expert groups;
  - Finalisation of the (proposed) register;
  - Presentation of the (proposed) register to the Article 21 Committee;
  - Approval of the final intercalibration register by the Article 21 Committee.

Table 3 ***Summary and proposed timetable of the site selection for the intercalibration network in 2003 and 2004.***

Month	Actions		Actors
Jan-03	Establishment of expert groups (for rivers, lakes, transitional and coastal waters); subdivision in (eco)regional groups		Member States, Commission
Feb-Mar-03	Selection of surface water body types. Selection of pressures and biological quality elements.		Expert groups, Intercalibration working group.
Apr-Jun-03	Selection of sites for the draft intercalibration register. Delivery of metadata to the Commission.		Member States
Apr-Oct-03	Metadata evaluation, possible checking of sites, preliminary draft register.		Expert groups and Commission .
Oct-03	**Workshop**	Approval of draft register	Intercalibration working group, Expert groups, Commission
Nov-03	Compilation of the draft register		Commission
Dec-03	Draft register submitted to the Art. 21 Committee		Commission
Jan-Jun-04	Submission of new information, if possible & available		Member States
Jan-Sep-04	Revision of the draft register, if possible		Expert groups
Sep-Nov-04	Compilation of the final register		Commission
Nov-Dec-04	Adaptation and publication of the final register		Committee

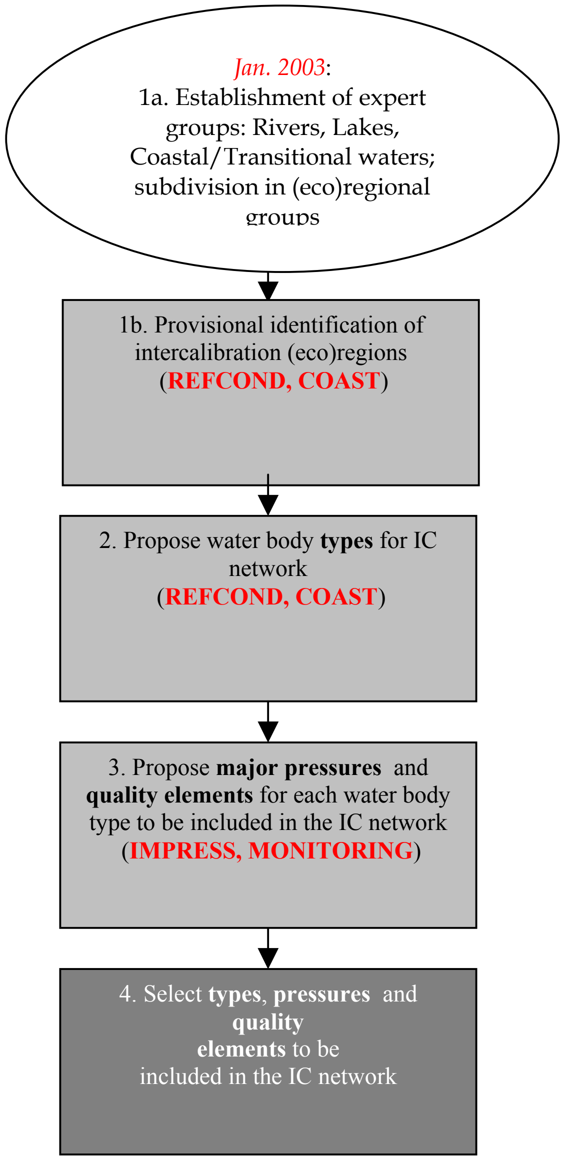


Figure 6a *Flow chart of the proposed process for the selection of types, pressures, and quality elements for the intercalibration network in 2003. Steps where guidance is required from other WFD CIS working groups are indicated. The colours of the boxes indicate the actors that have to carry out the steps: White – Ecological Status Cluster, Light grey – expert groups, Dark grey– Intercalibration working group.*

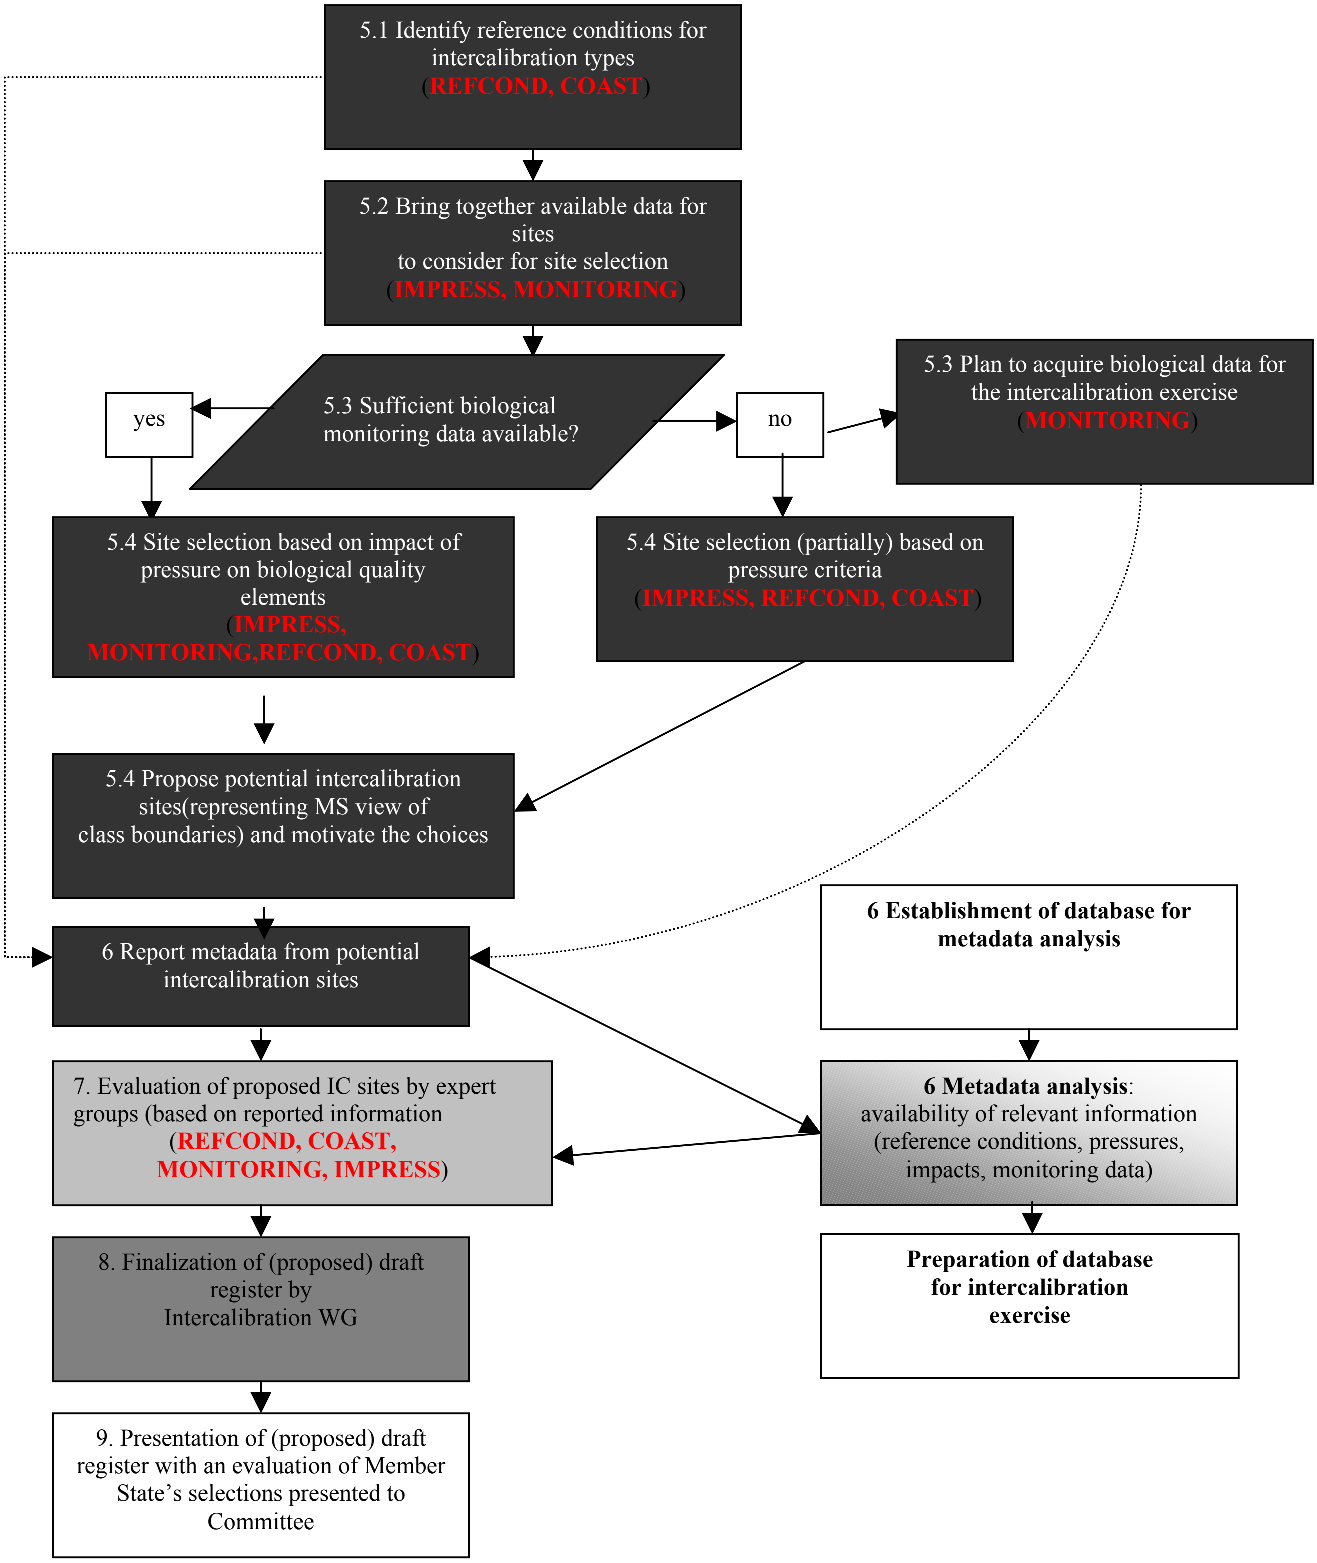

Figure 6b *Flow chart of the proposed process for the selection of sites for the draft intercalibration register. Steps where guidance compiled by other WFD CIS working groups is needed are indicated. The colours of the boxes indicate the actors that have to carry out the steps: Black - Member States, Light grey – expert groups, Dark grey – Intercalibration working group, White – Commission.*

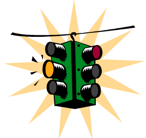
4.2. *Criteria for the selection of water body types for the intercalibration network*

The intercalibration network must consist of sites selected from a range of surface water body types present within each ecoregion[25].



Different Member States will not always use the same typology for the characterisation of water bodies[26]. For intercalibration it is necessary to agree on common types between countries of the same ecoregion.

The following points should be considered in the selection of ***typology system(s) for intercalibration***:

- Guidance for characterisation of the surface water types is prepared by REFCOND and COAST working groups (WFD CIS Guidance Document No.s 10 and 5, respectively). Based on this guidance, Member States may decide to implement a common typology framework throughout Europe or within certain (eco)regions, for certain water body categories. In these cases the intercalibration types should fit in this common typology framework;
- For water body categories and/or (eco)regions where no common typology will be used in the Member States implementation, it will still be necessary to agree on a common typological framework. In the absence of any other common classification system, the selection of types for the intercalibration network could be based on the factors of System A;
- During the process of type selection, the experts should have this information from their Member States in order to be evaluate the potential types to be selected.

The most important requirements for the selected intercalibration types are:

- *Are* ***common*** (found in at least 2 or more Member States, and covering sufficiently large geographical areas (or ecoregions) to enable comparison of different (national) assessment systems, and all ecoregions should be covered);
- *Are* ***sensitive to and impacted by different pressures*** (e.g., organic pollution, physical alterations, acidification, eutrophication; habitat degradation, discharge or exposure to toxic substances);
- allow Member States to identify ***reference conditions*** at the time of the site selection;
- Should have ***potential intercalibration sites*** corresponding to the boundary between high/good and good/moderate available, but accepting that in some ecoregions/types there might be only sites representative for the moderate/ good boundary.

[25] *WFD Annex V, 1.4.1(v)*
[26] *as required in WFD Art. 5*

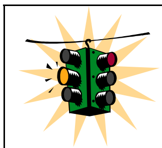
4.3. Artificial and heavily modified water bodies

In the common understanding (*Section 2*) it is concluded that **artificial or heavily modified water bodies should be considered** in the intercalibration, but **not as a separate category.**

Some artificial or heavily modified water bodies could be considered to be included in the intercalibration network, if they fit into one of the **natural water body types** selected for the intercalibration network.

Artificial and heavily modified water bodies that are not comparable with any natural water bodies should only be included in the intercalibration network if they are **dominant within a water category in one or more Member States**. In that case they should be treated as one or several separate water body types.

Final designation of heavily modified water bodies and definition of maximum ecological potential will be established in 2009.



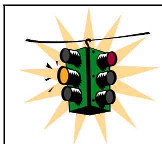
Heavily modified water bodies, which are provisionally identified in 2003 (i.e. water bodies that are at risk of failing 'good' status due to physical modification), can only be included in the intercalibration network, if they fulfil the same selection criteria as natural water bodies. This needs to be evaluated by the expert groups during the selection process (*Section 4.1*.)

4.4. Pressures

The intercalibration exercise has to deal with pressures separately because of the different ecological impact of different pressures, and because different indicators or assessment methods are used to assess different impacts.

For each selected intercalibration type it should be agreed which pressure(s) to focus on. The working group on intercalibration recommends that these should be the pressures that are most widespread in Europe.

The preliminary recommendation[27] is to focus the lake intercalibration on eutrophication and acidification, the river intercalibration on organic pollution and stream modification, as well as acidification and nutrient pollution for some types only, and intercalibration of coastal and transitional waters on eutrophication and habitat degradation (Table 4).



For practical reasons the intercalibration has to focus on specific pressures. However, pressures hardly ever come alone, and it will be difficult to find sites, which are impacted only by one pressure.

Eventually, if a revision of the intercalibration exercise will be possible, the other significant pressures could be included, in order to come to a harmonised classification of **good ecological status**, rather than harmonised indicators for specific pressures.

[27] *based on drafting expert group reports available on CIRCA: http://forum.europa.eu.int/Members/irc/env/wfd/library?l=/working_groups/intercalibration/drafts/expert_drafting&vm=detailed&sb=Title*

Table 4 Preliminary recommendation of the pressures for different surface water categories that should be in focus in the selection of the intercalibration network. Further specification should be considered on the level of selected types for each surface water category.

Surface water category	Pressures
Lakes	Eutrophication, Acidification
River	Organic pollution, stream modification, acidification (selected types only), nutrient pollution (selected types only)
Coastal and transitional waters	Eutrophication, habitat degradation

4.5. Geographical intercalibration groups

The intercalibration network must be confined to "ecoregions"[28]. "Ecoregions" can either be interpreted as those specified in Annex XI of the Directive (the Illies ecoregions for lakes and rivers, and much wider regions for coastal and transitional waters), or can be defined in a wider sense.

It is recommended that for rivers and lakes the geographical intercalibration groups of Member States should be larger than proposed by Illies ecoregional division, consisting of at least two or more countries sharing a similar climate.

Groups of Member States that share the same water body types in different sub-regions or ecoregions should carry out intercalibration using the same intercalibration sites.

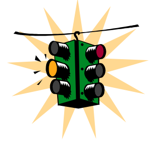
Some Member States will have to join two or more such intercalibration groups, thus acting as links between the different sub-regions or ecoregions, allowing intercalibration to take place across different ecoregions.

Preliminary proposals for intercalibration groups[29] are:

- For **rivers:** three intercalibration groups (Northern, Middle latitude, Mediterranean);
- For **lakes**: five intercalibration groups (Northern, Atlantic, Central, Alpine, Mediterranean);
- For **coastal and transitional waters** it is recommended to use the ecoregions of System A[30] (Baltic, North Sea, Northeast Atlantic, and Mediterranean).

If needed, each of the intercalibration groups may be further divided to smaller geographic regions.

[28] *WFD Annex V, 1.4.1 (vi)*
[29] *based on drafting expert group reports available on CIRCA: http://forum.europa.eu.int/Members/irc/env/wfd/library?l=/working_groups/intercalibration/drafts/expert_drafting&vm=detailed&sb=Title*
[30] *WFD Annex XI, Map B*



In this example the regional intercalibration groups for **rivers and lakes** are slightly different. It is recommended that when finalising the proposals, the expert groups and the Intercalibration working group should resolve this, and agree on the same geographical groups for lakes and rivers.

4.6. *Selection of intercalibration sites*

Member States should carry out the selection process (following steps 5.1.-5.4. in *Figure 6b, Section 4.1.*) and propose intercalibration sites for the draft register.

Selection should be based on the Member States' interpretation of the normative definitions of class boundaries (Annex V, 1.2).

A helpful tool (for the Member States) in the selection process could be ranking of water bodies (within the type selected for intercalibration) across a range of quantified pressure criteria (refer to WFD CIS Guidance Document No. 10) for identifying sites that are provisionally representative for the high-good and the good-moderate class boundaries (Figure 7). This could be done either on national or on (eco)regional level.

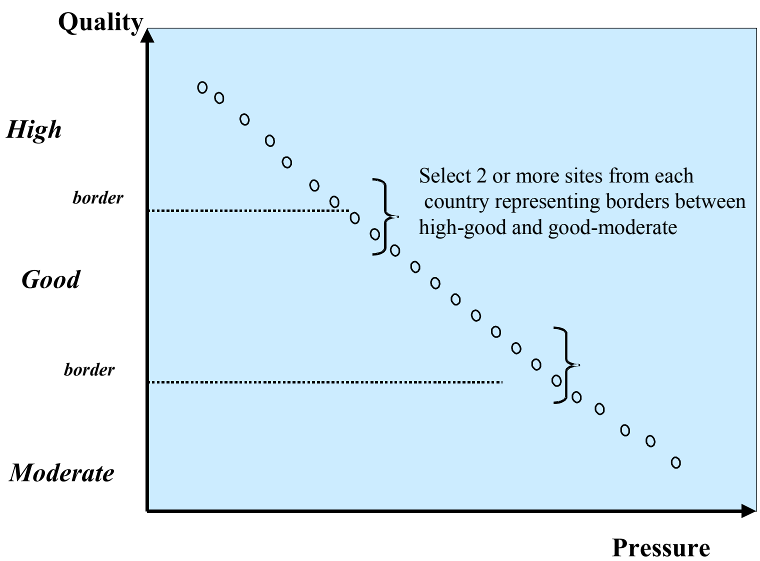


Figure 7 *Illustration of the ranking of the estimated ecological quality of the sites (varying as a function of certain pressure). The Member States evaluate their data, and select 2 or more sites provisionally representative for the borders between high-good and good-moderate from each country for each type selected for the intercalibration network.*

Member States should consider all available data for site selection. Ideally data should originate from national or regional monitoring systems, but national and international research projects should be considered as potential sources of information as well.

Member States should provide metadata and other information from the proposed sites to the Commission. The Commission will facilitate evaluation of the site selections by collecting metadata and making it available to the expert groups for evaluation (see *Section 4.8.*).

The following information of the proposed intercalibration sites should be reported:

- Information of the biological data (metadata);
- Information of the supporting hydromorphological, physico-chemical, and chemical data (metadata);
- If essential information is lacking at the time of the site selection, indication when and in what form the data will become available;
- A description of the pressures and an evaluation of their importance;
- Description of the type according to the national typology of the site;
- Type-specific reference conditions *at least* for the biological quality elements chosen for intercalibration, and the method used to obtain the reference conditions (if available);
- Description on the criteria and methodology for the provisional classification of the sites referring to normative definitions.

	Because of lack of data and absence of final assessment systems in 2003, the selected sites can in many cases only approximate the relevant class borders.

4.7. Number of intercalibration sites needed

The Directive requires that at least two (2) sites representative for each (provisional) quality status class boundaries (good- moderate, and high-good) for each type should be included in the intercalibration network.

In order to allow flexibility in the process Member States should consider proposing several sites (more than 2+2 for each type) provisionally classified representative for the relevant quality status class boundaries and provide metadata and other information from these sites to the Commission.

It is recommended that the draft intercalibration register should contain at least 5 sites at each of the quality status boundaries for each water body type and for each geographical intercalibration group.

	The total number of sites included in the final draft register will depend on the availability of sites provisionally matching the required status classification within each type and each Member State. Also the number of proposed intercalibration sites may be different in each Member State depending on their surface area and hydrological characteristics.

4.8. Metadatabase for establishment of the intercalibration network

A metadatabase (hosted and maintained by the Commission/EEWAI) will be established to contain all metadata and other relevant information from the sites proposed for the intercalibration network.

The purpose of this database is to provide consistent information of the selected intercalibration sites for the evaluation of the expert groups, and to allow maximum transparency in the selection process.

The metadatabase and analysis of metadata and other information will form the basis for the compilation of the draft register.

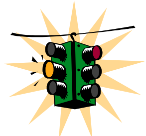
A clear format needs to be agreed how the metadata from the intercalibration sites will be organised and submitted for the metadatabase for the purpose of the expert evaluation and compilation of the draft register.

If possible, the planning for the metadata collection should be initiated in autumn 2002, in order to have an overview of the data in spring (April – June, 2003) (see Table 3).

The metadatabase will be further developed to hold all necessary information for the intercalibration exercise ('intercalibration database', see *Section 5.1.*).

Section 5 - Preliminary technical protocol for the intercalibration exercise

In this Section the preliminary description of the process during the intercalibration exercise in 2005 and 2006 is presented. This Section is not complete and further development will be required in 2003.



At present it is not possible to provide more detailed guidance, since there is not a clear overview what kind of data can be expected from the provisional intercalibration sites.

Such information will be obtained in the metadata analysis carried out during site selection process in 2003.

5.1. *Stepwise description of the intercalibration exercise and the tasks of the participants*

Intercalibration is carried out by the Member States. Co-operation between Member States belonging to the same geographical intercalibration group (*Section 4.6*) is needed. The role of the Commission is to facilitate the information exchange between the Member States.

Step 1. After adaptation and publication of the register for the intercalibration sites in December 2004, the intercalibration exercise will be initiated. All data from the selected intercalibration sites will be made available for Member States through an Intercalibration database[31] hosted by the Commission (EEWAI);

Step 2. Member States will use data from the sites, which are within the ecoregion/geographical area where their national assessment systems are applicable. For practical purposes, Member States belonging to the same geographical intercalibration group (*Section 4.6.*) will share data from the common intercalibration sites;

Step 3. Using this data and possibly carrying out voluntary additional sampling[32], the Member States will assess the Ecological Quality Ratio (EQR) values of the intercalibration sites representing the relationship of observed values with the type-specific reference conditions;

Step 4. If additional sampling is carried out, Member States will use this data for intercalibration and report this data to the Intercalibration database;

Step 5. Member States will report the results of the intercalibration exercise to the Commission;

Step 6. The Commission is assisted by the expert groups (selected following the procedure described in *Section 4.1.*) in the analysis and evaluation of the results;

[31] The intercalibration database can either hold all necessary data, or provide links to databases at the Member States where actual data would be available in structured form to be downloaded for the use of other Member States in the same intercalibration group.
[32] The Member States that need more data for assessment than available in the database for the particular site, may carry out additional sampling. This may not be needed if the available monitoring data would be compatible with WFD.

Step 7. The Commission will publish the results of the intercalibration exercise within six months after the completion of the intercalibration exercise. The report should at least include:

- ✓ An evaluation of the factors affecting comparability of the EQR values established by the Member States' monitoring and classification systems;
- ✓ proposals for the numerical values to set harmonised EQR–scales for the same water body types.

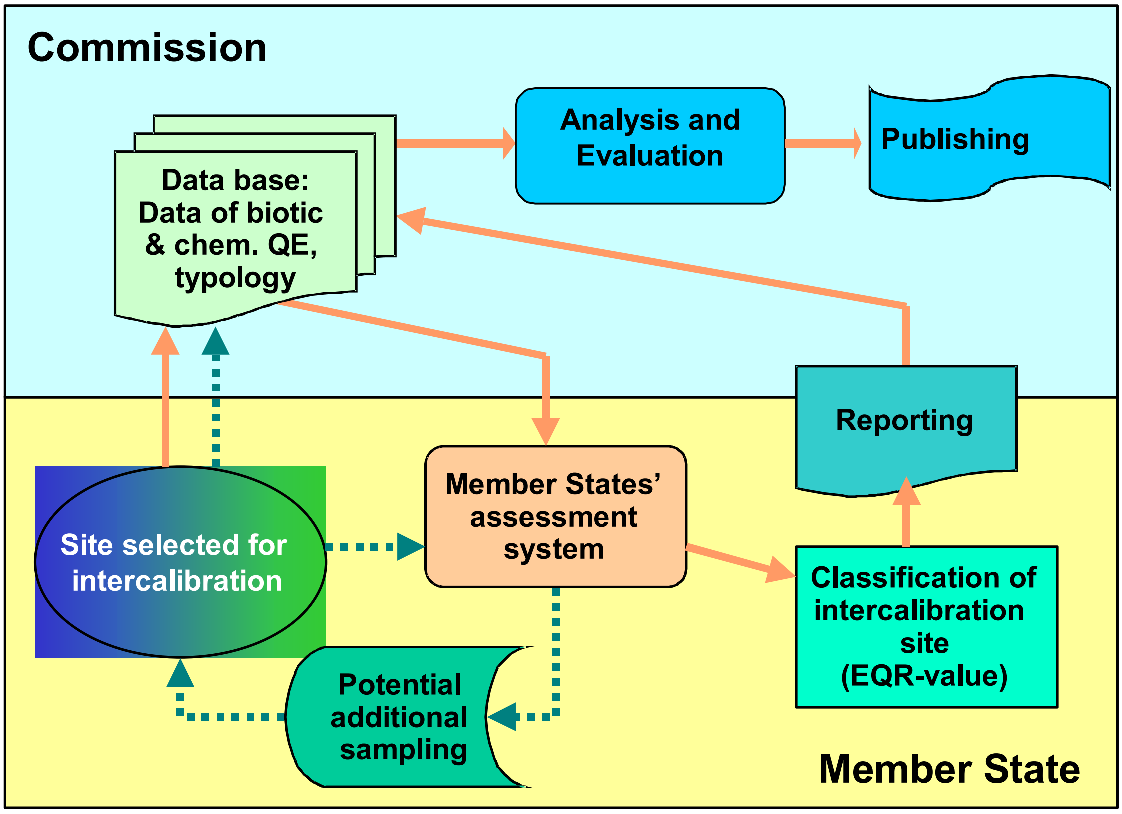


Figure 8 *Process of intercalibration showing the tasks of the Member States and the Commission (stippled green arrow: Flow of data in case, if additional sampling is carried out).*

Table 5 Summary and [tentative] timetable of the intercalibration exercise in 2005 and 2006.

Month	Actions	Actors
Jan-05	Establish intercalibration database	Commission
Jan-05-Jun-06	Reporting data from intercalibration sites to database; assessing EQR of applicable sites	Member States, assisted by Expert Groups
Jun-06	Reporting the results to Commission	Member States
Jul-Oct-06	Analysis and evaluation of the results	Commission , Expert Groups
Oct-Dec-06	Publication of the results	Commission

5.2. Geographical scope/ applicability of different national assessment systems

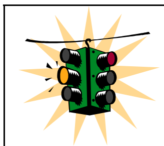
The intercalibration types should be as widespread and common as possible, thus allowing ***true intercalibration between the Member States belonging to the same geographical intercalibration groups*** as presented in *Section 4.5.*

Member States should apply their national assessment systems to all sites in the Intercalibration network within their national borders and all comparable sites within the geographical intercalibration groups where they belong.

5.3. Criteria for selection of biological quality elements.

The Directive (Annex V, 1.4.2) requires that the final ecological status (of a water body) is determined by the lower of the values of the relevant biological and physico-chemical monitoring results. ***Thus the relevant biological quality elements should be the level for intercalibration.*** This requires that it is clear which of the quality elements are the relevant ones for different types of waters.

It is the responsibility of Member States to select the biological quality elements most sensitive to impacts (e.g. depending on their ecological assessment system)



Refer to WFD CIS Guidance Document No.s 7, 5 and 10 for guidance on the selection of relevant biological elements (indicators) with regard to pressures relevant for intercalibration (i.e. elements/indices, which are sensitive for different pressures).

5.4. Guidance for additional sampling in the intercalibration sites.

Sampling and analysis methods for each biological quality element and parameter to be measured should be carried out following the relevant ISO/CEN standards, or if not existing, the best practice/guidelines approved by the expert groups and recommended by the MONITORING working group, and/or international conventions or other international organisations.

Guidance on reporting results of the additional sampling needs to be harmonised with the reporting process of existing data for the Intercalibration database.

5.5. Execution of (voluntary) intercalibration field campaigns

Intercalibration on the level of sampling and analysis methods for different ecological/biological parameters, which have low comparability and where there is little consensus on methods, could be carried out in selected water body types. Such experiments could be done between the countries, which will carry out intercalibration using the same sites. Bearing in mind the tight deadlines to be faced, it is questionable whether it will be possible to carry out this kind of voluntary intercalibration of methods before the 'official' intercalibration in 2005-6.

5.6. Reporting of the final classification results

The results of the classification of intercalibration sites based on each Member States' assessment system are reported as Ecological Quality Ratio (EQR) values for each intercalibration site.

Member States should report the results to the Commission.

Commission will be assisted by the expert groups (selected following the procedure described in *Section 4.1.*) in the evaluation of the results.

The results must be reported in detail and as transparently as possible. The following information should be included in reporting:

- Data and parameters of the biological quality elements, which were used in assessment and calculation of the EQR values;
- Details of assessment methods, including statistical methods, confidence limits of the estimates, etc;
- The method used for determination of the reference conditions of each intercalibration site should described in detail (for each biotic quality element), also taking into account statistical uncertainty in reference values[33];
- In case that additional sampling has been carried out, sampling and analytical methods should be reported in detail (see above, *Section 5.4*).

	It is not possible to give guidance how to calculate the EQR ratio in this stage, since this is dependent on Member States monitoring and assessment systems which they are using currently, or planning to adapt after guidance for Monitoring is completed. Further as EQR is calculated as a ratio, it is dependent on the method Member States choose to use for determination of the reference conditions. This guidance is prepared by REFCOND and COAST (WFD CIS Guidance Documents No's 10 and 5 respectively).

5.7. Expected outcome of the intercalibration exercise

Intercalibration sites selected in 2003 and 2004 represent Member States' interpretations of the normative definitions for the high-good and the good-moderate class boundaries - **not** common European "yard sticks" for those boundaries. There is no guarantee that different

[33] *The results of the intercalibration exercise are very much dependent on how the Member States define the reference conditions for each water body type. The reporting should include detailed description of the method (modelling, hindcasting, paleaoecological reconstruction, or site-dependent, etc.).*

Member States will have the same view on how the normative definitions of the quality class boundaries should be interpreted.

> Differences in interpretation of the normative definitions of the ecological quality class boundaries between Member States will be reflected in the intercalibration network, and therefore in the results of the intercalibration exercise.

If there is no agreement about which sites in the intercalibration network represent the boundaries, monitoring results (EQR values) can only be compared between Member States.

However, the WFD requires that the (EQR) values in the different Member State's classification systems representing the high-good and the good-moderate class boundaries shall be set through the intercalibration exercise.

> The intercalibration exercise will be able to set EQR values for Member States classification systems representing class boundaries, if an agreement can be reached which of the intercalibration sites represent those borders.

Annex A: Key activities and the Working Groups of the Common Implementation Strategy

Key activity 1: Information sharing

1.1 Tools for information sharing
1.2 Raising awareness

Key activity 2: Develop guidance on technical issues

2.1 Guidance on the analysis of pressures and impacts
2.2 Guidance on designation of heavily modified bodies of water
2.3 Guidance on classification of inland surface water status and identification of reference conditions
2.4 Guidance on the development of typology and classification systems of transitional and coastal waters
2.5 Guidance for establishing the inter-calibration network and inter-calibration exercise
2.6 Guidance on economic analysis
2.7 Guidance on monitoring
2.8 Guidance on tools on assessment and classification of groundwater
2.9 Guidance on best practices in river basin planning

Key activity 3: Information and data management

3.1 Development of a shared Geographical Information System

Key activity 4: Application, testing and validation

4.1 Integrated testing of guidelines in pilot river basins

Annex B: Members of the Working Group 2.5

Annex C: Legal texts related to committee procedure

Relevant articles of Decision 1999/468/EC:

***Article** 5,*
Regulatory procedure:
1. The Commission shall be assisted by a regulatory committee composed of the representatives of the Member States and chaired by the representative of the Commission.
2. The representative of the Commission shall submit to the committee a draft of the measures to be taken. The committee shall deliver its opinion on the draft within a time-limit which the chairman may lay down according to the urgency of the matter. The opinion shall be delivered by the majority laid down in Article 205(2) of the Treaty in the case of decisions which the Council is required to adopt on a proposal from the Commission. The votes of the representatives of the Member States within the Committee shall be weighted in the manner set out in that Article. The chairman shall not vote.
3. The Commission shall, without prejudice to Article 8, adopt the measures envisaged if they are in accordance with the opinion of the committee.
4. If the measures envisaged are not in accordance with the opinion of the committee, or if no opinion is delivered, the Commission shall, without delay, submit to the Council a proposal relating to the measures to be taken and shall inform the European Parliament.
5. If the European Parliament considers that a proposal submitted by the Commission pursuant to a basic instrument adopted in accordance with the procedure laid down in Article 251 of the Treaty exceeds the implementing powers provided for in that basic instrument, it shall inform the Council of its position.
6. The Council may, where appropriate in view of any such position, act by qualified majority on the proposal, within a period to be laid down in each basic instrument but which shall in no case exceed three months from the date of referral to the Council.
If within that period the Council has indicated by qualified majority that it opposes the proposal, the Commission shall re-examine it. It may submit an amended proposal to the Council, re-submit its proposal or present a legislative proposal on the basis of the Treaty.
If on the expiry of that period the Council has neither adopted the proposed implementing act nor indicated its opposition to the proposal for implementing measures, the proposed implementing act shall be adopted by the Commission.

Article 7
1. Each committee shall adopt its own rules of procedure on the proposal of its chairman, on the basis of standard rules of procedure, which shall be published in the Official Journal of the European Communities.
Insofar as necessary existing committees shall adapt their rules of procedure to the standard rules of procedure.
2. The principles and conditions on public access to documents applicable to the Commission shall apply to the committees.
3. The European Parliament shall be informed by the Commission of committee proceedings on a regular basis. To that end, it shall receive agendas for committee meetings, draft measures submitted to the committees for the implementation of instruments adopted by the procedure provided for by Article 251 of the Treaty, and the results of voting and summary records of the meetings and lists of the authorities and organisations to which the persons designated by the Member States to represent them belong. The European Parliament shall also be kept informed whenever the Commission transmits to the Council measures or proposals for measures to be taken.
4. The Commission shall, within six months of the date on which this Decision takes effect, publish in the Official Journal of the European Communities, a list of all committees which assist the Commission in the exercise of implementing powers. This list shall specify, in relation to each committee, the basic instrument(s) under which the committee is established. From 2000 onwards, the Commission shall also publish an annual report on the working of committees.
5. The references of all documents sent to the European Parliament pursuant to paragraph 3 shall be made public in a register to be set up by the Commission in 2001.

Article 8
If the European Parliament indicates, in a Resolution setting out the grounds on which it is based, that draft implementing measures, the adoption of which is contemplated and which have been submitted to a committee

pursuant to a basic instrument adopted under Article 251 of the Treaty, would exceed the implementing powers provided for in the basic instrument, the Commission shall re-examine the draft measures. Taking the Resolution into account and within the time-limits of the procedure under way, the Commission may submit new draft measures to the committee, continue with the procedure or submit a proposal to the European Parliament and the Council on the basis of the Treaty. The Commission shall inform the European Parliament and the committee of the action which it intends to take on the Resolution of the European Parliament and of its reasons for doing so.

Article 205 (2) of Treaty establishing the European Community:
Where the Council is required to act by a qualified majority, the votes of its members shall be weighted as follows:
Belgium 5, Denmark 3, Germany 10, Greece 5, Spain 8, France 10, Ireland 3, Italy 10, Luxembourg 2, Netherlands 5, Austria 4, Portugal 5, Finland 3, Sweden 4, United Kingdom 10.
For their adoption, acts of the Council shall require at least:
- 62 votes in favour where this Treaty requires them to be adopted on a proposal from the Commission,
- 62 votes in favour, cast by at least 10 members, in other cases.

Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 7

Monitoring under the Water Framework Directive

COMMON IMPLEMENTATION STRATEGY

FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 7

Monitoring under the Water Framework Directive

Produced by Working Group 2.7 - Monitoring

Disclaimer:

This technical document has been developed through a collaborative programme involving the European Commission, all the Member States, the Accession Countries, Norway and other stakeholders and Non-Governmental Organisations. The document should be regarded as presenting an informal consensus position on best practice agreed by all partners. However, the document does not necessarily represent the official, formal position of any of the partners. Hence, the views expressed in the document do not necessarily represent the views of the European Commission.

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. The focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, project 2.7 "Development of Guidance on monitoring" was launched in December 2000. An informal working group (working group 2.7) was established to facilitate the production of this Guidance. Project 2.7 was initiated to provide Member States with Guidance on monitoring of inland surface water, transitional waters, coastal waters and groundwater, based on the criteria provided in Annex V of the Water Framework Directive. Italy and the European Environment Agency have the joint responsibility, as co-leaders of Working Group 2.7, for the co-ordination of the working group that is composed of scientists and technical experts from governmental and non-governmental organisations.

The present Guidance Document is the outcome of this working group. It contains the synthesis of the output of the Working Group 2.7 activities and discussions that have taken place since December 2000. It builds on the input and feedback from a wide range of experts and stakeholders that have been involved throughout the procedure of Guidance development through meetings, workshops, conferences and electronic media, without binding them in any way to this content.

"We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders, Italy and the European Environment Agency, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation."

Table of Contents

1 Introduction

A Guidance Document: What For?

1.1 Purpose of this Guidance Document

The 26 articles of the Directive 2000/60/EC – establishing a framework for Community action in the field of water policy (The Water Framework Directive) describe what shall be done to implement the Directive and the annexes have been developed to assist Member States in ensuring that the articles are implemented in accordance with the requirements of the Directive. However, the complex nature of the Directive means that the annexes may not provide sufficient Guidance to provide Member States with the assistance they require.

The purpose of this document, along with the other Guidance Documents published by the Commission, is to provide experts and stakeholders with Guidance in the implementation of the Directive. The focus of the document is on providing Guidance on establishing programmes of measures with specific emphasis on the appropriate selection of quality elements and design of monitoring programmes in accordance with Articles 8 and 11 and Annex V.

1.2 To whom is this Guidance Document addressed?

If this is your task, we believe the Guidance will help you in doing the job, whether you are:

- Undertaking the monitoring programmes yourself;
- Leading and managing experts undertaking the monitoring;
- Using the results of the monitoring for taking part in the policy making process; or,
- Reporting on the results of monitoring to the European Union as required by the Directive.

1.3 What you can find in this Guidance document?

1.3.1 Common understanding of concepts and terms

Chapter 2 provides clarification of key concepts and terms of the Directive. This has been developed through an extensive process of review and represents, as far as possible, a common understanding between Member States who have been involved in Working Group 2.7. Clarification is provided on the following terms and concepts:

- The term 'supporting';
- The term 'water body';
- The concepts of risk, precision and confidence;
- Monitoring of wetlands;
- Surveillance, operational and investigative monitoring of surface waters;
- Surveillance, operational and quantitative status monitoring of groundwater;
- Surface water monitoring for protected areas; and,
- Other monitoring considerations such as intercalibration exercises and monitoring of heavily modified water bodies.

1.3.2 Guidance on the selection of Quality Elements

Chapter 3 provides a number of tables summarising the key features of each quality element for surface waters and how each of the quality elements are monitored in Member States. In addition Guidance is provided on the appropriate selection of mandatory and recommended quality elements and parameters that are most representative of catchment pressures for each surface water body type.

Guidance on the selection of groundwater parameters is provided in Chapter 4.

1.3.3 Best Practices and Tool Box

Chapter 5 provides Guidance on the design and implementation of monitoring programmes. Guidance is given on the appropriate selection of water bodies and monitoring sites within water bodies and sampling frequencies required for implementation of surveillance, operational, investigative and quantitative status monitoring programmes and for the monitoring of protected areas.

The chapter provides an overview of the process of establishing a monitoring programme based on the identified objectives and required outcomes of the Directive, with particular emphasis on achieving acceptable levels of risk, precision and confidence.

1.3.4 Best practice examples of current national monitoring

Chapter 6 provides an overview of national monitoring contributions received from Member States. A list of monitoring fact sheets, including the title of the programme, Member State who proposes the method and website link is provided in Annex IV.

1.4 Guidance on monitoring – a framework approach

This Guidance document proposes an overall methodological approach to monitoring for the implementation of the WFD. Because of the diversity of catchment pressures, water-body types, biological communities and hydromorphological and physico-chemical characteristics within the Europena Union the appropriate implementation of programmes of measures in accordance with the requirements of the Directive will vary between Member States and river basins. This proposed methodology will need to be tailored to specific circumstances.

It is not the intention of this Guidance to define prescriptive methods for the assessment and classification of ecological status. This is due to the following factors:

- There are a number of existing classification systems already in use throughout the EU that are potentially suitable for adaptation to meet the requirements of the WFD, some of which have been incorporated into National Standards;
- Individual Member States generally understand local natural variations in biological communities, hydromorphological conditions and physico-chemical variables;
- The level of habitat detail required varies for different indicators depending on their sensitivity to natural variation in habitat conditions; and
- There are existing international, European and national standards for a number of the required quality elements.

This Guidance, therefore, provides a framework within which Member States can either use/modify their existing methods, or where no appropriate monitoring and assessment systems exists, develop new systems that will incorporate all the requirements of the WFD.

Look Out! The methodology from this Guidance Document must be adapted to regional and national circumstances

The Guidance Document proposes an overall methodological approach. Because of the diversity of circumstances within the European Union, the way to apply a logical approach and answer questions will vary from one river basin to the next. This proposed methodology will therefore need to be tailored to specific circumstances.

While monitoring for surface and groundwater status will require the development/adaptation of specific assessment systems, it is critical that Member States ensure that the following key criteria are incorporated into the programmes of measures:

- An assessment on the deviation of observed conditions to those that would normally be found under reference conditions;
- Provides for natural and artificial physical habitat variation;
- Accounts for the range of natural variability and variability arising from anthropogenic activities of all quality elements in all water-body types;
- Accounts for interactions between surface and groundwaters; and,
- Provides for detection of the full range of potential impacts to enable a robust classification of ecological status.

Incorporation of the above key criteria into the assessment systems of each Member State will ensure that ecological quality is reported to the Commission using a unit-less classification scale based on ratios or fractions of reference values. This will enable Member States to continue using existing national assessment systems (where they exist), whilst reporting ecological status to the Commission on a common European scale.

Look Out! What you will not find in this Guidance Document

The Guidance Document focuses on the monitoring requirements of the Directive. The Guidance does not focus on:

- *Determination of reference conditions;*
- *Development of assessment and classification Systems;*
- *Monitoring wetlands; or,*
- *Data analysis and reporting.*

Implementing the Directive: Setting the Scene

1.5 December 2000: A Milestone for Water Policy

1.5.1 A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that today form the foundation of the Water Framework Directive.

1.6 The water Framework Directive: new challenges in EU water policy

1.6.1 What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

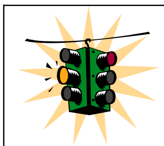
- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

1.6.2 …and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

1.7 What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (Article 3, Article 24);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (Article 5, Article 6, Annex II, Annex III);
- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (Article 2 (22), Annex V);
- To make the monitoring networks operational by 2006 (Article 8);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (Article 11, Annex III);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (Article 13, Article 4.3);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (Article 9);
- To make the programme of measures operational by 2012 (Article 11); and,
- To implement the programmes of measures and achieve the environmental objectives by 2015 (Article 4).



Look Out!

Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

1.8 Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007; and,
- The draft river basin management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of integration that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives,** combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general 'good' status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology, engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Freshwater Fish Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and civil society in decision making,** by promoting transparency and making information accessible to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;

- **Integration of different decision-making levels that influence water resources and water status** (these could be at a local, regional or national level), for an effective management of all waters;
- **Integration of water management by different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.

1.9 What is being done to support implementation?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

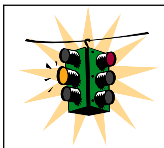
May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and Guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, and involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance. A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision body for the Common Implementation Strategy.

A working group has been created for dealing specifically with monitoring issues. The main short-term objective of this working group was the development of a non-legally binding and practical Guidance for supporting the implementation of the monitoring requirements of the Water Framework Directive. The members of this working group on monitoring are scientists, technical experts and stakeholders from European Union Member States, from a limited number of candidate countries to the European Union and from focal point organisations involved in water and environmental policy in candidate countries.

The working group on monitoring has organised several discussions and feedback events such as meetings and workshops, to ensure an adequate input and feedback from a wider audience during the Guidance development phase, and to evaluate earlier versions of the Guidance Document,. You will find the synthesis of key discussions and events in Annex VII.



Look Out! You can contact the experts involved in the working group on monitoring

The list of working group 2.7 (monitoring) members with full contact details can be found in Annex V. If you need input into your own activities, contact a member from the working group in your country. If you want more information on specific scoping and testing pilot studies, you can also contact directly the persons in charge of carrying out these studies.

Developing the Guidance Document: an interactive process

Within a very short time period, a large number of experts and stakeholders have been involved at varying degrees in the development of this Guidance Document. The process for their involvement has included the following activities:

- Regular meetings of the 40-plus experts and stakeholder members of working group 2.7;
- Organisation of four workshops to present and discuss the activities and preliminary output of Working group 2.7:
  - Working Group Meeting No. 1 June 2001 - Rome, Italy. Discussion of proposed work schedule and member state contributions;
  - Working group co-ordination team meeting November 2001 – Brussels, Belgium. Meeting held with small group of experts from lead countries to discuss progress on the work plan and agree on the next phases;
  - Working Group Meeting No. 2 January 2002 - Rome, Italy. Presentation and discussion of the first draft. Identification of areas for comment and Member State contributions;
  - Working Group Meeting No. 3 June 2002 - Brussels, Belgium. Revised draft presented and discussed;
  - Working Group Meeting No. 4 September 2002 – Copenhagen, Denmark. Presentation of final draft for comment and discussion.
- Regular interactions with experts from other working groups of the Common Implementation Strategy, mainly those dealing with the assessment of pressures and impacts, intercalibration, reference conditions, groundwater, coastal waters and river basin planning. Three events for discussing and evaluating the Guidance Document; and,
- A final evaluation of the draft Guidance (content and format) was undertaken following the Copenhagen working group meeting. Criteria for evaluating the Guidance were completeness, rigour, practicality, ease of use, ease of understanding and usefulness, and integration with other disciplines and elements of the Directive.

2 Common Understanding of the Monitoring Requirements of the Water Framework Directive

2.1 Monitoring requirements for the Directive

Article 8 of the Directive establishes the requirements for the monitoring of surface water status, groundwater status and protected areas. Monitoring programmes are required to establish a coherent and comprehensive overview of water status within each river basin district. The programmes have to be operational at the latest by 22 December 2006, and must be in accordance with the requirements of Annex V.

Annex V indicates that monitoring information from **surface waters** is required for:

- The classification of status. (*Note: Member States must provide a map for each river basin district in their territory illustrating the classification of the ecological and chemical status of each body of water using the colour-coding system specified by the Directive.)*
- Supplementing and validating the Annex II risk assessment procedure;
- The efficient and effective design of future monitoring programmes;
- The assessment of long-term changes in natural conditions;
- The assessment of long-term changes resulting from widespread anthropogenic activity;
- Estimating pollutants loads transferred across international boundaries or discharging into seas;
- Assessing changes in status of those bodies identified as being at risk in response to the application of measures for improvement or prevention of deterioration;
- Ascertaining causes of water bodies failing to achieve environmental objectives where the reason for failure has not been identified;
- Ascertaining the magnitude and impacts of accidental pollution;
- Use in the intercalibration exercise *(Note this is not an Article 8 requirement)*;
- Assessing compliance with the standards and objectives of Protected Areas; and,
- Quantifying reference conditions (where they exist) for surface water bodies. (*Note that this is an Annex II requirement).*

Annex V also indicates that monitoring information from **groundwater** is required for:

- Providing a reliable assessment of quantitative status of all groundwater bodies or groups of bodies; *(Note: Member States must provide maps illustrating the quantitative status of all groundwater bodies or groups of bodies using the colour-coding scheme set out in the Directive);*
- Estimating the direction and rate of flow in groundwater bodies that cross Member States boundaries;
- Supplementing and validating the impact assessment procedure;
- Use in the assessment of long term trends both as a result of changes in natural conditions and through anthropogenic activity;
- Establishing the chemical status of all groundwater bodies or groups of bodies determined to be at risk. *(Note: Member States must provide maps illustrating the*

chemical status of all groundwater bodies or groups of bodies using the colour-coding scheme set out in the Directive.);

- Establishing the presence of significant and sustained upwards trends in the concentrations of pollutants. *(Note: Member States must indicate on the maps of chemical status using a black-dot, those groundwater bodies in which there is a significant upward trend);* and,
- Assessing the reversal of such trends in the concentration of pollutants in groundwater *(Note: Member States must indicate on the maps of chemical status using a blue-dot, those groundwater bodies in which a significant upward trend has been reversed).*

2.1.1 Reporting

The following must be reported in the River Basin Management Plans:

- Maps of the monitoring networks;
- Maps of water status;
- An indication on the maps of the bodies of groundwater which are subject to a significant upward trend in concentration of pollutants and an indication of the bodies of groundwater in which such trends have been reversed; and,
- Estimates of the confidence and precision attained by the monitoring systems.

Three types of monitoring[1] for surface waters are described in Annex V: surveillance, operational and investigative monitoring. For groundwater a water level monitoring network is required which will provide a reliable assessment of the quantitative status of all groundwater bodies or groups of bodies including an assessment of the available groundwater resource. It should be noted that the water level network alone will not be able to achieve this assessment. In terms of groundwater chemical status, surveillance and operational monitoring are required. An additional objective of groundwater surveillance and operational monitoring is to provide information that can be used in the assessment and in establishing the presence of long term trends in pollutant concentrations. Surveillance monitoring data should also be used to assess long term trends in natural conditions.

These types are to be supplemented by monitoring programmes required for Protected Areas registered under Article 6. Annex V only describes requirements for Drinking Water Protected Areas in surface water and for Protected Areas for habitats and species. Member States may wish to integrate monitoring programmes established for other Protected Areas within the programmes established under the Directive. This is likely to improve the cost-effectiveness of the various programmes.

2.2 What Water bodies should be monitored

The Water Framework Directive covers **all** waters[2] including inland waters (surface water and groundwater) and transitional and coastal waters up to one sea mile (and for the chemical status also territorial waters which may extend to 12 sea miles) from the territorial baseline of a Member State independent of the size and the characteristics[3].

This totality of waters is, for the purpose of the implementation of the directive, attributed to geographical or administrative units, in particular the **river basin**, the **river basin district**,

---

[1] *In the context of the Directive monitoring means the gathering of data and information on the status of water, and does not include the direct measurement of emissions and discharges to water. The latter is being dealt with by WG 2.1, IMPRESS*

[2] *Taken from horizontal Guidance on the application of the term "water body", version 7.0*

[3] *Articles 2 (1), (2) and (3)*

and the "**water body**"[4]. In addition, groundwaters and stretches of coastal waters must be associated with a river basin (district).

Whereas the river basin is the geographical area related to the hydrological system, the river basin district must be designated by the Member States in accordance to the directive as the "**main unit for management of river basins**"[5].

One key purpose of the Directive is to prevent further deterioration of, and protect and enhance the status of aquatic ecosystems, and with regard to their water needs, terrestrial ecosystems and wetlands directly depending on the aquatic ecosystems. The success of the Directive in achieving this purpose and its related objectives will be mainly measured by the status of "water bodies". "Water bodies" are therefore the units that will be used for reporting and assessing compliance with the Directive's principal environmental objectives. However, it should be emphasised that the identification of a "water body" is a tool not an objective in itself.

Monitoring is a cross-cutting activity within the Directive and as such there are important interrelationships with other Articles and Annexes of the Directive. A key Article in relation to monitoring and the design of appropriate programmes for surface waters and groundwater is Article 5. Figures 2.1 and 2.2 summarise the relationship between articles 5 and 8 for surface waters and groundwater, respectively. Article 5 requires river basin districts to be characterised and the environmental impact of human activities to be reviewed in accordance with Annex II. The first assessments must be completed by 22 December 2004. Risk assessments will be on-going as they will be required for subsequent River Basin Management Plans. The first assessments must be completed 2 years before monitoring programmes have to be operational.

Annex II describes a process by which surface water bodies are identified, categorised and then typified according to one of two systems A or B given in section 1.2 of the Annex. Type-specific reference conditions have to be identified for each surface water body type. It is the type specific reference conditions from each surface water body type that the monitoring results will be compared with to give an assessment of the status of a water body categorised in the water body type. Information on the type and magnitude of the significant anthropogenic pressures to which the surface water bodies in each river basin district are subject has to be collected and maintained. There must then be an assessment of the susceptibility of the surface water status of bodies to the pressures identified, and of the likelihood that surface water bodies within the river basin district will fail to meet the environmental quality objectives set under Article 4. This assessment will use any available existing monitoring data: the extent of existing data will vary greatly from country to country. Also expert judgement and /or modelling approach (i.e. risk assessment) can be used. For the first assessment there will not be data arising from the Article 8 monitoring programmes as they do not have to be operational until the end of 2006: data should be available for subsequent assessments for future RBMPs. However, many countries already have extensive monitoring programmes.

---

[4] *Articles 2 (13), (15), (10), and (12) respectively*
[5] *Article 2 (15)*

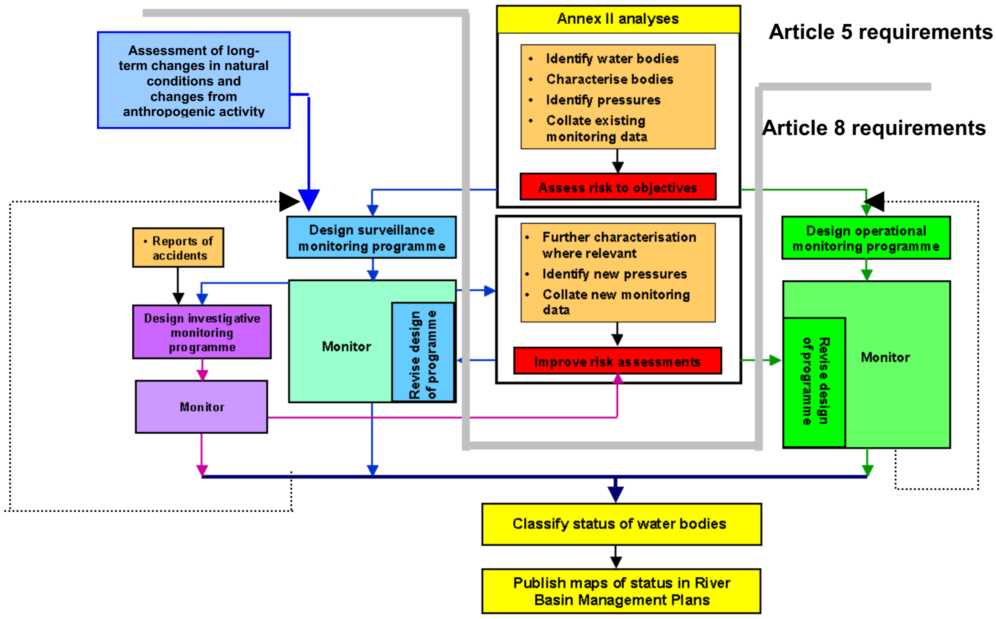


Figure 2.1 **Schematic diagram illustrating the relationship between Article 5 and Article 8 in the design of surface water monitoring programmes**

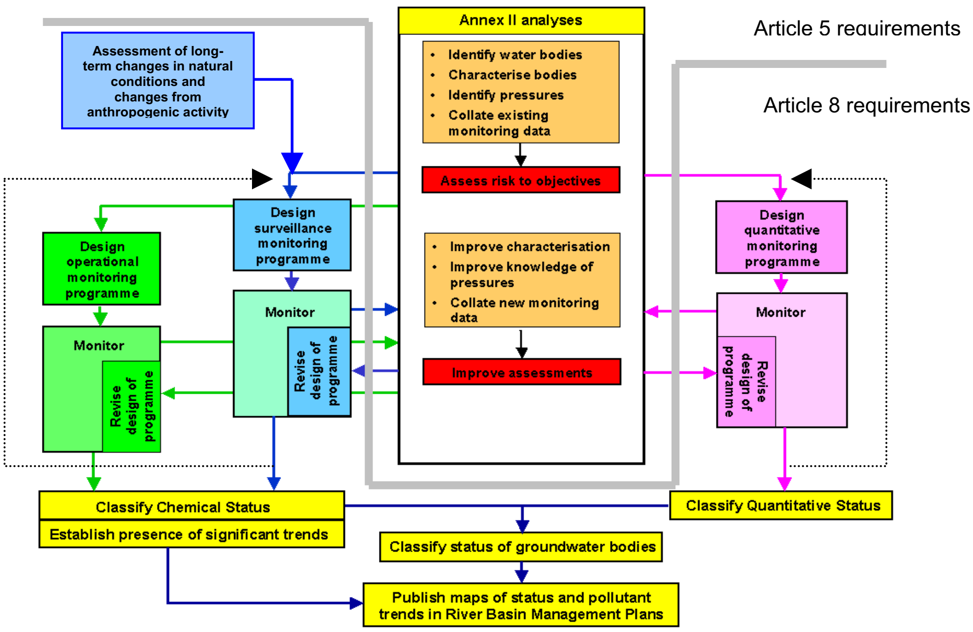

Figure 2.2 **Schematic diagram illustrating the relationship between Article 5 and Article 8 in the design of groundwater monitoring programmes**

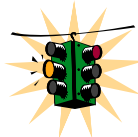
Thus the Annex II risk assessments play a key role in the initial design and subsequent revision of the monitoring programmes required by the Directive.

The Directive introduces a flexible hierarchical system for monitoring the very many different types of water body across Europe reflecting the fact that natural physical and geological conditions and anthropogenic pressures vary greatly across Europe. Because of this, a monitoring system designed for one part of Europe may not be entirely applicable in another. The Directive seeks ways of harmonising the results of monitoring systems and ecological assessments rather than imposing a common ecological quality assessment system in each country.



Look Out! The methodology from this Guidance Document must be adapted to regional and national circumstances
The Guidance Document proposes an overall pragmatic approach. Because of the diversity of circumstances within the European Union, Member States may apply this Guidance in a flexible way in answer to problems that will vary from one river basin to the next. This proposed Guidance will therefore need to be tailored to specific circumstances. However, these adaptations should be justified and should be reported in a transparent way.

The objective of monitoring is to establish a coherent and comprehensive overview of water status within each River Basin District and must permit the classification of all surface water bodies into one of five classes[6] and groundwater into one of two classes[7]. However, this does not mean that monitoring stations will be needed in each and every water body. Member States will have to ensure that enough individual water bodies of each water body type are monitored. They will also have to determine how many stations are required in each individual water body to determine its ecological and chemical status. This process of selecting water bodies and monitoring stations should entail statistical assessment techniques, and should ensure that the overview of water status has an acceptable level of confidence and precision.

There is flexibility in terms of monitoring frequencies reflecting that some determinands and quality elements (in terms of surface waters) will be more variable than others. Member States can also plan their monitoring programmes and resources so that not all the selected quality elements (for surface waters) and chemical parameters (for groundwater) have to be monitored every year at every station. This should prevent a situation where countries have to monitor for chemical substances even though they are known not to be present in the catchment, except where validation of the risk assessments is required. In short, cost-effective and targeted monitoring programmes can be designed.

An important aspect in the design of monitoring programmes is quantifying the temporal and spatial variability of quality elements and the parameters indicative of the quality elements in the surface water bodies being considered. Those that are very variable may require more sampling (and hence cost) than those that are more stable or predictable. Alternatively, variability might be reduced or managed by an appropriate targeted or stratified sampling programme which collects data in a limited but well-defined sampling window.

For surface water bodies, the Directive requires that sufficient surface water bodies are monitored in surveillance programmes to provide an assessment of the overall surface water status within each catchment and sub-catchment within the river basin district. Operational monitoring is to establish the status of those water bodies identified as being at risk of failing their environmental objectives, and to assess any changes in their status from the programmes of measures. Operational monitoring programmes must use parameters indicative of the quality element or elements most sensitive to the pressure or pressures to which the body or group of bodies is subject. This means that the least number of estimated quality element values may be used in status classification. This will help reduce the errors in the assessment of status. It will therefore be inherently less error prone than surveillance

[6] *Annex V 1.3*
[7] *Annex V 2.2.4 and 2.4.5*

monitoring which uses estimates of all quality elements (i.e. the chance of a water body being wrongly classified will in theory be lower in operational monitoring, everything else being equal).

Indicators must be used in monitoring to estimate the value for the relevant biological quality element. Where the confidence in the estimate provided by one indicator is considered unacceptable, several indicators may be used and a weighting procedure adopted to obtain an acceptable confidence in the estimated value of the quality element. This will also help reduce errors in the assessment of status. Indicators can also be chosen for which reference conditions can be most reliably established and for which errors in monitoring are small and well known.

The purpose of delineating water bodies is to provide for an accurate description of the status of surface water and groundwater and provide a sound basis for management of the water environment. The number of water bodies required in monitoring programmes will, therefore, be strongly dependent on the degree of variation in the status of the water environment as well as on the extent and characteristics of surface waters in a Member State's territory (e.g. number of lakes, whether the State has a coast, etc). Where there are numerous and significant differences in status, water bodies will be equally numerous to reflect those differences. Where status is similar, water bodies will tend to be larger and therefore fewer in number. The scale of monitoring programmes will be dependent to some degree on the numbers of water bodies – or more accurately on the extent of, and variability in, impacts on the water environment. However, the amount of monitoring required will also depend on the degree to which the characteristics of, and range of pressures on, a Member State's water bodies allow them to be grouped for monitoring purposes.

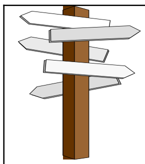
2.3 Clarification of the term "supporting"

The Directive specifies quality elements for the classification of ecological status[8] that include hydromorphological elements supporting the biological elements and chemical and physico-chemical elements supporting the biological elements. For surveillance monitoring, parameters indicative of all the biological, hydromorphological and all general and specific physico-chemical quality elements are required to be monitored. For operational monitoring, the parameters used should be those indicative of the biological and hydromorphological quality elements most sensitive to the pressures to which the body is subject, all priority substances discharged and other substances discharged in significant quantities. The ecological status classification[9] of a body of water is to be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the normative definitions[10].

Supporting means that the values of the physico-chemical and hydromorphological quality elements are such as to support a biological community of a certain ecological status, as this recognises the fact that biological communities are products of their physical and chemical environment. The latter 2 aspects fundamentally determine the type of water body and habitat, and hence the type-specific biological community. It is not intended that these supporting elements can be used as surrogates for the biological elements in surveillance and operational monitoring. The monitoring or assessment of the physical and physico-chemical quality elements will support the interpretation assessment and classification of the results arising from the monitoring of the biological quality elements.

---

[8] *Annex V.1.1*
[9] *Annex V.1.4.2*
[10] *Annex V.1.2*



The classification of ecological status is being considered by Working Group 2.3 on *"establishing reference conditions and ecological status class boundaries for inland surface waters*", and Working Group 2.4 on *"typology, reference conditions and classification systems for transitional and coastal waters"* .The reader should refer to the Guidance Documents produced by these 2 Working Groups (WFD CIS Guidance Document Nos. 10 and 5). for information on the use of quality elements for the classification of ecological status.

The Directive permits Member States to make estimates of the values of the biological quality elements using monitoring data for parameters indicative of the biological quality elements. The use of indicator parameters should facilitate reliable and cost-effective assessments:

1. Monitoring whole biological quality elements, such as the abundance of all fish species, in each water body could be a very onerous task. The Directive therefore provides that Member States may use species or groups of species representative of the quality element as a whole in their monitoring systems[11].
2. Second, the possibility of using more than one indicator to estimate the value for a biological quality element could provide an important means of avoiding unacceptable risks of misclassification. This is because the results for different indicators can be cross-checked. If the result for one is at odds with the result for another, this may suggest that more data is needed to achieve the required confidence in the estimated value of the quality element.

In some situations, one or more of the indicators used may need to be non-biological. For example, where the pressure to which a water body is subject results in hydromorphological changes, such as a reduction in habitat area, estimates of the values for the abundance of biological elements in the remaining habitat could be made using biological indicators. However, to provide the necessary estimate of the effect of the loss of habitat on the abundance of the quality elements in the water body as a whole, these estimates would need to be combined with a non-biological measure of the reduction in habitat area.

In another situation, a biological indicator is able to provide an estimate of the value of a biological quality element, such as phytoplankton abundance, but the errors in that estimate do not provide for an acceptable level of confidence in status classification. The pressure to which the water body is subject also affects a non-biological parameter; phosphorous concentration. Monitoring information on this parameter could therefore be used to improve confidence in the value of the biological quality element estimated by the biological indicator.

Key Principal

The use of non-biological indicators for estimating the condition of a biological quality element may complement the use of biological indicators but it cannot replace it. Without comprehensive knowledge of all the pressures on a water body and their combined biological effects, direct measures of the condition of the biological quality elements using biological indicators will always be necessary to validate any biological impacts suggested by non-biological indicators.

2.4 Horizontal Guidance on the application of the term "water body"

Article 2.10 of the Directive provides the following definition of a body of surface water: *"Body of surface water" means a* ***discrete and significant element*** *of surface water such as a*

[11] *Annex V 1.4.1(i)*

lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.

Article 2.12 defines a groundwater body as: "*Body of groundwater" means a distinct volume of groundwater within an aquifer or aquifers*.

The Commission, at the request of many of the Working Groups, is developing a horizontal Guidance Document on the identification of water bodies under the Water Framework Directive[12]. Some key aspects with regards to the design and implementation of appropriate monitoring programmes are reproduced below.

Key Principal

The "water body" should be a coherent sub-unit in the river basin (district) to which the environmental objectives of the directive must apply. Hence, the main purpose of identifying "water bodies" is to enable the status to be accurately described and compared to environmental objectives[13].

It should be clear that the identification of water bodies is, first and foremost, based on geographical and hydrological determinants. However, the identification and subsequent classification of water bodies must provide for a sufficiently accurate description of this defined geographic area to enable an unambiguous comparison with the objectives of the Directive. This is because the environmental objectives of the Directive, and the measures needed to achieve them, apply to "water bodies". A key descriptor in this context is the "status" of those bodies. If water bodies are identified that do not permit an accurate description of the status of aquatic ecosystems, Member States will be unable to apply the Directive's objectives correctly. At the same time, an endless sub-division of water bodies should be avoided in order to reduce administrative burden if it does not fulfil any purpose as regards the proper implementation of the Directive. In addition, the aggregation of water bodies may, under certain circumstances, also help to reduce meaningless administrative burden, in particular for smaller water bodies.

However, identifying water bodies that will provide for an accurate description of the status of surface water and groundwater will require information from the Article 5 analyses and reviews, and the Article 8 monitoring programmes. Some of the necessary information will not be available before 2004. The information that is available is likely to be updated and improved in the period prior to the publication of each river basin management plan.

Geographical or hydromorphological features can significantly influence surface water ecosystems and their vulnerability to human activities. These features can also differentiate discrete elements of surface water. For example, the confluence of one part of a river with another could clearly demarcate a geographically and hydromorphologically distinct boundary to a water body.

However, the Directive does not exclude other elements, such as a part of a lake or part of transitional water, from being considered as water bodies. For example, if part of a lake is of a different type to the rest of the lake, the lake must be sub-divided into more than one surface water body.

A requirement that is implicit in the Directive is that the purpose of identifying "water bodies" is to enable the **status** of surface waters and groundwater to be accurately described.

---

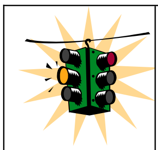
[12] *Version 8.0, 31 October 2002*

[13] *An estimate of the status of water bodies will be required to assess the likelihood that they will fail to meet the environmental quality objectives set for them under Article 4 [Article 5; Annex II 1.5 & 2]. The status of water bodies must be classified using information from the monitoring programmes [Article 8, Annex V 1.3, 2.2 & 2.4]. The status of water bodies must be reported in the river basin management plans [Article 13, Annex VII] and, where necessary, measures must be prepared [Article 11, Annex VI].*

A discrete element of surface water should not contain significant elements of different status. A "water body" must be capable of being assigned to a single ecological status class with sufficient confidence and precision through the Directive's monitoring programmes.

The delineation of bodies of groundwater must ensure that the relevant objectives of the Directive can be achieved. This does not mean that a body of groundwater must be delineated so that it is homogeneous in terms of its natural characteristics, or the concentrations of pollutants or level alterations within it. However, bodies should be delineated in a way that enables an appropriate description of the quantitative and chemical status of groundwater.

It is clearly possible to progressively subdivide waters into smaller and smaller units that would impose significant logistic burdens. However, it is not possible to define the scale below which subdivision is inappropriate. It will be necessary to balance the requirement to adequately describe water status with the need to avoid the fragmentation of surface waters into unmanageable numbers of water bodies. In addition, it may be appropriate to aggregate water bodies under certain circumstances, to reduce meaningless administrative burden. In the end, it is a matter for Members States to decide on the basis of the characteristics of each River Basin District.



Look Out!
The Directive only requires sub-divisions of surface water and groundwater that are necessary for the clear, consistent and effective application of its objectives. Sub-divisions of surface water and groundwater into smaller and smaller water bodies that do not support this purpose should be avoided.

Key Principal
Surface water bodies or bodies of groundwater may each be grouped for the purposes of assessing the risk of failing to achieve the objectives set for them under Article 4 (pressures and impacts). They may also be grouped for monitoring purposes where monitoring sufficient indicative or representative water bodies in the sub-groups of surface water or groundwater bodies provides for an acceptable level of confidence and precision in the results of monitoring, and in particular the classification of water body status.

2.5 Risk, precision and confidence

Risk[14] and confidence[15] are words used in Annex II[16] (in terms of risk of failing environmental objectives, and confidence in the values of reference conditions), and risk, confidence and also precision[17] are words used in Annex V[18] (design of monitoring programmes). Their interpretation will affect the scale and extent of the monitoring required to assess status at any particular time and changes in status with time. What are considered to be "acceptable", "adequate" and "sufficient" levels of precision and confidence, and a "significant" risk, will determine aspects such as the:

- number of water bodies included in the various types of monitoring;
- number of stations that will be required to assess the status of each water body; and

[14] *At the simplest level, a risk can be thought of as the chance of an event happening. It has two aspects: the chance, and the event that might happen. These are conventionally called the probability and the consequence.*
[15] *The probability (expressed as a percentage) that the answer obtained (e.g. by the monitoring programme) does in fact lie within calculated and quoted limits, or within the desired or designed precision.*
[16] *Annex II.1.1.5, 2.1 and 1.3*
[17] *The discrepancy between the answer (e.g. a mean) given by the monitoring and sampling programme and the true value.*
[18] *Annex V 1.3, 2.3 and 2.4*

- frequency at which parameters indicative of surface water quality elements will have to be monitored.

Choosing levels of precision and confidence would set limits on how much uncertainty (arising from natural and anthropogenic variability) can be tolerated in the results of monitoring programmes. In terms of monitoring for the Directive, it will be necessary to estimate the status of water bodies and in particular to identify those that are not of 'good' status or good ecological potential or are deteriorating in status. Thus status will have to be estimated from the sampled data. This estimate will almost always differ from the true value (i.e. the status which would be calculated if all water bodies were monitored and sampled continuously for all components that define quality).

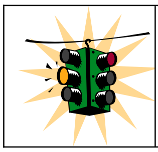
The level of acceptable risk will affect the amount of monitoring required to estimate a water body's status. In general terms, the lower the desired risk of misclassification, the more monitoring (and hence costs) required to assess the status of a water body. It is likely that there will have to be a balance between the costs of monitoring against the risk of a water body being misclassified. Misclassification implies that measures to improve status could be inefficiently and inappropriately targeted. It should also be borne in mind that in general the cost of measures for improvement in water status would be orders of magnitude greater than the costs of monitoring. The extra costs of monitoring to reduce the risk of misclassification might therefore be justified in terms of ensuring that decisions to spend larger sums of money required for improvements are based on reliable information on status. Further, from an economics point of view, stronger criteria should be applied to avoid a situation where water bodies fulfilling the objective are misjudged and new measures applied. Also it should be noted that for surface water surveillance monitoring, and all groundwater monitoring, sufficient monitoring should be done to validate risk assessments and test assumptions made.

The Directive has not specified the levels of precision and confidence required from monitoring programmes and status assessments. This perhaps recognises that achievement of too rigorous precision and confidence requirements would entail a much-increased level of monitoring for some, if not all, Member States.

Key Principal
On the other hand the actual precision and confidence levels achieved should enable meaningful assessments of status in time and space to be made. Member States will have to quote these levels in RBMPs and will thus be open to scrutiny and comment by others. This should serve to highlight any obvious deficiencies or inadequacies in the future.

The starting point for many Member States will probably be an assessment of existing stations and samples to see what level of precision and confidence can be achieved by those resources. It is likely that this will have to be an iterative process with modification and revision of monitoring programmes to achieve levels of precision and confidence that allow meaningful assessments and classification.

It is also likely that Member States will use expert judgement to some extent in assessing the risk of misclassification. For example in the case of a misclassifying bodies "at risk" the persons responsible for making the decision to implement expensive measures will clearly secure their decisions by further assessments before implementing the measures. In the case of misclassifying bodies as "not being at risk" there will be much local experience and expert judgement (by water managers or public persons) to doubt the monitoring results and assessment and look for further clarification.



Look Out!
Guidance on the level of precision required for classification is being discussed by WG 2.3 Reference conditions inland surface water and WG 2.4 Typology, classification of transitional, coastal waters.

2.6 Inclusion of wetlands within the monitoring requirements of the Directive

“Wetland ecosystems are ecologically and functionally significant elements of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in CIS horizontal Guidance Documents water bodies (WFD CIS Guidance Document No. 2) and further considered in the Guidance Document on wetlands (currently under development).

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal Guidance Document on wetlands (currently under development).

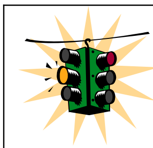
Wetlands are not defined as a separate water category or water body type within the Directive. There are, however, explicit references to wetlands within the Directive[19]. Wetlands could be considered as relevant under the Directive in three contexts:

1. As part of the structure and condition of riparian zones of rivers, shore zones of lakes and intertidal zones of transitional and coastal waters. The structure and condition of these zones is one of the hydromorphological quality elements specified in Annex V 1.1 – 1.2;
2. As directly dependent terrestrial ecosystems in the definition of good groundwater quantitative status and good groundwater chemical status (Annex V 2.1.2 and 2.3.2); and
3. For use in supplementary measures, which MSs may use where cost-effective, to achieve the Directive’s objectives (Annex VI B vii).

"Wetlands" are defined by Articles 1.1 and 2.1 of the Ramsar Convention (Ramsar, Iran, 1971) as shown below:

Article 1.1: *".. Wetlands are areas of marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six metres."*

Article 2.1, wetlands: *"may incorporate riparian and coastal zones adjacent to the wetlands, and islands or bodies of marine water deeper than six metres at low tide lying within the wetlands".*



Look Out!
The inclusion of wetlands in the monitoring requirements of the Directive is a matter of discussion between Members States, NGOs and other stakeholders. As a result the EEB and WWF prepared a draft paper regarding wetlands and WFD. It was presented at the Strategic Co-ordination Group (SCG) (30.09.0 -01.10.02) meeting in order to determine what actions are required. At this meeting it was agreed that the SCG should take the issue of wetlands under the umbrella of the CIS and to prepare a ‘horizontal guidance’ within 2003.

[19] *e.g. Article 1(a), Preamble (8), (23)*

2.7 Surveillance monitoring of surface waters

2.7.1 Objectives and timing

The objectives[20] of surveillance monitoring of surface waters are to provide information for:

- Supplementing and validating the impact assessment procedure detailed in Annex II;
- The efficient and effective design of future monitoring programmes;
- The assessment of long term changes in natural conditions; and
- The assessment of long term changes resulting from widespread anthropogenic activity.

The results of such monitoring should be reviewed and used, in combination with the impact assessment procedure described in Annex II, to determine requirements for monitoring programmes in the current and subsequent River Basin Management Plans (RBMP).

As has already been described, there will be no information arising from surveillance monitoring for the first risk assessment undertaken under Article 5 – monitoring programmes have to be operational by December 2006, and the first Article 5 characterisation/risk assessment completed by December 2004. However, any existing monitoring data should be used in the assessment. Many countries have already established extensive monitoring programmes.

Surveillance monitoring has to be undertaken for at least a period of one year during the period of a RBMP. The deadline for the first RBMP is 22 December 2009. The monitoring programmes must start by 22 December 2006. The first results will be needed for the first draft RBMP to be published at the end of 2008[21], and then for the finalised RBMPs at the end of 2009. These plans must include status maps.

2.7.2 Selection of monitoring points

The Directive requires that sufficient water bodies should be included in the surveillance monitoring programme to provide an assessment of the overall surface water status within each catchment and sub-catchment of the river basin district. This would imply that more water bodies would have to be monitored in a heterogeneous river basin district in terms of types of water body characteristics and anthropogenic pressures than in a more homogenous catchment. In both cases a statistically representative sub sample would be adequate. A good example of representative sub sampling is in some Nordic lake monitoring programmes where only relatively few of the many thousands of lakes are monitored and directly assessed. The results from the 'few' lakes are then extrapolated to the whole 'population' of lakes being assessed.

If there is low confidence in the Annex II risk assessments (e.g. because of limited existing monitoring data), more surveillance monitoring will be required initially to supplement and validate the assessments than will be the case where existing information is extensive.

Surveillance monitoring may also initially need to be more extensive in terms of the number of water bodies included, monitoring stations within bodies and the range of quality elements. This is because:

- of the probable lack of appropriate existing monitoring information and data;
- the Directive requires Member States to consider a different range of quality elements and a different range of pressures than have previous Directives.

---

[20] *Annex V.1.3.1*
[21] *Article 14.1.c*

Member States may also wish or have the need to (depending on the amount of existing information and the confidence in the first Annex II risk assessments) undertake surveillance monitoring each year, at least during the first three years (2006-2008).

For subsequent surveillance monitoring programmes the same principles, outlined above, of validating the risk assessment (which may well have changed) etc, should be used to develop the programme but, depending on the additional information provided from the other monitoring programmes, such as the operational monitoring programmes, the extent of the surveillance monitoring programme will change with time.

Annex II risk assessments are to identify those water bodies at risk of failing EQOs. If confidence in the identification of water bodies at risk is still low after both the Annex II risk assessments and their supplementation and validation using surveillance monitoring data, bodies that are actually not at risk should be assumed to be at risk. Consequently, a larger operational monitoring network will be required than would be the case if water bodies at risk and not at risk were more reliably differentiated by the risk assessments.

Key Question

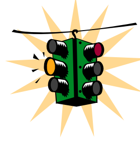
For risk assessments, and therefore surveillance monitoring what is the acceptable risk of a body being described as not at risk of failing the objectives when it is in fact at risk of such a failure?

The Directive also stipulates that monitoring should be carried out at points where:

- The rate of water flow is significant within the river basin district as a whole; including points on large rivers where the catchment is greater than 2 500 km^2;
- The volume of water present is significant within the river basin district, including large lakes and reservoirs;
- Significant bodies of water cross a Member State boundary;
- Sites are identified under the Information Exchange Decision 77/795/EEC; and
- At such other sites as are required to estimate the pollutant load which is transferred across Member States boundaries, and which is transferred into the marine environment.

The size typology given in Annex II (System A) implies that rivers with catchment areas greater than 10 km^2 and (b) lakes greater than 0.5 km^2 in surface area are water bodies that fall under the requirements of the Directive and might need to be included within the water status assessment and monitoring. Surface waters below the System A typology size thresholds could be Protected Areas, be important to the ecology of the river basin as a whole (e.g. important spawning and breeding grounds), or be subject to pressures that have significant consequences elsewhere in the river basin district. In the System B typology no such size limits are implied, though the typology used must achieve at least the same degree of differentiation as would be achieved using System A. Member States may thus wish or need to include small water bodies within the monitoring and assessment requirements of the Directive.

In practice Member States will determine the size of water body that needs to be included in monitoring programmes. It will depend on the nature (natural and anthropogenic) of each River Basin District being characterised and the attainment of the objective to obtain a coherent and comprehensive overview of water status within the River Basin District.

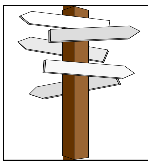


Look Out!

The horizontal guidance on water bodies (see section 3) indicates that Member States have flexibility to decide whether the purposes of the Directive, which apply to all surface waters, can be achieved without the identification of every minor but discrete element of surface water as a water body.

Surveillance monitoring is also required to provide information on long-term natural changes and long-term changes resulting from widespread anthropogenic activity. Information on the first will be important if such changes are likely to affect reference conditions. Monitoring for long-term natural changes is likely to be focused on high and maybe 'good' status water bodies. This is because such changes (possibly relatively small and gradual) are more likely to be detectable in the absence of the impact of anthropogenic activities which may mask natural changes. In terms of changes resulting from widespread anthropogenic activity, monitoring will be important to determine or confirm the impact of, for example, long range transport and deposition of pollutants from the atmosphere. If this is likely to lead to a risk of water bodies deteriorating in status (any status level down to poor) then those water bodies or groups of bodies will have to be included in operational monitoring programmes.

The first surveillance programme should also seek to establish a quantitative baseline for future assessments of long-term natural or anthropogenically induced changes, and also against which reductions in pollution from Priority Substances (PH), and cessation and phasing out of emissions of Priority Hazardous Substances (PHS) will be judged. This will be important in supplementing and validating the assessment of whether water bodies are at risk of failing Article 4 EQOs[22] or not.



The EAF Expert Group on the Analysis and Monitoring of Priority Substances will also be considering the assessment of compliance of PS and PHS in terms of the WFD.

2.7.3 Selection of quality elements

For surveillance monitoring, Member States must monitor at least for a period of a year parameters indicative of all biological, hydromorphological and general physico-chemical quality elements. The relevant quality elements for each type of water are given in Annex V.1.1. Thus for rivers, the biological parameters chosen to be indicative of the status of each biological element such as the aquatic flora, macro-invertebrates and fish must be monitored for. For example, in the case of the aquatic flora, the parameters might be presence or absence of indicator species or the population structure. The Directive indicates that monitoring of the biological quality elements must be at an appropriate taxonomic level to achieve adequate confidence and precision in the classification of the quality elements. This applies equally to the three types of surface water monitoring.

Those priority list substances discharged into the river basin or sub-basins must be monitored. Other pollutants[23] also need to be monitored if they are discharged in significant quantities in the river basin or sub-basin. No definition of 'significance' is given but quantities that could compromise the achievement of one of the Directive's objectives are clearly significant, and as examples, one might assume that a discharge that impacted a Protected Area, or caused exceedence of any national standard set under Annex V 1.2.6 of the Directive or caused a biological or ecotoxicological effect in a water body would be expected to be significant.

A structured approach should be used to inform the process of selecting which chemical should be monitored for in the surveillance monitoring programme. This should be based on a combination of knowledge of use patterns (quantity and locations), pathways for inputs (diffuse and/or point source) and existing information on potential ecological impacts. This is a basis for the risk assessment required under Annex II of the Directive.

Additionally the selection should be informed by information on the ecological status where indications of toxic impacts are found or from ecotoxicological evidence. This will help to

---

[22] *Article 4.1.a.i and 4.1.a.iv*
[23] *Annex VIII*

identify situations where unknown chemicals are entering the environment which need investigative monitoring.

Further guidance on the selection of chemicals is being provided by the IMPRESS working group (WFD CIS Guidance Document No. 3).

In the case of transboundary river basins, pollution may originate from sources which cannot be identified by the Member State. For example, it may originate from a country not covered by the requirements of the WFD. In these cases there would be no Annex II assessments on which to base the monitoring (unless the effects of the pollution have been detected through existing monitoring programmes). For this reason, a Member State might decide to monitor parameters indicative of all priority substances and all other relevant pollutants at a selection of surveillance sites established to detect possible transboundary pollution problems. In addition, Member States may suitably decide to monitor for all priority substances and other relevant pollutants during the first year of surveillance, especially in the case of transboundary water bodies or pollutants with long-range mobility.

2.8 Operational monitoring of surface waters

2.8.1 Objectives

The objectives of operational monitoring[24] are to:

- Establish the status of those bodies identified as being at risk of failing to meet their environmental objectives; and
- Assess any changes in the status of such bodies resulting from the programmes of measures.

Operational monitoring (or in some cases investigative monitoring) will be used to establish or confirm the status of bodies thought to be at risk. Therefore, it is operational monitoring that will produce the environmental quality ratios used for status classification for those water bodies included in operational monitoring. It is highly focused on parameters indicative of the quality elements most sensitive to the pressures to which the water body or bodies are subject.

Key Question

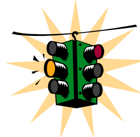
For operational monitoring, what is the acceptable level of risk of a body being wrongly classified?

The answer partly depends on what action is likely to be required if the objective is failed. Expensive measures would require higher certainty of failure to obtain EQOs to justify them than would low cost measures. Because the implications of misclassification could be serious for water users, there should be a high level of confidence in the estimates produced from operational monitoring data. In some cases failing objectives can be serious for water users, but in many cases implementation of unnecessary measures have more serious consequences for the community and therefore it is important to judge whether or not a water body is fulfilling its objectives.

Thus the required confidence in establishing the status of a water body will be highest where the implications of a misclassification to below ‘good’ status are high with costs potentially being wrongly imposed on a water user. Similarly there needs to be high confidence in ensuring that water bodies of less than ‘good’ status are not misclassified as good. In short a high level of confidence will be required close to the boundary of good/moderate status.

[24] *Annex V.1.3.2*

The more water bodies identified as being at risk of failing to achieve an environmental objective, the more operational monitoring will be required. Put more accurately: the more significant pressures there are upon the water environment, the more monitoring will be required to provide the information for managing those pressures. Generally it should be easier to achieve high levels of confidence in status classification where the pressure is very high and well identified, than at sites that lie close to the good/moderate status boundary.



Look Out!
Outputs from the Working Group on Pressures and Impacts will influence the monitoring programmes for environmental pressures such as the Priority Substances.

2.8.2 Selection of monitoring sites

Operational monitoring has to be undertaken for all water bodies that have been identified, by the review of the environmental impact of human activities (Annex II) and/or from the results of the surveillance monitoring, as being at risk of failing the relevant environmental objectives under Article 4. Monitoring must also be carried out for all bodies into which priority substances are discharged. This implies that monitoring in all such bodies will not necessarily be required as the Directive allows similar[25] water bodies to be grouped and representatively monitored.

In addition, monitoring sites for those priority list substances with environmental quality standards should be selected according to the requirements of the legislation establishing the standards.

The Directive gives further guidance on the selection of monitoring sites for other water bodies and those receiving discharges of priority list substances without specific guidance in legislation. The guidance differentiates between bodies at risk (of failing EOs) from significant point source, diffuse source and hydromorphological pressures. The number of monitoring stations selected needs to be sufficient to assess the magnitude and impact of the three specified pressures:

- In terms of all significant pressures more than one station per water body may be required to do this;
- In cases where a body of water is subject to more than one point source, stations may be selected to represent the magnitude and impact of the sources as a whole. In theory, it may sometimes be sufficient to have no monitoring points in a body where information from adjacent similar bodies, for example, allows an adequate assessment of the magnitude and impact of the point source. The confidence in any judgement of 'sufficiency' must be set out in the RBMP;
- In terms of diffuse sources and hydromorphological pressures, stations may be required in a number of those water bodies at risk;
- For diffuse sources, the selected water bodies need to be representative of the relative risks of the occurrence of the diffuse source pressures, and of the relative risks of the failure to achieve good surface water status. However, in selecting the representative water bodies for operational monitoring it should be taken into account that water bodies can only be grouped, for example, where the ecological conditions are similar or almost similar in terms of the magnitude and type pressure as well as in terms of hydrological and biological conditions such as retention time and food web structure. In all cases grouping must be technically or scientifically justifiable;

[25] *For example, in terms of type, pressures to which they are subject and sensitivity to those pressures.*

- For hydromorphological pressures, the selected water bodies should be indicative of the overall impact of the pressure to which all the bodies are subject;
- If only one source of pollutant is present in a water body included in the operational monitoring programme, the monitoring station should be selected according to what is judged to be the most sensitive location. If there are several sources of pollution or other pressures, it might be desirable or necessary (from the management perspective) for the operational monitoring system to be able to discriminate between the different pressures and sources. This could, for example, help in the apportionment of reduction measures relative to the impact of the pressures. Thus more than one monitoring station and different quality elements might be considered. It should also be noted that in many cases it will not be possible to measure the impact of each source of pressure, and that the impact of groups of pressures will have to be considered.

2.8.3 Selection of quality elements

For operational monitoring, Member States are required to monitor for those biological and hydromorphological quality elements most sensitive to the pressures to which the body or bodies are subject. For example, if organic pollution is a significant pressure on a river then benthic invertebrates might be the most sensitive and appropriate indicator of that pressure. Thus in the absence of other pressures, aquatic flora and fish populations may not need to be monitored in those bodies of water. However, the monitoring and assessment system must still be based on the concept of ecological status and not just reflect degrees of organic pollution without comparison to the appropriate reference conditions. This is because its ecological status must be defined.

As discussed in section 3, the use of non-biological indicators for estimating the condition of a biological quality element may complement the use of biological indicators but it cannot replace it. This does not exclude the use of non-biological indicators (such as physico-chemical parameters) when it is operationally appropriate, for example when measures to reduce pressures (e.g. discharges from Urban Waste Water Treatment Works) are related to specific physico-chemical parameters (e.g. total organic carbon, BOD or nutrients). In this case it might be appropriate to monitor non-biological indicators and biological indicators (e.g. macrozoobenthos) at different frequencies with the results from the physico-chemical monitoring being periodically validated by the results of the biological monitoring. This would be necessary because non-biological indicators cannot be relied on without checking their inference using biological indicators because we do not have perfect knowledge of cause-effect relationships, pressures, the effects of pressure combinations etc.

If a body is not identified as being at risk because of discharges of priority substances or other pollutants, no operational monitoring for these substances is required. A pollutant is defined[26] as ‘any substance liable to cause pollution in particular those listed in Annex VIII’. As such nutrients and substances that have an unfavourable influence on oxygen balance must also be considered as well as metals and organic micropollutants. Operational monitoring must use parameters relevant to the assessment of the effects of the pressures placing the body at risk.

2.9 Investigative monitoring

Investigative monitoring[27] may also be required in specified cases. These are given as:

- where the reason for any exceedences (of Environmental Objectives) is unknown;

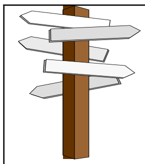
[26] *Article 2.31*
[27] *Annex V.1.3.3*

- where surveillance monitoring indicates that the objectives set under Article 4 for a body of water are not likely to be achieved and operational monitoring has not already been established, in order to ascertain the causes of a water body or water bodies failing to achieve the environmental objectives; or
- to ascertain the magnitude and impacts of accidental pollution.

The results of the monitoring would then be used to inform the establishment of a programme of measures for the achievement of the environmental objectives and specific measures necessary to remedy the effects of accidental pollution.

Investigative monitoring will thus be designed to the specific case or problem being investigated. In some cases it will be more intensive in terms of monitoring frequencies and focused on particular water bodies or parts of water bodies, and on relevant quality elements. Ecotoxicological monitoring and assessment methods would in some cases be appropriate for investigative monitoring.

Investigative monitoring might also include alarm or early warning monitoring, for example, for the protection of drinking water intakes against accidental pollution. This type of monitoring could be considered as part of the programmes of measures required by Article 11.3.1 and could include continuous or semi-continuous measurements of a few chemical (such as dissolved oxygen) and/or biological (such as fish) determinands. Such monitors are used on the River Rhine, for example.



Information on the use of bioassays to support implementation of the Directive is provided in the document:
“The potential role of bioassays in meeting the monitoring needs of the Water Framework Directive” < http://forum.europa.eu.int/Members/irc/env/wfd/library?l=/working_groups/wg_2_monitoring/factsheets_monitoring/bioassays >.

2.10 Frequency of monitoring for surface waters

2.10.1 General aspects

Some determinands and quality elements will be very variable (natural, anthropogenically caused and due to sampling error) in particular water bodies. A lot of monitoring in terms of numbers of sites and frequency of monitoring might thus be required to obtain high or sufficient levels of confidence and precision in a water body’s status. There will of course be a cost implication for Member States for the required monitoring. It is likely therefore, that the levels of confidence and precision achievable will be balanced against the costs, i.e. an assessment of the cost-effectiveness of the monitoring programme may be undertaken. In short the provision of reliable information from monitoring programmes will allow measures to be effectively and efficiently targeted.

The actual confidence and precision achieved by monitoring at any particular monitoring site will depend partly on the variability (both natural and resulting from anthropogenic activities) of the determinand being measured, and the frequency of monitoring. Member States are able to target their monitoring to particular times of year to take into account variability due to seasonal factors. An example would be the sampling for nutrients in marine waters in winter when uptake by biota is at its minimum. Seasonal sampling to reflect seasonal human pressures is also permitted.

Thus the Directive allows Member States to tailor their monitoring frequencies according to the conditions and variability within their own waters. These are likely to differ greatly from determinand to determinand, from water body type to water body type, from area to area and from country to country, recognising that a frequency adequate in one country may not be so in another. However, the key is to ensure that a reliable assessment of the status of all water bodies can be achieved, and the reliability of that assessment in terms of confidence and precision must be provided. The latter will have to be published in RBMPs and will therefore, be open to review and scrutiny by other experts, members of the public and the Commission.

As already described, lower monitoring frequencies and on some occasions even no monitoring may be justified when previous monitoring reveals/has revealed that concentrations of substances are below detection limits, declining or stable and there is no obvious risk of increase. An increase will not be likely for instance when the substance is not used in catchment and there is no atmospheric deposition. This corresponds with the thoughts to the principles used by OSPAR/HELCOM in their monitoring and assessment programmes

The minimum monitoring frequencies quoted in the Directive[28] may also not be adequate or realistic for transitional and coastal waters. There will generally be a lower level of confidence in most marine systems because of the much higher natural variability and heterogeneity. Natural variability can be reduced by targeting monitoring to specific seasons such as measuring nutrient concentrations in transitional and coastal waters during winter. Similarly the OSPAR guidelines for the monitoring of biota help programme managers to reduce variability by avoiding the spawning season, sampling pre-spawning for a worst-case scenario etc.

2.10.2 Surveillance monitoring

Surveillance monitoring must be carried out for each monitoring site for a period of one year during the period covered by a RBMP for parameters indicative of all biological quality elements, all hydromorphological quality elements and all general physico-chemical quality elements. Annex V[29] provides tabulated guidelines in terms of the minimum monitoring frequencies for all the quality elements. The suggested minimum frequencies are generally lower than currently applied in some countries. More frequent samples will be necessary to obtain sufficient precision in supplementing and validating Annex II assessments in many cases, for example phytoplankton and nutrients in lakes. Less frequent samples for the general physico-chemical quality elements are permissible if technically justified and based on expert judgement. In addition not all quality elements need to be monitored during the same year, there can be phased monitoring from year to year as long as all are monitored at least once over a year during the lifetime of the RBMP.

There is also an additional clause in Annex V that allows Member States to only undertake surveillance monitoring in specific water bodies once every three river basin management plans (RBMPs) (i.e. once in 18 years) when that body has reached ‘good’ status and when there is no evidence that impacts on that body have changed.

An objective of surveillance monitoring is to assess the long term changes in natural conditions and long term changes resulting from widespread anthropogenic activity. The minimum frequencies given in the Directive may not be adequate to achieve an acceptable level of confidence and precision in this assessment. It may therefore be necessary to increase the frequencies of at least some surveillance monitoring parameters and monitor more than once every sixth year at those surveillance sites designed to detect long-term changes.

2.10.3 Operational monitoring

In terms of operational monitoring Member States are required to determine monitoring frequencies that will provide a reliable assessment of the status of the relevant quality element. The same guidance given on minimum monitoring frequencies for surveillance

[28] *Annex V.1.3.4*
[29] *Annex V.1.3.4*

monitoring is also used for operational monitoring. Again more frequent monitoring will mostly likely be necessary in many cases, but also less frequent monitoring is justified when based on technical knowledge and expert judgement.

The statistical interpretation of results from monitoring is an important topic to ensure a reliable assessment of status etc. Data arising from traditional sampling programmes (e.g. regular monthly sampling) and from more targeted sampling, as might be used in operational monitoring, must be treated in an appropriate manner. These statistical issues are discussed in more detail in the Tool Box, chapter 5.

Member States can also amend their operational monitoring programmes (particularly the monitoring frequency) during the duration of a RBMP where an impact is found not to be significant or the relevant pressure is removed, and the ecological status is no longer less than good.

2.10.4 Summary

In summary, sampling frequencies for surveillance and operational monitoring should be critically assessed in terms of the confidence in the estimates they will provide. For example, Member States may have to undertake additional surveillance monitoring at least during the first 3 years from 2006 to 2008. Also, it may be that data needs to be gathered in every year of subsequent RBMP periods in order to get enough to meet adequate confidence targets in assessing compliance with monitoring objectives and associated Environmental Objectives.

2.11 Monitoring for Protected Areas

There are additional monitoring requirements for protected areas[30]. Protected Areas include bodies of surface water and groundwater used for the abstraction of drinking water and habitat and species protection areas identified under the Birds Directive or the Habitats Directive. Thus for the former areas monitoring sites must be designated in bodies of surface water which provide more than 100 m^3 a day as an average. For groundwater there appears to be no additional monitoring requirements.

In terms of drinking water protected areas, all priority list substances discharged into the water body and all other substances discharged in significant quantities which could affect the status of the body of water and which are included in the requirements of the Drinking Water Directive should be monitored.

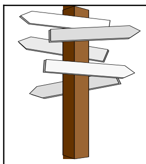
In other words, the monitoring requirements appear to be the same as for other water bodies at risk, except that grouping may not usually be permitted if the body supplies more than 100 m^3 per day. There may be special cases where there is a high number of small mosaic groundwater body types where grouping may be permitted. One of the objectives for Drinking Water Protected Areas is to aim to prevent deterioration in quality in order to reduce the level of purification treatment required. This objective was added to the Directive after the Annex V requirements had been effectively finalised. This means that there are no explicit monitoring requirements designed to provide information for the purposes of assessing and securing achievement of this Protected Area objective. The provisions quoted above do not cover it because they focus on risks to status rather than risks to the relevant quality parameters.

Monitoring frequencies are also given for certain Drinking Water Protected Areas[31] and relate to the size of the population that the Protected Area serves – the greater the population the greater the frequency.

In terms of habitat and species protection areas, bodies of water forming these areas must be included in operational monitoring if they are identified (by the Annex II risk assessment

[30] *Annex V.1.3.5*
[31] *Annex V.1.3.5*

and surveillance monitoring) as being at risk of not meeting their environmental objectives. Monitoring must be carried out to assess the magnitude and impact of all relevant significant pressures on these bodies, and where necessary, to assess changes in the status of such bodies resulting from the programmes of measures. Monitoring should also continue until the areas satisfy the water-related requirements of the legislation under which they are designated and met their objectives under Article 4.



Additional monitoring is required for drinking water abstraction points and habitat and species protection areas. However the register or registers of protected areas also includes areas designated as bathing waters under Directive 76/160/EEC, as vulnerable zones under Directive 91/676/EEC and areas as sensitive under Directive 91/271/EEC. These latter Directives also have monitoring and reporting requirements. The EAF on Reporting is considering not only the reporting required under the WFD but also existing reporting requirements with the aim of 'streamlining' the reporting process. The Working Group on Monitoring also recommends that ways of integrating, rationalising and streamlining the monitoring requirements under the other Directives should also be considered in future work that might revise this Guidance Document.

2.12 Other requirements for surface water monitoring

2.12.1 Reference conditions

Member States have the opportunity of establishing reference conditions based on existing high status water bodies where they still exist. In this case monitoring will be required to define the values of the biological quality elements. Type-specific hydromorphological and physico-chemical conditions have also to be established for each type at high ecological status. Reference conditions can also be derived from modelling approaches. These could utilise data from existing water bodies in which the relevant quality element is subject to no more than very minor anthropogenic disturbance. As high status is the anchor point for the classification of ecological status, it would be expected that the results from the monitoring would have a high level of confidence and precision. In particular, the natural variability (e.g. diurnal, monthly, seasonal and inter-annual) of the quality elements needs to be quantified and understood if the impact of anthropogenic pressures on water bodies of lesser status is to be determined. Thus more stations per water body and a higher sampling frequency per station over a number of years may be required.

It should also be noted that the errors in reference conditions and in estimates of the actual conditions will sum. Making sure the errors in the reference conditions are small will be beneficial only if the errors in the estimates of current conditions are not large.

In addition, reference stations, for which there are long time series of data, which indicate stable conditions under the present conditions, may not need high sampling frequencies.

There are linkages here with Working Groups 2.3 on reference conditions for inland surface waters (WFD CIS Guidance Document No. 10) and 2.4 on typology and classification of transitional and coastal water (WFD CIS Guidance Document No. 5). Thus this subsection may be modified to reflect conclusions reached by these other groups.

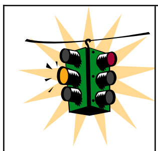
2.12.2 Intercalibration

Annex V.1.4.1 deals with the comparability of biological monitoring results and the intercalibration exercise between countries. Monitoring of the biological quality elements will be undertaken at those sites included in an intercalibration network. The network will consist of sites selected from a range of surface water body types present within each ecoregion. The sites shall be selected by expert judgement based on joint inspections and all other available information. A Member State's monitoring and assessment system will also be applied to the appropriate identified sites and water bodies in one or more other Member States. It would be valuable also to intercalibrate other monitoring results and methodologies.

The results from the monitoring of the biological quality elements will then be formulated as Ecological Quality Ratios (EQRs) for the purpose of classification and comparison with the results from other appropriate Member States.

It has been proposed in the Intercalibration working group 2.5, and supported by different Member States, that monitoring methods of the different Member States sharing the same natural water body should undertake measurements simultaneously, to permit a real comparison of the assessment of 'good' status.

The intercalibration exercise is intended to be a one-off exercise and should be completed within 5.5 years of the entry into force of the Directive (22 June 2006).



Look Out!

However, it has been proposed in the Intercalibration group, and supported by different Member States, that the intercalibration exercise should be repeated. An intercalibration exercise will also be required once the Accession countries have joined the EU. This will by necessity involve at least some of the existing EU Member States.

Its purpose is to define the boundary between high and good and between good and moderate status. The achievement of 'good' status is one of the major Environmental Objectives of the Directive and hence its level will determine how many water bodies require measures to be applied to achieve 'good' status. The definition of this boundary is thus a crucial aspect of the implementation of the Directive.

It is stated that at least two sites corresponding to the boundary between good and high status and two sites corresponding to the boundary between good and moderate status should be selected for an intercalibration network for each water body type within each ecoregion. In practise, because of the natural variability between the same types of water bodies, the number of sites may have to be much larger to be able to define the borderlines between the status groups and the variability of this borderline.

Key issue

The issues surrounding the intercalibration exercise are being discussed with Working Group 2.5 on intercalibration. Thus this subsection may be modified to reflect conclusions reached by this other group.

2.12.3 Heavily Modified and Artificial Water Bodies

According to the WFD, the biological status of surface water is to be assessed using the elements phytoplankton, other aquatic flora, macroinvertebrates and fish fauna. It is suggested that the preliminary assessments of ecological status should be based on the most sensitive quality elements with respect to the existing physical alterations. Effects resulting from other impacts (e.g. toxic effects on macroinvertebrates, eutrophication concerning macrophytes) should be excluded as far as possible. Some suggestions on the suitability of biological elements as indicators for physical alterations can be made:

- Benthic invertebrate fauna and fish are the most relevant groups for the assessment of hydropower generation impacts;
- Long distance migrating fish species can serve as a criterion for the assessment of disruption in river continuum;

- Macrophytes are good indicators of changes in flow downstream of reservoirs as well as for the assessment of regulated lakes because they are sensitive to water level fluctuation; and,
- For linear physical alterations such as flood works, benthic invertebrate fauna and macrophytes/phytobenthos are most appropriate indicators.

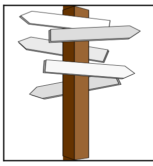
Annex VI of the Guidance Document provides an overview of the key issues for each water body and should be referred to for more details.

Key issue

The issues surrounding the heavily modified water bodies are covered by Working Group 2.2. Thus this subsection may be modified to reflect conclusions reached by this other group.

2.12.4 Standards for monitoring of surface water quality elements

The Directive also indicates that the monitoring of type parameters for surface waters should conform to appropriate international standards (such as those developed by CEN and ISO) which should ensure the provision of data of an equivalent scientific quality and comparability.



It is recommended that appropriate standards are developed as a matter of priority and urgency for those aspects of monitoring for which there are no internationally agreed standards or techniques/methods

The use and development of standards and quality assurance in sampling and laboratory work is further elaborated in Chapter 5.

2.13 Monitoring of groundwater

The Water Framework Directive requires the establishment of monitoring programmes covering groundwater quantitative status, chemical status[32] and the assessment of significant, long-term pollutant trends resulting from human activity[33] by 22 December 2006 at the latest. The programmes must also provide for any additional monitoring requirements relevant to Protected Areas. The programmes must provide the information necessary to validate the Annex II risk assessment procedure and to assess the achievement of the Directive's objectives for groundwater. The relevant objectives are:

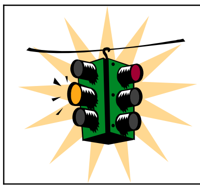
- To prevent deterioration in the status of all bodies of groundwater [Article 4.1(b)(i)];
- To prevent or limit the input of pollutants into groundwater [Article 4.1(b)(i)];
- To protect, enhance and restore all bodies of groundwater and ensure a balance between abstraction and recharge with the aim of achieving good groundwater status [Article 4.1(b)(ii)];
- To reverse any significant and sustained upward trend in the concentration of any pollutant in groundwater in order to progressively reduce pollution of groundwater [Article 4.1(b)(iii)];
- To achieve compliance with any standards and objectives for Protected Areas [Article 4.1(c)]. Relevant Protected Areas include areas designated for the abstraction of water intended for human consumption under Article 7 (Drinking Water Protected Areas),

[32] *Article 8*
[33] *Annex V*

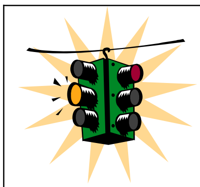
Nitrate Vulnerable Zones established under Directive 91/676/EEC, and areas designated for the protection of habitats and species in which the status of water is an important factor in their protection;

Key principle

The monitoring programmes must provide the information necessary to assess whether the Directive's environmental objectives will be achieved. This means that a clear understanding of the environmental conditions required for the achievement of the objectives, and of how these could be affected by human activities, is essential to the design of effective monitoring programmes.



Look Out!
The Article 17 Daughter Directive may establish additional criteria for the assessment of groundwater status. This guidance may need to be updated once such criteria have been established.



Look Out!
The Article 17 Daughter Directive is expected to establish criteria for the identification of significant and sustained upward trends. Until such criteria have been established, Member States must decide whether a trend in pollutant concentrations is significant and sustained according to their own criteria. In developing such criteria, Member States should take into account the objective to progressively reduce pollution of groundwater [Article 4.1(b)(iii)].

The monitoring programmes should be designed on the basis of the results of the Annex II[2] characterisation and risk assessment procedure. Guidance on characterisation and risk assessment for bodies and groups of bodies of groundwater can be found in the WFD CIS Guidance Document No. 3 - IMPRESS. The results of the assessments should provide the necessary information on, and understanding of, the groundwater system and the potential effects of human activities on it with which to design the monitoring programmes. In particular, monitoring programme design will require:

- Estimated boundaries of all bodies of groundwater;
- Information on the natural characteristics, and a conceptual understanding, of all bodies or groups of bodies of groundwater;
- Information on how bodies may be grouped because of similar hydrogeological characteristics and therefore similar responses to the identified pressures;
- Identification of those bodies, or groups of bodies, of groundwater at risk of failing to achieve Directive's objectives, including the reasons why those are considered to be at risk;
- Information on (a) the level of confidence in the risk assessments (e.g. in the conceptual understanding of the groundwater system, the identification of pressures, etc), and (b) what monitoring data would be required to validate the risk assessments.

To ensure the targeted and cost-effective development of the groundwater monitoring programmes, this information and understanding should serve as the basis for identifying (see Figure 2.3):

- The bodies, or groups of bodies relevant to each monitoring programme;
- The appropriate monitoring sites in those bodies, or groups of bodies;
- The appropriate parameters for monitoring at each site; and
- The monitoring frequencies for those parameters at each site.

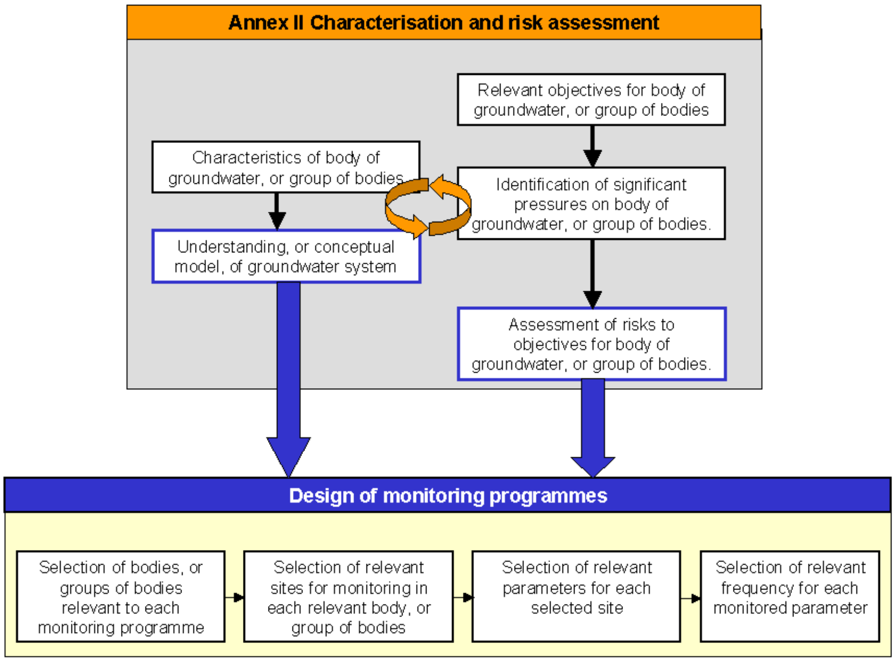


Figure 2.3 The basic information necessary for the design of groundwater monitoring programmes

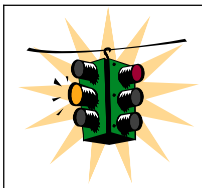
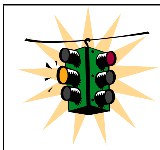
The Directive sets out its requirements for the different groundwater monitoring programmes in Annex V (2.2 and 2.4). The monitoring programmes must include:

A 'groundwater level monitoring' network to supplement and validate the Annex II characterisation and risk assessment procedure with respect to risks of failing to achieve good groundwater quantitative status in all bodies or groups of bodies of groundwater. Good groundwater quantitative status requires that: (a) the available groundwater resource for the body as a whole is not exceeded by the long-term annual average rate of abstraction; (b) abstractions and other anthropogenic alterations to groundwater levels have not caused, and are not such as will cause, significant diminution in the status of associated surface water bodies or significant damage to directly dependent terrestrial ecosystems; and (c) anthropogenic alterations to flow direction have not caused, and are not likely to cause, saltwater or other intrusions.

A 'surveillance monitoring' network to: (a) supplement and validate the Annex II characterisation and risk assessment procedure with respect to risks of failing to achieve good groundwater chemical status; (b) establish the status of all groundwater bodies, or groups of bodies, determined as not being at risk on the basis of the risk assessments; and (c) provide information for use in the assessment of long term trends in natural conditions and in pollutant concentrations resulting from human activity. Surveillance monitoring should be undertaken in each plan period and to the extent necessary to adequately supplement and validate the risk assessment procedure for each body or group of bodies of groundwater. The programmes should be operational from the beginning of the plan period where necessary to provide information for the design of the operational monitoring programmes, and may operate for the duration of the planning period if required. The programmes should be designed to help ensure that all significant risks to the achievement of the Directive's objectives have been identified. Where confidence in the Annex II risk assessments is inadequate, parameters indicative of pressures from human activities, which may be affecting bodies of groundwater but which have not been identified as causing a risk to the objectives, should be included in the surveillance monitoring programmes in order to supplement and validate the risk assessments.



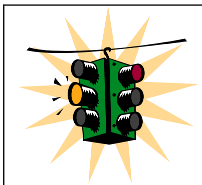
Look Out!
No minimum duration for the surveillance programme is specified. For the first river basin planning period, Member States that already have extensive groundwater monitoring networks may only need a short period of surveillance monitoring to help design their operational monitoring programmes. However, Member States whose existing networks are more limited may require more information from surveillance programmes before the design of their operational programmes can be completed.



Look Out!
Surveillance monitoring is only specified in the Directive for bodies at risk or which cross a boundary between Member States. However, to adequately supplement and validate the Annex II risk assessment procedure, validation monitoring will also be needed for bodies, or groups of bodies, not identified as being at risk. The amount and frequency of monitoring undertaken for these bodies, or groups of bodies, must be sufficient to enable Member States to be adequately confident that the bodies are at 'good' status and that there are no significant and sustained upward trends.

An 'operational monitoring' network to: (a) establish the status of all groundwater bodies, or groups of bodies, determined as being at risk; and (b) establish the presence of significant and sustained upward trends in the concentration of any pollutant. Operational monitoring has to be carried out for the periods between surveillance monitoring. In contrast to surveillance monitoring, operational monitoring is highly focused on assessing the specific, identified risks to the achievement of the Directive's objectives.

The results of monitoring must be used to estimate the chemical and quantitative status of bodies of groundwater. Colour-coded maps[34] of the status of bodies of groundwater, or groups of bodies, and an indication on the maps of which bodies are subject to a significant and sustained upward trend in pollutant concentrations and in which bodies such trends have been reversed must be included in the draft river basin management plans and in the finalised river basin management plans. The first of these plans must be published by 22 December 2008[35] and 22 December 2009[36] respectively. The results of monitoring should also assist in designing programmes of measures, testing the effectiveness of these measures and informing the setting of objectives. Later on monitoring results should be used in the reviews of the Annex II risk assessment procedure, the first of which must be complete by 22 December 2013.



Look Out!
For many Member States, the estimates of groundwater body status included in the first draft river basin management plans at the end of 2008 will have to be based more on surveillance monitoring results and less on operational monitoring data than will be the case in the finalised plan published at the end of 2009 and in subsequent river basin management plans. Accordingly, the confidence in the status classifications included in the first plan may be lower than will be the case in subsequent plans. Member States must report the confidence and precision achieved in the results of monitoring in each plan.

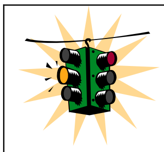
The detailed purposes of, and requirements for, each of the groundwater monitoring programmes are discussed in Chapter 4. Chapter 5.3 contains a toolbox of good practice examples illustrating how the guidelines could be implemented. The tools developed by CIS

[34] *Annex V 2.5*
[35] *Article 14*
[36] *Article 15*

2.8, Statistical aspects of groundwater trends and aggregation of monitoring results, should also be taken into account when designing the monitoring programmes.

3 What Quality Elements should be monitored for Surface Waters?

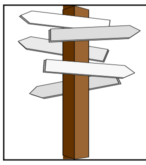
The following sections provide guidance on the appropriate selection of quality elements and parameters for rivers, lakes, transitional waters and coastal waters to support the implementation of the WFD. The selection of quality elements has been based primarily on Annex V.1.1 and Annex V.1.2 of the WFD. Guidance on the selection of quality elements and parameters for rivers, lakes, transitional and coastal waters are summarised in Figures 3.1 - 3.4. These figures show the quality elements as specified in Annex V, and additional recommended quality elements which have been identified by Member States for that particular water body type.



Look Out!

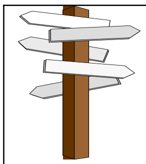
The proposed selection of recommended quality elements and parameters is intended as a guide only. Member States should use their own discretion based on local knowledge and expertise as to what specific sub-element or parameter will provide the best representation of catchment pressures for each quality element.

The key features of each quality element, their existing use in classification systems throughout the EU and their relevance to the Directive are summarised in Tables 3.1-3.12.



Quality Element Descriptions

An overview of the key issues for surface waters description of each of the Quality Elements and sub-elements identified in this chapter, and their relevance for each water body type are provided in Annex VI.



For further details on monitoring guidance for surface waters refer to the full contributions received from Member States:

3.1 Selection of Quality Elements for Rivers

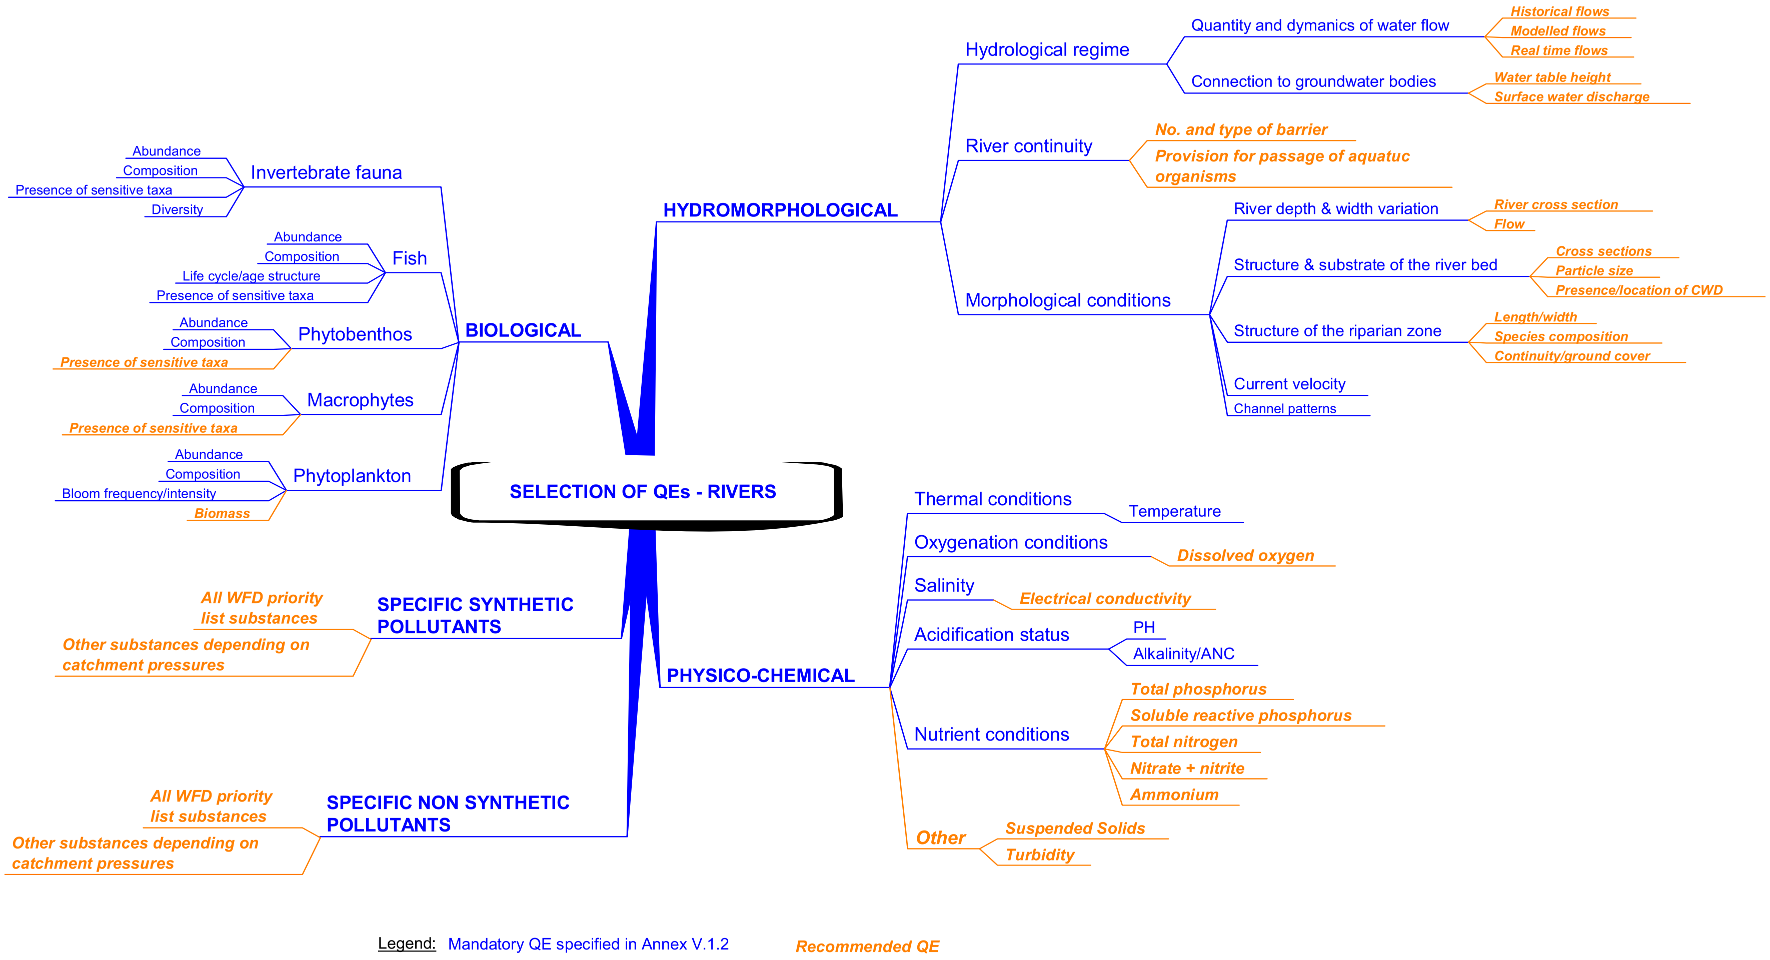

Figure 3.1 Selection of quality elements for rivers

Table 3.1 Key features of each biological quality element (QE) for rivers

Aspect/feature	Benthic invertebrates	Macrophytes	Benthic Algae	Fish	Phytoplankton
Measured parameters indicative of QE	Composition, abundance diversity, and presence of sensitive taxa.	Composition and abundance , and presence of sensitive taxa	Composition and abundance, , and presence of sensitive taxa	Composition and abundance, sensitive species diversity, age structure,	Composition, abundance and planktonic blooms, and presence of sensitive taxa
Supportive/interpretative parameters measured or sampled at the same time	Morphology, physico-chemical parameters (e.g. Temp/DO, nutrients, pH etc), river flow, substrate/habitat sampled	Morphology, river flow, depth, transparency	Substrate/habitat sampled, morphology, nutrients (N, P, Si), TOC, pH, hydrological regime, light conditions	Substrate/habitat sampled, river size (depth/width), river flow, temp, oxygen	Chlorophyll *a,* flow, physico-chemical parameters (e.g. temp, DO, N, P, Si)
Pressures to which QE responds	Mainly developed to detect organic pollution or acidity, can be modified to detect full range of impacts.	Mainly used to detect eutrophication, river dynamics including hydropower effects.	Mainly used as an indicator of productivity. Can be used to detect eutrophication, acidification, river dynamics.	Can be used to detect habitat and morphological changes, acidification and eutrophication.	Used as indicator of productivity/eutrophication.
Mobility of QE	Low, although unfavourable conditions may cause drift	Low. Generally fixed position.	Low	High. Tendency to avoid undesirable conditions (e.g. low oxygen conditions).	High. Drifting with river water
Level and sources of variability of QE	High seasonal variation in community structure. Influenced by climatic events e.g. rainfall/flooding	High seasonal variation in community structure and abundance.	High seasonal variation in community structure. Limited by light and nutrient availability and available substrate for colonisation. Influenced by climatic events	High seasonal variation in community structure (e.g. spawning/migration) and abundance. High interannual variation due to age structure.	High inter and intra-seasonal variation in community structure and biomass. Influenced by climatic events, light, nutrient availability, stability and residence time
Presence in rivers	Abundant	Abundant if suitable habitat. Limited in fast flowing streams.	Abundant if suitable habitat. Limited in large, deep rivers with poor habitat	Abundant	Generally low. May be abundant if conditions conducive to growth
Sampling methodology	ISO 8265, 7828, 9391 (surber sampler, handnet, grab)	CEN –standard under development	CEN –standard under development	Depending on habitats – nets, electrofisher	Integrated sample (3-4m), depth sampler
Habitats sampled	Riffle, pool (rocks/logs), edge (littoral), macrophytes,	Littoral, deposition areas (e.g. pools)	Benthic substrate/artificial substrate	All habitats	Water column
Typical sampling frequency	6 monthly/Annual	Annual/6 monthly	Quarterly/6 monthly	Annual	Monthly/Quarterly
Time of year of sampling	Summer and winter. Spring and autumn in Scandinavia.	Mid to late summer.	All seasons/summer and winter. Summer & autumn in Nordic countries.	Varied	Should cover all seasons. Only during ice free periods in Nordic countries.
Typical sample size	Variable depending on sampling methodology and habitat	Variable, may be standardised	Variable, may be standardised	Variable, may be standardised	Single integrated sample
Ease of sampling	Relatively simple. Difficulties in deep or fast flowing rivers.	Simple due to fixed position and general proximity to banks	Relatively simple. Difficulties in deep or fast flowing rivers. Observations and % cover	Requires specialised sampling equipment (e.g. electrofisher).	Simple using integrated hosepipe (or grab sample in shallow water)
Laboratory or field measurement	Field collection and sorting. Microscopic identification in laboratory	Field collection and identification	Field collection, microscopic identification in laboratory	Field collection, measurement and identification	Field collection, laboratory preparation followed by microscopic identification
Ease and level of Identification	Relatively simple to Genus. Requires expert identification to species level for some (e.g. chironomids). May be damaged during sampling/preservation	Simple to identify to species, except some genera (e.g. potamogeton)	Requires expert identification for majority of species (see phytoplankton)	Simple to identify to species, except some cyprinids which require expert knowledge	Requires expert identification of majority of genera and species. Some small unicellular species (e.g. unicellular greens) difficult to identify unless under high power microscopy

Aspect/feature	Benthic invertebrates	Macrophytes	Benthic Algae	Fish	Phytoplankton
Nature of reference for comparison of quality/samples/stations	Yes: UK, France, Germany, Austria, Denmark, Sweden, Norway	No but underway in some European institutions	No	Yes: UK (HABSCORE) and France.	No
Methodology consistent across EU?	No	No	No	No	No
Current use in biological monitoring or classification in EU	Austria, Belgium, Denmark, Finland, France, Spain, Germany, Italy, Ireland, Luxembourg, Portugal Netherlands, Sweden, Norway and the UK	Austria, Belgium, France, Germany, Ireland, Netherlands and the UK	Austria, Belgium, France, Germany, Ireland, Norway, Sweden, Finland, Spain, Netherlands and the UK	Austria, France, Belgium, Ireland, Norway and the UK	None
Current use of biotic indices/scores	Yes. UK (BMWP), France (IBGN), Germany (Saprobic), Austria (Saprobic), Spain (SBMWP), Belgium (BBI), Netherlands (K-value)	No but some indices under development/calibration (Austria)	Yes. Sweden (developing). Norway and Germany – Index of occurrence of sensitive taxa	Yes. UK (HABSCORE).	No
Existing monitoring system meets requirements of WFD?	No	No	No	No	No
ISO/CEN standards	ISO 7828:1985 ISO 9391:1993 ISO 8265: 1988	CEN-Standard under development	CEN-Standard under development	CEN-Standard under development	
Applicability to rivers	High	Moderate	High	High	Low-Moderate
Main advantages	• Currently most common biological indicator used for ecological classification. • Existing classification systems in place • Possibility of adapting existing systems to incorporate requirements of WFD. • Less variable than physico-chemical elements	• Easy to sample and identify. • Low interannual variability	• Easy to sample (in shallow water) • Some existing methods developed • Less variable than physico-chemical elements • Responds quickly to changes in environmental and anthropogenic conditions • Possibility of adapting existing systems to incorporate requirements of WFD.	• Existing river classification systems in place • Possibility of adapting existing classification systems to incorporate requirements of WFD.	• Easy to sample • May be relevant in rivers where residence times enough to sustain growth (e.g. lowland rivers, upstream of impoundments)

Aspect/feature	Benthic invertebrates	Macrophytes	Benthic Algae	Fish	Phytoplankton
Main disadvantages	• Methods require adaptation to meet requirements of WFD • Some require specialist expertise to identify to species • High substrate-related spatial variability and high temporal variability due to hatching of insects and variation of water flow • Time consuming and expensive • Presence of exotic species in some EU rivers.	• Not commonly used in EU • Lack of information for comparison to reference • Methodology needs to be adapted to incorporate requirements of WFD	• Not commonly used in EU • Lack in information for comparison to reference • Methodology needs to be adapted to incorporate requirements of WFD. • Difficult to sample in deep rivers • High substrate related spatial variability • High seasonal variation • Requires specialist expertise for species identification	• Requires specialist sampling equipment • High mobility • Horizontal and vertical distribution patters (differs between species)	• Not routinely used in river quality assessment in EU • Not generally present in flowing rivers • High variability requires frequent sampling • Difficult to establish dose-response relationships due to flow-related variability.
Conclusions/ Recommendations	This QE is best developed in EU and hence it is recommended as one of the key elements for monitoring especially for organic pollution.	Under certain hydrological conditions this QE is not suitable. However, in good conditions it can give a robust assessment.	Recommended, particularly for assessment of trophic status.	It is recommended as one of the key elements for monitoring for habitat and morphological changes. Further work required for assessing the impact of pollution on fish populations.	Only recommended for large, slow flowing rivers.

Table 3.2 Key features of each hydromorphological quality elements for rivers

Aspect/feature	Quantity and dynamics of water flow	Connection to groundwater bodies	River Continuity	River depth and width variation	Structure and substrate of the river bed	Structure of the riparian zone
Measured parameters indicative of QE	Historical flows, modelled flows, real-time flow, current velocity	Water table height, surface water discharge	No and type of barrier and associated provision for fish passage	River cross section, flow	Cross section, particle size, presence and location of CWD	Length, width, species present, continuity, ground cover
Pressures to which QE responds	Used to detect impact of water storage, abstraction and discharge on biota, hydropower regulation	Provides information on surface-groundwater relationship	Used to detect impact on upstream migration of fish	Used to detect impact on biota from changing flows and habitat availability	Determines impact on biota from changing habitat availability	Influences structure of banks, provides habitat and shading for biota, filters diffuse runoff
Level and sources of variability of QE	Highly variable depending on geographical and climatic conditions. Variations reduced as response to barriers	Moderate variability	Low variability. Based on presence/modification of infrastructure	Moderate variability. Influenced by hydropower regulation	Variable depending on particle size and flow (e.g. gravel/sand scour/sedimentation prevalent following high flows)	Variable. Possibility of physical clearing, accessibility from livestock, erosion etc
Sampling methodology	ISO standard for current velocity. No common methodology for dynamics	No common methodology	No common methodology	No common methodology	No common methodology	No common methodology
Typical sampling frequency	In-situ, real time	6 monthly, depending on climatology and geology	Every 5-6 years	Annual	Annual	Annual
Time of year of sampling	All year	Winter and summer	varied	varied	varied	varied
Typical "sample" size or survey area	Common standard for No of monitoring points in cross sections developed	Not defined	Entire reach	No common agreement	No common agreement	50m in headwaters 100m in middle and lower reaches
Ease of sampling /measurements	Simple using in-situ flow gauging stations in small rivers. Greater effort required for large rivers.	Simple. Measurement of groundwater height (boreholes) and river flow	Simple. Survey to determine location and type of structures and abstraction sites/volumes	Can be simple using observation and measurement or detailed using laser survey equipment	Simple following minimal training	Simple following minimal training. Collection and laboratory identification of species may be required
Basis of any comparison of results/quality/stations e.g. reference conditions/best quality	No	No	No	No	No	No
Methodology consistent across EU?	No	No	No	No	No	No
Current use in monitoring programmes or for classification in EU	Yes. Belgium, France, Sweden, UK, Finland and Norway	Yes. Belgium, UK	Yes. Belgium, Germany, France	Yes. Belgium, Germany, France, UK and Norway	Yes. Belgium, Germany, France, UK and Norway	Yes. Belgium, Germany, France, Italy , UK
Existing monitoring systems meet requirements of WFD?						

Aspect/feature	Quantity and dynamics of water flow	Connection to groundwater bodies	River Continuity	River depth and width variation	Structure and substrate of the river bed	Structure of the riparian zone
Existing classification systems meet requirements of WFD?	No	No	No	No	No	No
ISO/CEN standards	ISO/TC 113 CEN?TC 318 under development	No	No	No	No	No
Applicability to rivers	High	High	High	High	High	High
Main Advantages	• Possibility of adapting existing systems to incorporate requirements of WFD.	•	• Methodology needs to be developed to incorporate requirements of WFD.	• Methodology needs to be developed to incorporate requirements of WFD.	•	•
Main disadvantages	• Not commonly used	• Not commonly used	• Not commonly used	• Not commonly used	• Not commonly used	• Not commonly used
Conclusions/ recommendations	Simple to monitor. Key supporting parameter for interpretation	Can not be commonly used. Only relevant under certain conditions when groundwater plays a major role in water balance. Methodology must be elaborated.	Very relevant for some species. One extensive survey is sufficient – supplied when necessary	Not applicable for all rivers such as rivers with high natural variation. Methodology needs further elaboration	Essential for interpreting the biological quality elements and possibility of sediment accumulation	Applicability depends on the shape, size etc. of the riparian zone. Methodology must be further elaborated

Table 3.3 Key features of each chemical and physico-chemical quality element for rivers

Aspect/feature	Thermal Conditions	Oxygenation Conditions	Salinity	Acidification Status	Nutrients
Measured parameters indicative of QE	Temperature	Dissolved oxygen (mg/L and % sat)	Conductivity, ca concentration	pH, ANC, Alkalinity	TP, TN, SRP, NO_3 + NO_2, NH_4
Pressures to which QE responds	Inflows, water releases, industrial discharges	Organic pollution, industrial discharges	Agricultural runoff, industrial discharges	Industrial discharges, acid rain	Agricultural, domestic and industrial discharges
Level and sources of variability of QE	Variable. Influence d by climatic conditions	Moderate. Diel changes due to respiration. Lower variation in fast flowing rivers.	Low variability although influenced by water flow	Variable depending on buffer capacity, water flow etc	Variable depending on landuse, buffer capacity, temp/DO, presence of binding metals etc
Monitoring considerations	Seasonal stratification and mixing (in deep water), cold water releases	Diel/diurnal variations	Seasonal stratification and mixing in deep waters	Seasonal variations	Sources (diffuse/point), sufficient speciation to enable source discrimination
Sampling methodology	In-situ using submersible probe	In-situ using submersible probe, or sample collection and Winklers titration	In-situ using submersible probe	In-situ using submersible probe, sample collection	Sample collection in field followed by laboratory analysis
Typical sampling frequency	Fortnightly-monthly	Fortnightly-monthly	Fortnightly-monthly	Fortnightly-monthly	Fortnightly-monthly. More frequently during flooding.
Time of year of sampling	All seasons.	All seasons	All seasons	All seasons. Special attention when sea salt or snow melt episodes.	All seasons. Particularly following inflow events. Not during ice cover.
Typical "sample" size	Single measurement or water column profile	Single measurement or water column profile	Single measurement	Single measurement	Single sample, or profile in deep waters
Ease of sampling /measurements	Simple using in-situ submersible probe	Simple using in-situ submersible probe, or sample collection followed by Winklers titration	Simple using in-situ submersible probe	Simple using in-situ submersible probe. Sample collection followed by laboratory analysis	Simple. Surface water sample or profile using depth sampler (e.g. van dorn)
Methodology consistent across EU?	No	No	No	No	No
Current use in monitoring programmes or for classification in EU	All	All	All	All	All
Existing monitoring systems meet requirements of WFD?	Yes	Yes	Yes	Yes	Yes
Existing classification system meets requirements of WFD?	No	No	No	No	No
ISO/CEN standards	Yes	Yes	Yes	Yes	Yes
Applicability to rivers	Moderate. Stratification may be present in deep, slow flowing rivers. Can help detect thermal pollution.	Moderate. Oxygen depletion may be present in deep, slow flowing rivers or upstream of impoundments	High	Low. Problem in stagnant waters.	High

Aspect/feature	Thermal Conditions	Oxygenation Conditions	Salinity	Acidification Status	Nutrients
Main advantages	• Simple to sample in-situ • Able to implement standard methodology	• Simple to sample in-situ • Able to implement standard methodology	• Simple to sample in-situ • Able to implement standard methodology	• Simple to sample in-situ • Able to implement standard methodology	• Can provide information as to pollutant sources • Simple to sample in-situ • Able to implement standard methodology
Main disadvantages	• Does not provide long-term indication	• Diel variations may require frequent monitoring • Does not provide long-term indication	• Does not provide long-term indication	• Does not provide long-term indication • May require intensive monitoring following rainfall events	• Does not provide long-term indication • May require intensive monitoring following rainfall events
Recommendations	Basic determinand for assessment of biocenosis.	Basic determinand for assessment of biocenosis.	Recommended in rivers in semi-arid climate and/or with high salinity.	Recommended in rivers with risk of acidification	Very important indicator for human activity/ eutrophication. Total N and P, nitrate and orthophosphate should be monitored as a minimum. Ammonia monitored where concentrations are expected to be problematic e.g. exceedences of limit values over a specific limit.

3.2 Selection of Quality Elements for Lakes

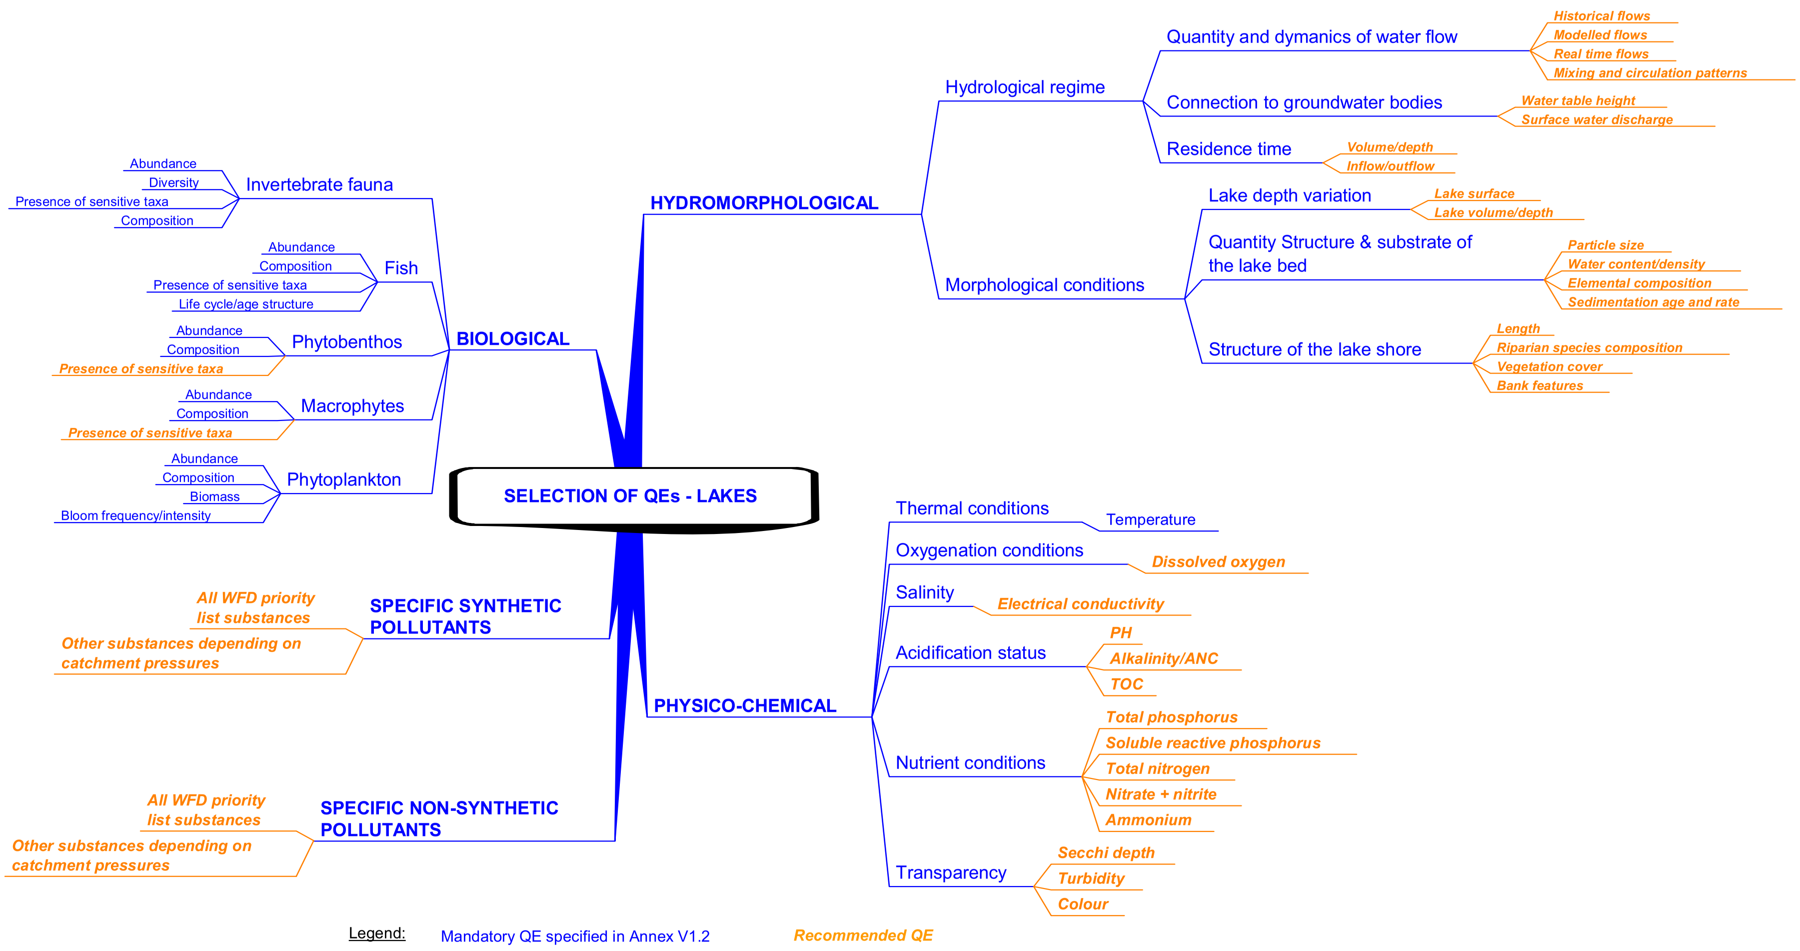

Figure 3.2 Selection of quality elements for lakes

Table 3.4 Key features of each biological quality element (QE) for lakes

Aspect/feature	Phytoplankton	Macrophytes	Phytobenthos	Benthic invertebrates	Fish
Measured parameters indicative of QE	Composition, abundance biomass (Chla), blooms	Composition and abundance	Composition and abundance	Composition, abundance, diversity and sensitive taxa	Composition, abundance, sensitive species and age structure
Supportive/interpretative parameters often/typically measured or sampled at the same time	Nutrient concentrations (total/soluble), chlorophyll, DO, POC, TOC, pH, alkalinity, temperature, transparency, Fluorometric in-situ monitoring	Nutrient concentrations (total/soluble) in lake water, sediment and pore water, substrate type, pH, alkalinity, conductivity, transparency, Secchi disc, ca concentration	Nutrient concentrations (total/soluble) in lake water, sediment and pore water, substrate type, pH, alkalinity, conductivity, transparency, Secchi disc, ca concentration	Nutrient concentrations (total/soluble), DO, pH, alkalinity, sediment analysis, toxicity bioassays	Nutrient concentrations (total/soluble), DO, pH, alkalinity, temperature, toxicity bioassays, trophic condition, Zooplankton dynamics, ANC, TOC
Pressures to which QE responds	Eutrophication, organic pollution, acidification, toxic contamination	Eutrophication, acidification, toxic contamination, siltation, river regulation, lake water level, introduction of exotic species	Eutrophication, acidification, toxic contamination, siltation, river regulation, lake water level, introduction of exotic species	Eutrophication, organic pollution, acidification, toxic contamination, siltation, river regulation, hydro-morphological alteration (littoral)	Eutrophication, acidification, toxic contamination, fisheries, hydro-morphological alteration, Introduction of exotic species
Mobility of QE	Medium	non-mobile	non-mobile	Low to Medium, high when hatching	High
Level and sources of variability of QE	High inter and intra seasonal variation in community structure and biomass Medium to high spatial variability	Medium-high seasonal variability in community structure and biomass High spatial variability	Medium-high seasonal variability in community structure and biomass, Low interannual variability High spatial variability	Medium-high seasonal variability in community structure and biomass High spatial variability	High spatial and seasonal variability Populations clumped in respect to habitat variables
Presence in lakes	Abundant	Abundant, rare in reservoirs	Abundant, rare in reservoirs	Abundant	Abundant
Sampling methodology	Integrated or discrete samples in the water column 1-5 sites per lake A number of sampling gears are commonly used such as hand-held bottles or flexible hose	Aerial photography or/and transect sampling perpendicular to the shore line	In-situ observations of occurrence of natural substrate in littoral zone and/or among macrophyte beds and scraping of sub-strata	Qualitative or semi-quantitative hand net or kick-sampling; Ekman grab or core sampling Gear type depends on type of substrate, e.g. submerged aquatic vegetation – dip net; sand and clay - Peterson, Van Veen grabs; mud – Ponar, Ekman grabs	Electrofishing Net captures, several types (e.g. gill nets, trammel net) Trawls Acoustic
Habitats sampled	Water column (i.e. epilimnion, euphotic zone, metalimnion)	Macrophytes: littoral zone	benthic substrata/ artificial substrata	Littoral, sub-littoral and profundal	Littoral, open waters
Typical sampling frequency	Monthly/ quarterly In Nordic countries 6 times/summer	Yearly (late summer in Nordic countries), in natural lakes every 3-6 years	Varied from several times during the growing season to once a year	Yearly, in natural lakes every 3-6 years Twice yearly in littoral	Depend upon water body physical characteristics and objective, yearly
Time of year of sampling	All seasons, at least twice a year during spring overturn and summer stratification In Nordic countries no sampling during ice coverage. More stations required if high spatial variation.	Late summer, decided through expert judgement	Quarterly/ 6 monthly/ several times during the growing season In Nordic countries no sampling during ice coverage	Early spring and late summer	Late Spring through to early Autumn

Aspect/feature	Phytoplankton	Macrophytes	Phytobenthos	Benthic invertebrates	Fish
Typical sample effort	Often 1 station located in the centre of the lake	3-10 transects per lake with 2-3 quadrats on each transect should be sufficient for the majority of the lakes	Lake wide, 3-10 transects, littoral to sub-littoral	Lakewide composite samples of 2/ 3 grabs at each of 3-5 sub-littoral sites (7-15 grabs total	Dependent on type of sampling gear: For electrofishing multiple habitats are selected in littoral areas based on the substrate and cover. CEN-standard in preparation In shallow lakes fish can be sampled with multimesh gillnets and random sampling. Sampling time 10-12 h overnight. Time less in small lakes and those where fish densities are high. In deeper lakes stratification related to depth zones is recommended. CEN standard under development
Ease of sampling	Relatively simple	Variable, requires specialised sampling equipment and relatively specialised personal with diving qualifications Alternative methods can be used such as drop cameras/ROV/Rakes.	Relatively simple, some difficulty in deep lakes, boat required and expert knowledge of potential hazards in specific lakes	Relatively simple, some difficulty in deep lakes, boat required and expert knowledge of potential hazards in specific lakes	Difficult, requires specialised sampling equipment
Laboratory or field measurement	Laboratory sample preparation followed by identification, counting and biomass determination under microscopy. Algal toxin determinations in laboratory, chla.	Field measurements through aerial photography; samples from transects, laboratory identification to species; analysis of chl-a content, fresh, dry and ash free dry biomass (AFDM), organic content		Sample processing in the laboratory, at least 100 organisms per sub-sample (if possible) are identified to the appropriated taxonomic level frequently to species	Sampling duration and area or distance sampled are recorded in order to determine the level of effort. In the laboratory the specimens are identified to species, enumerated, measured, weighted and examined for the incidence of external abnormalities
Ease and level of Identification	Relatively simple for measures based on high taxonomic levels (e.g. family), difficult for identification to lower taxonomic levels (i.e. genus and species) Biomass evaluation is difficult	Identification to species relatively easy with exception of vegetative stages of certain genera (e.g. Potamogeton)	Identification to species relatively easy for high taxonomic groups (e.g. family), difficult for genus or species. Biomass evaluation difficult.	Relatively simple for measures based on high taxonomic levels, difficult for identification to lower taxonomic levels (i.e. species)	Relatively easy, some difficulties may appear with rare specimens and early fry
Nature of reference for comparison of quality/samples/stations	Estimates of phytoplankton indicators/ indices (e.g. cell density, biovolume) to be expected in the absence of significant anthropogenic pressures	Reference values refer to typical indicator values (TRS) and species diversity of flora in lakes not significantly affected by human activities	Little knowledge of reference conditions for phytobenthos in lakes. No established methodology	Reference values for the diversity, abundance and distribution indices indicate expected conditions if the lakes are not significantly affected by human activities. References set using the 25 percentile of sites considered unimpaired-Sweden.	Difficult to determine because only impacts of the physico-chemical and hydromorphological pressures are to be addressed not fisheries/ stocking/ species introductions

Aspect/feature	Phytoplankton	Macrophytes	Phytobenthos	Benthic invertebrates	Fish
Methodology consistent across EU?	No	No	No	No	No
Current use in biological monitoring or classification in EU	Denmark, Finland, Ireland, Netherlands, Sweden, UK and Norway	Denmark, Netherlands, Sweden, UK for conservation and Norway	No	Finland, Netherlands, Sweden and Norway	Finland, Netherlands, Sweden and Norway
Current use of biotic indicators and indices/scores	Taxonomic analyses (e.g. diversity indices, taxa richness, indicators species) Phytoplankton total volume, presence of spring diatom blooms, occurrence of harmful algae, number and proportion of toxin- producing cyanobacteria (blue-greens)	Trophic Ranking Score (TRS), species with low TRS values occur primarily in waters poor in nutrients, while high values are associated with eutrophic waters); level of diversity. Relative occurrence of functional groups. Macrophyte Trophic Index (TIM)	No	Shannon's diversity index (measure of variation and dominance within animal communities); ASPT index (Average Score Per Taxa, related to the occurrence of sensitive (high index value) and tolerant (low value) species); Danish fauna index (evaluation of the effects of eutrophication and organic pollution in the exposed littoral zone of lakes); Benthic Quality Index (BQI, to evaluate eutrophication and organic pollution in the deep bottom areas); O/C Index (complementary or alternative to BQI); acidity index (reflects the presence of species with varying pH tolerances)	Index of Biotic Integrity (IBI) incorporates measurements of fish assemblage composition and relative abundance; % of piscivore/ zooplanktivore (a surrogate for age structure of fish community); % of invertevore/ omnivore
Existing monitoring system meets requirements of WFD?	No	No	No	No	No
ISO/CEN standards	Under development	Under development	Under development	Under development	Under development
Applicability to lakes	High	High (very low in reservoirs)	High (moderate in reservoirs, depending on water management)	Moderate	High (moderate to low in reservoirs).
Main advantages	• Easy to sample • Relevant for water quality and trophic state • Used in many countries to evaluate eutrophication • Easy to standardise	• Easy to sample and identify (especially in shallow water) • Good indicator of a broad range of impacts, especially eutrophication and siltation	• Easy to identify to family level • Good indicator of eutrophication	• Easy to sample (particularly in shallow waters) • Relatively simple to analyse • Some existing methods developed • Combines chemical and biological features	• Possibility of adapting classification systems to incorporate requirements of WFD

Aspect/feature	Phytoplankton	Macrophytes	Phytobenthos	Benthic invertebrates	Fish
Main disadvantages	• Requires taxonomic expertise for species identification; • High temporal variability requires frequent sampling • Vertical and horizontal sample profiles required due to spatial heterogeneity	• Difficult to sample in deep waters • Not commonly used in EU • Lack of information for comparison to reference • Methodology needs to be developed to incorporate requirements of WFD	• No standard methods • Lack of information for comparison to reference conditions • Not commonly used in EU • Methodology needs to be developed to incorporate requirements of WFD	• Not commonly used in EU • Lack of information for comparison to reference • Methodology needs to be developed to incorporate requirements of WFD • Time consuming and expensive to analyse	• Requires specialised sampling equipment • Methodology needs to be developed to incorporate requirements of WFD
Conclusions/ recommendations	Responds rapidly to changes in phosphorus concentration levels. Identification to order or genus are suitable/ recommended levels for monitoring phytoplankton taxonomic composition. While at present it is not clear that identification to species represents a substantial improvement of the information value of the data. More work required in this area.	Key parameter for evaluating other biological components in lakes. Macrophytes hold an important role in the metabolism of lakes. However their monitoring is not frequently used in the assessment of ecological quality.	The phytobenthos holds an important role in the metabolism of lakes. However there is very little experience and information on the use of phytobenthos. Further work is required in this area.	Important parameter for evaluating other biological components. Their use is at an early stage of development. It is required to develop meaningful methodologies. The drafting of a suitable guideline is the part of method development of CEN. The CEN group recommends that the identification of benthic invertebrate fauna should be carried out to the species level.	Key biological quality element. Can be difficult to interpret (fishery, biomanipulation etc.) Integrate all anthropogenic and natural impacts. The composition, abundance and structure of fish communities can be very useful indicators of ecological quality. Fish are only included in monitoring systems of very few EU member states

Table 3.5 Key features of each hydromorphological quality element for lakes

Aspect/feature	Quantity and dynamics of water flow	Residence time	Connection to the groundwater body	Lake depth variation (water level variation)	Quantity, structure and substrate of lake bed	Structure of lake shore
Measured parameters indicative of QE	Inflow and outflow rates. Water level, spillway and bottom outlets discharges (reservoirs), mixing and circulation patterns	volume, depth, inflow and outflow	Lake surface, lake volume	Lake surface, lake volume, lake depth	Grain size, water content, density, LOI, elemental composition, sedimentation rate, sediment age (Cs 137), microfossils in paleolimnological studies	Length, riparian vegetation cover, species present, bank features and composition
Pressures to which QE responds	Climate variability, flood control, man made activities	Climate variability, man made activities	Climate variability, man made activities	Climate variability, siltation, water use, flow discharges	Siltation	Man-made modifications, erosion, run-off Water level fluctuations in reservoirs
Level and sources of variability of QE	Med variability	Low but may vary under extreme climatic conditions	High variability	Generally low variability, high variability in reservoirs (epilimnetic/ hypolimnetic discharges)	Highly variable, dependent on spread patterns and pollution by historical development	Variable
Sampling methodology	Water level gauge, flow meters, and current meters. In situ using scales or submersible probes associated or not to teletransmission	Echo sounding necessary for depth-volume curves, hypsographic curves	Depth-volume curves, hypsographic curves. Water level gauge.	Sonar device (echosounder), phathometer, Transect methodology with metered sounding poles	Core and grab samplers depending on study objectives 3 main sampling types may be distinguished: deterministic, stochastic and regular grid systems	Transects, aerial photography, planimetry
Typical sampling frequency	Weekly/monthly. Hourly/daily (reservoirs)	Every 5/ 10 year, or less frequently if no changes are suspected. Once per year for reservoirs.	variable	Natural lakes: every 15 yr. Reservoirs: variable	Mostly once a year, or less frequently if no changes expected (reference conditions), in polluted lakes every 3rd to 5th year	Every 6 years
Time of year of sampling	All seasons	All seasons, not during ice cover	All seasons	Reservoirs: generally during operational functioning, spring/ begin fall	Usually winter (from ice in Nordic countries)/ summer	Varied. Spring/summer during growing period
Typical "sample" size or survey area	Inflowing/outflowing waters; gauging stations	Entire lake	Entire lake	Entire lake	Varied depending on study objective	Entire lake shore habitat
Ease of sampling /measurements	Simple following minimal practical training	Easy for theoretical residence time estimation Difficult for the evaluation of effective residence time	difficult	Relatively easy following minimal training	Relatively easy following minimal practical training	
Basis of any comparison of results/quality/stations e.g. reference conditions/best quality	Historical data	Historical data	Historical data	Historical data	Paleolimnology/ sediment core studies	Historical data
Methodology consistent across EU?	Yes, according to other countries practices	No	No	No	No	No

Aspect/feature	**Quantity and dynamics of water flow**	**Residence time**	**Connection to the groundwater body**	**Lake depth variation (water level variation)**	**Quantity, structure and substrate of lake bed**	**Structure of lake shore**
Current use in monitoring programmes or for classification in EU	No/yes (reservoirs)	No	No	No, France, UK, Spain	No	No
Existing monitoring systems meet requirements of WFD?	no	No	No	No	No	No
Existing classification systems meet requirements of WFD?	no	No	No	No	No	No
ISO/CEN standards	Yes, refer to ISO/TC 113, CEN/TC 318	No	No	No	No	No
Applicability to lakes	high	High	High	High	High	High
Main Advantages	• Hydrological measurements are essential for the interpretation of water quality data and for water resource management	• Lake hydrology forms the basis for water quality assessment; • Water residence time influences nutrient retention and development of anoxia in deep, stratified water bodies	• Lake hydrology forms the basis for water quality assessment.	• Water level fluctuation has a direct impact on littoral aquatic life • Lake basin morphology influences lake hydrodynamics and sensitivity to nutrient loading	• Can be regarded as environmental tachometers. The paleolimnological study is often the only tool to gather knowledge of past reference conditions. • The contaminants accumulate often in sediments, the contents are high and the sampling frequency may be quite low.	• Indicators in protection of biological integrity
Main disadvantages	Time consuming and costly	Time consuming and costly	Time consuming and costly	Accurate Hydrographic maps of lakes are rarely available in sufficient detail for ecological analysis even if bathymetric maps are available their accuracy should be checked carefully *	Paleolimnological examinations are often relative expensive and the result depends on the undisturbed state of the sedimental archive. The preservation of microfossils may vary.	Methodology needs to be developed to incorporate requirements of the WFD

Aspect/feature	Quantity and dynamics of water flow	Residence time	Connection to the groundwater body	Lake depth variation (water level variation)	Quantity, structure and substrate of lake bed	Structure of lake shore
Conclusions/ recommendations	Important for calculating mass balances etc. A basic element for use with other relevant parameters	Important for characterising and assessing lake quality data.	Only relevant where groundwater constitutes a major part of the lake water balance. Methodology needs further development	Only relevant where it is of ecological significance. Important consideration in the design of monitoring programmes. Very important in reservoirs. As a supporting elements the measurement of depth over time and space are both important. Thus recommended that both are used.	Not generally used in monitoring programmes. Exchange processes between sediment and water are important in determining the quality of many lakes.	Necessary for interpretation of biological parameters (e.g. macrophytes, some fish species) especially for shallow lakes or lakes with an extensive shallow littoral zone.

Only limited monitoring of hydrological features is currently included in existing classification systems in Europe
With the exception of lake depth variation, monitoring for morphological features is not included in any existing classification system in the EU

Table 3.6 Key features of each chemical and physico-chemical quality element for lakes

Aspect/feature	Transparency	Thermal Conditions	Oxygenation Conditions	Salinity	Acidification	Nutrients
Measured parameters indicative of QE	Secchi depth, turbidity, colour, TSS	Temperature	DO, TOC, BOD, COD DOC	Conductivity	Alkalinity, pH, ANC	Total P, SRP, Total N, N-NO3, N-NO2, N-NH4
Relevance of quality element	Eutrophication, acidification	Hydrological cycle, biological activity	Production, respiration, mineralisation		Buffering capacity, sensitivity to acidification	Eutrophication
Pressures to which QE responds	Agricultural, domestic and industrial discharges	Thermal discharges. Water management in reservoirs.	Eutrophication, organic pollution, industrial discharges	Industrial discharges, run-off	Acid rain, industrial discharges	Agricultural, domestic and industrial discharges
Level and sources of variability of QE	High, influenced by allocthonous and autocthonous material	High, influenced by climate conditions, topography, morphology and waterbody dimensions	Variable, diel changes due to respiration/ photosynthesis	Low-medium, influenced by climatic events	Low-medium, influenced by climatic events	Low-medium, influenced by climatic events
Monitoring considerations	Seasonal variation	Seasonal variation (mixing and stratification)	Diel variation High gradient in stratified lakes	Seasonal variation	Seasonal variation	Sufficient speciation to enable discrimination (point and diffuse)
Sampling methodology	*In situ* using Secchi disc TSS: field sample collection followed by laboratory analysis Turbidity: *in situ* turbidimeters, nephelometers Colour: *in situ* comparison to Forel-Ule scale or in lab.	*In situ* using thermistor probes or reversing type Hg thermometer	On-line data acquisition; *in situ* submersible probes; field sample collection followed by laboratory Winkler titration	*In situ* using submersible probes	*In situ* measurement of pH with probe. Sample collection followed by laboratory analysis	Sample collection in the field followed by laboratory analysis
Typical sampling frequency	Monthly/ quarterly related to the biological elements sampling periodicity. Fortnightly of monthly during growth season in Nordic countries.	Monthly/ quarterly	Depends on morphological characteristics of lake: daily/monthly, or at the end of stratification periods (late winter if ice cover or late summer.	Monthly/ quarterly. Should be measured during snow melt or heavy rainfall events	Monthly/ quarterly. Should be measured during snow melt or heavy rainfall events	Monthly/ quarterly Fortnightly of monthly during growth season in Nordic countries.
Time of year of sampling	All seasons.	All seasons	All seasons	All seasons	All seasons	All seasons, or mainly during growth season, SRP also measured during late winter in bottom waters
Typical "sample" size	In-situ observations. Sample collections for chemical analyses (turb, TSS)	Water column profile	Single measurements, water column profiles. 100mL for Winkler titration	In-situ water column profile, integrated epilimnion or single sample from outlet (depending on monitoring purpose)	Single sample from outlet of lake or water column profile	integrated epilimnion, single samples or water column profile (100-500mL)
Ease of sampling /measurements	Simple , using *in situ* probes or surface water sample	Simple, using *in situ* probes or water samplers	Simple, using *in situ* submersible probes or sample collection followed by titration	Simple, using *in situ* probe	Simple	Relatively easy, depth sampler need for deep lakes

Aspect/feature	Transparency	Thermal Conditions	Oxygenation Conditions	Salinity	Acidification	Nutrients
Basis of any comparison of results/quality/statio ns e.g. reference conditions/best quality	Historical data or data from comparable pristine lakes	Historical data or data from comparable pristine lakes	Historical data or data from comparable pristine lakes	Historical data or data from comparable pristine lakes	Historical data or data from comparable pristine lakes	Statistical methods: MEI index for total phosphorus Historical data or data from comparable pristine lakes
Methodology consistent across EU?	No	No	No	No	No	No
Current use in monitoring programmes or for classification in EU	Yes	Finland, France, Italy, Norway	Finland, France, Italy, Norway Sweden	Finland, Belgium, France, Italy	Belgium, Finland, France, Italy, Norway, Sweden, UK	Germany, Spain, Finland, France, Italy, Ireland, Netherlands, Norway, Sweden, UK
Existing monitoring systems meet requirements of WFD?	No	No	No	No	No	No
Existing classification system meets requirements of WFD?	No	No	No	No	No	No
ISO/CEN standards	No	No	ISO 5813:1983 DO ISO 5815:1989 BOD_5	Yes	Yes, no standard for ANC	Yes, several ISO standards exist
Applicability to lakes	high	High	High	Moderate	High	High
Main advantages	• Simple to sample • It is possible the most universally used parameter in limnology: it is a simple and powerful tool for tracking long-term trends	• Simple to measure • Fundamental to understand the hydrological cycle and lake ecology	• Simple to sample and to measure • Extremely useful because it can act as an integrator of the lake health	• Simple to measure • Conductivity is little influenced by anthropogenic inputs. A good correlation was found with the MEI cond and P concentration allowing the determination of natural background (reference) concentrations for P	• Simple to measure • Provides long term trends in acidification • Alkalinity is little influenced by anthropogenic inputs(except in acidified and limed lakes). A good correlation was found with the MEI alk and P concentration allowing the determination of natural background (reference) concentrations for P	• Provide information and long-term information on the trophic state
Main disadvantages	• No disadvantages	• May require intensive monitoring for appropriate description of thermal conditions	• May require intensive monitoring following depletion events in stratified lakes	• Does not provide long term information on trends	• None	• Need for standardisation of analytical techniques

Aspect/feature	Transparency	Thermal Conditions	Oxygenation Conditions	Salinity	Acidification	Nutrients
Conclusions/ recommendations	Easy to monitor. Secchi disc is widely used in limnology for assessing the biological condition of lakes. However, in humic lakes Secchi disc is not useful for assessment of eutrophication..	Important supporting parameter for interpreting ecological conditions. Seasonal variation, variation with depth and in large lakes horizontal variation should be monitored.	Recommended, and particularly important in deep/stratified lakes and lakes with ice cover.	Important for at characterisation of a lake. For example, it gives an indication of lake mixing processes and of metabolic activity of the lake.	Important for lake characterisation. Acidity is important because it governs the chemical form which metals occur in water body. Alkalinity and Its related variables, pH and conductivity are important classification parameters	Very important indicator for human activity/eutrophication. Total N and P, nitrate and orthophosphate should be monitored as a minimum. Ammonia monitored where concentrations are expected to be problematic e.g. exceedences of limit values over a specific limit. Phosphorus is most often considered to be the nutrient that determines algal production in lakes Thus the focus is mainly on P with regards to lake eutrophication. Nutrients should be monitored not only in water but also in sediments where sediment water interchange processes are expected to be important

3.3 Selection of Quality Elements for Transitional Waters

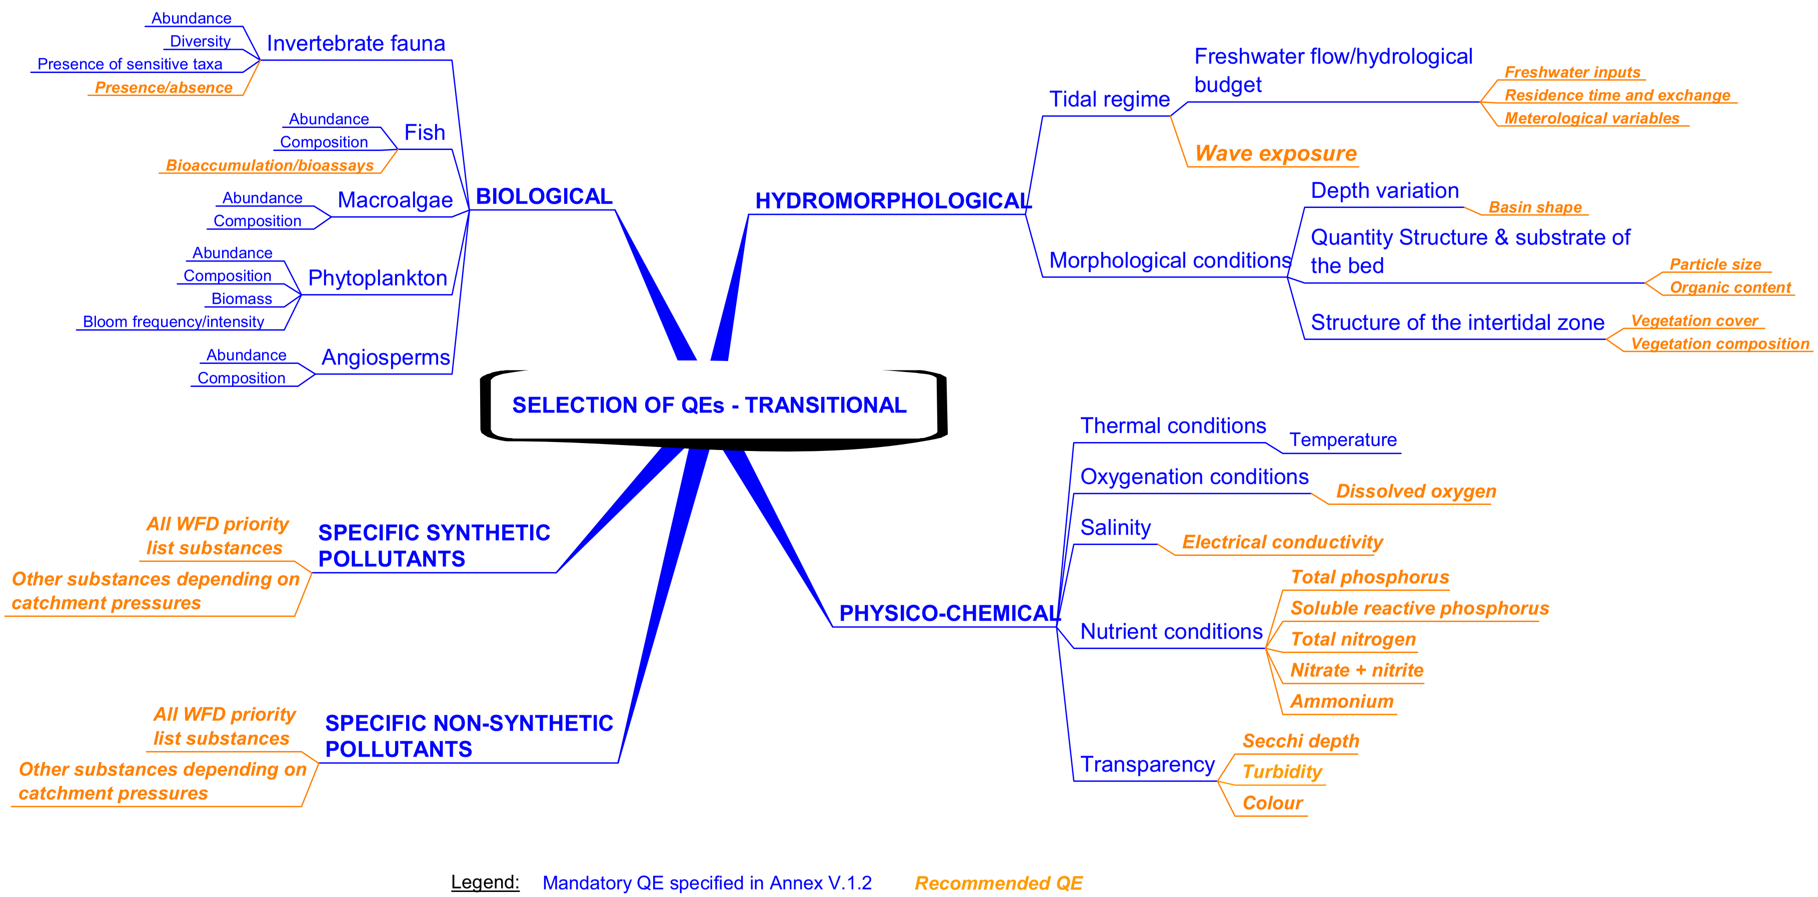

Figure 3.3 Selection of quality elements for transitional waters

Table 3.7. Key features of each biological quality element for transitional waters

Aspect/feature	Phytoplankton	Macroalgae	Angiosperms	Benthic invertebrate fauna	Fish fauna
Measured parameters indicative of QE	Composition, abundance, biomass (biomass as Chl. a), blooms.	Composition, abundance and cover	Composition and abundance	Diversity, abundance and sensitive taxa	Composition, abundance [37], sensitive species.
Supportive/interpretative parameters measured or sampled at the same time (optional parameters)	Transparency, currents, clorophyll "a", Physics-chemical parameters (e.g. temperature, salinity, oxygen, nutrients) Metereological factors Seston	Biomass, density, depth distribu-tion. Physic-chemical (temperature, salinity, nutrients, light/transpa-rency, waves, tides) Sediment and nature of substratum Metereological factors Seston	Biomass, density, depth distribution Physic-chemical (temperature, salinity, nutrients, light/transparency, waves, tides) Sediment and nature of substratum Meteoreological factors Seston	Biomass Characteristics of the habitat (topographic complexity, nature of the substratum, redox, organic matter, etc.) Physico-chemical parameters	Dissolved oxygen, salinity, temperature, pH, tide. Fish biometry and body condition.
Pressures to which QE responds	Environmental pressures such as water temperature, salinity and others have strong influence on phytoplankton composition and abundance; eutrophication; Other impacts affecting nutrient loading	Nitrogen and phosphorus loadings Human exploitation from fishery, aquaculture, tourism, power plants River/land use changes	Nitrogen and phosphorus loadings Human exploitation from fishery, aquaculture, tourism, power plants River/land use changes	Many types of anthropogenic disturbances (i.e. eutrophication, organic pollution and mechanical pollution or sediment disturbance)	Can be used to detect impacts like dams, water regulation measures, lack of natural habitats like rubble beds for spawning etc.
Mobility of QE	Moderate-high at the small scale at which the dynamic processes mainly occur	Low	Low	Low (sessile/semisessile species) to moderate/high (meroplanctic larvae, migratory gammarid species)	Very high (also, transitional waters are transient habitats of migrating species)
Level and sources of variability of QE	Highly variable on a short term temporal scale (i.e., hours-days) affected by : - trophic conditions - phisico-chemical features - hydrodynamics	High to intermediate variability due to: - chemical-physical and biological variables - hydrodynamics and meteo conditions - anthropogenic impacts	Intermediate to low variability due to: - chemical-physical and biological variables - hydrodynamics and meteo conditions - anthropogenic impacts	Highly variable on spatial and temporal scales caused by both natural and anthropogenic processes (i.e., seasonality, trophic conditions, chemical stress, land use, substrate features)	High seasonal variation. Anthropogenic and natural impacts determine changes/absences of species
Presence in transitional waters	Yes	Yes	Yes	Yes	Yes

[37] *Contaminant bioaccumulation and bioassays are not required for monitoring of ecological quality, only composition and abundance of fish fauna required; only relevant for chemical status if Quality Standards are set for transitional water fish*

Aspect/feature	Phytoplankton	Macroalgae	Angiosperms	Benthic invertebrate fauna	Fish fauna
Sampling methodology	Water sampling	Destructive: bottom sampler(hand corer , benthic grabs, etc.) Non-destructive (counts in quadrats or photographic/video methods, including aerial photography for larger species)	Destructive: bottom sampler(hand corer, benthic grabs, etc.) Non-destructive (counts in quadrats or photographic/video methods, including aerial photography)	Destructive: bottom sampler(hand corer, Van Veen grabs, etc.); use 500 micron sieve instead of or together with 1 mm sieve Non-destructive (counts in quadrats or photographic method) Litter bag or leaf pack techniques (in brackish transitional waters?), artificial substrates Use expert knowledge and pilot studies to determine best regional/type-specific sampling design Remote video techniques (ROV, towed sledge) where appropriate Acoustic methods for biogenic structures from a small boat	Fish-Net sampling (stationary: stake net fishery covering full tidal cycle; supported by trap/fixed net fishing and bottom trawls; mesh 8 mm at cod end) Use expert knowledge and pilot studies to determine best regional/type-specific sampling design
Habitats sampled	Water column	Hard and soft bottom	Hard and soft bottom	Hard and soft bottom in eulittoral and sublittoral zone	All main habitats in transitional waters
Typical sampling frequency	Seasonal sampling Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	Seasonally preferable At least twice per year (max/min cover) Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	Seasonally preferable Once or twice per year (max/min cover) Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	Preferable every three months At least twice per year Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	Twice per year Use expert knowledge and pilot studies to determine best regional/type-specific sampling design
Time of year of sampling		Seasonally preferable At least twice per year (max/min cover) Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	Seasonally preferable At least once per year at max cover Use expert knowledge and pilot studies to determine best regional/type-specific sampling design	During peak growth period; sampling in spring and autumn with several days of sampling each to find growth peak As recommended in OSPAR/HELCOM/ICES guidelines	. Spring and autumn; cover full tidal cycle

Aspect/feature	Phytoplankton	Macroalgae	Angiosperms	Benthic invertebrate fauna	Fish fauna
Typical sample size	50-250 ml of water	50x50 cm		0.1 m^2 for soft bottom; for hard bottom use standard sampling time of 20-30 minutes	. [38]
Ease of sampling	Easy	Intermediate to low	Intermediate to low	Intermediate	Intermediate
Laboratory or field measurement	Field collection, laboratory preparation followed by microscopic identification and photo/video documentation	Field collection, laboratory preparation and identification, photo/video documentation, and storage of type material	Field collection, laboratory preparation and identification, photo/video documentation and storage of type material	Field collection, laboratory preparation and identification, photo/video documentation; storage of type material	Field collection, identification and documentation Optional, not mandatory:: assessment of biometry parameters and body weight
Ease and level of Identification	Difficult at the species level. Usually simple to identify to genus	Simple after adequate training, but requires taxonomic experts, particularly for some groups of macroalgae.	Simple after adequate training but requires taxonomic experts, particularly for some groups of macroalgae.	Requires expert identification to species level and for some groups	Easy for experts
Nature of reference for comparison of quality/samples/stations and quality assurance	No. BEQUALM Reference type material partly available at universities and research institutions; quality assurance acc. to national and international programmes	No Reference type material partly available at universities and research institutions; quality assurance acc. to national and international programmes	No Reference type material partly available at universities and research institutions; quality assurance acc. to national and international programmes	Reference type material partly available at universities and research institutions; quality assurance acc. to national and international programmes (OSPAR/HELCOM/ICES, BEQUALM)	No. usually not necessary. If needed, reference type material partly available at universities and research institutions. Quality assurance acc. to national and international programmes (HELCOM Guidelines for coastal fish monitoring might be adapted)
Methodology consistent across EU?	No, but consistent among HELCOM and OSPAR countries for Baltic Sea and North East Atlantic BEQUALM scheme under development.	No, but consistent in Baltic countries (HELCOM Guidelines for phytobenthos monitoring)	No, but consistent in Baltic countries (HELCOM Guidelines for phytobenthos monitoring)	HELCOM/OSPAR Guidelines for macrozoobenthos, to be adapted to transitional waters if necessary; BEQUALM scheme under development	. Use expert knowledge and pilot studies to determine best regional/type-specific methodology

[38] *OSPAR Guidelines for fish are for contaminant analysis, not relevant for abundance and composition*

Aspect/feature	**Phytoplankton**	**Macroalgae**	**Angiosperms**	**Benthic invertebrate fauna**	**Fish fauna**
Current use in biological monitoring or classification in EU	Part of national monitoring in different EU countries	Part of national monitoring in different EU countries	Part of national monitoring in different EU countries	Part of national monitoring in different EU countries	Part of national monitoring in different EU countries
Current use of biotic indices/scores	No	No, but ratio of fast-growing opportunistic versus slowly growing perennial species can be used (shifts due to eutrophication)	No	No	No
Existing monitoring system meets requirements of WFD?	No	No	No	No	No
ISO/CEN standards **Other standards**	OSPAR JAMP Eutrophi-cation Monitoring Guide-lines: Phytoplankton Species Composition; HELCOM COMBINE Monitoring Guidelines *i)* for phytoplankton species composition, abundance and biomass and *ii*) for phytoplankton Chlorophyll a ISO 10260 (1992) for the determination of chlorophyll a	ISO/CEN: No HELCOM COMBINE Guidelines on Phytobenthos Monitoring	ISO/CEN: No HELCOM COMBINE Guidelines on Phytobenthos Monitoring	ISO 7828:1985 (Guidance on handnet sampling of aquatic benthic macro-invertebrates) ISO 9391:1993 (Sampling in deep waters for macro-invertebrates – Guidance on the use of colonization, qualitative and quantitative samplers) ISO 16665 (marine soft-bottom macrofauna; in preparation) HELCOM/OSPAR Guidelines for macrozoobenthos, to be adapted to transitional waters if necessary;	No
Applicability to Transitional waters	low	High	High	High	with restrictions

Aspect/feature	Phytoplankton	Macroalgae	Angiosperms	Benthic invertebrate fauna	Fish fauna
Main advantages	Ease of sampling	Identify potential disturbance phenomena Evaluation of community evolution Cost-effective, objective and amenable to optimisation through statistical procedures	Identify potential disturbance phenomena Evaluation of community evolution Cost-effective, objective and amenable to optimisation through statistical procedures	Identify potential disturbance phenomena Evaluation of community evolution Cost-effective, objective and amenable to optimisation through statistical procedures	Relatively easy to compare fish fauna at "pristine state" by use of historical list of fish species with list in actual condition. Identifies natural and anthropogenic impacts from a wide range of sources. [Passage of migratory fish is an excellent indicator of good water quality in freshwater part of river only; in trans. water indicative of good hydromorphological conditions – no dams/constructions or sufficient number of fish passages]
Main disadvantages	High spatial-temporal variability, occurrence of freshwater, marine and brackish species in varying physiological state (brackish water zone as "graveyard" of freshwater and marine species), high influence of temperature and salinity fluctuations on phytoplankton composition Taxonomic identification can be difficult and time-consuming. Lack of quality assurance protocols	No standardized method except in HELCOM countries Lack of taxonomic detail (looping of tiny species into morphological groups). Lack of quality assurance protocols	No standardized method except in HELCOM countries Lack of taxonomic detail (looping of tiny species into morphological groups). Lack of quality assurance protocols	High spatial-temporal variability Lack of taxonomic detail (looping of tiny species into morphological groups). Lack of quality assurance protocols High taxonomic expertise required. High sampling frequency and high number of samples required due to variability in time and space	The high mobility, occurrence of eurytolerant marine and freshwater fish and of migrating fish species makes it difficult to relate to impacts occurring at the local scale Long life cycles Large sample sizes requirements Long time series needed for reliable accounts on composition and abundance

Table 3.8 Key features of each hydromorphological quality element for transitional waters

Aspect/feature	Morphological conditions			Tidal regime Hydrological budget
	Depth variation	**Quantity, structure and substrate of the bed**	**Structure of the transitional zone**	
Measured parameters indicative of QE	Shape of the basin	Grain size Organic content	Vegetation cover Vegetation type	Freshwater inputs Exchange with the ocean Water residence time Metereological variables
Pressures to which QE responds	Hydrological modification Suspended solids Dredging	Mechanical and organic pollution Hydrological modification Suspended solids. Dredging	Land use and modification of hydrology	Modifications of land use Modifications of the marine sandy coasts Outlet modification
Level and sources of variability of QE	Slow changes due to impaired decomposition, Solid transport through the ecotone from the terrestrial environment, freshwater transport High variability for some typology due to sand transport and accumulation.	Low natural variability Moderate variability due to human impact	Low natural variability Moderate variability due to human impact	High temporal variability due to hydrological and meteo-conditions Low temporal variability due to groundwater uses and land use
Sampling methodology	Echo soundings Remote sensing	Corers	Remote sensing images and field surveys	In situ measurements of water flows
Typical sampling frequency	Once every 5 years	Once every 3 years	Once every 3 years	A complete annual cycle with quarterly samplings, every 3 years
Time of year of sampling	Indifferent	Indifferent	Spring-summer	Seasonal
Typical "sample" size or survey area	Grid from 1 X 1 m up to 10 m X 10 m	Undisturbed bottom sample from 10 cm X 10 cm up to 200 cm X 200 cm	Entire ecotone	All water inputs and outputs
Ease of sampling /measurements	Rapid electronic measurements	Rapid sampling, time consuming laboratory analysis	Easy Rapid using remote sensing technology, if possible.	Easy and rapid sampling when supported by expensive field equipment
Basis of any comparison of results/quality/stations e.g. reference conditions/best quality	Maps of the National Hydrographical services	No	Corine habitat maps	No
Methodology consistent across EU?	No	FOLC method	No	No
Current use in monitoring programmes or for classification in EU	No	No	No	No
Existing monitoring systems meet requirements of WFD?	No	No	No	No

ISO/CEN standards				
waters	Yes	Yes	Yes	Yes
Main Advantages	Rapidity of sampling and map making	Rapid sampling	Rapid sampling and map making	Rapid sampling and map making
Main disadvantages	None	Time consuming laboratory analysis		Expensive instrumentation

Table 3.9 Key features of each chemical and physico-chemical quality element for transitional waters

Aspect/feature	Transparency	Thermal conditions	Oxygenation	Salinity	Nutrients
Measured parameters indicative of QE	Light penetration & quality	Thermal Profiles along water column	Oxygen profiles	ppt psu	Reactive species and total budgets (N,P,Si)
Relevance of quality element	High	High	High	High	High
Pressure to which the QE responds	Resuspension Solids transport by rivers Aquaculture Eutrophication	Climate variables Thermal pollution Provides information on mixing conditions	Organic matter loading Eutrophication Aquaculture	Freshwater and marine water inflows Water hydrodynamics	Nitrogen and phosphorus loading from river discharge, local point and non-point pollution, aquaculture
Level and sources of variability of QE	High natural variability due to seasonal plankton blooms, freshwater runoff and meteorological factors	Predictable high natural variability due to seasonal and mixing condition Some variability due to human impact	High natural variability due to daily changes in temperature and production/respiration.	Predictable high natural variability due to the thermohaline circulation and freshwater inputs Anthropogenic inputs	High natural variability due to seasonal variation (meteo and biological) Anthropogenic inputs
Monitoring considerations	Dependence from daylight and salinity	Special attention to water column profile Dependence on salinity	Dependence from hydrodynamics, physical characteristics and day time of measurement Due to fast dynamics characterising lagoons and coastal lakes, repeated 24-72 hours continuous samplings are strongly recommended at least twice per year (winter-summer)	Dependence from hydrodynamics (and salinity)	Dependence from hydrodynamics and biological factors Special attention to sediments exchange for total budget consideration
Sampling methodology	Secchi disc, autographic photometers	Portable electronic equipment Automated on site buoy	Portable electronic equipment Automated on site buoy	Portable electronic equipment Automated on site buoy	Water sampling, followed by laboratory analysis
Typical sampling frequency	Monthly	Daily measurements with on site buoy Monthly controls	Daily measurements with on site buoy Monthly controls	Daily measurements with on site buoy Monthly controls	Monthly
Time of year of sampling	Every month	Daily + Every month	Daily + Every month	Daily + Every month	Every month
Typical sample size	none	none	None/100 ml	None/100 ml	1-2 litres
Ease of sampling/measurements	High	High	High	High	High
Basis of any comparison of results/quality/stations e.g. reference conditions/best quality quality/samples/stations					Spatial comparisons and site-based trend assessment
Methodology consistent across EU			OSPAR JAMP Eutrophication Monitoring Guidelines: Oxygen		OSPAR Nutrient Monitoring Guidelines
Current use in monitoring or classification programme in EU					OSPAR Nutrient Monitoring Guidelines

Aspect/feature	**Transparency**	**Thermal conditions**	**Oxygenation**		**Nutrients**
Existing monitoring system meets requirements of WFD					
ISO/CEN standards	No	No	No	No	No
Applicability to transitional waters	High	High	High	High	High
Main advantages	Ease of measurement	Ease of measurement	Ease of measurement if autographical	Ease of measurement.	Rapid sampling
Main disadvantages	Extreme temporal variability.	Account must be taken of diurnal and seasonal variability.	Account must be taken of diurnal and seasonal variability. Time consuming if not autographical	Account must be taken of the tidal state at the time of sampling.	Time consuming High spatial and temporal variation Antagonistic with phytoplankton and seaweeds biomass

3.4 Selection of Quality Elements for Coastal Waters

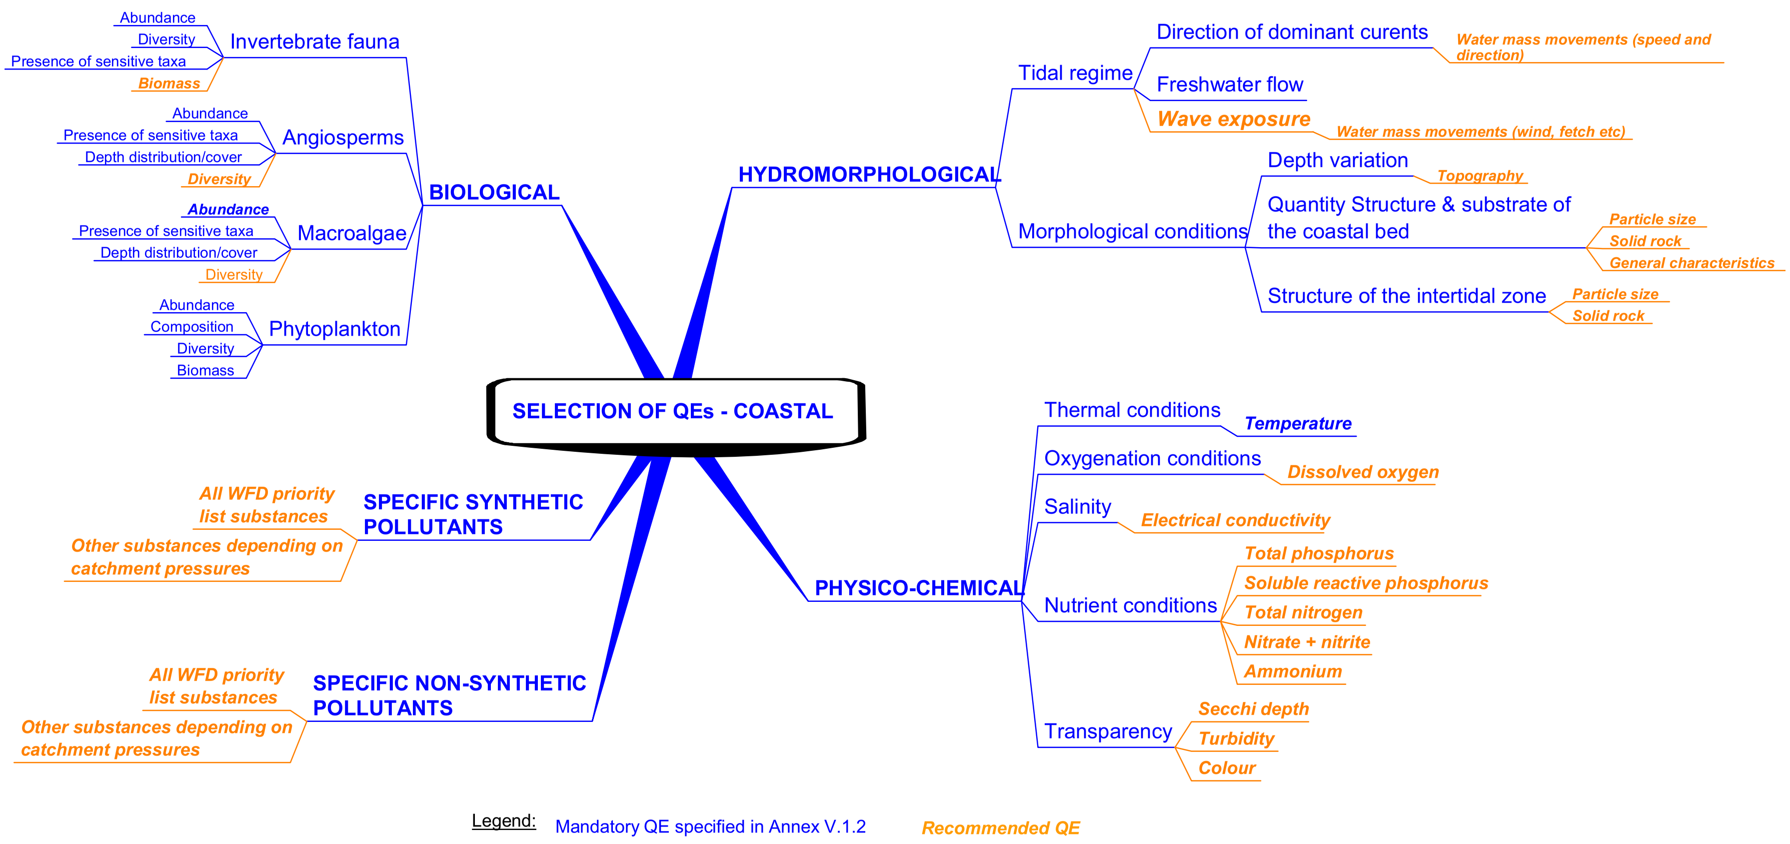

Figure 3.4 Selection of quality elements for coastal waters

Table 3.10 Key features of each biological quality element for coastal waters

Aspect/feature	AQUATIC FLORA		AQUATIC FAUNA
	Phytoplankton	**Macroalgae/Angiosperms (Phytobenthos)**	**Benthic invertebrate fauna**
Measured parameters indicative of QE As reported in Annex V (1.1.4 and 1.2.4)	Composition, abundance, biomass, blooms	Composition, abundance, sensitive taxa, cover	Composition, abundance, diversity, sensitive taxa
Supportive/interpretative parameters measured or sampled at the same time	Physico-chemical parameters: transparency, , temperature, salinity, oxygen, nutrients chlorophyll “a” Hydromorphological parameters: currents Key species	Very important supporting parameter :distribution (Horizontally and vertically) Biomass, density Physico-chemical (transparency , temperature, salinity, nutrients) Hydromorphological parameters: tides, wave exposure, bearing, slope, Sediment and nature of substratum Height above/below tidal datum	Very important supporting parameter: biomass Characteristics of the habitat (morphology, wave exposure, bearing, slope texture, topographic complexity, nature of the substratum etc.) Physico-chemical parameters (temperature, salinity, oxygen, nutrients) Presence and distribution/extent of particular biogenic aggregations (i.e. molluscs beds, polychaete “reefs”)
Pressures to which QE responds	Eutrophication Nutrients discharges, suspended matters, toxic substances	Many types of anthropogenic disturbances (i.e. nutrient loading, fishing, modification of shore and bed structure suspended matter input)	Many types of anthropogenic disturbances (i.e. :eutrophication, organic pollution, mechanical disturbance, physical modification of seabed , sediments dynamics and fishing)
Mobility of QE	High	Low	Low
Level and sources of variability of QE	High inter and intra-seasonal variation in community structure and biomass. Spatial patchiness Influenced by: irradiance, nutrient availability, water column stability and residence time.	Small-scale spatial patchiness and temporal variation, seasonal trends for some taxa Influenced by climatic seasonality (i.e. events, irradiance, nutrient availability)	Small-scale spatial patchiness and temporal variation, seasonal trends for some taxa Influenced by seasonal growth patterns Influenced by substrate variability and physical environmental parameters variations
Presence in coastal waters	Abundant	Abundant to rare: Regional differences: (e.g. seagrass beds are rare in the North Sea)	Abundant
Sampling methodology	Water sampling (plankton net, water samples)	Direct by SCUBA diving or walking in the intertidal: non-destructive (quantitative counts in quadrats or photographic method, semi-quantitative abundance estimation according to defined scale) , destructive (suction or bottom sampler) Indirect: Shipboard sampling using box samplers (grab, corer) Remote sensing surveys (satellite, airborne multispectral or aerial photography) (e.g. density on mudflats) Remote video techniques (ROV, towed sledge) where appropriate	Direct by SCUBA diving or walking in the intertidal: non-destructive (quantitative counts in quadrats or photographic method, semi-quantitative abundance estimation according to defined scale) destructive (suction or bottom sampler) Indirect: Shipboard sampling using box corers, grabs, dredges Remote video techniques (ROV, towed sledge)where appropriate Echo sounding technique (ROXANN) which can be used to measure the extent of biological habitats

Aspect/feature	AQUATIC FLORA		AQUATIC FAUNA
	Phytoplankton	**Macroalgae/Angiosperms (Phytobenthos)**	**Benthic invertebrate fauna**
Habitats sampled	Water column.	Hard and soft bottom	Hard and soft bottom
Typical sampling frequency	Best: 15 days At least: monthly sampling at standard depths Determine best regional/type-specific sampling design (i.e. maximum and minimum levels)	Seasonally preferable (4 times for year) At least twice per year (max/min cover); regionally different (HELCOM: once per year) Frequency may be less for seagrasses and/or other long-lived species	Seasonally preferable at least during peak growth period As recommended in OSPAR/HELCOM/ICES guidelines once per year (same season) At least twice per year for Mediterranean Ecoregion
Time of year of sampling	Should cover all seasons, with emphasis on bloom seasons. And particular events related (exceptional blooms)	Seasonally preferable (4 times for year) At least twice per year (max/min cover) with timing depending on ecoregion As recommended in OSPAR/HELCOM/ICES guidelines(once per year, June-September)	Seasonally preferable at least during peak growth period
Typical sample size	Variable: usually 50-250 ml, /1 litre As recommended in OSPAR/HELCOM/ICES guidelines	Variable dependent on methodology and phytobenthos group types Quadrats of different sizes (from 15x15cm to several m2 depending on the size of the group) As recommended in OSPAR/HELCOM/ICES guidelines or SCUBA Diving transects (ISO std under development)	Variable dependent on methodology Quadrats of different sizes (20÷50 cm) for hard bottom Combination of nets and corers for soft bottom As recommended in OSPAR/HELCOM/ICES guidelines SCUBA Diving transects (ISO std under development)
Ease of sampling	Simple water sampling.	In situ techniques: simple after training of skilled personnel (SCUBA-diving) for species identification and methodology; but variable due to meteo-marine conditions and methodology Shipboard sampling: easy on soft bottom, difficult on hard bottom. Aerial photography is technically demanding	In situ techniques :simple after minimum training but variable due to meteo-marine conditions and methodology Relatively easy shipboard sampling
Laboratory or field measurement	Field collection, laboratory preparation followed by microscopic identification.	Field collection, laboratory preparation, sorting and identification	Field collection, laboratory sorting and identification
Ease and level of Identification	Taxonomy expert work. Difficult at the species level. Usually simple to identify to genus	Simple after adequate training but requires taxonomic experts, particularly for some groups of macroalgae.	Taxonomy expert work. Simple after adequate training.
Nature of reference for comparison of quality/samples/stations	Ref. type material at Universities & research Institutions; quality assurance according to national and international programmes and recommendation (OSPAR/HELCOM/ICES) BEQUALM, under development QUASIMEMME (chlorophyll a)	Ref. type material at Universities & research Institutions; quality assurance according to national and international programmes and recommendation (/HELCOM COMBINE guidelines)	Ref. type material at Universities & research Institutions; quality assurance according to national and international programmes and recommendation (OSPAR/HELCOM/ICES;) BEQUALM (UK and NL)
Methodology consistent across EU?	No but consistent across NE Atlantic and across Baltic Sea (OSPAR and HELCOM Countries)	No but consistent across NE Atlantic and across Baltic Sea (OSPAR and HELCOM Countries)	No but consistent across NE Atlantic and across Baltic Sea (OSPAR and HELCOM Countries)

Aspect/feature	AQUATIC FLORA		AQUATIC FAUNA
	Phytoplankton	**Macroalgae/Angiosperms (Phytobenthos)**	**Benthic invertebrate fauna**
Current use in biological monitoring or classification in EU	Italy, Norway (partly) , Netherlands, Germany, Sweden (monit), Spain	Norway (partly) Germany (tentative),Denmark, Sweden(monit & class), UK, Spain	Norway (partly), Netherlands, Germany, Spain, , Sweden(monit & class)
Current use of biotic indices/scores	Norway	No Spain (Catalonia)	Norway, Sweden UK, Spain
Existing monitoring system meets requirements of WFD?	Generally No Partially in: Italy, Germany, Norway, Sweden	Partially in Germany, Norway, UK, Sweden	Norway, Partially in Germany, Sweden
ISO/CEN standards	No CEN/TC 230 N 0423 in preparation	No Rocky shore ISO standard in preparation (Norway standard 9424):	National Norwegian soft bottom standards (ISO in preparation: TC 230/SC 5: ISO/TC 147/SC5 N350) In preparation ISO16665
Applicability to Coastal waters	High	High	High
Main advantages	Good indicator of changes in trophic status Ease of sampling Indicators of short-term impact due to rapid turn-over times Important monitoring of harmful algae (DSP/PSP)	Good integrating indicator of general state of environment Identify potential disturbance phenomena Evaluation of community evolution: provides information on ecosystem stability Key element in coastal ecosystems Good integrating indicator of broad range of impacts Cost-effective, consistent and amenable to optimisation through statistical procedures	Good integrating indicator of general state of environment Identify potential disturbance phenomena Evaluation of community evolution Cost-effective, consistent and amenable to optimisation through statistical procedures
Main disadvantages	High spatial-temporal variability requires frequent sampling and good spatial coverage Consistent identification requires consistent training and quality assurance procedures as well as intercalibration Taxonomic identification can be difficult and time-consuming	Require certified and skilled divers Not standardised method Lack of taxonomic detail (looping of tiny species into morphological groups) Consistent identification requires consistent training and quality assurance protocols	Lack of taxonomic detail (looping of tiny species into morphological groups) Consistent identification requires consistent training and quality assurance protocols Require certified and skilled divers
Recommendation/ Conclusion	Good indicator of changes in trophic status and of short-term impact, due to rapid turnover times. Identification of nuisance or potential toxic species is a particularly important assessment parameter. Bloom frequency and intensity are indicative parameters for classification of ecological status. WFD minimum frequency (every 6 months) can be inadequate for many regions: pilot studies and local expert knowledge could help in establishing the most appropriate frequencies.	Key elements in coastal ecosystems. Good integrating indicators of the status of the environment, responding to a broad range of impacts. Provide important information on the ecosystem stability, as variations may indicate long-term changes in the physical conditions at the site. For angiosperms, the most important parameter is distribution (extension and variation in time and space).	Good integrating indicators of the status of the environment. Important variables to be considered together with the required parameters (composition and abundance) are diversity of species and presence of sensitive or higher taxa as well as biomass, the latter being indicative of eutrophication. Several indexes exist and their use is quite spread, although not commonly agreed.

Table 3.11 Key features of each hydromorphological quality element in coastal waters

Aspect/feature	Morphological conditions			Tidal regime	
	Depth variation	**Structure and substrate of the coastal bed**	**Structure of the intertidal zone**	**Direction of dominant currents**	**Wave exposure**
Measured parameters indicative of QE	Topography of the type of water body	- Grain size - Solid rock - Other general characteristics: coarse description (mud, sand, gravel, hard soils or rocks sedimentological structures (ripples, sand reefs, under water dunes etc.) - bioturbation, lamination in sediment cover, oxigenation conditions in sediments	- Rock type , form and exposure to waves, - Grain size - Distribution of biological communities - H/L tide levels - erosion/deposition	Water mass movements (speed and direction)	Water mass movements (wave, wind, Fetch-index) frequency of storms directions H/L tide/surge levels
Pressures to which QE responds	Landfill, dredging, dumping, and natural large scale bottom dynamics	Mechanical disturbance and variation in structure and substrate composition due to anthropogenic input	- Mechanical disturbance and variation in structure and substrate composition due to anthropogenic input - Change in macroalgal composition due to chemical inputs. - diking - beach nourish	Natural modification (mechanical and climatic) of coastline Anthropogenic modifications (constructions)	Natural modification (mechanical) of coastline climate constructions
Level and sources of variability of QE	Very low variability due to natural erosion and sedimentation. Moderate variability due to human impact Seasonal variations are important in nearshore areas	Low natural variability Moderate variability due to human impact Seasonal variations are important in nearshore areas	High natural variability (regularly: tidal flooding and drought periods. irregularly: storms, etc.). High variability due to human impact	High natural variability depending on winds, tides and climatic changes low frequency climatic changes (e.g. NAO) (Germany)	Seasonal variability Low frequency climatic changes
Sampling methodology	Echo soundings ROV	Corers Scanning acoustic techniques Diving Video	- Skindiving , photo, corer (intertidal soft bottom) - Remote imaging (satellite airborne systems); - Viewpoint photography; In-situ measurements along transects[39]s	Drifters, in situ measurements, autographic instruments, Doppler Historical flows data , modelled flows (mainly large scale)	In situ measurements, autographic instruments, Fetch calculations Calculations (mainly large scale) from maps and meteorological data modelling gauging

Aspect/feature	Morphological conditions			Tidal regime	
	Depth variation	**Structure and substrate of the coastal bed**	**Structure of the intertidal zone**	**Direction of dominant currents**	**Wave exposure**
Typical sampling frequency	Once every 5/6 years Before and after significant pressure applied	Once every 5/ 6 years Sampling "ad hoc" for specific reasons (i.e. construction, benthic studies support)	Once /twice every 5/ 6 years Sampling for specific reasons (i.e. construction, mapping)	Annual cycle.	Annual cycle.
Time of year of sampling	Indifferent Important if seasonal variations in nearshore areas	Indifferent	Summer (to avoid winter with possible ice cover) and if using biological communities	Annual cycle	Annual cycle
Typical "sample" size or survey area	Hydromorphological grids vary according to desired scales. Suggestion: grid from 100 m X 100 m up to 500 m X 500 m	Undisturbed bottom sample from 10 cm X 10 cm up to 200 cm X 200 cm box grab samples (50cm x 50 cm, where appropriate) (Germany) Larger areas covered by ROV/divers Side Scan Sonar	Whole intertidal zone using imaging techniques Sediment samples collected by 5cm diameter corer, 15cm depth.(UK) Undisturbed bottom sample from 10 cm X 10 cm up to 200 cm X 500 cm (Norway)	Instruments integrate information from large spatial and temporal areas Importance of instrument's location operational modelling	Instruments integrates information from large spatial and temporal areas Importance of instrument's location
Ease of sampling /measurements	Rapid electronic measurements	Rapid sampling, time consuming laboratory analysis	Rapid sampling, time consuming laboratory analysis depending on substrate type or sampling technique	Rapid sampling and map making with autographic instruments	Rapid sampling and map making with autographic instruments
Basis of any comparison of results/quality/stations e.g. reference conditions/best quality	Maps of National Hydrographical /Geological services,	Seabed sediment maps from National Geological Surveys (i.e. British Geological Survey)	Biological maps should use a standard classification such as EUNIS (e.g. UK has the Marine Biotope classification) Maps from National Geological Surveys (e.g. British Geological Survey)	No	No
Methodology consistent across EU?	No	No	No	No	No
Current use in monitoring programmes or for classification in EU	Used in operational monitoring, but not continuously in most of the countries	Italy Sweden (in connection with benthic studies)	UK – SAC monitoring programme		
Existing monitoring systems meet requirements of WFD?			Partially for UK?		
Existing classification systems meet requirements of WFD?					

Aspect/feature	**Morphological conditions**			**Tidal regime**	
	Depth variation	**Structure and substrate of the coastal bed**	**Structure of the intertidal zone**	**Direction of dominant currents**	**Wave exposure**
ISO/CEN standards					
waters	Yes	Yes	Yes	Yes	Yes
Main Advantages	Rapidity of sampling and map making	Rapid sampling Provides information about hydrodynamism and different community distribution	Rapidity of sampling and map making Provides an overview of a whole system to identify extent of localised effects Provides link with biological QE	Continuous measurement, ease of mapping. Information on dispersion of pollution (i.e. oil spill) and loads dilution	Continuous measurement, ease of mapping. Information on dispersion of pollution (i.e. oil spill) and loads dilution
Main disadvantages	None	Time consuming laboratory analysis	Time consuming laboratory analysis for sediment characterisation Mapping can be expensive	Expensive instrumentation.	Expensive instrumentation
Recommendation/ Conclusion	Depth variations could be important elements to be monitored in areas where disturbances are expected: anthropogenic changes will have relevance for the status classification of the water body.	Indicator of hydrodynamism and supporting element for community distribution; Changes in morphological conditions and/or nature of the substratum may exert severe detrimental effects on benthic organisms.	Note relevant for the Mediterranean and the Baltic ecoregions, given their low tidal range. Thus it is suggested to use the "intertidal/ *mediolittoral*" term for meaningful ecological relevance (see Annex VI).	Direction and intensity (speed) of dominant currents are important parameters, especially in ecoregions or part of ecoregions with low tidal range (Baltic, Mediterranea, Skagerrak) where tidal currents play a very minor role, if any. Can be particularly relevant in areas where anthropogenic disturbance occur (see Annex VI). It can be necessary to take into account short term effects.	To be monitored in areas submitted to anthropogenic disturbances. Suggested parameters are frequencies of storm, direction, high/low tide surge levels.

Table 3.12 Key features of each chemical and physico-chemical quality element for coastal waters

Aspect/feature	Transparency	Thermal Conditions	Oxygenation Conditions	Salinity	Nutrient conditions
Measured parameters indicative of QE	Light penetration & quality	Temperature Water column structure (in stratified waters)	D.O. concentration O2 % saturation	ppt psu	NO3, NO2, NH4, P04, Si concentration, total N, total P
Relevance of quality element	High	High	High	High	High
Pressures to which QE responds	Nutrient surplus (plankton enrichment). Organic matter pollution (sewage, sludge) Particulate load Land runoff Riverine discharges	Thermal point source pollution Thermal alteration due to reduced water exchange and modified dynamics by coastal constructions Climatic changes	Organic pollution, anthropog. enhanced productivity Reduced water exchange by human impacts .	Freshwater runoff. Mixing condition and origin of the water masses Reduced water exchange by human impacts	nutrient surplus, organic pollution (sewage, sludge) Land runoff Local point and diffuse source inputs Atmospheric input (especially N)
Level and sources of variability of QE	High natural variability due to seasonal plankton blooms freshwater runoff, wind and tidal currents action	High natural variability due to seasonal and mixing condition	High natural variability due to daily changes in temperature and production/respiration. and water exchange conditions. Main disadvantages	High temporal variability	None	Time consuming if not autographical	None	Time consuming
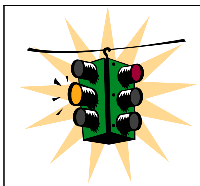
Recommendation/ Conclusion	Easy measure. Routinely used in most national monitoring programmes. Measurement is difficult in “troubled waters”, e.g. the NE Atlantic Wadden Sea with high loads of resuspended sediments.	Easy measure. Routinely used in most national monitoring programmes. Temperature profiles along the water column easily obtained by in *situ* autographic instruments. The thermal structure of the water column is a very important information (see Annex VI).	Easy measure. Routinely used in most national monitoring programmes. Important parameter. % of saturation is particularly relevant (see Annex VI).	Easy measure. Routinely used in most national monitoring programmes. Important parameter (see Annex VI).	The concentration of nutrients, together with the concentration of chlorophyll ‘a’, indicator of actual production, provide information on the general trophic conditions. Important parameter (see Annex VI).

4 Design of groundwater monitoring programmes

4.1 Introduction

This Section of the guidance provides specific advice on the design of groundwater monitoring programmes. It also describes the general principles applicable to all of the groundwater monitoring programmes, as well as the specific requirements for each of the groundwater monitoring programmes.



Look Out!

This guidance uses the term conceptual model as shorthand for the understanding, or working description, of the real hydrogeological system that is needed to design effective groundwater monitoring programmes. The term should NOT be taken to imply that a mathematical model is required for all bodies of groundwater. On the contrary, complex mathematical models are only likely to be required to properly design and justify very expensive restoration measures for bodies that are failing to achieve the Directive's objectives.

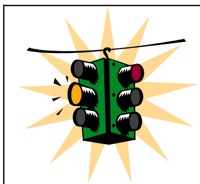
4.2 Principles for the design and operation of groundwater monitoring programmes

4.2.1 Identify the purposes for which monitoring information is required

The design of monitoring programmes involves deciding what to monitor, where and when. The answers to these questions depend first and foremost on the purpose which monitoring will serve. The first step before designing a network is therefore to clearly identify the purpose, or purposes, for which the monitoring information is needed.

The monitoring required by the Directive is intended to provide information to help assess the achievement of the Directive's environmental objectives. Monitoring programmes should therefore be designed to provide the information needed to establish whether the particular environmental conditions specified by these objectives are being achieved. Among other things, this will involve monitoring to test the understanding of the groundwater system on which assessments are based and the effectiveness of any measures applied.

The relevant environmental objectives for groundwater are listed in Section 2.13 of the common understanding.



Look Out!

The requirements of the Directive's 'prevent or limit inputs of pollutants' objective [Article 4.1(b)(i)] are unclear. The Directive does not specify which pollutants[40] should be prevented from entry, and to what extent the entry of others on the list should be limited nor does it describe any relevant monitoring requirements in Annex V. It is therefore not possible to provide guidance on what, if any, monitoring should be implemented to assess the achievement of this objective.

Additional criteria for assessing good groundwater chemical status, including the application of quality standards, may be established by the

[40] *Annex VIII provides an indicative list of the main pollutants*

new groundwater directive envisaged by Article 17. It is assumed that the daughter directive will indicate how compliance with any quality standards it establishes should be assessed. This document only provides monitoring guidance for the good chemical status criteria that are not dependent on the daughter directive.

Annex V of the Directive describes the purposes of the different groundwater monitoring programmes. It also specifies certain criteria for determining what, where and when to monitor in respect of these purposes. Figure 4.1 below summarises these requirements.

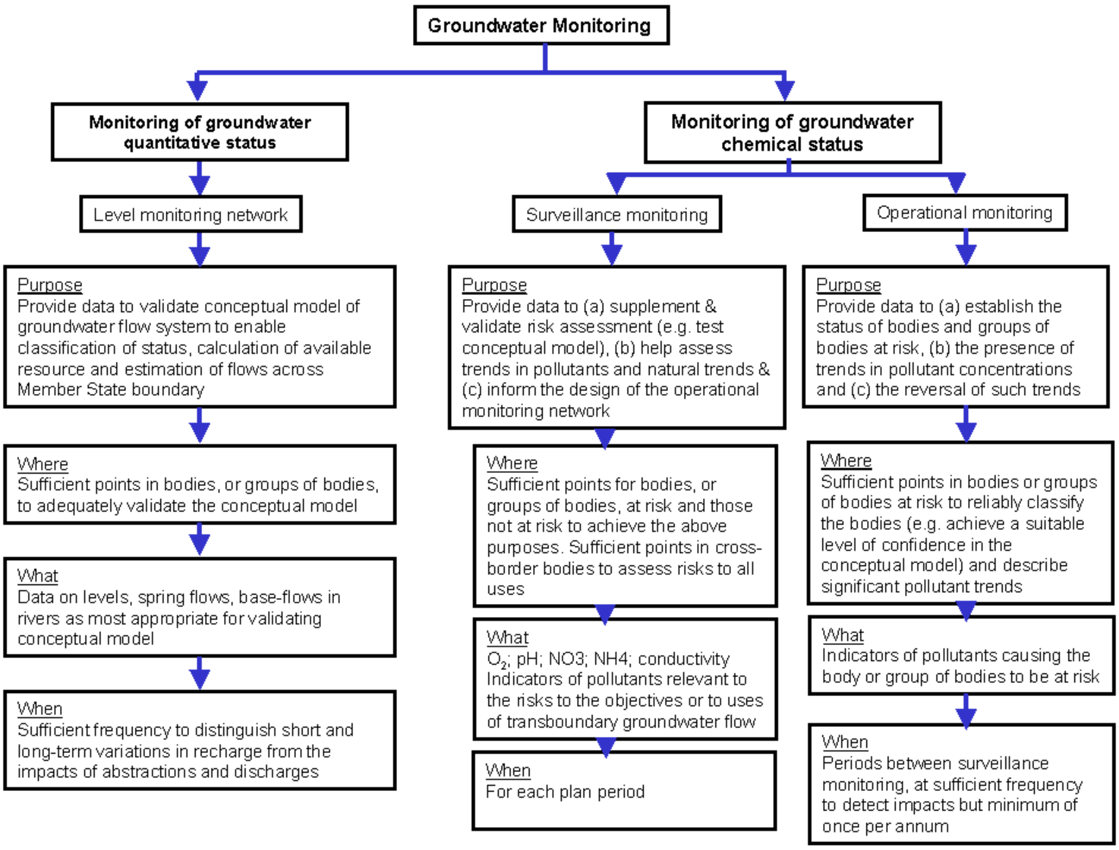


Figure 4.1 Summary of the purposes of, and requirements for, the groundwater monitoring programmes specified in Annex V of the Directive.

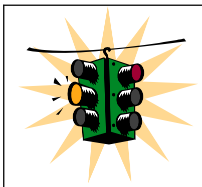


Look Out!

Monitoring of spring flows (e.g. flow rate, chemical composition;) and/or river base-flows will often be an important, and sometimes the principal, means of obtaining reliable information for use in assessing quantitative and chemical status.

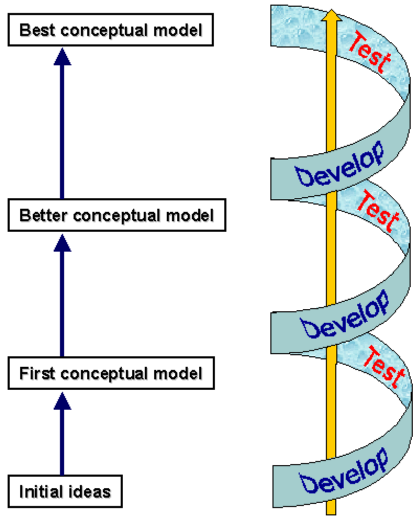
4.2.2 Monitoring should be designed on the basis of an understanding of the groundwater system

The Annex II risk assessment procedure is intended to help target and prioritise monitoring effort to where there are likely to be environmental problems. The monitoring programmes should be designed to provide the information needed to validate the risk assessment procedure and establish the magnitude, and spatial and temporal distribution, of any impacts. Risks assessments for groundwater should be based on a conceptual model/understanding of the groundwater system and how pressures interact with that system. A conceptual model/understanding is not only necessary to design monitoring programmes. It is also needed to interpret the data provided by those programmes, and hence assess the achievement of the Directive's objectives (Figure 4.2).

Definition of conceptual modelling/ understanding

A conceptual model/understanding is a simplified representation, or working description, of how the real hydrogeological system is believed to behave. It describes how hydrogeologists believe a groundwater system behaves.

- It is a set of working hypotheses and assumptions
- It concentrates on features of the system that are relevant in relation to the predictions or assessments required
- It is based on evidence
- It is an approximation of reality
- It should be written down so that it can be tested using existing and/or new data.
- The level of refinement needed in a model is proportionate to (i) the difficulty in making the assessments or predictions required, and (ii) the potential consequences of errors in those assessments.



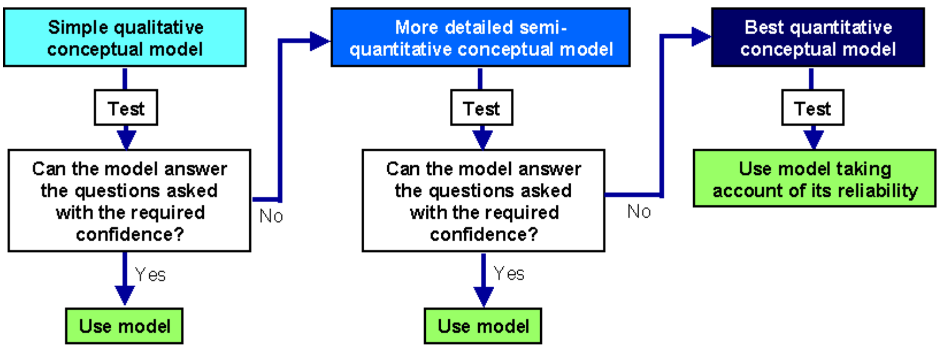


Figure 4.2 Definition of conceptual modelling/understanding

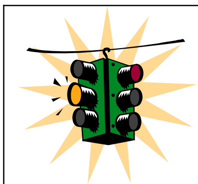

Look Out!

The testing of conceptual models/understandings is important to ensure they provide for acceptable levels of confidence in the assessments they enable. The Directive requires the confidence in the results of monitoring to be reported in the River Basin Management Plans. Guidance on testing conceptual models/understandings using water balances is provided in the toolbox. It is important to note that although the guidance recommends testing models numerically this does not mean that the models themselves have to be mathematical. On the contrary, complex mathematical models are only likely to be required to properly design and justify very expensive restoration measures for bodies that are failing to achieve the Directive's objectives.

The level of detail in any conceptual model/understanding needs to be proportional to the difficulty in judging the effects of pressures on the objectives for groundwater. The first model will be a simple, generalised sketch of the groundwater system. Where necessary, the spatial specificity of this first conceptual model/understanding can be gradually improved (Figure 4.3). Monitoring data is required to test or validate the conceptual model/understanding. Such testing will require some monitoring data for all bodies, or groups of bodies, identified as being at risk as well as a selection of those identified as not being at risk of failing to meet their objectives.

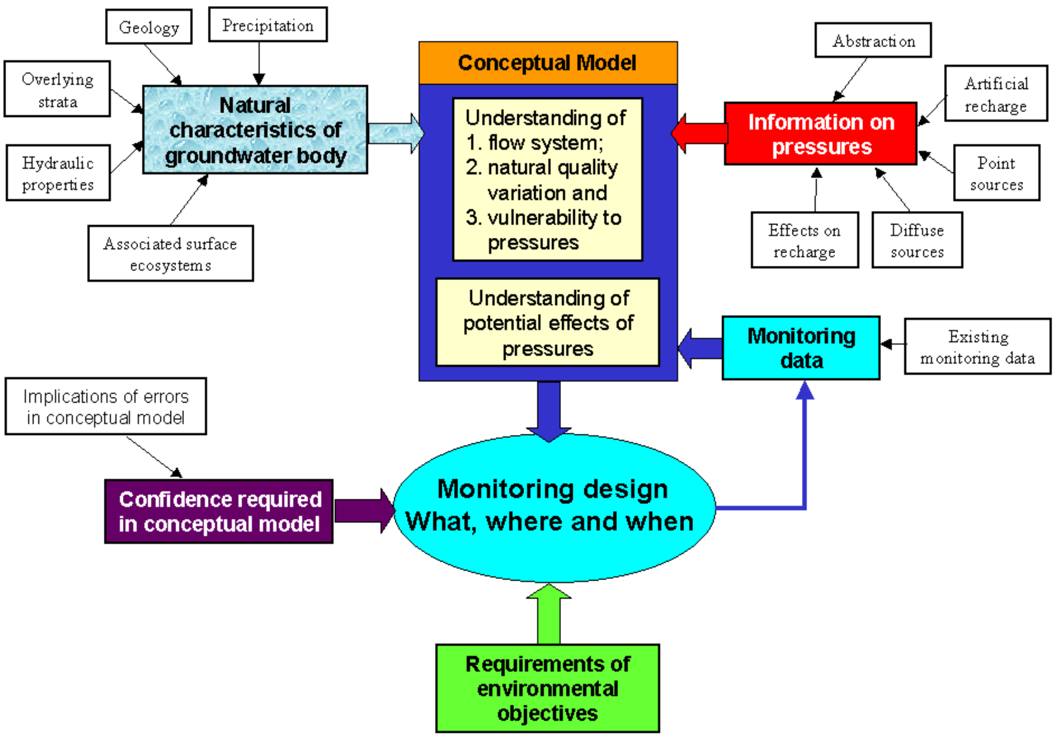

Figure 4.3 **Monitoring programmes should be designed on the basis of a conceptual model/understanding of the groundwater system. The model will represent the current understanding of the groundwater system based on information on its natural characteristics and the pressures on it. Monitoring should provide the information needed to test the model and, where necessary, improve it so that an appropriate level of confidence can be achieved in the prediction and assessment of groundwater problems.**

The amount of monitoring information needed to validate the Annex II risk assessments will depend in part on the level of confidence in, and complexity of, the conceptual model/understanding. The greater the difficulty in judging the risks to the objectives, the more monitoring information is likely to be required. The greatest amount of monitoring will be necessary where the implications of misjudging the risks to the objectives would be very serious (e.g. lead to substantial costs being unnecessarily imposed on water users or fail to identify risks of significant damage that could be averted).

During the course of each planning cycle, and between one planning cycle and the next, new monitoring data will contribute to improved understanding of groundwater systems and their vulnerability to pressures. This will increase confidence in the conceptual model/understanding and the risk assessments it enables.

> **Key principle**
>
> **The amount of monitoring that is required will be proportional to the difficulty in judging (a) the status of a body, or group of bodies, of groundwater and (b) the presence of adverse trends, and (c) to the implications of errors in such judgements.**

Designing the monitoring programmes on the basis of conceptual models/understandings ensures that the programmes will be appropriate to the hydrogeological characteristics of the body, or group of bodies, of groundwater and, where relevant, to the behaviour of pollutants in the groundwater system. For example, monitoring quantitative or chemical status in a low permeability fractured medium will require a different strategy (in terms of what to measure, where and when) than would monitoring quantitative or chemical status in a high permeability inter-granular flow medium.

> **Key principle**
> **The design and operation of monitoring programmes should be informed by:**
>
> **(a) the objectives applying to the body;**
> **(b) the characteristics of the groundwater body, or group of bodies;**
> **(c) the existing level of understanding (i.e. the confidence in the conceptual model/understanding) of the particular groundwater system;**
> **(d) the type, extent and range of the pressures on the body, or group of bodies;**
> **(e) the confidence in the assessment of risk from pressures on the body, or group of bodies; and**
> **(f) the level of confidence required in the assessment of risk.**

Groundwater systems are 3-dimensional. In some circumstances, where a body is at risk of failing to achieve its objectives and potentially costly restoration and improvement measures may be needed, monitoring information from different layers in a body of groundwater may be required to enable appropriate measures to be designed and targeted. The need for this sort of monitoring should be indicated by the risk assessments required under Annex II. However, most pressures are likely to have significant effects in the upper layers of aquifers.

Different types of objectives demand different environmental outcomes. They may therefore require different monitoring strategies to provide the information needed to assess their achievement. However, the design of the monitoring programme should always be based on an appropriate conceptual model/understanding. For example, objectives requiring the protection of associated surface water bodies, directly dependent terrestrial ecosystems, drinking water abstraction points or other legitimate uses from point sources of pollution might require monitoring in the predicted flow path between the source and one of the receptors listed above. However, monitoring data to assess objectives for general groundwater quality could be provided by more dispersed monitoring depending on the conceptual model/understanding of the distribution of pollutants in the groundwater.

4.2.3 Ensuring the cost-effective development of groundwater monitoring networks

Reliable monitoring data are essential for the cost-effective achievement of objectives for groundwater. However, installing groundwater monitoring networks is expensive. Member States may have networks comprising a variety of site types ranging from infrequently used private wells to large yielding public water supply boreholes. The use of conceptual models/understanding as the basis for developing and reviewing monitoring networks should help ensure that each selected monitoring point provides relevant and reliable data for use in assessing the achievement of the Directive's objectives. It will also enable Member States with limited existing networks to iteratively build up their networks to the extent needed to test or develop their conceptual models/understandings. The alternative of installing a very extensive network and reducing this overtime would be far less effective and much more costly.

The Directive permits bodies of groundwater to be grouped for monitoring purposes. This is also important to ensure the most cost-effective design of monitoring networks. For example, in areas of high rainfall and only low levels of groundwater abstraction, existing data and monitoring information from a representative selection of bodies should provide sufficient information to confirm that the bodies achieve good quantitative status. However, such grouping must be undertaken on a scientific basis so that monitoring information obtained for the group provides for a suitably reliable assessment that is valid for each body in the group. This means that either:

- The conceptual models/understandings for the bodies in the group should be similar such that the testing of the models and the predictions made on the basis of those models, for a selection of the bodies in the group will also provide sufficient confidence in the models and predictions for the other bodies in the group; or

- Monitoring information from a selection of the most sensitive bodies in a group demonstrates that those sensitive bodies, and hence the group as a whole, are not failing to achieve 'good' status because of the effects of a pressure, or pressures, to which all the bodies in the group are subject (e.g. diffuse pollution). Monitoring information may be needed initially from a range of bodies in the group to determine which are the most sensitive bodies.

The adequate testing of a conceptual model/understanding may require new, targeted monitoring data. However, particularly where pressures are low, adequate validation of a model may be achieved using existing data or data from a surface water monitoring programme.

Key principle

Groundwater bodies may be grouped for monitoring purposes provided that the monitoring information obtained provides for a reliable assessment of the status of each body in the group and the confirmation of any significant upward trends in pollutant concentrations.

Monitoring data from surface water bodies may be important in assessing the condition of bodies of groundwater. Surface waters with a large base flow can be used to indicate the quality of groundwater. The effects of human alterations to groundwater quality and levels on the status of large base flow surface waters are also likely to be larger than the effects of the same alterations on the status of low base flow surface waters.

Key principle

Designing and operating integrated groundwater and surface water monitoring networks will produce cost-effective monitoring information for assessing the achievement of the objectives for both surface and groundwater bodies.

4.2.4 Quality assurance of monitoring design and data analysis

The confidence in any assessment of groundwater will depend on the confidence in the conceptual model/understanding of how pressures are interacting with the groundwater system. The confidence in any model needs to be evaluated by testing its predictions with monitoring data. However, errors in the monitoring data could lead to errors in the evaluation of the reliability of the conceptual model/understanding. It is important that the probability and magnitude of errors in the monitoring data are estimated so that the confidence in the conceptual model/understanding can be properly understood. For the surveillance and operational monitoring programmes, estimates of the level of confidence and precision in the results of monitoring must be given in the river basin management plans[41].

An appropriate quality assurance procedure should reduce errors in monitoring data. Such a procedure should review the location and design of monitoring points to ensure that the data they provide are relevant to the aspects of the conceptual model/understanding being tested. Errors can also occur in sampling and in the analysis of water samples. Quality assurance procedures may take the form of standardisation of sampling and analytical methods (e.g. ISO standards); replicate analyses; ionic balance checks on samples; and laboratory accreditation schemes.

4.3 Characterisation of groundwater bodies

The Annex II initial and further characterisation should provide the basic information for designing targeted and cost-effective monitoring programmes. To do this, the Annex II procedure must produce a conceptual model/understanding for each body of groundwater, or group of bodies, that is (a) relevant to assessing how the identified pressures could affect the objectives for the body, or group of bodies, and (b) proportionate in terms of its detail and complexity to the likely risks to the objectives for that body, or group of bodies. Monitoring information may be used to iteratively improve the conceptual model/understanding so that it provides for appropriately reliable assessments.

The initial results of the Annex II assessments must be reported at the end of 2004. However, the assessments may need further development to help design the monitoring programmes for implementation at the end of 2006. The monitoring data provided by the monitoring programmes will then be available to validate and refine the assessments and the conceptual models/understandings on which they were based.

4.4 Monitoring of quantitative status

4.4.1 Purpose of monitoring

The Directive's requirements for good groundwater quantitative status are three-fold. Firstly, there is a requirement to ensure that the available groundwater resource[42] for the body as a whole is not exceeded by the long-term annual average rate of abstraction[43]. Secondly, abstractions and other anthropogenic alterations to groundwater levels should not adversely affect associated surface water bodies and terrestrial ecosystems that depend directly for their water needs on the body of groundwater. Thirdly, anthropogenic alterations to flow direction must not have caused, or be likely to cause, saltwater or other intrusion.

In assessing quantitative status, the water needs of associated surface water bodies and directly dependent terrestrial ecosystems must be taken into account. For the latter, good groundwater status requires that human alterations to groundwater flows and levels have not caused, and, taking account of lag times, will not cause, significant damage. However, the Directive does not provide an explanation of what constitutes 'significant damage'. Existing data held by Member States about the ecological, cultural and socio-economic significance of dependent terrestrial systems should be used as the basis of a 'significance test' in this context.

---

[41] *Annex V 2.4.1*
[42] *Article 2.27*
[43] *Annex V 2.1.2*

Even if long-term level monitoring data are available, the measurements of groundwater levels may not be sufficient on their own to assess the available groundwater resource (see Table 4.1). For example, there may have been an impact prior to the start of the monitoring or a new abstraction may be proposed. The prediction of adverse impacts on associated surface water bodies or terrestrial ecosystems using level monitoring will normally need to be supported by an estimate of recharge, a conceptual model/understanding of the flow system and a water balance estimate to test the conceptual model/understanding (see Section 1 of the toolbox).

Table 4.1 The role of water level and spring flow data, conceptual modelling and water balance estimation in assessing quantitative status. In scenarios 2, 3 and 4 monitoring data may be required to test the conceptual model/understanding.

Scenario 1	Scenario 2	Scenario 3	Scenario 4
(a) Long-term level monitoring data is available (b) No trends in data indicating falling water levels noted (c) No impacts thought to be present on the water needs of surface ecosystems (d) No increase in the level of abstraction is proposed	(a) Long-term level monitoring data is not available	(a) Long-term level data may or may not be available (b) A new abstraction is proposed	(a) Long-term level data may or may not be available (b) Impacts are thought to be present on the water needs of surface ecosystems
The available level data is sufficient to indicate that the water balance is satisfactory	**Conceptual model/ understanding and water balance calculation will be necessary**	**Conceptual model/ understanding and water balance calculation will be necessary**	**Conceptual model/ understanding and water balance calculation will be necessary**

Key principle

Information on levels (spring flows etc) should be used in conjunction with estimates of recharge and an appropriate conceptual model/understanding of the groundwater flow system when assessing the quantitative status of bodies of groundwater, or groups of bodies.

The estimation of recharge and the development of a suitable conceptual model/understanding should be part of the characterisation of bodies of groundwater, or groups of bodies.

4.4.2 Water Level Monitoring Network Design

The water level monitoring network should be designed so that it supports and aids the development and testing of the conceptual model/understanding. The development of the network will be an iterative process, evolving over time where necessary. The amount of monitoring required also depends on the extent of existing information on water levels and the groundwater flow system. Where this is adequate and reliable, it may not be necessary to extend monitoring programmes.

What to monitor

The most appropriate parameters to monitor quantitative status will depend on the conceptual model/understanding of the groundwater system. For example, spring flows or even base-flows in rivers may be more appropriate than the use of boreholes in low permeability fractured media or where the risks of failing to achieve good quantitative status are low and information from the surface water monitoring network can adequately validate this assessment.

Where to monitor

The choice of where to monitor will depend on what is needed to test the conceptual model/understanding and the predictions it provides. In principle, the more spatially variable the groundwater flow system or the pressures on it, the greater the density of monitoring points that will be required to provide the data needed to make suitably confident assessments of the status of a groundwater body, or group of bodies.

When to monitor

The most appropriate monitoring frequency will depend on the conceptual model/understanding of the groundwater system and the nature of the pressures on the system. The frequency chosen should allow short-term and long-term level variations within the groundwater body to be detected. For example, for formations in which the natural temporal variability of groundwater level is high or in which the response to pressures is rapid, more frequent monitoring will be required than will be the case for bodies of groundwater that are relatively unresponsive to short-term variations in precipitation or pressures. Where monitoring is designed to pick up seasonal or annual variations, the timing of monitoring should be standardised from year to year.

4.5 Monitoring of chemical status and pollutant trends

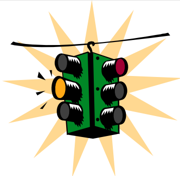
	***Look Out!*** ***Article 17 requires the Commission to come forward with a proposal for a daughter directive on groundwater by the end of 2002. Among other things, this proposal may include further criteria for assessing good groundwater chemical status and for the identification of trends. This may have implications for the design of the monitoring programmes described in this section.***

4.5.1 Purpose of monitoring

Groundwater quality monitoring carried out in accordance with the WFD should be designed to answer specific questions and support the achievement of the environmental objectives. The principal purposes of groundwater quality monitoring are to:

(a) Provide information for use in classifying the chemical status of groundwater bodies or groups of bodies;

(b) Establish the presence of any **significant** upward trend in pollutant concentrations in groundwater bodies and the reversal of such trends.



Look Out!

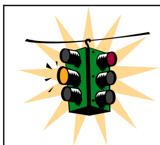
Article 4.1.b.iii requires the reversal of any significant upward trend in pollutant concentrations in groundwater. However, the monitoring requirements set out in Annex V only refer to monitoring in bodies of groundwater. Since all groundwater that could adversely affect surface ecosystems or is capable of providing more than 10 m^3 a day for abstraction will be part of an aquifer (see Horizontal Guidance on Water Bodies), nearly all groundwater will be included within bodies of groundwater. By definition, pollutant trends in groundwater that is not part of a body of groundwater should not be able to significantly affect any surface water bodies, terrestrial ecosystems or uses of groundwater requiring significant abstraction. Therefore, trends in pollutants in any groundwater that is not part of a body of groundwater would not normally be expected to constitute pollution as defined in Article 2.33.

The requirements of good groundwater chemical status are threefold:

1. The concentrations of pollutants should not exhibit the effects of saline or other intrusions as measured by changes in conductivity;
2. The concentration of pollutants should not exceed the quality standards applicable under other relevant Community legislation in accordance with Article 17. The daughter directive will clarify this criterion; and
3. The concentration of pollutants should not be such as would result in failure to achieve the environmental objectives specified under Article 4 for associated surface waters nor any significant diminution of the ecological or chemical quality of such bodies nor in any significant damage to terrestrial ecosystems which depend directly on the groundwater body.

All three criteria must be satisfied for a body to achieve 'good' groundwater chemical status. If not, the body should be classified as 'poor' groundwater chemical status. The classification of groundwater chemical status is only concerned with the concentrations of substances introduced into groundwater as a result of human activities. The concentration of substances in an undisturbed body of groundwater (e.g. naturally high concentrations of arsenic) will not affect the body's status. However, naturally occurring substances released by human activities, such as mining, will be relevant to the assessment of status.

Additional criteria for starting points for trend reversal may be specified in the daughter directive under Article 17. However, it is already clear that the purpose of trend reversal is to reduce pollution of groundwater, where pollution is defined in terms of risks of harm to the quality of aquatic and terrestrial ecosystems, human health, damage to material property and interference with legitimate uses of the environment[44]. A conceptual model/understanding of the groundwater system and the fate and behaviour of pollutants should therefore be used to predict those trends that have resulted, or would result, in pollution.



Look Out!

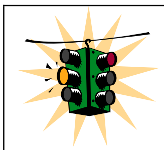
The Directive says surveillance monitoring must be undertaken during each planning cycle, and operational monitoring must be carried out during periods not covered by surveillance monitoring. No minimum duration or frequency is specified for the surveillance programme. Operational monitoring must be carried out at least once a year during periods between surveillance monitoring. Member States should undertake sufficient surveillance monitoring during each plan period to allow adequate validation of the Annex II risk assessments and obtain information for use in trend assessment, and sufficient operational monitoring to establish the status of bodies at risk and the presence of significant and sustained upward trend in pollutant concentrations.

[44] *Article 2.33*

4.5.2 Surveillance monitoring

The confidence in the Annex II risk assessments will be variable depending on the confidence in the conceptual model/understanding of the groundwater system. Surveillance monitoring is intended to provide information to:

- **supplement and validate the assessments** of risks of failing to achieve (1) good groundwater status [Article 4.1(b)(i) and Article 4.1(b)(ii)]; (2) any relevant Protected Area objectives [Article 4.1(c)]; or (3) the trend reversal objective [Article 4.1(b)(iii)]; and
- **contribute to the assessment of significant long-term trends** resulting from changes in natural conditions and anthropogenic activity.



Look Out!

Surveillance monitoring is only specified in the Directive for bodies at risk or which cross a boundary between Member States. However, to adequately supplement and validate the Annex II risk assessment procedure, validation monitoring will also be needed for bodies, or groups of bodies, not identified as being at risk. The amount and frequency of monitoring undertaken for these bodies, or groups of bodies, must be sufficient to enable Member States to be adequately confident that the bodies are at 'good' status and that there are no significant and sustained upward trends. Colour-coded maps of the status of all bodies must be published in the river basin management plans.

Validation will involve testing the conceptual models/understanding to the extent necessary to confidently differentiate bodies at risk from those not at risk and thus classify as 'good' status those bodies considered not to be at risk. Surveillance monitoring may also provide sufficient information to reliably classify, as 'poor' status, some bodies thought to be at risk.

4.5.3 Operational monitoring

Operational monitoring must provide the monitoring data needed to achieve an appropriate level of confidence to classify bodies at risk as either poor or 'good' status or to establish the presence of significant upward trends in pollutants (see Figure 4.4).

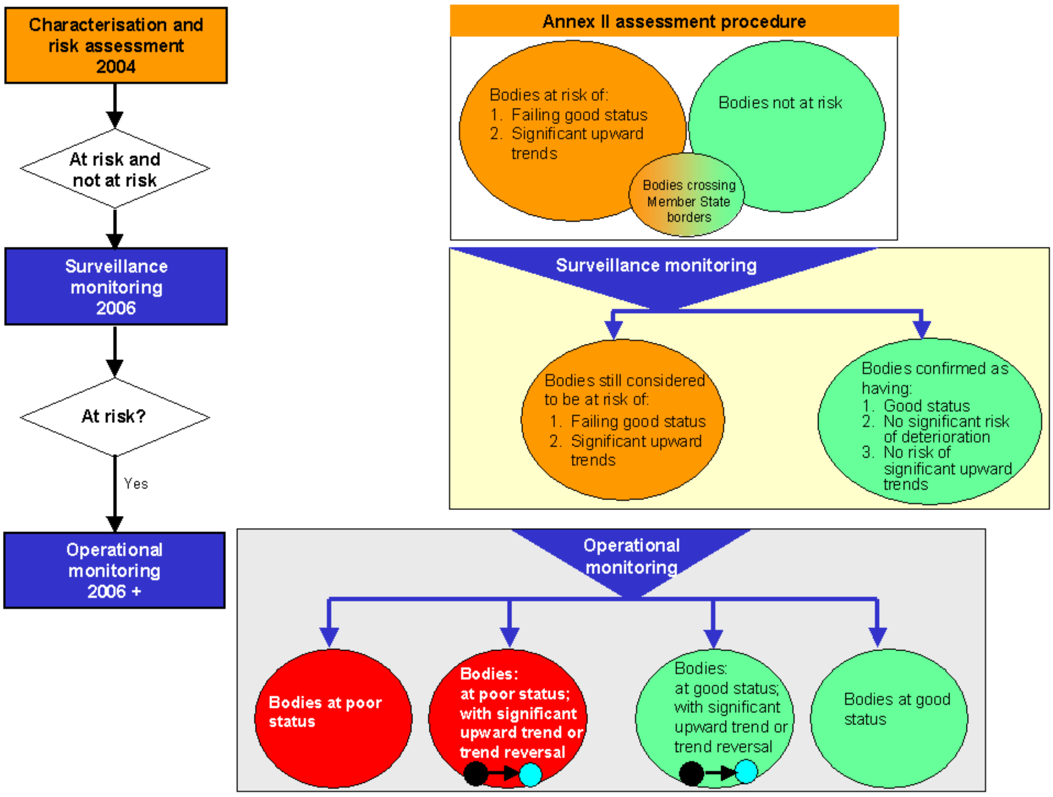


Figure 4.4 The outputs of risk assessment, surveillance and operational monitoring.

The surveillance monitoring programmes must be designed on the basis of the results of Annex II characterisation and risk assessment procedure. Operational monitoring programmes must be designed on the basis of the characterisation and risk assessment as refined by the data from the surveillance monitoring programmes. To supplement and validate the Annex II risk assessments, surveillance monitoring will be necessary in bodies, or groups of bodies, identified as being at risk and a selection of those identified as not being at risk. Operational monitoring is focused exclusively on bodies, or groups of bodies, at risk. Note the information provided by operational monitoring may establish that some bodies, or groups of bodies, considered likely to fail to achieve environmental objectives on the basis of the Annex II risk assessment and the surveillance monitoring programme are at 'good' status.

4.5.4 Where to monitor

Information on pressures, the conceptual model/understanding of the groundwater system, the fate and behaviour of pollutants in it and the consequent risks to the objectives should be used to determine the most appropriate locations for monitoring points. For example, where a surface water body or a directly dependent terrestrial ecosystem is at risk from a significant point source, the monitoring locations to test the prediction provided by the conceptual model/understanding (see Figure 4.5) would be different from those needed to test a conceptual model/understanding suggesting a risk to the objectives from diffuse pollution distributed uniformly across a groundwater body.

Where the conceptual models/understandings of a group of groundwater bodies and the pressures on each of the bodies in the group is similar, the validation of the model may be achieved using monitoring information from a selection of water bodies rather than using monitoring data for each body. In some cases, existing monitoring data or monitoring data collected by the surface water monitoring programmes may be sufficient to adequately test a conceptual model/understanding.

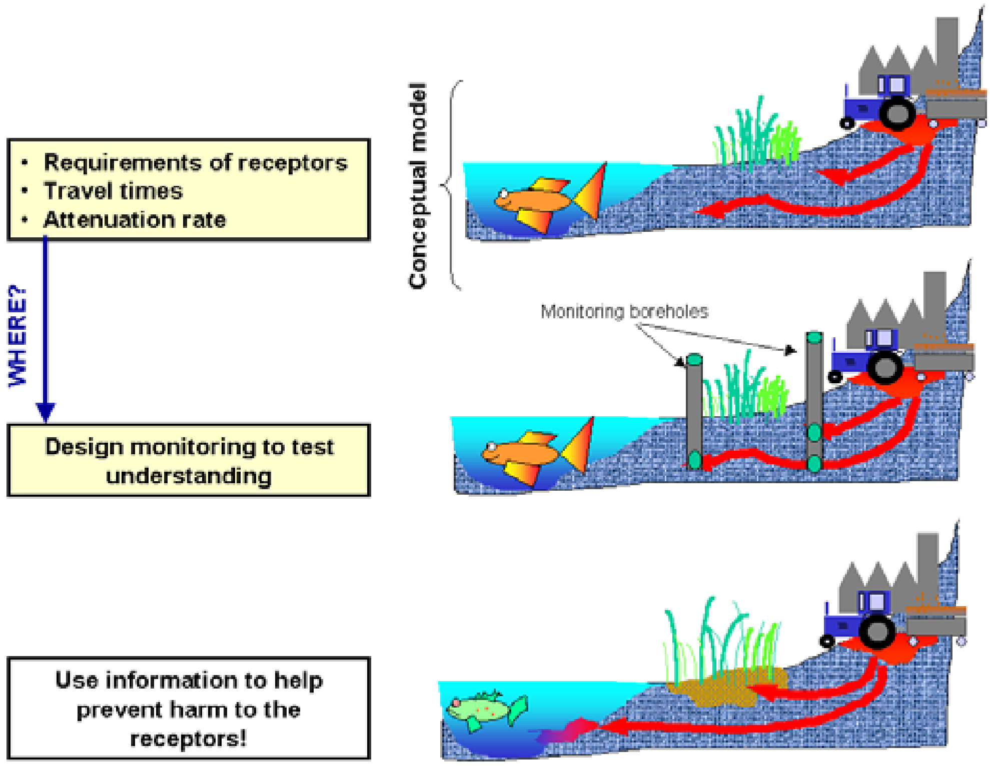

Figure 4.5 The selection of monitoring locations will depend on the development of a conceptual model/understanding of how the objectives for the body of groundwater may be at risk (see Section 1 of the Toolbox). For example, a pollutant plume from a point source discharge that may be adversely affect an associated surface water body may require the use of targeted monitoring compared to that needed to assess risks from pollutants distributed uniformly across a body of groundwater.

4.5.5 What to monitor

Where surveillance monitoring is required, the Directive requires that a core set of parameters be monitored. These parameters are oxygen content, pH value, conductivity, nitrate and ammonium. Other monitored parameters for both surveillance and operational monitoring must be selected on the basis of (a) the purpose of the monitoring programme, (b) the identified pressures and (c) the risk assessments made using a suitable conceptual model/understanding of the groundwater system and the fate and behaviour of pollutants in it. For example, the principal purpose of surveillance monitoring is to supplement and validate the Annex II risk assessments. To do this, the predictions of risk made during the Annex II assessments must be tested. Such testing should involve consideration of:

(a) the predicted effects of pressures identified during the Annex II risk assessment procedure; and

(b) whether there are any significant effects due to pressures not identified during the Annex II assessment procedure.

In the case of point (b) above, the guidance recommends that Member States select monitoring parameters that, if present, would indicate effects associated with different types of human activity. Some examples of indicators relevant to different activities that may be present in the recharge area of bodies, or groups of bodies, of groundwater are suggested in Table 5.2 (Chapter 5).

Table 5.3 (Chapter 5) provides examples of pollutants typically associated with different human activities, and which may therefore be appropriate to consider in monitoring programmes depending on the conceptual model/understanding and the likely risks to the objectives. For example, suites of parameters commonly associated with certain types of pressures have been identified (e.g. gas works: PAH, Phenol, hydrocarbons, etc). Parameters indicative of the pollutants that are liable to be present can be used to ensure cost-effective monitoring. The toolbox outlines some of the indicators used by Member States.

Other chemical parameters may need to be sampled for quality assurance purposes. For example, measuring the concentrations of major ions in a water sample so that an ion balance can be used as a check that the water analysis results are representative of the sampled groundwater should be considered as a routine quality assurance procedure.

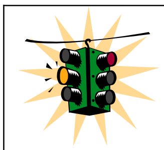
4.5.6 When to monitor

The conceptual model/understanding of the groundwater system and the understanding of the fate and behaviour of pollutants within it, and the aspect of the model being tested should also determine the appropriate frequency of monitoring. The toolbox provides examples of frequencies that Member States have found appropriate in a number of hydrogeological circumstances and in relation to different pollutant behaviours.

4.6 Monitoring of Protected Areas

The Water Framework Directive establishes a planning framework to, among other things, support the achievement of the standards and objectives for Protected Areas established under Community legislation. In the context of groundwater, these areas may include Natura 2000 sites established under the Habitats Directive (92/43/EEC) or the Birds Directive (79/409/EEC), Nitrate Vulnerable Zones established under the Nitrates Directive (91/676/EEC) and Drinking Water Protected Areas established under Article 7 of the Water Framework Directive.

To ensure monitoring programmes are as efficient and as effective as possible, it would be appropriate to ensure that the quantitative status and the chemical status monitoring programmes described above complement, and are integrated with, the programmes established for Protected Areas so that the groundwater monitoring networks are as far as possible multi-purpose



Look Out!

For Drinking Water Protected Areas, Article 7.1 requires Member States to make sure they monitor, in accordance with Annex V, bodies of groundwater providing more than 100 m^3 a day as an average. Annex V does not define any specific additional monitoring requirements for such bodies. In contrast, Annex V does define specific monitoring requirements for surface water bodies used to provide more than 100 m^3 a day as an average.

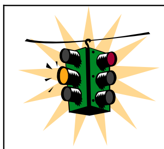
No specific monitoring requirements are described in relation to the Drinking Water Protected Area objective of preventing deterioration in quality in order to reduce the level of purification treatment required in the production of drinking water [Article 4.1(c), Article 7.3]

The achievement of the Drinking Water Protected Area objective requires that the quality of the abstracted groundwater prior to treatment does not change as a result of human activities in a way that would require an increased level of purification treatment to meet the standards required at the point of consumption under Directive 80/778/EEC, as amended by Directive 98/83/EC. Assessing compliance with, and providing the necessary information to achieve, this objective requires:

- Establishing the chemical composition of the abstracted water prior to any purification treatment. This analysis should take account of any parameters that could affect the level of treatment required to produce drinking water. Member States are required under Annex II 2.3(c) to collect and maintain information on the chemical composition of water abstracted from (i) any points providing an average of 10 m^3 or more per day, whether or not that water is intended for human consumption, and (ii) points serving 50 or more persons;

- During each planning period, collecting information, where relevant, on the composition of water abstracted in a way that is proportionate to the risks to the quality of that water identified in the Annex II risk assessment procedure. This should enable the detection of any deterioration in the abstracted water's quality that could affect the level of purification treatment required to produce drinking water – and hence indicate a failure to achieve the Protected Area objective;

- Establishing a conceptual model/understanding of the groundwater system from which the abstracted water is drawn. The model should be proportionate to the likely risks to the objective and should enable measures to be designed, where necessary, to protect the recharge area from any inputs of pollutants that would result in a failure to achieve the Protected Area objective (see Section 6 of the groundwater toolbox).



Look Out!

Revisions are currently being proposed to the draft guidelines for the monitoring required under the Nitrates Directive (91/676/EEC).

4.7 Reporting Requirements

A summary report of the network must be submitted to the Commission by 22 March 2007[45], and a map showing the network must be included in the river basin management plan.

4.7.1 Chemical and quantitative status assessment

The results of monitoring should be used to assess whether any of the criteria defining 'good' status have been failed. If so the body should be classed as 'poor' status. The Directive specifies that in assessing chemical status for a groundwater body, the results of individual monitoring points within a groundwater body should be aggregated for the body as a whole. Figure 4.5 describes the tests involved in assessing the status of a body of groundwater.

[45] *Article 15*

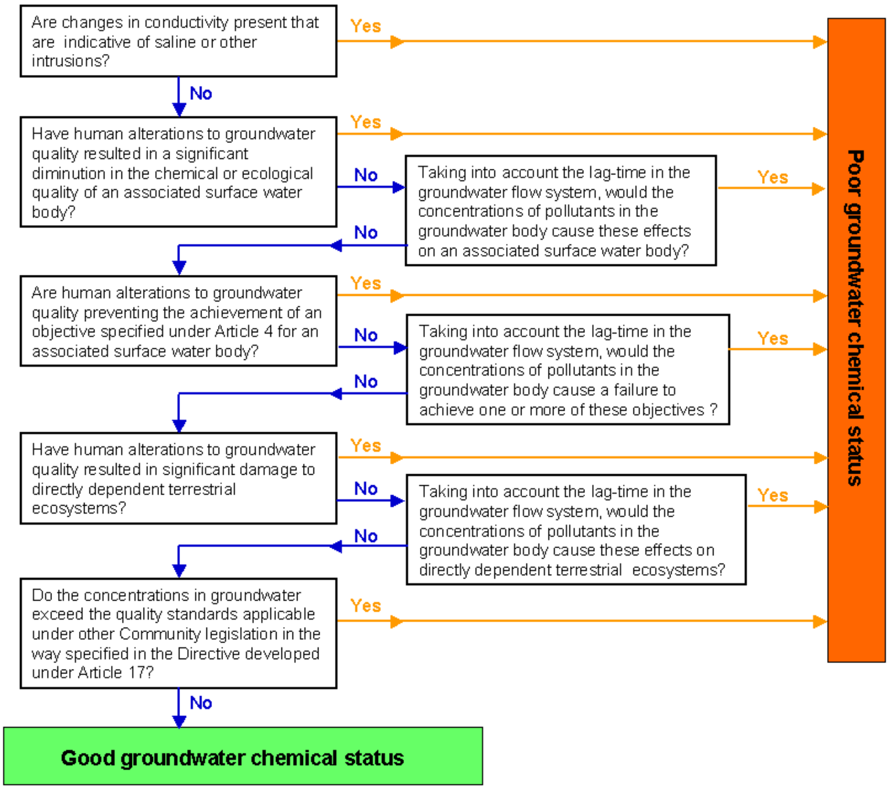


Figure 4.6 **Tests involved in determining the chemical status of a body of groundwater. In conjunction with a suitable conceptual model/understanding of the groundwater system, information from monitoring points in the body of groundwater, or group of bodies should be used to make an assessment of the chemical status of the body, or bodies. Such an assessment requires consideration of each of the tests shown in the Figure.**

4.8 Schedule of Monitoring

Table 4.2 Critical Path Analysis for Work Needed on Monitoring for WFD

FORMAL WFD REQUIREMENT	Monitoring Work needed to aid decisions	Related work from other CIS WGs, EAF	Time needed	When start to hit critical path	To be completed
Initial delineation of water bodies		Water body paper is being prepared by the Commission	1 yr	2002	Beginning 2003

Continuation of first monitoring cycle			7 yrs	2008	2015
Second cycle of monitoring	Aim: inter alia validation of effects of measures		6 yrs	2016	2021

5 Best Practices and Tool Box

5.1 General Guidance for Optimisation of Monitoring Programmes

5.1.1 Issues for Consideration

The key processes involved in designing an environmental monitoring programme are to determine what to monitor, where, when and how often. The answers to these questions depend on:

- The objective(s) of the monitoring (e.g. to determine the chemical status of a water body, or to test for a trend);
- The desired precision and confidence with which the required statistic (e.g. a percentile, or the slope of a linear trend) is to be estimated; and
- The types and magnitudes of variability exhibited by the water body or bodies to be monitored.

It is therefore imperative to clearly identify the key objectives that the monitoring needs to address. This will govern the approach to programme design and enable identification of:

- The hypotheses to be tested;
- Realistic and measurable goals/targets; and
- The acceptable level of risk, precision and confidence.

The information obtained can then be used to formulate an understanding of the system to be studied and develop the appropriate questions to be asked, based on the identified hypotheses. This can be formalised using a conceptual process model, which links the driving forces, pressures and current state of the system. The assumptions underlying the model can be reviewed and validated throughout the study, as more information becomes available.

Temporal and spatial heterogeneity, both natural and anthropogenic, should be considered, as this will influence the location and number of water bodies monitored, the location and number of monitoring stations within each water body, and the frequency of sample collection.

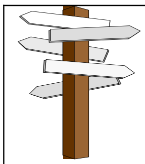
Selecting acceptable levels of risk, precision and confidence would set limits on how much uncertainty (arising from natural and anthropogenic variability) can be tolerated in the conclusions obtained from monitoring programmes.

Once the acceptable levels of risk, precision and confidence associated with the identified objectives have been defined, an optimal monitoring programme can be developed using a range of statistical tools. These tools will ensure that the programme:

- Meets the required objectives of the programme;
- Monitors a sufficient number of sites and at a frequency that provides the required precision and confidence in the results; and
- Is implemented in a cost effective and scientifically robust manner.

Statistical planning tools covering a comprehensive range of common monitoring objectives are provided by the ‘Manual of Best Practice for the Design of Water Quality Monitoring Programmes’. This manual presents the results of a collaborative study between the UK and Italy to assist organisations charged with monitoring activities. The manual provides step-by-step guidance on the choice of an appropriate monitoring strategy, the quality elements to be monitored, the sample numbers needed to achieve the desired precision and confidence, and appropriate data analysis methods. The manual emphasises the importance of ensuring that the method of data analysis is specified at the programme planning stage, as this forms an integral part of the calculation of required sample numbers. For example, if the required number of samples to achieve a specified precision and confidence were calculated on the assumption that linear regression would be the method of trend analysis, that precision would not subsequently be achieved if it were later decided to switch to the use of Sen's test for trend.

The guidance covers the use of both chemical and biological monitoring methods, for rivers, estuaries and coastal waters.



Information to assist with the Statistical Design of Monitoring Programmes can be found in:

5.1.2 Development of a Conceptual Understanding

Conceptual models[46] play a key role in the guidance and should be used as a basis for the development and review of monitoring programmes in accordance with the Directive.

The level of detail required in the model is proportional to the difficulty in judging the effects of pressures on the objectives. Monitoring data is required to test or validate the conceptual model/understanding. Such testing will require some monitoring data for all bodies, or groups of bodies, identified as being at risk as well as a selection of those identified as not being at risk of failing their objectives.

The amount of monitoring information needed to validate the Annex II risk assessments will depend in part on the level of assurance in the conceptual model/understanding. The greater the difficulty in judging the risks to the objectives, the more monitoring information is likely to be required. The greatest amount of monitoring will be necessary where the implications of misjudging the risks to the objectives would be very serious - where, for example, it could lead to substantial costs being unnecessarily imposed on water users (the Type I error), or fail to identify risks of significant damage that could be averted (the Type II error).

The amount of monitoring that is required will be related to:

- **the difficulty in judging (a) the status of a water body, or group of water bodies and (b) the presence of adverse trends, and the implications of errors in such judgements.**

[46] A conceptual model in this context does not refer to a quantitative mathematical model, rather a 'qualitative conceptual understanding' of the interrelationships occurring within the system.

During the course of each planning cycle, and between one planning cycle and the next, new monitoring data will contribute to improved understanding of the water bodies concerned and their vulnerability to pressures. This will increase confidence in the conceptual model/understanding and the risk assessments it enables.

Key Principle

The conceptual model/understanding represents the current understanding of the system based on information on its natural characteristics and the pressures on it. Monitoring should provide the information needed to test the model and, where necessary, improve it so that it produces an appropriate level of assurance in the assessment pressures and impacts.

5.1.3 Quality assurance/Quality control

ISO 5667-14 describes a variety of quality control techniques for monitoring all types of water samples.

Where available, methods standardised by ISO, CEN or national standardisation bodies should be used. In any case, the laboratory using a method should be responsible for ensuring that the method is adequately validated. If the method has been validated by a standards approving organisation, the user will normally need only to establish performance data for their own use of the method.

In the case of methods that have not been validated by a standardisation body, the documentation describing the method should be clear and unambiguous in order to allow easy implementation. ISO 78-2 advises on methods documentation for general chemical methods.

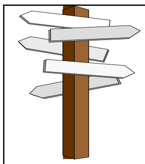
In order to assure comparability across Europe, laboratories must document a programme of quality assurance/quality control (EN ISO 17025) and participate regularly in proficiency testing programmes.

A requirement of the WFD is that all monitoring shall conform to the relevant standards on the national, European or international scale to ensure the provision of data of an equivalent scientific quality and comparability. Therefore, all biological and physico-chemical assessment systems must comply with the relevant international and national standards where they exist.

At present there are a number of standards covering the sampling of macroinvertebrates. Equivalent standards are currently lacking for phytoplankton, macrophyte, benthic algae, and fish sampling, but they all are under development in CEN, and will probably be ready before 2006. Though there are appropriate standard methods for many of the physico-chemical quality elements, for many of the priority substances there are no standard analytical techniques. The expert working group on the analysis and monitoring of priority substances will deal with standard analytical methods for priority substances.

Key Issue

It is recommended that appropriate standards are developed as a matter of priority and urgency for those aspects of monitoring for which there are no internationally agreed standards or techniques/methods.



You can obtain ISO/CEN Standards

For details of the available ISO/CEN standards, refer to the following sites:

- *CEN www.cenorm.be/catweb*
- *ISO www.iso.ch*

For rivers, lakes and ground water there are monitoring guidelines prepared by UN/ECE Working Group on Monitoring and Assessment.

For coastal and transitional waters, there are also monitoring guidelines of OSPAR (Joint Monitoring and Assessment Programme) and HELCOM (COMBINE-Programme). Ongoing work of the ICES/OSPAR and ICES/HELCOM Steering Groups on Quality Assurance in the North East Atlantic (SGQAE) and in the Baltic (SGQAB), and the work of quality assurance groups like QUASIMEME and BEQUALM should also help to ensure that comparable and quality monitoring data are produced for the Water Framework Directive.

Implementation of QA programmes

Errors inevitably occur both in the process of sampling and in the analysis of water samples. The aim of an appropriate quality assurance procedure is to quantify and control these errors. Quality assurance procedures may take the form of standardisation of sampling and analytical methods, replicate analyses, ionic balance checks on samples and laboratory accreditation schemes.

Notwithstanding the benefits of the one-off intercalibration exercise for the purpose of classification and comparison with the results from other appropriate Member States, a continuous quality assurance system should be developed to ensure that all monitoring results meet assured target levels of precision and bias. Therefore, QA measures should be implemented for each monitoring institution as well as in data collection centres, and encompass all operational facets of a monitoring programme, including:

- Field sampling and sample receipt;
- Sample storage and preservation; and
- Laboratory analysis;

These measures are based on:

- Developing comprehensive and understandable Standard Operating Procedures (SOPs);
- Using validated monitoring methods (sampling, chemical or biological analysis, reporting), that means experimental proof and related documentation confirms that each method is fit for its intended purpose;
- Establishing routine internal quality control measures (control charts, reference materials, internal QA audits); and
- Participation in external QA schemes (laboratory proficiency testing schemes, taxonomical workshops, external QA audits, QA accreditation).

It is generally accepted that approximately 25% of a laboratory's effort is required to establish and maintain an effective quality assurance system.

Experimental evidence must be supplied and documented in SOPs such that:

- All methods possess sufficient sensitivity, selectivity and specificity;
- Method accuracy and precision meet the requirements (still to be established) for each programme of measures developed for implementation of the Water Framework Directive; and
- Analytical detection limits (i.e. the smallest concentrations that are quantitatively detectable with a defined uncertainty) do not jeopardise the assessment of compliance with quality limits/targets or decisions made between good and moderate status.

In routine monitoring, quality assurance should ensure at any time that the methods used are strictly controlled and monitored. For that purpose, all monitoring institutions should have implemented an internal QA system according to ISO 17 025 (2000). To obtain long-term control of the performance of monitoring methods, results of internal QA measures (e.g. analysis of certified reference materials) must be recorded in control charts.

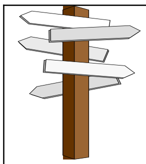
To evaluate the comparability of monitoring data throughout the Member States, participation in external quality audits and in external quality assessment schemes like international laboratory proficiency testing or taxonomical workshops is highly recommended.

An acceptable level of quality must be achieved for all monitoring data generated within the WFD Monitoring. It is possible to evaluate if monitoring data is fit for the intended purpose using the following QA criteria:

- Monitoring data are reported with an uncertainty estimate calculated from method validation or from inter-comparison exercises;
- Limits of detection are well below the principal levels of interest and allow the control of quality objectives;
- Satisfactory results can be obtained in analysing independent reference materials/samples, and this is demonstrated by appropriate control charts (or electronic equivalent) for the determinands of interest; and,
- Participation in relevant proficiency testing schemes at least once per year (with the proportion of results identified as outside limits of error being below 20% for all parameters) Quality Assurance

Expression of results

The results of measurements must indicate any rounding of numbers, final units, ± combined uncertainty, confidence interval. The detection limit (limit of quantification) of the method should be reported. The procedure of calculation of the detection limit (limit of quantification) should also be clearly reported.



Key sources of information on sampling protocols and quality assurance

- *The European Environment Agency provides technical guidance on design and operation of monitoring networks through its EUROWATERNET initiative (www.eea.eu.int).*

5.2 Best Practice and Tool Box for Monitoring Surface Waters

5.2.1 Objectives of monitoring

While the overall objectives of monitoring for the Directive are clearly defined, the specific monitoring objectives cannot be specified in any detail, as they will change depending on the purpose i.e. surveillance, operational or investigative monitoring, or monitoring for protected areas. In this respect, monitoring programme objectives will be different when assessing ecological status, as opposed to monitoring seasonal or long-term trends. Similarly, investigative monitoring may involve different determinands, sites and frequencies than general operational or surveillance monitoring, as the programme will be designed to assess a specific stress or impact.

Key Principle

The monitoring programmes must provide the information necessary to assess whether the Directive's environmental objectives will be achieved. This means that, to design monitoring programmes in accordance with the requirements of the Directive, a clear understanding of the environmental conditions required for the achievement of the objectives, and how these could be affected by human activities, is essential.

5.2.2 Holistic Assessment of Ecological Quality

Most ecological assessment systems used to date have been restricted to the assessment of a single impact element, such as organic pollution or acidification, and are not applicable to a broad range of waterbody types or geographical regions. As identified by Nixon *et al* (1996), the WFD (then the Ecological Directive) requires that a classification system be capable of incorporating the full range of impacts. However, the system should also be capable of detecting specific impacts, such as organic pollution, where this has been identified as a key stressor during the surveillance monitoring period.

Numerous predictive systems have been developed, which compare the observed communities to those expected under reference conditions. The outputs of such systems give rise to unitless ratios of observed to expected values that are ideally suited to the WFD.

It has been agreed that the results of the systems operated by each Member State will be expressed as EQRs for the purposes of classification of ecological status. These ratios will represent the relationship between observed values and the values expected under the reference conditions applicable to that particular site. Member States will be required to express the ratio as a numerical value between zero and one, with 'good' ecological status represented by values close to one and 'bad' ecological status by values close to zero.

5.2.3 Incorporation of Natural and Artificial Habitat Variation

While a number of different assessment systems for rivers have attempted to incorporate natural habitat variation, the majority of biological classification systems do not account for variations in physical habitat. As a result, the observed diversity at many sites (e.g. lowland rivers, naturally silted) will not meet the expected diversity of the prescribed reference conditions, even if the site has pristine water quality.

Examples of systems which have attempted to include artificial habitat variation are the UK's RIVPACS (macroinvertebrates) and HABSCORE (salmonid fish abundance) systems. In these cases the reference condition is defined in terms of pristine water quality and existing physical habitat. Therefore, if the community is as would be expected for the existing physical habitat, and the water quality is pristine, it will receive that same EQI score as a pristine site that is not physically impacted.

5.2.4 Locations of water bodies to be monitored

It is not economically feasible to monitor all water bodies for all conditions. Therefore, it is necessary to group 'similar' water bodies (as discussed below) and to select appropriate representative sites for the determination of ecological status for that particular group of sites. As discussed in Chapter 2, while the Directive requires that monitoring is undertaken for all surface and groundwater bodies, grouping is permitted as long as sufficient water bodies are monitored within a group to provide an accurate assessment of status for that group.

Member States should firstly determine which water bodies are required to be monitored in accordance with the Directive. The water bodies selected will vary depending on the objectives of the programme. For example, Annex V of the Directive provides different criteria for the selection of water bodies, depending on whether the objectives of the programme are established to satisfy the requirements for surveillance, operational or investigative monitoring, or for protected areas. Therefore each Member State must first discriminate according to the specific requirements of the Directive (e.g. size/population boundaries) and eliminate those water bodies in which monitoring is not required.

Once the relevant water bodies have been identified, further grouping may be required due to economic constraints. Water bodies may be grouped based on similar hydrological, geomorphological, geographical or trophic conditions. Alternatively water bodies could be grouped based on similar catchment impacts or land-uses. However, the latter may only be possible in catchments that are dominated by a single land-use. Another possibility is to use multivariate classification procedures for identifying groups of sites that form relatively homogenous areas (although this 'black box' approach should be used with caution as there is no guarantee that the composition of the resulting groups will have a recognisable or obvious rationale). Whatever the method by which the water bodies are grouped, it is essential that sufficient water bodies are selected from each group to enable the specific objectives of the monitoring programme to be met with the required levels of precision and confidence.

The characterisation required by Annex II makes possible a characterisation of water bodies based on environmental variables. Water body characterisation as a function of pressures would be made possible through an assessment of pressures and impacts, in which optimisation of the monitoring programme could be achieved by a grouping of pressures.

A relationship may exist between the defined typologies and human pressures due to the fact that the human race tends to adapt to environmental conditions. This theory is supported by the results of a regionalisation study based on the geomorphology, physiography, climate and macroinvertebrate communities undertaken in the Ebro River Basin. The study found that almost 50% of the control stations investigated were considered as non-or less perturbed by human activity. However, substantial regional variation was reported. For instance, in mountain and high mountain regions, the percentage rose to between 70 and 90%, whereas in the southern mountain area the percentage decreased to 60%. In the central zone and in the hollow area, where there is the greatest concentration of human activity, the area assessed as "natural state" decreased to 20%.

5.2.5 Risk, Precision and confidence in the assessment of surface water and groundwater status

The concepts of risk, precision and confidence and how they relate to the Directive are discussed in Chapter 2. For convenience the definitions are repeated here:

Risk At the simplest level, a risk can be thought of as the chance of an undesirable event happening. It has two aspects: the chance, and the event that might happen. These are conventionally called the probability and the consequence.

Confidence The long-run probability (expressed as a percentage) that the true value of a statistical parameter (e.g. the population mean) does in fact lie within calculated and quoted limits placed around the answer actually obtained from the monitoring programme (e.g. the sample mean).

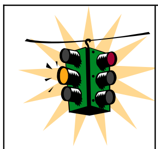
Precision Most simply, precision is a measure of statistical uncertainty equal to the half-width of the C% confidence interval. For any one monitoring exercise, the estimation error is the discrepancy between the answer obtained from the samples and the true value. The precision is then the level of estimation error that is achieved or bettered on a specified (high) proportion C% of occasions.

Where the monitoring objective relates to quality characterisation (e.g. to determine the status of a water body) the statistical objective is specified by stating:

- the parameter to be estimated (e.g. the mean or the 90-percentile);
- the desired precision (e.g. 0.5 mg/l; 20%); and
- the desired confidence (e.g. 90%, 99%).

Then, given an estimate of the variability of the determinand of interest in the water body, the required number of samples can be calculated. As a simple example, if s is the standard deviation, d is the desired precision, and u is the standard Normal deviate corresponding to the desired confidence level (e.g. u = 1.65 for 90% confidence), then the required number of samples is given approximately by:

$$n = (us/d)^2$$



Look Out!
Further information on methodology for the calculation of sample numbers to achieve desired levels of precision and confidence, or desired Type I and II errors, can be found in:

- ***Matheron G., la theorie des variables regionalisees, et ses applications. Les cahiers du centre de morphologie mathematique, fascicule 5. Ecole des Mines de Paris, 1970.***

Other monitoring objectives will relate to the detection of trends or differences. The statistical objective is then expressed slightly differently, because there are two types of error to consider. It is now necessary to specify:

- the parameter to be estimated (e.g. the before-after mean difference, or the slope of a trend line);
- the desired confidence (C%) associated with any assertion that a change has been detected (e.g. 90%, 99%). The 'Type I error' - the risk of a false positive - is then given by (100 - C)%.
- the Type II error - the risk that a difference which is truly present fails to be detected by the monitoring programme.

As before, the required number of samples can be calculated given chosen values for the above items together with an estimate of the variability of the determinand of interest in the water body. As a simple example, if s is the standard deviation, D is the before-after mean difference that it is desired to detect, and u_1 and u_2 are the standard Normal deviates corresponding to the desired Type I and II errors, then the required total number of samples (split equally between the two periods of comparison) is given approximately by:

$$n = 2(\{u_1+u_2\}s/D)^2$$

Although a confidence level of 95% is commonly used, scope is available to trade off precision against confidence to produce a more congenial statistical specification for a given amount of sampling effort. However, Ellis (1989) points out that reducing the confidence level much below 90% represents a spurious saving. There is nothing to be gained by having a high degree of precision if there is only a poor level of confidence that it will actually be achieved. As a possible starting point Member States may wish to set the required confidence level at 90% and compare the achievable precision obtained for the different water body types, quality elements and summary statistics. Similarly the Type II error (the risk of failing to detect a change that has truly occurred) could be set at 10% when determining the amount of change or differences that can practically be detected by existing monitoring programmes.

Look Out!

Guidance on the level of precision required for classification should arise from WG 2.3 Reference conditions inland surface water and WG 2.4 Typology, classification of transitional, coastal waters, particularly for the different monitoring types – Surveillance, operational and investigative. This will influence advice on sampling frequencies and spatial distribution of sites.

The appropriate level of confidence and precision will, in part, relate to the implications of getting the assessments wrong (e.g. misclassifying a water body and thus imposing costs on water users). In a sub-catchment with no pressures upon it, relatively little monitoring information would be required to enable reliable classification. In a sub-catchment in which severe and obvious environmental damage is extensive, high confidence in status classification could also be achieved with limited monitoring. In contrast, considerable monitoring effort may need to be directed at sub-catchments subjected to a range of different pressures and with a range of sensitivities to those pressures.

Note that the number of water bodies in these sub-catchments has only a slight bearing on the required monitoring effort. Monitoring effort is dictated by the difficulty of determining the effects of significant pressures upon the water environment.

Figure 5.1 provides a practical example of how the number of stations required changes with different levels of precision for the same level of confidence. It concerns the estimation of mean phosphate concentration for different types of rivers (grouped as river types not as individual water bodies) in England and Wales. To achieve 50% precision with 90% confidence, the number of samples varies from 13 in small upland rivers to 39 in small lowland rivers. This indicates that the variability of phosphate is greater in the latter compared to the former and hence more stations are required to achieve the same precision. The numbers of stations to achieve 10% precision are much higher, namely 214 for small upland rivers and 675 in small lowland rivers. However, it should be pointed out that the Directive would only require such monitoring information if it were relevant to the assessment of significant effects upon the status of water bodies in the basin district.

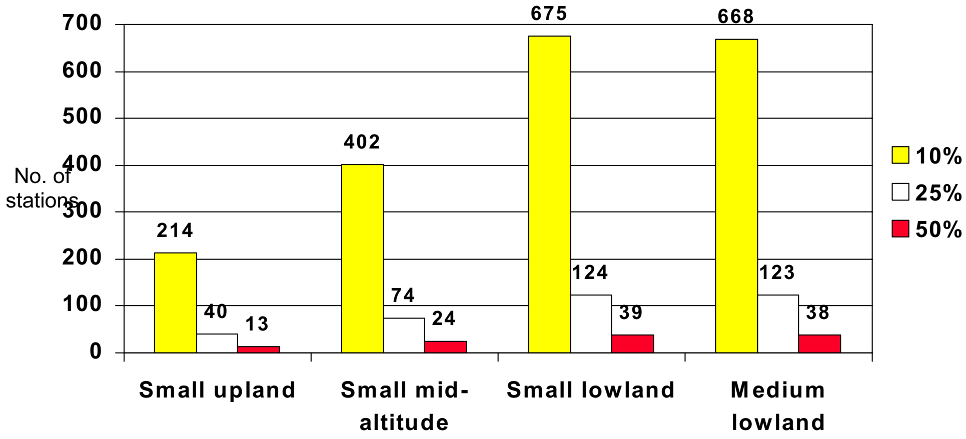

Figure 5.1 **Number of river stations required to estimate phosphate mean concentrations to 10%, 25% and 50% precision with 90% confidence***

**Note there were 103 stations on small upland rivers, 653 on small mid-altitude rivers, 3769 stations on small lowland rivers and 425 stations on medium lowland rivers*

Risk of failing environmental quality objectives

The Directive refers to the identification of water bodies at risk of failing environmental quality objectives as defined in Article 4. This identification will be partially based on existing monitoring data (initially) and then on data arising from surveillance monitoring for subsequent periods of RBMPs. Those water bodies identified as being at risk will then be subject to operational monitoring which will confirm or reject their status in terms of failure to meet the relevant objectives. By implication this means that operational monitoring may need to provide a more precise assessment of the status of those water bodies identified at-risk than that originally obtained from surveillance monitoring.

Not all the Environmental Objectives given in Article 4 will be applicable to all water bodies: they can be summarised as follows:

- To achieve good groundwater status, good ecological status, good ecological potential or good chemical status;
- To comply with any standards and objectives associated with Protected Areas;
- To prevent deterioration in the status of a body of surface water or groundwater;
- To progressively reduce pollution from priority substances, and cease or phase out emissions, discharges and losses of priority hazardous substances; and,
- To reverse any significant and sustained upward trend in the concentration of any pollutant in groundwater.

Objectives 1 and 2 imply that assessments will have to be made as to whether status is better or worse than that which defines the threshold value between good and moderate status (or potential), or is in compliance with defined standards. Objectives 3 to 5 relate to assessing whether status is deteriorating with time or pollution is decreasing with time. In the latter cases, threshold levels or concentrations of substances against which risk of failure is judged will be specific to the water body of interest and will relate to levels or concentrations specified at a particular time.

As indicated above, the assessment of the risk of failure of a water body will make use (when possible) of data from monitoring stations within the body. The discrimination between good and moderate and hence the risk of failure could be determined based on comparison of the calculated 'confidence of compliance' with the appropriate standard or threshold value.

As noted earlier, the assessment of failure would have to consider what would be acceptable Type I and Type II errors. A Type I error would occur when a water body that was truly satisfactory was failed on the evidence of the monitoring programme. Conversely, a Type II error would occur when a water body that was truly unsatisfactory was passed by the monitoring programme.

In the figure below (Figure 5.2), where the parameter of interest might for example be the 90%ile, the judgement will be easy to make when the sample 90%ile and the entire confidence interval better than the threshold or standard (case A, or when they are worse than the threshold or standard (case D. However, there will be many cases where there is an overlap between the confidence limits and the thresholds (cases B and C). There are three possible approaches to assess failure in these cases. In a benefit-of-the-doubt approach, a monitoring station/water body is deemed to have passed, even when the estimate P has marginally failed, as long as part of the confidence interval falls into the 'good' status range. In a fail-safe approach, conversely, the monitoring station/water body fails, even when the estimate P has marginally passed, as long as part of the confidence interval falls into the less than 'good' status. Finally, in a face-value judgement sampling error is ignored and the pass/fail rule depends solely on the observed value of the summary statistic P.

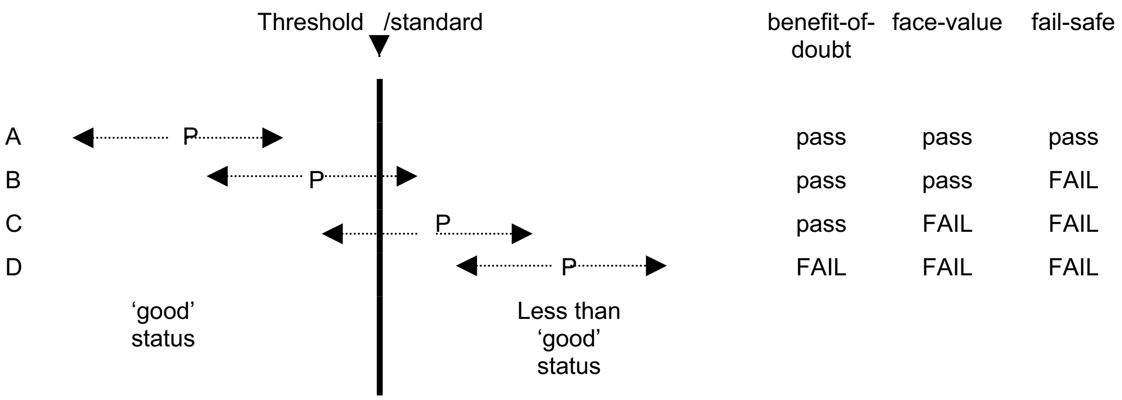

Figure 5.2 Methods of classification for groundwater bodies

NB: P denotes the parameter of interest (e.g. 90%ile) calculated from the sample data
represents the confidence interval for the unknown true value of P

The agreed or desired level of precision required in the estimate of the parameter P of interest and the desired level of confidence will determine how easy the above judgement of success or failure is going to be. For a given level of confidence, an increasingly precise estimate of P (obtained by increasing the number of samples) will reduce the width of the confidence interval, thus making the judgement of success or failure easier.

Risk of misclassification of status

The design of surveillance and operational monitoring should aim to control to acceptable levels the risk of a water body's status being wrongly assessed and hence misclassified.

Many water bodies and stations will lie close to class/status boundaries, and this, coupled with the uncertainty produced by infrequent/discrete monitoring, means that there is a substantial risk that such water bodies will be misclassified. This issue was examined by the Environment Agency of England and Wales. For their chemical general quality assessment ('GQA') scheme, it was demonstrated that, for any particular stretch of river, there was an average misclassification risk of 19%. The equivalent risk of misclassification based on sampling river invertebrates was calculated to be 22%.

The issue of misclassification was discussed at the REFCOND workshop held in Uppsala in May 2001. Two presentation slides from the workshop are reproduced below (Figure 5.3). They illustrate how the statistical uncertainty in the estimate of a water quality parameter (in this case 90%ile BOD) may cross a number of class boundaries. In this instance, the 'statistical confidence' curve spans three different classes. With 70% of the area of the curve lying within the moderate class, on a face value assessment the station would be classified as moderate.

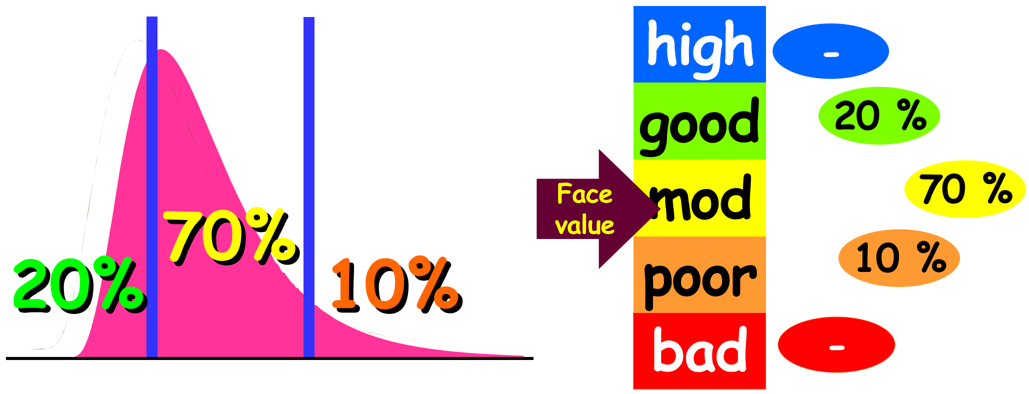

Figure 5.3 **Classification of a monitoring station based on 'face value' assessment of quality (from presentation by Tony Warn the EA (England and Wales) at the REFCOND workshop, May 2001).**

5.2.6 Surveillance monitoring of surface waters

Number and location of monitoring stations

Surveillance monitoring is required in a sufficient number of surface water bodies to provide an assessment of the overall surface water status within each catchment or sub-catchment within the river basin district. The location of monitoring stations within a water body should provide information that is representative of the general conditions of the water body, and which specifically addresses the objectives of the surveillance monitoring programme (as defined in Section 2.7.1). Therefore, it must enable the assessment of long term changes resulting from natural or anthropogenic activity and provide sufficient information to both supplement the Annex II risk assessments and assist with design of future monitoring programmes.

It is often assumed that a waterbody is well mixed and that a mid-water or mid-stream sample will be sufficiently representative. However, this is often not the case. For example, in thermally stratified waters the depth of sampling is critical because the concentrations of many measured parameters can vary greatly between the thermal layers. Ideally, therefore, monitoring should be undertaken at sufficient stations to provide an adequate description of the key spatial effects. However, it is worth noting the considerable resource implications of such investigations, any one of which would need at least 20 or 30 samples. This is in marked contrast with the minimum frequencies specified in Annex V of the WFD - typically four per year.

It was noted earlier that although the Directive requires assessments of status to be made for each individual water bodies, it does nevertheless permit water bodies to be grouped, provided they are sufficiently similar in all critical characteristics, and a group assessment made using just a representative sample of water bodies selected from the group. This is an instance of the well-established statistical principle of stratified random sampling[47]. Here, however, the aim is not to produce the most precise overall estimate of average status across all groups. Each group of water bodies is individually of interest, and the aim is to produce acceptably precise estimates of the relevant water quality measures for each of those groups. Thus the optimal allocation of samples across groups is not a relevant issue here. What is critical, however, is the requirement for the groups to be relatively homogeneous.

The grouping of water bodies has been discussed in some detail earlier in the document. How this would be done in practice depends very much on the statistical definitions of the boundaries determining whether the quality status is ’high’, ’good’ or ’moderate’. For chemical quality, for example, it would be possible for the assessment to be based on (a) mean concentrations, (b) extreme percentiles (such as the 10%ile for dissolved oxygen or the 90%ile for ammoniacal nitrogen), or (c) the proportion of samples falling below a given concentration limit. Thus it is not possible to go into detail here. Some general points can nevertheless be made.

The validity of the approach depends critically on the within-group variation shown by the water bodies in a selected group being **small in relation to the difference between the ‘High’/’Good’ and the ‘Good’/’Moderate’ limits**. For example, suppose these two status boundaries were defined by mean BOD values of 1.0 mg/l and 2.0 mg/l. On the one hand, if it were the case that the mean BODs for the various water bodies in the group all fell within 0.2 mg/l of each other, then given a sampled group mean of, say, 1.3 mg/l, this would provide sound evidence that all the water bodies in the group could be classified as ’good’. But if, on the other hand, the group had been formed less tightly and within-group mean BODs spanned a range of 1.2 mg/l, it would no longer be valid to assume that, because a sample of water bodies had a mean of 1.3 mg/l, all water bodies fell into the ’good’ category. (In that example, we might expect about 10% of water bodies to have mean BODs below 1.0 mg/l - and hence be misclassified by the group sampling approach.)

Any consideration of the water body grouping option should therefore include a thorough assessment of (a) the degree of homogeneity of the group, and (b) the likely size of misclassification risks introduced by applying the estimated average group class to all individual water bodies in the group.

Frequency of monitoring

Minimum monitoring frequencies for surveillance monitoring are outlined in Annex V of the WFD. The Directive states that the frequencies identified should be applied unless "greater intervals would be justified on the basis of technical knowledge or expert judgement". Furthermore, it is the requirement of the directive that "frequencies shall be chosen so as to achieve an acceptable level of confidence and precision" and that "monitoring frequencies shall be selected which take account of variability in parameters resulting from both natural and anthropogenic pressures. The times at which monitoring is undertaken shall be selected so as to minimise the impact of seasonal variation on the results".

A number of important questions are prompted by these extracts from the Directive - especially in relation to the proposed ‘minimum frequencies’, which are typically 4 per year. Assuming that the confidence level is set at 90%, it is worth noting what can be achieved with just 4 samples in a year. If the aim were to estimate annual mean concentration, the

[47] *With stratified sampling, the population is divided into a number of strata (in this case, groups of water bodies) in such a way that the within-stratum variations are small in relation to differences between strata. Then, for any given total number of samples, statistical theory shows how samples can best be allocated across strata so as to produce the most precise overall estimate of the mean.*

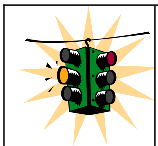
90% confidence interval for this would be "sample mean ±1.18s" (where s is the standard deviation). For many common determinands, the relative standard deviation (i.e. s/mean) is at least 50%. Thus the annual means would be estimated to no better than ±60%, which for many purposes might be thought unacceptably wide. Confidence intervals for percentiles would generally be a lot wider - and furthermore dependent on the assumed statistical distribution (which there would be no way of testing with so little data). This means that in practice it would be unrealistic to address any percentile-based objective:

The position is substantially worse when considering the magnitude of change that could be detected between any two years - the procedure envisaged under surveillance monitoring. The 90% confidence interval for the true mean difference would be sample mean difference ±1.37s. Thus, assuming the same relative standard deviation as before, the two sample means would need to differ by at least 70% before it could be claimed with 90% confidence that there was a genuine difference between the two years. This, again, will be unhelpfully wide for many purposes.

Given this background, the suggestion that greater sampling intervals (i.e. lower frequencies than 4 per year) could be justified on the basis of expert judgement needs to be treated with some caution.

The recommendation made in the Directive to target sampling times so as to minimise the impact of seasonal variation is sound in principle. This will reduce the standard deviation, and so, for a given level of confidence, improve the precision (i.e. narrow the width of the confidence interval). However, it is important that the basis on which the targeting is justified is made clear, as the very act of targeting causes the samples to be drawn from a sub-population whose characteristics will usually be different from those of the overall population. For example, sampling a river only in summer will commonly generate much lower dissolved oxygen values (and hence a lower mean and 10%ile) than if sampling spans the full year. It is critical, therefore, to check that the process of targeting does not introduce bias in relation to the original purpose of the monitoring. For example, if High status is defined in terms of an annual 10%ile dissolved oxygen value, summer-only sampling could produce a very biased assessment of the water body.

In view of the above comments about sampling frequency, and as discussed in Section 2.7.2, monitoring may initially need to be more extensive to account for the expected lack of background data and information and the more comprehensive requirements of the Directive as compared to previous Directives. It is especially important to ensure that an adequate amount of data has been collected to characterise the 'before' or baseline conditions, as any shortcomings at this stage clearly cannot be corrected retrospectively. Nor can they be compensated for simply by increasing the 'after' frequency. For example, a comparison based on 12 samples in each of two time periods has a greater power to detect a change in mean than does a comparison with 6 samples before and 100 afterwards. It should be noted that the greater the analytical error in relation to environmental variability, the poorer the precision will be for a given number of samples and confidence level.



Look Out!

Specific guidance on statistical design for individual monitoring programmes cannot be provided at this stage. Monitoring program design will be influenced by:

- *The levels of confidence and precision identified in individual River Basin Management Plans;*
- *Outcomes of working group 2.3 REFCOND (guidance document No. 10);*
- *How the physico-chemical status boundaries will be classified; and,*
- *The outcomes of the pilot testing exercises*

Further guidance on statistical analysis for the design of surveillance and operational monitoring programs will be required following the pilot testing exercises and subsequent development of River Basin Management Plans.

5.2.7 Operational monitoring of surface waters

The number and locations of monitoring stations required for operational monitoring are, in part, governed by the outcomes of the Annex II risk assessments and surveillance monitoring. Therefore, specific guidance on the number and location of water bodies and sites cannot be provided until those bodies at risk of failing the environmental objectives of the Directive are determined. However, random or stratified random sampling will be needed for bodies at risk from diffuse sources or hydromorphological pressures.

In any case, the same principals mentioned in the preceding discussions on sampling frequency in the context of surveillance monitoring should equally be applied to the design of an operational monitoring programme.

5.3 Best Practice and Tool Box for Groundwater

5.3.1 Introduction

5.3.2 Description of conceptual model/understanding approach

Conceptual models/understandings are simplified representations, or working descriptions, of how real hydrogeological systems are believed to behave. Their development under the Annex II characterisation procedure will be necessary to allow assessments of the risks of failing to meet the Directive's environmental objectives to be made. Conceptual models/understandings will also be required for designing effective monitoring programmes, classifying the status of water bodies and designing suitable programmes of measures. Because of their importance in the planning process, conceptual models/understandings should be tested numerically to ensure that they are adequately reliable and sufficiently precise for the purposes for which they will be used. The testing of the models should be based on water balance calculations. If a model accurately reflects the real hydrological system, over the long-term groundwater recharge would be expected to equal groundwater discharges to surface ecosystems and to adjacent bodies of groundwater. As well as validating conceptual models/understandings, water balance calculations will also be involved in assessing quantitative status (see Section 7 of the toolbox).

The level of complexity involved in any model will depend on the difficulty in judging the status of the body of groundwater and the implications of that status assessment. For example, where a body of groundwater is subject to no or only minor pressures, a very basic conceptual model/understanding will be adequate. However, to justify, and properly target, very costly restoration or enhancement measures for bodies failing to achieve 'good' status, relatively complex models are likely to be required. Different sorts of data, and different levels of confidence and precision in data, will be relevant to the development and subsequent testing of conceptual models/understandings in these different circumstances (Figure 5.4). This Section describes the development and testing of basic conceptual models/ understandings, and provides examples of under what circumstances and in what ways such models may need to be improved (Figure 5.6 to Figure 5.10).

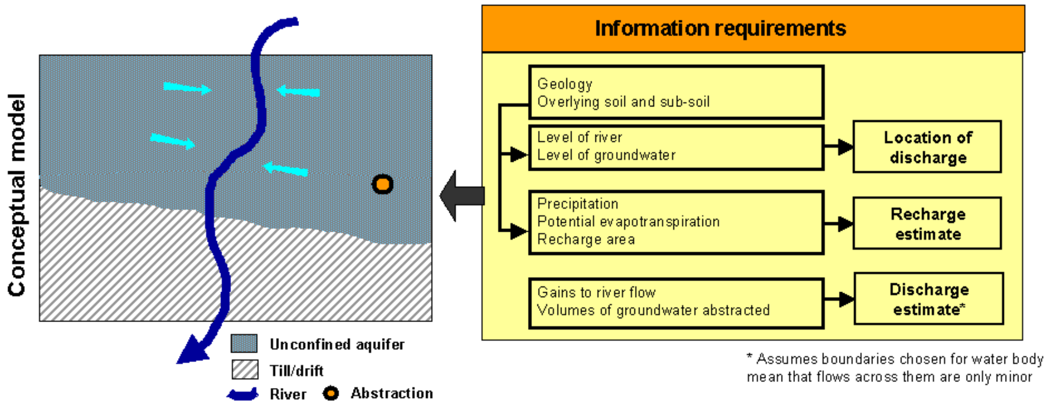


Figure 5.4 **Schematic illustration of a simple conceptual model/understanding of a body of groundwater in which the only significant groundwater discharge is to a river [i.e. the groundwater body has been delineated in such a way that any flows across its boundaries are negligible - See WFD CIS Guidance Document No. 2 on Water Bodies].**

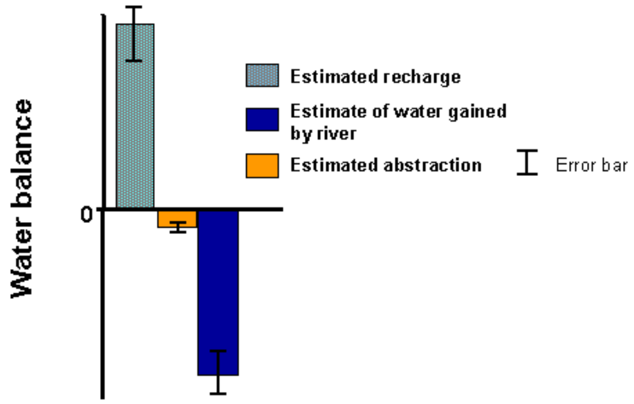

Figure 5.5 **Water balance used to test the conceptual model/understanding illustrated in Figure 5.4.**

The simple conceptual model/understanding illustrated in Figure 5.4 can be tested by lumped estimates of recharge, discharge and abstraction to see if it explains the bulk flows of water in the hydrogeological system (see Figure 5.5). If the water balance calculation balanced, and the model was adequate for use in assessing the status of the body of groundwater, no further development of the model would be necessary (see Figure 5.6). Where there is an apparent long-term water balance deficit, this could indicate over-abstraction but it could also result from errors in the conceptual model/understanding or the estimation of one or more of the components of the water balance (e.g. error in the recharge estimate). An improved, more detailed conceptual model/understanding would be required to enable a reliable assessment of status.

The level of precision required in the water balance will vary with the complexity, and likely significance, of the pressures to which a water body is subject (see Figure 5.7). For example, if a water body were subject to only minor pressures, provided there were no orders of magnitude imbalances in the water balance calculation, the model would be adequate. Where pressures were greater, in terms of numbers, distribution and/or significance, improvements to the conceptual model/understanding would be necessary in order to adequately assess status and design appropriate measures. Improving on a basic conceptual model/understanding involves reducing the errors in the estimates of recharge, groundwater discharge and abstraction, and appropriately refining its spatial and temporal resolution.

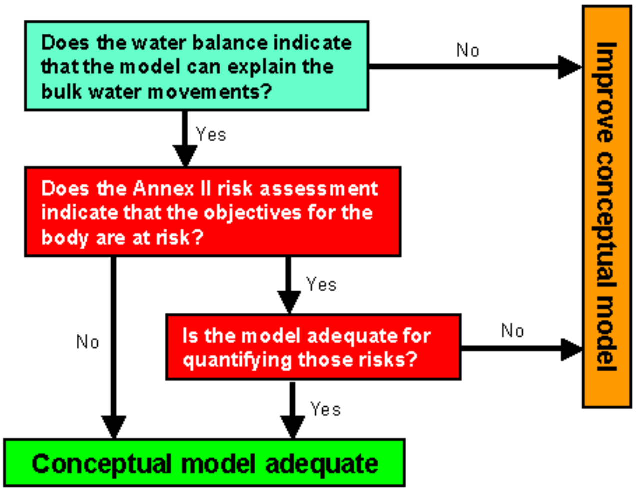

Figure 5.6 Considerations involved in determining the adequacy of a conceptual model/understanding.

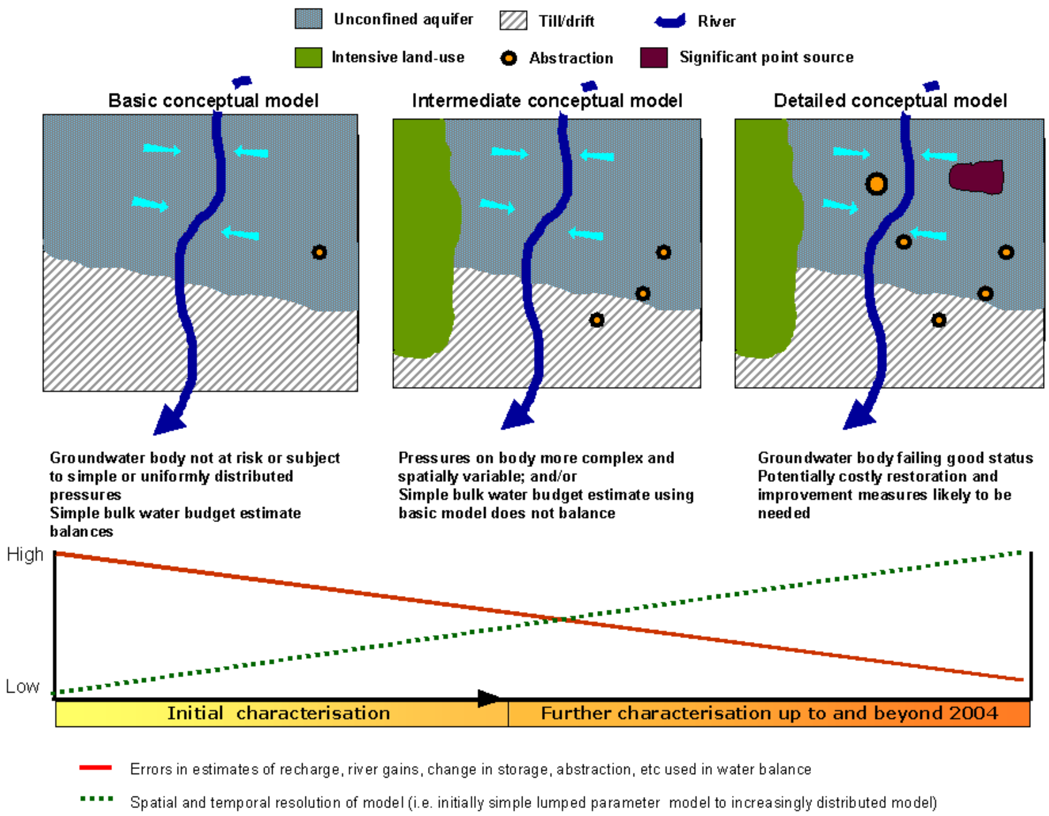

Figure 5.7 Development of a conceptual model/understanding in relation to the increasing complexity of pressures on the body and the cost of restoration and improvement measures.

For example, a complex quantitative model would tend to be based on (and tested), using estimates of the properties of different parts of the body of groundwater rather than relying on lumped estimates for the groundwater body's catchment. This produces a better understanding of spatial and temporal variability in the hydrogeological system and reduces the errors in the estimates of recharge and discharge used to test the model.

Table 5.1 Illustration of potential differences in data requirements for simple and best quantitative conceptual model/understandings.

	Basic conceptual model/understanding	Best quantitative model
Recharge	➢ Precipitation	➢ Precipitation
	-	➢ Estimate of artificial sources of recharge (e.g. leaking drinking water supply pipes etc)
	➢ Lumped estimate of potential evapotranspiration	➢ Estimate of actual evapotranspiration based on properties of land cover (e.g. types of crops).
	➢ Recharge area based on simple assumption of unconfined/confined	➢ Detailed properties of overlying soils and sub-soils; land-sealing (sub-balances to test properties)
River Gain	➢ Use of river flow data if available ➢ Standard length/gain coefficients for different geological settings ➢ Expert judgement	➢ Naturalisation estimates of river flows (e.g. estimated hydrograph with all river abstractions and discharges (other than groundwater) removed. Hydrograph separation to determine groundwater contribution. ➢ Estimate of change in storage.

Monitoring programmes should be designed to provide the data needed to appropriately test conceptual models/understandings (Table 5.1). The monitoring data needed to test any particular model will depend on the extent and quality of existing data and on the difficulty in assessing the status of the body, or group of bodies, and the implications of that assessment for the programmes of measures. Different types of monitoring data may be used in validating a conceptual model/understanding. For example, information on the physico-chemical properties of the groundwater and the surface water body at low river flows may improve confidence in the estimates of the extent of groundwater – surface water connectivity.

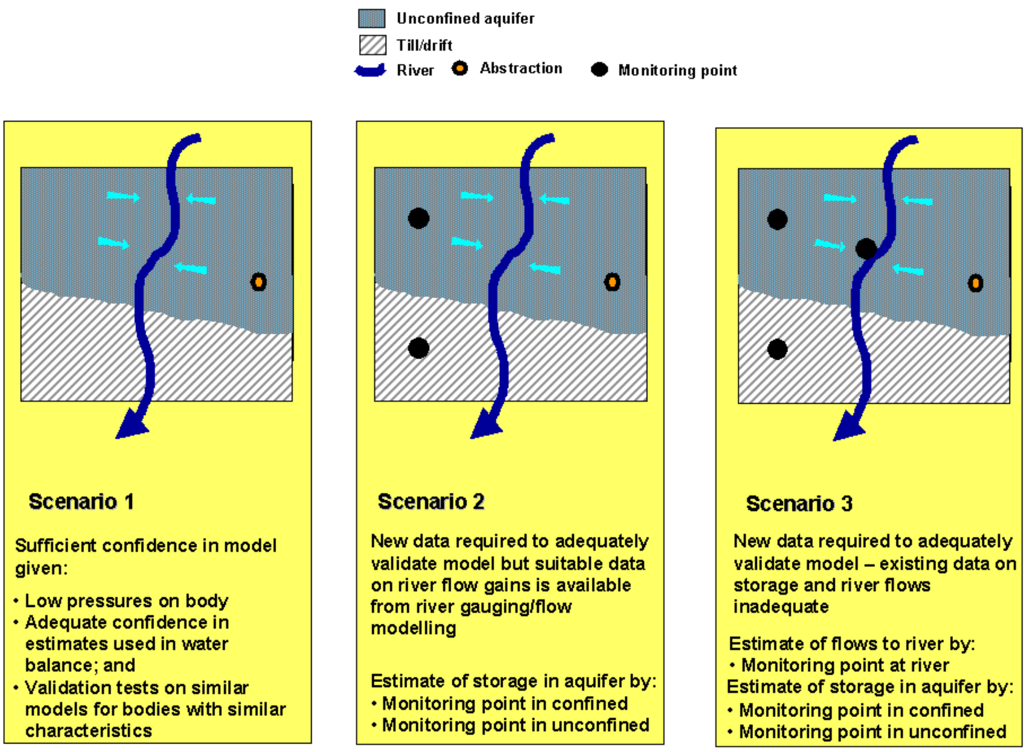

Figure 5.8 **Monitoring design in relation to conceptual model/understanding validation. Groundwater monitoring requirements will depend on the confidence required in the model and the extent and quality of existing data.**

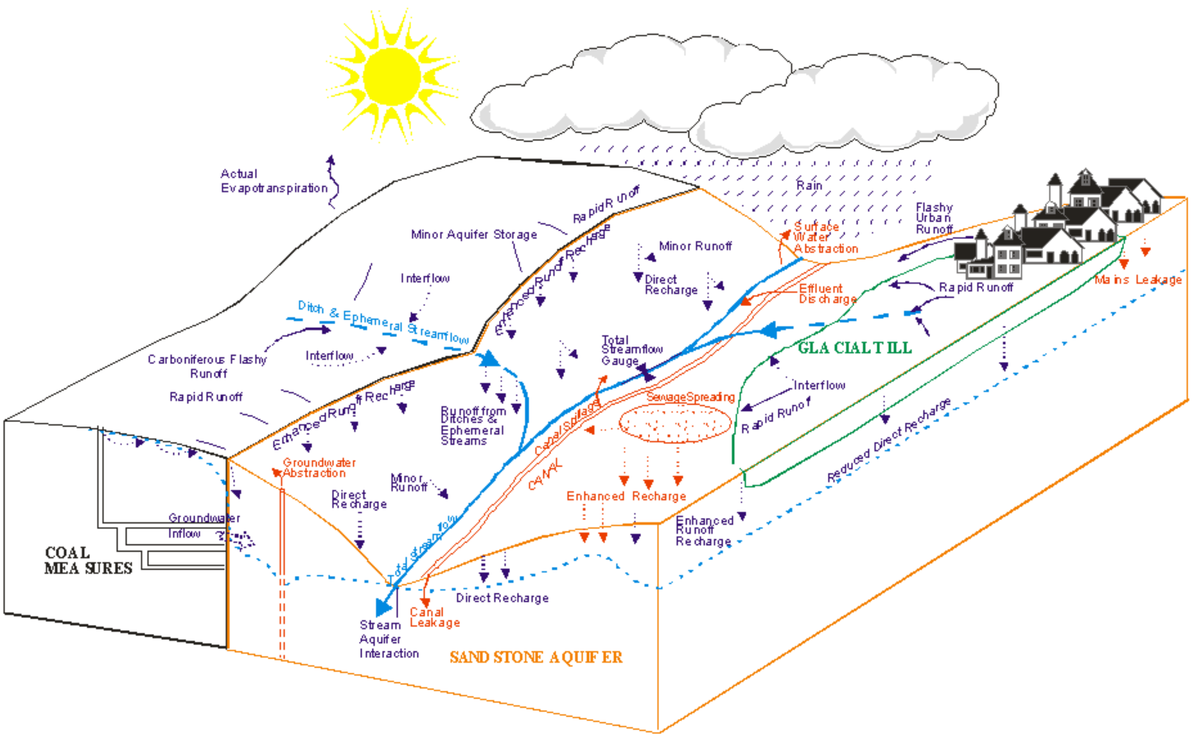

Figure 5.9 **Illustration of an intermediate conceptual model/understanding**

5.3.3 Chemical Status Monitoring

Approaches to selecting pollutant suites in relation to particular human activities

Table 5.2 Examples of analytical suites that have been used in monitoring programmes in the UK to provide data on the risks to groundwater objectives from particular types of land use.

	Land use					
	Arable	Managed grassland	Managed woodlands	Urban	Sheep	Amenity
Field parameters						
Major ions	✓	✓	✓	✓	✓	✓
Trace metals				✓		
Special inorganics				✓		
Organonitrogen pesticides	✓		✓		✓	
Organochlorine pesticides	✓					✓
Acid herbicides	✓	✓		✓		✓
Uron/urocarb pesticides	✓			✓		✓
Phenols				✓		
VOCs				✓		
PAHs				✓		
Special Organics	✓				✓	

Useful indicators for monitoring in relation to different types of human activity

Table 5.3 Examples of parameters that may be used in monitoring programmes to indicate that a particular human activity may be affecting groundwater quality.

Parameter(s)	Source
Nitrate	Agriculture
Ammonia	Urban areas, agriculture, land-fill
Phosphorous	Agriculture
Pesticides	Agriculture, traffic areas (rail tracks)
Sulphate	Agriculture, atmospheric depositions (acid rain), urban areas
pH-value	Atmospheric deposition (acid rain)
Chloride	Traffic (de-icing salt, road salt), agriculture, urban areas
Tetrachloroethene and Trichloroethene	Housing area, small trade (e.g. dry cleaner), industry
Micro-biological parameters	Animal or human waste disposal

The UN-ECE's guidelines also identify indicator parameters related to different problems, functions and uses. These are summarised in Table 5.4.

Table 5.4 Parameter suites for groundwater quality assessment related to some problems and functions/uses. (After Chilton *et al*, 1994)

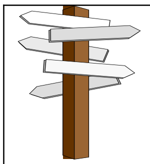
Problems	Functions and Uses	Suite/groups	Parameters
Acidification, salinization	Ecosystems, agriculture	1. Field parameters	Temperature, pH, Dissolved Oxygen (DO), Electrical Conductivity (EC)
Salinization, excess nutrients	Drinking water, agriculture, ecosystems	2. Major ions	Ca, Mg, Na, K, HCO_3, Cl, SO_4, PO_4, NH_4, NO_3, NO_2, TOC, EC, ionic balance.
Pollution with hazardous substances	Drinking water, ecosystems	3. Minor ions and trace elements	Choice depends partly on local pollution sources as indicated by land-use approach.
Pollution with hazardous	Drinking water, ecosystems substances	4. Organic compounds	Aromatic hydrocarbons, halogenated hydrocarbons, phenols, chlorophenols. Choice depends partly on local pollution sources as indicated by land-use approach.
Pollution with hazardous substances	Drinking water, ecosystems	5. Pesticides	Choice depends in part on local usage, land-use approach and existing observed occurrences in groundwater.
Pollution with hazardous substances	Drinking water, agriculture	6. Bacteria	Total coliforms, faecal coliforms.

List II substances are Fe, Mn, Sr, Cu, Pb, Cr, Zn, Ni, As, Hg, Cd, B, F, Br and Cyanide.
(Drinking Water and Nitrate Directive)

Assessing background chemistry

An understanding of the natural chemical composition of a body of groundwater is important where:

- it is not clear whether concentrations of non-synthetic substances detected in the groundwater (e.g. As, Cd) are: (i) part of the natural chemical composition of the body of groundwater; (ii) occur as a result of human activities and should therefore be regarded as pollutants; or (iii) are a combination of (i) and (ii); or
- estimates of the background (i.e. reference condition) values for the physico-chemical quality elements are required for an associated surface water body. Where groundwater contributions to river base flows are high, the base flow chemistry of the river will be significantly influenced by groundwater chemistry.



Further information on assessing background chemistry is available from:

- **The EU Framework V funded Baseline project (EVK1 – CT1999-0006) (E-mail: hydro@bgs.ac.uk; Website: www.bgs.ac.uk/hydro/baseline)**

Designing chemical status monitoring networks; General principles

Definition of the objectives of groundwater monitoring is an essential prerequisite before identifying monitoring strategies and methods. Monitoring design includes: selection and design of monitoring sites, frequency and duration of monitoring, monitoring procedures, treatment of samples and analytical requirements. ISO 5667-1 and EN 25667-1 give the principles on the design of sampling programmes in aquatic environments.

Selecting monitoring sites and density in relation to risk

The assessment of chemical status and the identification of pollutant trends require a flexible, risk-based approach to selecting sites for monitoring. The conceptual model/understanding and the risk assessment it enables should be used to identify locations for, and the density of, monitoring points in relation to different land use pressures. The actual density of monitoring sites and location of individual sites will depend on the difficulty of reliably assessing the effects of pressures on the status of the body and the likelihood of costly measures being required. Such decisions must be made locally and be iteratively based on an appropriately detailed conceptual model/understanding of the groundwater system coupled with the assessment of risks to the Directive's objectives.

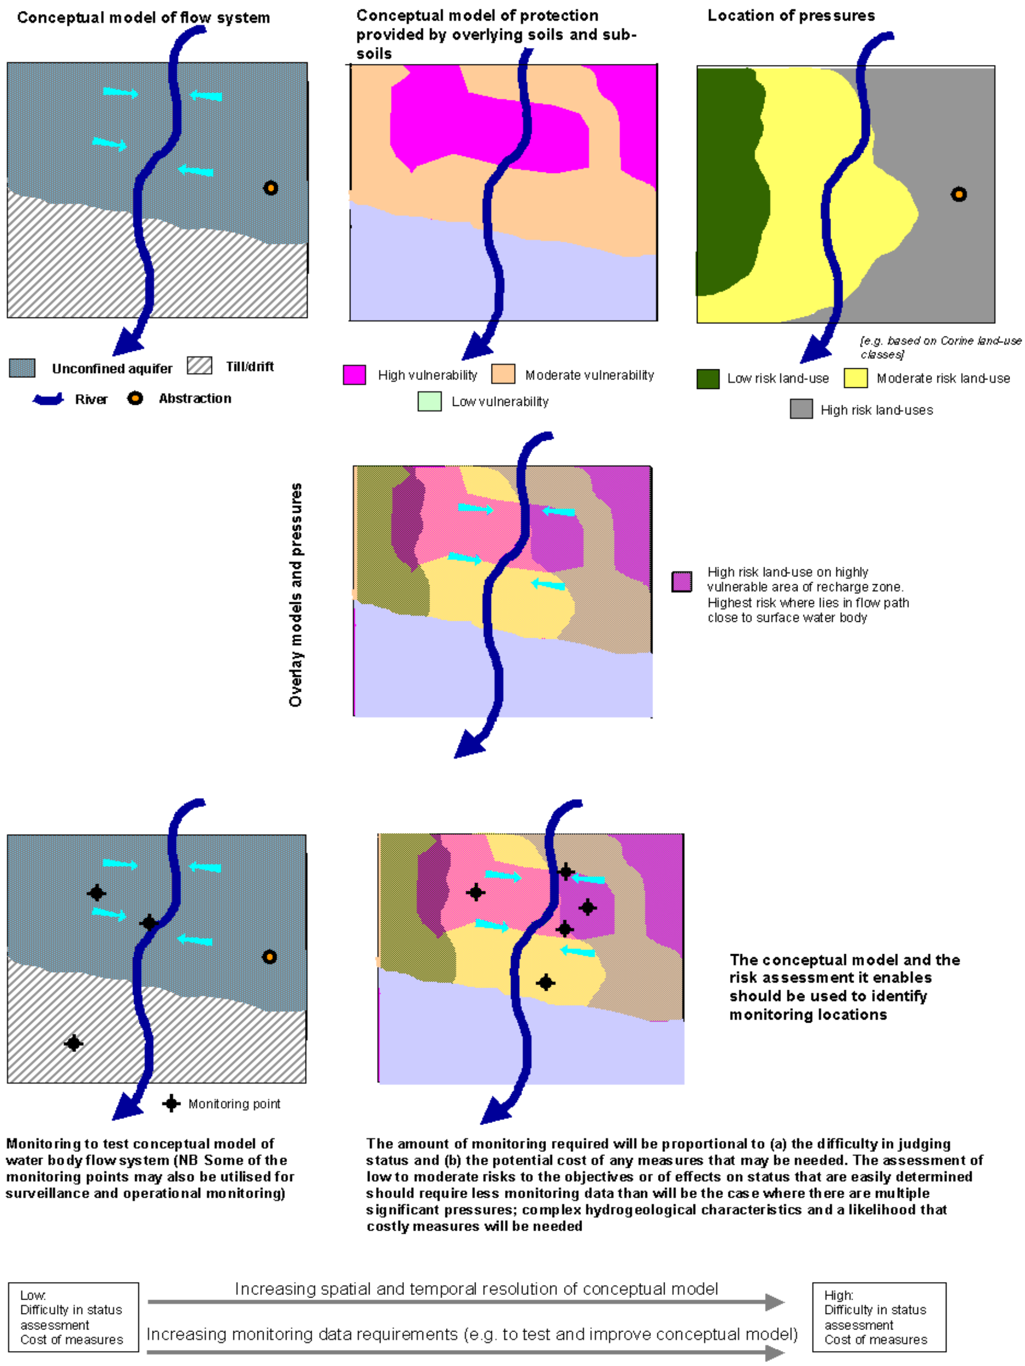


Figure 5.10 **Monitoring locations for assessing chemical status should be selected on the basis of the Annex II risk assessments.**

Where a body is at risk (illustrated in **Figure 5.10**) its status is difficult to determine because of its complex hydrogeological characteristics and/or the complex range of pressures to which it is subject; and costly measures may be required, improved conceptual models/ understandings and greater monitoring density will be necessary.

Approaches to determining monitoring frequencies in relation to groundwater body characteristics and the behaviour of pollutants

The sampling frequency for pollutants should be based on:

- the conceptual model/understanding of the groundwater system and the fate and behaviour of pollutants in it; and
- the aspect of the conceptual model/understanding being tested.

In the UK, a sampling frequency for groundwater quality is used that combines the requirements of the Directive with the main hydrogeological factors that influence groundwater flow. The framework ensures more frequent sampling in aquifers in which groundwater flow is rapid and less frequent in aquifers with slower movement (Table 5.5). It also builds in a less frequent requirement for sampling in confined aquifers than in unconfined aquifers, reflecting the greater degree of protection from pollution provided by the confining layers. The schedule is consistent with the Directive's requirements for operational monitoring to be undertaken at least annually between surveillance monitoring periods and for surveillance monitoring to be undertaken during each planning cycle. These frequencies may not be relevant for trend assessment. Guidance on monitoring frequencies for trend assessment are provided in CIS 2.8.

Table 5.5 Sampling frequency for groundwater hydrogeology

			SURVEILLANCE	*OPERATIONAL*
Hydrogeology	SLOW	Unconfined	3 years	6 monthly
		Confined	6 years	Annual
	FAST	Unconfined	Annual	Quarterly
		Confined	3 years	6 monthly

In Germany, the following table (Table 5.6) provides guidance on monitoring frequencies in relation to aquifer properties. The table does not address monitoring frequencies in relation to point sources, especially infiltrating dense liquid phases.

Table 5.6 German guidance on monitoring frequencies in relation to aquifer properties

Scenarios	Frequencies					
	Monthly	Quarterly	Half yearly	Yearly	Every two Years	Every five Years
shallow ground-water (depth to table ≤ 3 m), unconfined porous aquifer	x	X	X	x		
deep ground-water (depth to table ≥ 10 m), unconfined porous aquifer				x	X	X
shallow ground-water (depth to table ≤ 3 m), unconfined fractured aquifer	x	X	X	x		
deep groundwater (depth to table ≥ 10 m), unconfined fractured aquifer		x	X	X		
karst aquifer (without more or less impermeable cover)	X	X	X			
karst aquifer (with more or less impermeable cover)	x	X	X	x		
confined groundwater (with more or less impermeable cover with thickness < 2 m)				X	X	x
confined groundwater (with more or less impermeable cover with thickness > 2 m)				x	X	X
high rate of recharge		x	X	X		
Trend assessment			X	X		
season-dependent human activities		x	X	x		

Notes on Table: Large X indicates the most likely frequency. Small x indicates the range of frequencies depending on the particular circumstances. The frequencies suggested may not be relevant for trend assessment. Guidance on monitoring frequencies for trend assessment are provided in CIS 2.8.

Intrusions

One of the criteria required to achieve both good groundwater quantitative status and good groundwater chemical status is that a body of groundwater is not subject to saline or other intrusions resulting from human induced changes in flow direction. Some alterations to flow direction, however localised, would be expected to accompany any abstraction. Sometimes these will induce movements of water into a body of groundwater from an adjacent groundwater body or an associated surface water body. This water may well have a different chemical composition to that of the body of groundwater, either because of the pollutant concentrations it contains or because of its natural chemistry. The Directive does not regard temporary or continuous changes in flow direction and their associated effects on chemical composition as intrusions so long as they are limited spatially and do not compromise the achievement of any of the Directive's other environmental objectives for the body of groundwater (see Figure 5.11).

An assessment of whether an intrusion is present requires:

- the development of a conceptual model/understanding of the groundwater system;

- the use of that model to predict whether the pressures on the water body may have caused an intrusion; and
- the testing of that prediction to the extent necessary to develop the required confidence in the model and in the classification decisions it enables.

The testing of the conceptual models/understandings and the validation of their predictions will require the use of monitoring data.

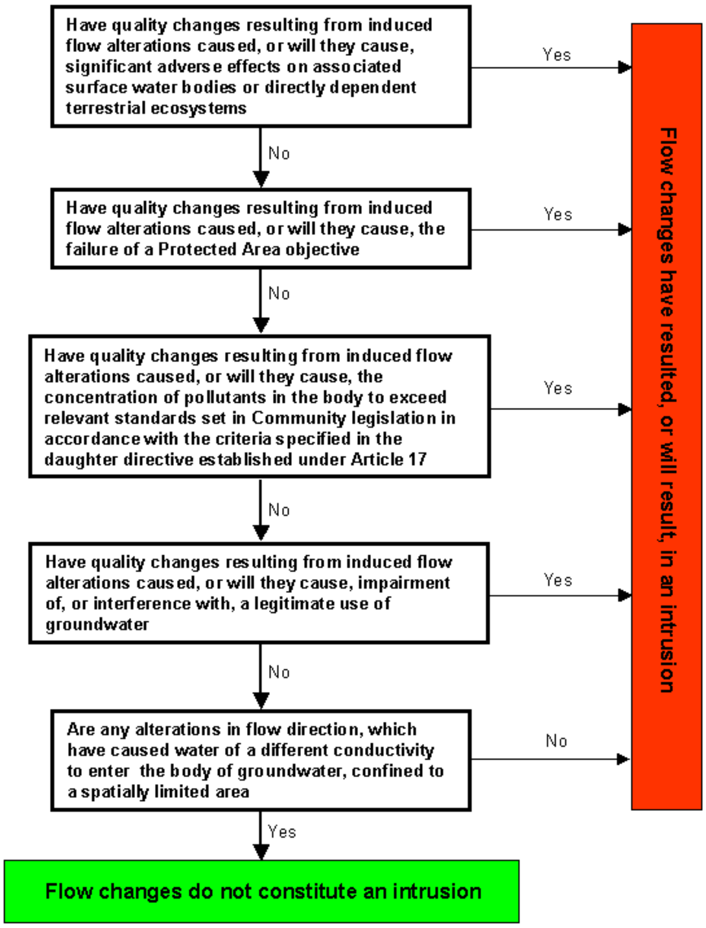

Figure 5.11 **Criteria for defining a saline or other intrusions into groundwater bodies. Where one of the intrusions defined in the figure occurs, a body of groundwater will fail to achieve good quantitative status and good chemical status.**

5.3.4 Sampling protocols

General principles

Care should be taken in the construction and operation of sampling points and in the analysis of samples collected so that they do not inadvertently affect the data provided.

Sampling design

A definition of the purpose of groundwater sampling is an essential prerequisite before identifying the sampling strategies and methods. Sampling design includes: selection and design of sampling sites, frequency and duration of sampling, sampling procedures, treatment of samples and analytical requirements. ISO 5667-1 and EN 25667-1 give the principles on the design of sampling programmes in aquatic environments.

Sampling methods

ISO 5667-11 (1993) gives the principles for groundwater sampling methods focused to survey the quality of groundwater supplies, to detect and assess groundwater pollution and to assist in groundwater resource management. ISO 5667-18 (2001) gives the principles of groundwater sampling methods at contaminated sites.

ISO 5667-2 gives the general information on the choice of material for sampling equipment. Generally polyethylene, polypropylene, polycarbonate and glass containers are recommended for most sampling situations. Opaque sample containers should be used if the sampled parameter degrades in light (e.g. some pesticides). Contamination or modification to the chemistry of groundwater samples should be minimised by selecting suitable materials for sampling equipment and borehole construction.

Sample storage, conditioning and transportation

Groundwater samples storage, conditioning and transportation from the sampling sites to the laboratory are extremely important, because the results of the analysis should be representative of the conditions at the time of sampling. General guidance on these aspects is given in ISO 5667-2 and ISO 5667-3. Specific indications for groundwater samples are given in ISO 5667-11.

Sample identification and records

An identification system that provides an unambiguous method for sample tracking should be adopted. It is crucial that a clear and unambiguous labelling system be used for samples to enable effective management of samples, accurate presentation of results and interpretation. ISO 5667-11 gives guidance on sample identification and record procedures. In addition, other relevant environmental data should be reported and recorded in order that any repeat sampling can be carried out and any variability in results examined.

Monitoring points

The influence of the construction of a monitoring point and its condition and maintenance on the data obtained should be evaluated. For example, could the condition of the casing of the borehole be affecting the results? Are the intended geological strata exposed in the borehole? Is water entering the borehole from the surface?

5.3.5 Quantitative status monitoring

Guidance on how to estimate the interaction of groundwater with surface waters and terrestrial ecosystems

An understanding of groundwater connections to surface waters and terrestrial ecosystems is necessary for:

- the development of a conceptual model/understanding of the hydrogeological system;
- the determination of the available groundwater resource;
- the assessment of quantitative status; and
- the assessment of groundwater chemical status.

The degree of precision and confidence needed in this understanding will depend on the risks of failing to meet the objectives for the body of groundwater and the implications of errors in an assessment of groundwater status.

Figure 5.12 outlines a series of steps that may be used to develop an initial understanding of where and how groundwater may interact with surface waters, and in particular river water bodies. This initial understanding should be tested and improved to the extent needed to provide an appropriate level of confidence in the assessments that depend on it. For example, where abstraction and pollution pressures are low, a generalised estimate of the extent of interaction is likely to be sufficient to enable a conceptual model/understanding of the interaction of groundwater and surface water to be developed and then tested using a water balance (see Section 1).

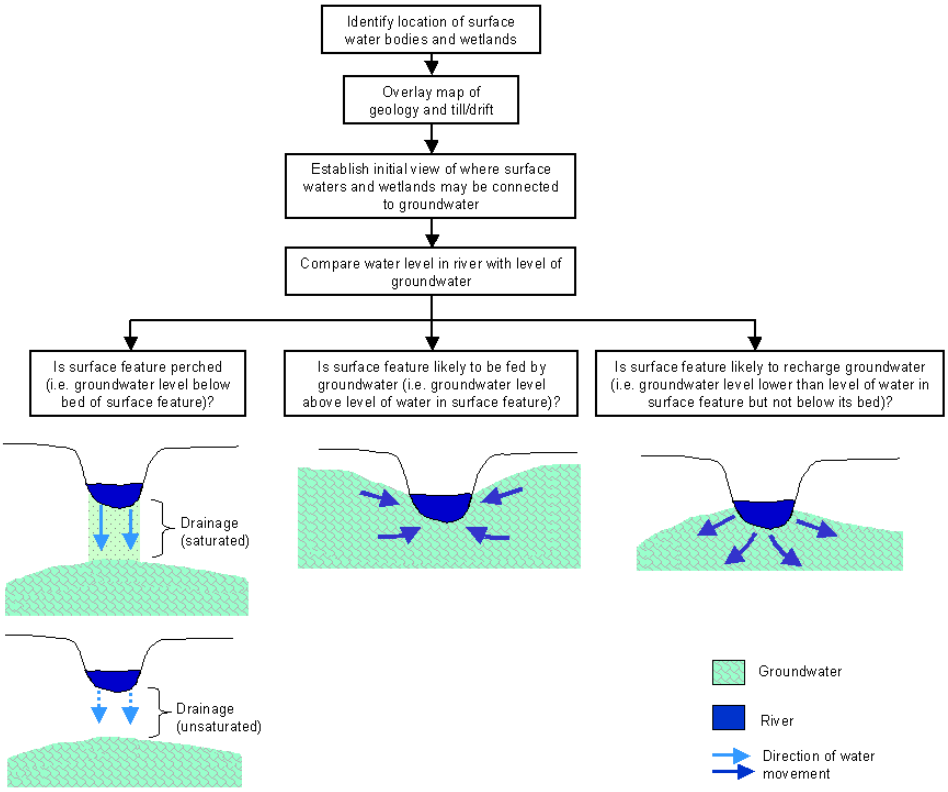

Figure 5.12 Suggested steps in the development of an understanding of the locations and types of interaction between groundwater and surface ecosystems.

Different approaches to testing the understanding of groundwater interactions with surface waters will be appropriate in different geological settings and for bodies subject to different pressures and associated risks of failing to achieve their objectives. Figure 5.13 lists some general approaches and the circumstances in which they may be appropriate.

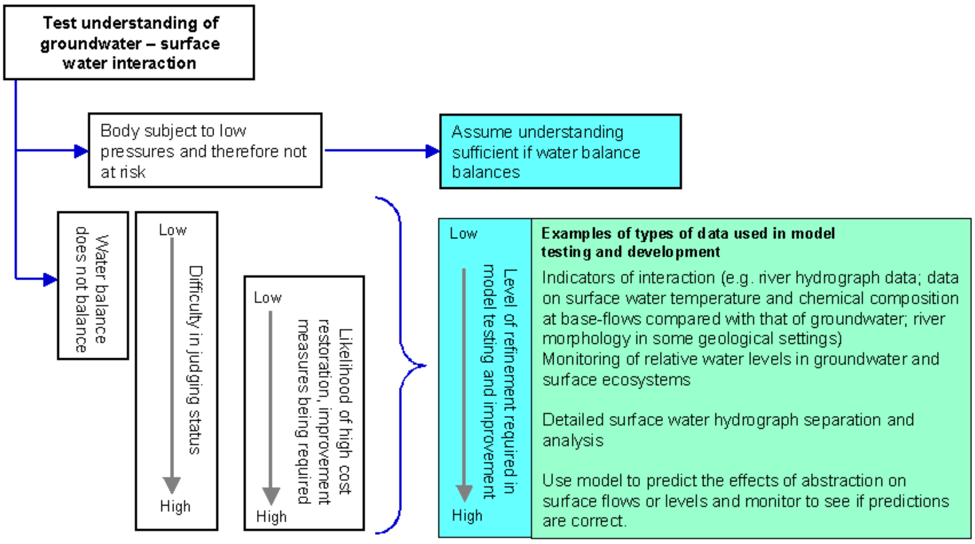

Figure 5.13 Approaches to testing and developing initial assessment of groundwater interactions with surface waters

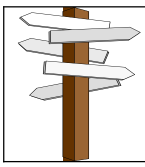
5.3.6 Where to get further information

Interactions with rivers

To achieve 'good' status, the Directive requires the control of abstractions that could cause a significant diminution in the ecological or chemical quality of a surface water or significant damage to a directly dependent terrestrial ecosystem. An important means of testing a conceptual model/understanding of how groundwater interacts with surface water and terrestrial ecosystems is to use it to predict the effects of an abstraction on water flows and levels in the surface ecosystems, and then use monitoring (e.g. in conjunction with a pump test) to see if the predictions made by the model were correct.

A system has been developed in the UK called 'Interaction of Groundwater Abstraction and River Flows' for providing a consistent means of using a conceptual model/understanding to predict the effects of an abstraction on river flows (e.g. design of pump tests etc). Monitoring to see if the predicted effects have occurred provides information for assessing the accuracy and precision of the conceptual model/understanding and for helping to improve the model if required.



Interaction of Groundwater Abstraction and River Flows (IGARF)] Environment Agency, Bristol England. [Will be available from web site: www.environment-agency.gov.uk in early 2003].

Interactions with terrestrial ecosystems

An assessment of groundwater body status also requires an understanding of how groundwater interacts with terrestrial ecosystems. As with surface water interactions, this requires the development and testing of a suitable conceptual model/understanding. It also requires information on the dependence of those ecosystems on the quality and the levels and flows of groundwater. The level of detail required in an estimate of the water needs of terrestrial ecosystems will depend on the likelihood of (a) those water needs being significantly affected, given the pressures on the body of groundwater, and (b) potentially costly improvement and restoration measures being required. Generic, orders of magnitude estimates of water needs may be adequate where risks are low. Where risks are high, specific research to establish the water needs of the terrestrial ecosystems may be required.

	A guide to monitoring water levels and flows at wetland sites (2000). Environment Agency, Bristol, England (Website: www.environment-agency.gov.uk)

How to measure available groundwater resource

Good quantitative status requires that the available groundwater resource is not exceeded by the long term annual average rate of abstraction and that any alterations to groundwater levels resulting from human activities have not resulted, and will not result, in (i) a failure to achieve any of the environmental objectives for associated surface water bodies; (ii) any significant diminution in the status of those bodies; nor significant damage to terrestrial ecosystems directly depending on groundwater.

The estimation of the available groundwater resource requires:

- an appropriate conceptual model/understanding of the groundwater body tested using a water balance; and;
- an estimate of the groundwater flow/levels needed by associated surface water bodies and directly dependent terrestrial ecosystems to achieve the criteria described above.

The steps involved in the estimation are illustrated in Figure 5.14. The accuracy and precision needed in the conceptual model/understanding and in particular the estimates of groundwater recharge and surface water - groundwater interaction it provides, will depend on the difficulty in judging whether the recharge to the body of groundwater, less the water needs of surface ecosystems, exceeds the rate of abstraction (see Figure 5.15). For example, for groundwater bodies, or groups of bodies, subject to only small groundwater abstractions (e.g. the recharge and river base-flow greatly exceed the rate of abstraction), orders of magnitude estimates of recharge and river flow needs are likely to be sufficient for testing the water balance, determining the available groundwater resource and assessing quantitative status.

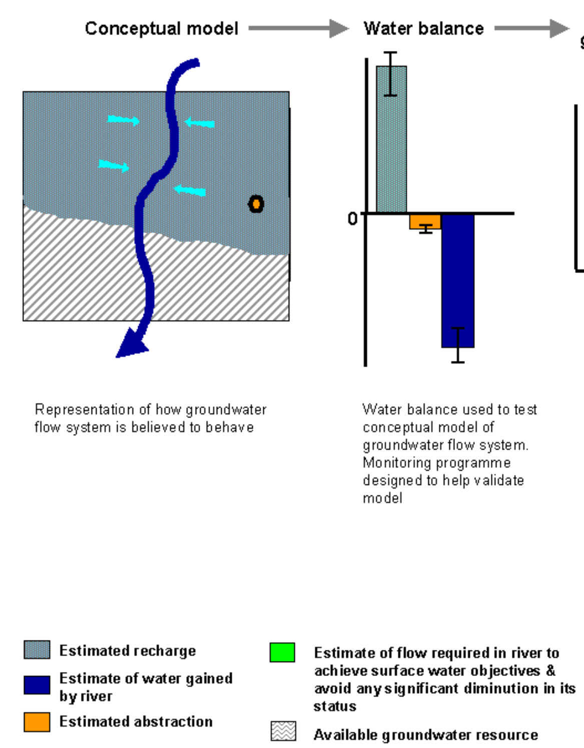


Figure 5.14 Illustration of the steps involved in estimating the available groundwater resource for a body of groundwater

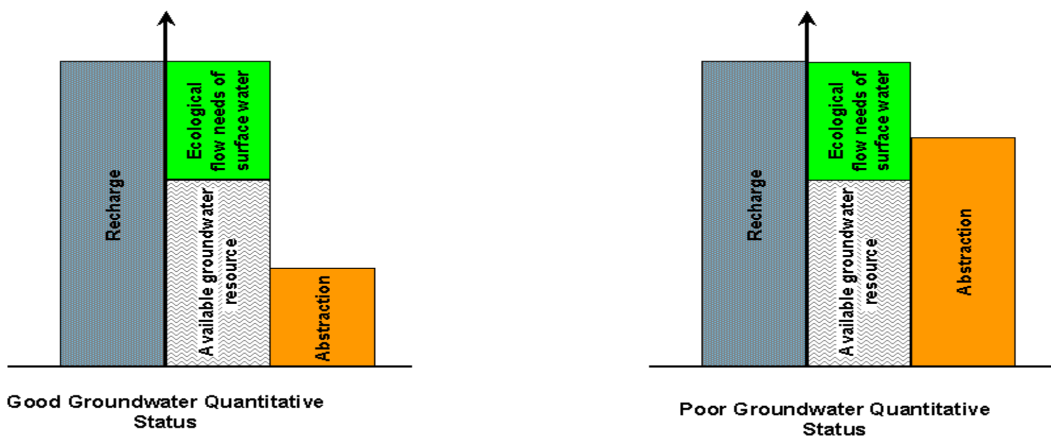

Figure 5.15 Illustration of bodies at poor and 'good' status in terms of the requirement to have a positive available groundwater resource once abstractions have been taken into account.

Approaches to estimating flow across Member State boundaries

The Directive requires Member States to estimate groundwater flows across their boundaries. This is a separate requirement from the assessment of the status of bodies of groundwater. It will provide management information to Member States on how groundwater and its associated surface ecosystems may be affected by pressures in neighbouring States, and therefore how the measures needed to achieve the Directive's objectives should be apportioned between those States.

To provide estimates of flows across a national border, conceptual models/understandings tested using water balances will be needed for the groundwater systems on both sides of the border. The degree of accuracy and precision needed in such models will be proportionate to the difficulty in reliably judging the status of water bodies on either side of the border and in assessing the achievement of other relevant objectives, and should be such as to enable effective measures to be designed.

5.3.7 Application of CIS 2.8 Guidance in trend analysis

Summary of Technical Report No. 1 (CIS Working Group 2.8)

One of the focuses of Technical Report No. 1 prepared by CIS Working Group 2.8 was the development of particular statistical methods for the identification of upward trends in pollutants and the reversal of trends in accordance with Annex V 2.4.4 of the Directive. The Guidance also outlines the monitoring design considerations needed to provide suitable for time series data trend analysis.

The main results of CIS Working Group 2.8 (www.wfdgw.net) consist of the:

- Development of an appropriate data aggregation method for the assessment of groundwater quality at the groundwater body level respectively for groups of groundwater bodies including the determination of minimum requirements for calculation; and,
- Development of an appropriate statistical method for trend assessment and trend reversal including the determination of the minimum requirements for calculation.

The following general requirements are met by the proposed statistical procedures:

- Statistical correctness;
- Development of a pragmatic way;
- One data aggregation method suitable for small, large and groups of GW-bodies as well as for small GW-bodies with few sampling sites; and
- Applicability for all types of parameters.

The Guidance also outlines the monitoring design considerations for providing suitable data for chemical status assessment and time series data for trend analysis. All results are expressed at a certain level of confidence.

Application of Technical Report No. 1

Figure 5.16 below illustrates the role of Tecnical Report No. 1 in the assessment of trends in pollutant concentrations in groundwater.

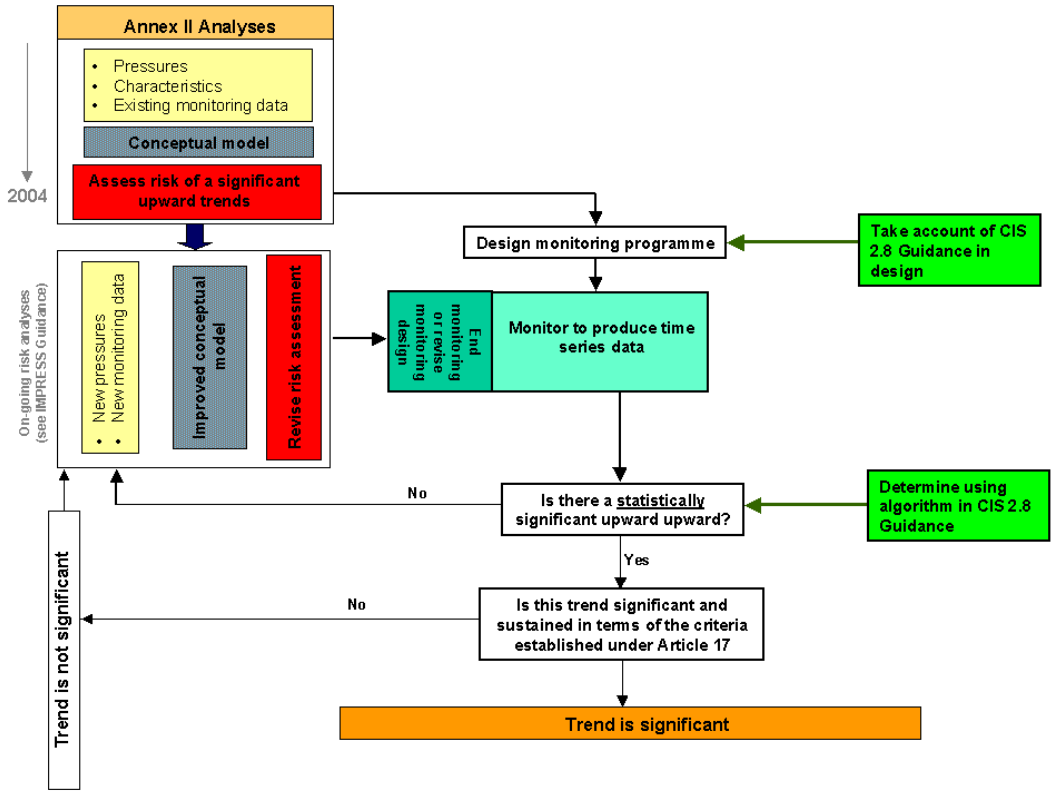

Figure 5.16 Use of CIS 2.8 Guidance in trend analysis

The Article 17 Daughter Directive is expected to establish criteria for the identification of significant and sustained upward trends. Until these criteria have been established, Member States must decide whether a trend is significant and sustained according to their own criteria. In developing such criteria, Member States should take into account the purpose of the trend reversal objective, which is to progressively reduce pollution of groundwater [Article 4.1(b)(iii)].

5.3.8 Drinking Water Protected Area Monitoring

One of the objectives for drinking water Protected Areas is to avoid deterioration in groundwater quality in order to reduce the level of purification treatment. Compliance with this objective can be simply monitored by assessing changes in the quality of abstracted water prior to any purification treatment. However, the design of the protection measures needed to ensure that the objective is achieved will require a means of predicting which pressures could cause a deterioration in the quality of the abstracted water. An appropriate conceptual model/understanding for the Protected Area will be necessary to enable such predictions. The complexity of any such model should be proportionate to the likely risks to the achievement of the objective. Where risks are minor (e.g. because pressures are low or the soil and sub-soils are impermeable) a simple conceptual model/understanding will be sufficient (Figure 5.17). Where the risks of quality deterioration are high, a more accurate and precise conceptual model/understanding, which includes more detailed consideration to groundwater flow characteristics, will be required, and monitoring data will be needed for its validation.

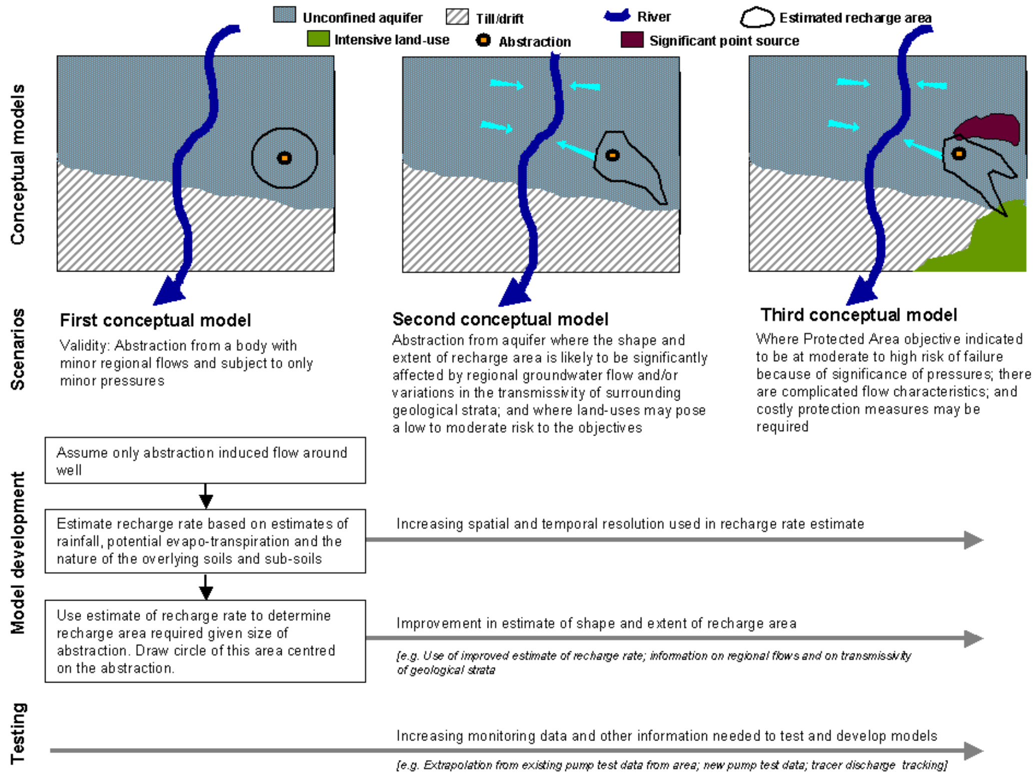

Figure 5.17 Development of conceptual models/understandings for drinking water protected areas.

6 Best Practice Examples for Using the Guidance

6.1 Contributions from Member States on Monitoring Methods -Fact Sheets

As a result of the third workshop in Brussels, Member States were requested to provide fact sheets on current monitoring methods undertaken in their country, which could be used or developed for the implementation of monitoring programmes in accordance with Annex V of the Directive.

Due to the overwhelming response from a number of countries, it was decided that, rather than include only a selection of fact sheets in the Guidance Document, all fact sheets would be uploaded directly to Circa. These fact sheets are available for Member States to review and use at their discretion.

Each fact sheet provides the following information:

- Details of the water category and quality element;
- Name and brief description of the method;
- Which country proposes the method, and where the method is currently being used;
- If the method provides a comparison to reference conditions/communities, and whether or not this is compliant with the requirements of the Directive;
- If there are existing national or international standards for the method;
- If the method is currently published in scientific literature;
- Applicability of the proposed method for use in implementation of the Directive;
- Relevant references; and
- Contact details to obtain additional information about the method.

Annex IV provides a list of fact sheet contributions, including the fact sheet title, country that has proposed the method and weblinks to the fact sheet.

7 Summary and Conclusions

A common strategy for the implementation WFD was developed in May 2001. The strategy aims provide support to Member States to ensure a coherent and harmonious implementation of this Directive.

An informal working group Working Group 2.7 was established within the CIS to facilitate the production of a practical and non-legally binding Guidance Document to assist Member States with developing surface and groundwater monitoring programmes in accordance with Article 8 and Annex V of the Directive.

The Guidance document provides a common understanding on the monitoring requirements of the Water Framework Directive. Guidance and principles generic to all water categories are provided as well as more specific Guidance on groundwater, rivers, lakes, transitional waters and coastal waters. This is largely based on current best practice in Member States and Norway. In addition, details of current monitoring practices in Member States and Norway are also given with details of national experts that could provide additional assistance.

The Guidance Document proposes an overall pragmatic approach. Because of the diversity of circumstances within the European Union, Member States may apply this Guidance in a flexible way in answer to problems that will vary from one river basin to the next. This proposed Guidance will therefore need to be tailored to specific circumstances. However, these adaptations should be justified and should be reported in a transparent way.

It is recommended that the Commission considers establishing a drafting group to further develop horizontal Guidance on the classification of ecological status of surface waters particularly in relation to Annex V.1.4.2 and Annex V.1.2. This is to do with the interpretation of the normative definition of good ecological status in terms of the physico-chemical quality elements, and the role of physico-chemical and hydromorphological quality elements as supporting the biological quality elements. This issue is also of relevance to Working Groups 2.3 on reference conditions for inland surface waters and 2.4 on typology and classification of transitional and coastal waters.

The Article 17 Groundwater Directive may establish additional criteria for the assessment of groundwater status. This Guidance may need to be updated once such criteria have been established.

Additional monitoring is required for drinking water abstraction points and habitat and species protection areas. However the register or registers of protected areas also includes areas designated as bathing waters under Directive 76/160/EEC, as vulnerable zones under Directive 91/676/EEC and areas as sensitive under Directive 91/271/EEC. These latter Directives also have monitoring and reporting requirements. The EAF on Reporting is considering not only the reporting required under the WFD but also existing reporting requirements with the aim of 'streamlining' the reporting process. The Working Group on Monitoring also recommends that ways of integrating, rationalising and streamlining the monitoring requirements under the other Directives should also be considered in future work that might revise this draft Guidance Document.

It is recommended that appropriate standards are developed as a matter of priority and urgency for those aspects of monitoring for which there are no internationally agreed standards or techniques/methods.

It is anticipated that the Guidance can be further developed by work undertaken in the next phase of the Common Implementation Strategy, for example, by the development of further horizontal Guidance on some aspects, and in the light of experience gained during the pilot basin testing phase.

ANNEX I GLOSSARY

Glossary of terms (excluding terms already defined in Article II of the Directive).

Term	Definition
Common Implementation Strategy	The Common Implementation Strategy for the Water Framework Directive (known as the CIS) was agreed by the European Commission, Member States and Norway in May 2001. The main aim of the CIS is to provide support in the implementation of the WFD, by developing a common understanding and Guidance on key elements of this Directive. Experts from the above countries and candidate countries as well as stakeholders from the water community are all involved in the CIS to: • Raise awareness an exchange information; • Develop Guidance Documents on various technical issues; • Carry out integrated testing in pilot river basins; and A series of working groups and joint activities has been developed to help carry out the activities listed above. A Strategic Co-ordination Group (or SCG) oversees these working groups and reports directly to the Water Directors of the European Union, Norway, Switzerland, the Candidate Countries and Commission, the engine of the CIS. For more information refer to the following website: http://europa.eu.int/comm/environment/water/water-framework/index_en.html.
Conceptual Model	A conceptual understanding of the interrelationships occurring within a system. The conceptual model graphically describes how experts believe the system behaves. Once developed the model is continuously refined as scientists obtain an improved understanding of the water bodies concerned and their vulnerability to pressures.
Confidence	The long-run probability (expressed as a percentage) that the true value of a statistical parameter (e.g. the population mean) does in fact lie within calculated and quoted limits placed around the answer actually obtained from the monitoring programme (e.g. the sample mean).
Ecological Quality Ratio	Ratio representing the relationship between the values of the biological parameters observed for a given body of surface water and values for these parameters in the reference conditions applicable to that body. The ratio shall be represented as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero (Annex V 1.4(ii)).
Impact	The environmental effect of a pressure (e.g. fish killed, ecosystem modified).
Intercalibration	An exercise facilitated by the Commission to ensure that the high/good and good/moderate class boundaries are consistent with the normative definitions in Annex V Section 1.2 of the Directive and are comparable between Member States (see Guidance produced by WG 2.5) (Annex V 1.4. (iv)).

Term	Definition
Monitoring Standards	International or national standards developed to ensure provision of data or an equivalent scientific quality and comparability (e.g. those developed by CEN and ISO).
Parameter	Parameters indicative of the quality elements listed in Annex V, Table 1.1 in the Directive that will be used in monitoring and classification of ecological status. Examples on parameters relevant for the biological quality element composition and abundance of benthic invertebrate fauna are.: number of species or groups of species, presence of sensitive species or groups of species and proportion of tolerant/intolerant species.
Precision	A measure of the statistical uncertainty equal to the half width of the C% confidence interval. For any one monitoring exercise, the estimation error is the discrepancy between the answer obtained from the samples and the true value. The precision is then the level of estimation error that is achieved or bettered on a specified (high) proportion C% of occasions.
Pressure	The direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry of surface and groundwater.
Quality Assurance	Procedures implemented to ensure results of monitoring programmes meet the required target levels of precision and confidence. Can take the form of standardised sampling and analytical methods, replicate analyses, ionic balance checks and laboratory accreditation schemes.
Quality Element	Annex V, Table 1.1 in the Directive, explicitly defines the quality elements that must be used for the assessment of ecological status (eg. composition and abundance of benthic invertebrate fauna). Quality elements include biological elements and elements supporting the biological elements. These supporting elements are in two categories: ‘hydromorphological’ and ‘chemical and physicochemical’.
Risk	2.7 Monitoring: Chance of an undesirable event happening. It has to aspects: the chance and the event that it might happen. These are conventionally called the probability and the confidence.
WFD, The Directive	Directive 2000/60/EC establishing a framework for Community action in the field of water policy.

Managing water resources on the river basin scale as the proper physical unit to account for the interaction between surface water and ground water as well as water quantity and quality. Status: recommended.	?
5	Analysis of characteristics	**FP5 Hydrological and Hydrometeorological Systems for Europe – HYDROMET (FP 4)** Contact persons: Professor M.A.Mimikou, Dr. E.A.Baltas. This project aimed to develop weather radar system for hydrological applications. Status: completed.	?
5	Analysis of characteristics	**FP5 Impact of Climate Change on Hydrological and Water Resource Systems in the European Community (FP 4).** Contact persons: Professor M.A.Mimikou, Dr. E.L.Varanou. This project aims to assess the impacts of climate change on water resources in Northern Greece on a regional basis (catchment scale). Status: completed.	?
5	Analysis of characteristics	**FP5 European River Flood Occurrence & Total Risk Assessment System – EUROTAS (FP 4).** Contact persons: Professor M.A.Mimikou, E.L.Varanou. To develop and demonstrate an integrated catchment model for the assessment and mitigation of flood risk. Status: current.	?
5	Analysis of characteristics	**FP5 Climate Hydrochemistry and Economics of Surface – Water Systems – CHESS (FP 4).** Contact persons: Professor M. A. Mimikou, E. C. Gkouvatsou. This project aims to investigate how expected changes in climate and land cover will affect the quality of freshwater resources in Europe. Status: current.	?
5	Integrated Catchment Management	**FP5 (EVK1) Data assimilation within a unifying modelling framework for improved river basin water resources management (contact Cees Veerman).** The aim of this project is to develop, implement and test a model that incorporates stream channel, land surface and soil components.	2000 - 2001
5	Integrated Catchment Management	**FP5 (EVK1) Integrated evaluation for sustainable river basin governance (contact Leopoldo Guimaraes).** This project aims to develop a set of guidelines for river basin authorities describing an integrated evaluation process, establishing criteria for assessing the sustainability of an evaluation process and providing practical tools to make the guidelines operational.	2001 - 2004
5	Integrated Catchment Management	**FP5 (EVK1) Freshwater integrated resource management (contact Peter Brooks, University of Surrey).** The aim of this project is to improve water resource planning through the use of multi-agent models that integrate hydrological, social and economic aspects of water resource management through the representation of stakeholder decision making.	
8	Determine ecological status .	**EA (E1-S01). Use of macrophytes for environmental monitoring of rivers.** This project aimed to develop a macrophyte-based methodology for monitoring the ecological health of river environments, and assessing their rehabilitation requirements. Status: completed.	?
8	Determine ecological status	**EA (E1D(01)15. Assessment of LIFE scores to link freshwater invertebrate communities to flow conditions.** Status: current.	?
8	Determine ecological status	**EA (E1A (01)02. Implementation of the PYSM system for the ecological assessment of ponds.** The aim is develop a co-ordinated monitoring programme for ponds and small water bodies in England and Wales. Status: current.	?
8	Determine ecological status	**EA (PR W1/017/1). PLANTPACS – A Study into the Feasibility of Producing a Predictive System to Assess River Quality and Ecological Status using Macrophytes.** This project was designed to develop a predictive system for macrophytes in rivers to determine overall environmental quality. Status: completed.	Published January 2000
8	Determine ecological status	**EA (E1-091). Still water ecological classification systems.** This project aims to review ecologically based classification systems that would be applicable to temperate standing freshwaters over 0.5km^2 surface area. Status: current.	04/05/99-31/03/01
8	Determine ecological status	**FP5 TARGET - Integrated assessment tools to gauge local functional status within freshwater ecosystems.** Develop a suite of generic tools for assessing functional status of running water ecosystems, based on modified versions of existing limnological and ecotoxicological tests. Has created	2000-2002

Article	Directive Requirements	Research: Completed / Current/ Recommended	Start/End
		Ecological Quality Manual containing procedures for the selection of tools and interpretation of results within ecoregion studied. Status: current.	
8	Determine ecological status	**FP5. EMERGE European Mountain Lake Ecosystem Regionalisation Diagnostic and Socio-economic Evaluation (contact: Simon Patrick Environmental Change Research Centre UCL).** Assessing the status of remote mountain lake ecosystems following the requirements of the WFD. Provides an evaluation of findings in ecological, environmental and socio-economic terms. Status: current.	2000-2002
8	Determine ecological status	**FP5 (contact: Dr Daniel Hering Institute of Ecology, Department of Hydrobiology University of Essen DE). AQEM, assessment method for defining ecological quality of surface water using benthic macroinvertebrates.** To develop an assessment procedure for rivers that meets the demands of the WFD using benthic macroinvertebrates. System based on fauna of near natural reference streams, new data sets to be comparable. Status: current.	2000-2002
8	Determine ecological status	**FP5 (contact: Prof. Brian Moss, school of Biological Sciences, University of Liverpool). ECOFRAME - Ecological quality and functioning of shallow lake ecosystems with respect to the needs of the WFD.** Shallow lakes are complex systems due to importance of higher plants, and thus pose particular problems for the implementation of WFD. Aims to test robustness of proposed sampling frequencies, to decide best criteria for determination of ecological status (high, good, moderate and worse). Status: current.	2000-2002
8	Determine ecological status	**FP5 (contact: Prof. Edwin Taylor; School of Biological Sciences, University of Birmingham, UK). CITYFISH.** This is a project that is modelling ecological quality of urban rivers: ecotoxicological factors limiting restoration of fish populations. Status: current.	2000 - 2002
8	Determine ecological status	**EPA (contact: Larry Stapleton, Environmental Monitoring and Laboratory Services Division, Ireland). Remote sensing of lakes: improved chlorophyll calibration and data processing.** Project developed aerial remote sensing facility to produce routine chlorophyll estimations for Irish lakes, as well as information on lake macrophytes and catchment land-use. Led to creation of a GIS suitable for lake management purposes. Status: completed.	1995-98
8	Determine ecological status	**EPA (contact: Larry Stapleton, Environmental Monitoring and Laboratory Services Division, Ireland). Ecological assessment of Irish lakes.** Developed field based assessment technique similar to that developed for rivers, to allow lakes to be graded using a range of ecological characteristics – flora, fauna, catchment type, and trophic status. Provided a data set of biological and chemical characteristics and catchment data (land use, rainfall) to investigate associations between patterns of land use and lake nutrient concentrations. Status: completed.	1995-99
8	Determine ecological status	**FP5 Predicting aquatic ecosystem quality using artificial neural networks: impact of environmental characteristics on the structure of aquatic communities (contact Raymond Bastide Universite Paul Sabatier de Toulouse III).** This project aims to develop the methodology for linking environmental characteristics and community structure and at a functional level the sensitivity of organisms and their response to disturbance.	2003
8	Determine ecological status	**FP5 Integrated assessment tools to gauge local functional status within freshwater ecosystems (contact Amadeu Mortagua, Universidade de Coimbra).** The aims of this study, which is based in Portugal, The Netherlands and the UK, are to develop an integrated set of tools for assessing ecological processes that maintain ecosystem services. The bioassays include energy supply, energy consumption and transfer.	2000 - 2003
8	Determine ecological status	**FP5 (EKV1) Towards harmonised procedures for quantification of catchment scale nutrient losses from European Catchments.** The aim of this project is to evaluate 10 tools that are currently used to support policy reporting at national and international level for estimating diffuse losses of N and P across a range of catchment types.	?

ANNEX III SUMMARY OF FACTSHEETS ON CURRENT MONITORING UNDERTAKEN BY MEMBER STATES

Fact Sheet Title	Quality Element	Proposed by
Rivers		
Biological http://forum.europa.eu.int/Members/irc/env/wfd/library?l=/working_groups/wg_2_monitoring/factsheets_monitoring/rivers&vm=detailed&sb=Title		
Determination of the acute lethal toxicity of substances to a freshwater fish (*Brachydanio rerio* Hamilton-Buchanan (*Teleostei, Cyprinidae*))	Fish	Finland
IBGN Expert System	Benthic invertebrate fauna	France
Acidification index	Benthic invertebrate fauna	UK
Fresh water algal growth inhibition test with *Scenedesmus subspicatus* and *Selenastrum capricornutum*	Setting EQS -chronic toxicity data	Finland
HBMWP (Hellenic BMWP) +HASPT+Hindex	Benthic invertebrate fauna	Greece
IBE Extended Biotic Index modified for Italian rivers	Benthic invertebrate fauna	Italy
Environmental Quality Criteria – Benthic fauna - rivers	Benthic invertebrate fauna	Sweden
Determination of the inhibition of the mobility of *Daphnia magna* Straus (*Cladocera, Crustacea*)- Acute toxicity test	Setting EQS -chronic toxicity data	Finland
Protocol for monitoring epilithic diatoms at ECN river sites	Aquatic flora	UK
Protocol for monitoring aquatic macrophytes at ECN rivers sites	Aquatic flora	UK
Electric Fishing	Fish	UK
Swedish fish index	Fish	Sweden
IP (Indice poissons)	Fish	France
Quantitative sampling of fish with electricity	Fish	Sweden
Determination of toxicity to embryos and larvae of freshwater fish – semi-static method	Setting EQS -chronic toxicity data	Finland
IBD (Indice biologique diatomées)	Aquatic flora	France
Biological GQA (General Quality Assessment) classification	Benthic invertebrate fauna	UK
Acidification index based on invertebrates	Benthic invertebrate fauna	Norway
Lotic-invertebrate Index for Flow Evaluation (LIFE) Index	Benthic invertebrate fauna	UK
River Ecosystem Survey	General biological QEs	France
FBI monitoring method – Fish based index, indice poissons	Fish fauna	France
Determination of the inhibitory effect of water samples on the light emission of *Vibrio fischeri* (Luminescent bacteria test)	Setting EQS -chronic toxicity data	Finland
Mean Trophic Ranking (MTR)	Aquatic flora	UK
IBMR (Indice biologique macrophytes en rivière)	Aquatic flora	France
Occurrence of river macrophytes	Aquatic flora	Sweden
Periphyton method in running waters	Aquatic flora	Finland
Guidance standard for routine sampling of benthic algae in swift running water	Aquatic flora	Norway
Diatoms in running waters	Aquatic flora	Sweden

ANNEX V KEY CONSIDERATIONS FOR MONITORING QUALITY ELEMENTS

V1.1 Rivers

V1.1.1 Key considerations for rivers

River systems across Europe are extremely variable in size and structure and, although they have a long and very intense history of study in relation to their responses to an equally varied range of pressures, monitoring the effects of the impacts on biological communities is complex. The choice of the quality elements to be used in the monitoring programmes will improve over time but, in the first instance, choosing the quality elements most relevant to specific pressures will depend on the size of the river system, availability of existing monitoring methods and data-sets, and local knowledge of the significant pressures.

V1.1.2 Key Biological Quality elements

The use of macroinvertebrates to assess the effects of organic pollution of rivers has a long history throughout Europe and, although the details in methodologies might vary from country to country, their use for this purpose is well understood. Currently, this is the most commonly used element for biological classification of rivers in Europe.

More recently methods for using macroinvertebrates as indicators of other pressures including toxic chemicals and alterations in river flows and channel morphology, have or are being developed. The sensitivity of macroinvertebrates to a wide range of impacts makes them a very useful tool for assessing river quality. They are less useful in deep rivers where they may be difficult to sample.

Monitoring macrophyte community structure and biomass is most relevant for assessing the impacts of eutrophication in small to medium-sized rivers. They can be used for assessing the impacts of high flows and flow variation associated with hydropower effects and of stream maintenance. As with macroinvertebrates, they are not widely used in large, deep river systems or in more shallow rivers subject to wide flow variations, such as those subject to the impact of melting snow. Further macrophytes can absent in streams in dense forested areas.

Methods are available and several countries use macrophytes for river quality assessment. A CEN sampling method is currently nearing completion but further work will be needed on the use of macrophytes for the Directive.

Benthic algae currently have limited use in European countries but are valuable under some circumstances, particularly for describing the impacts of eutrophication. Diatoms and filamentous algae have been used most effectively for this purpose.

River phytoplankton species and abundance are important indicators of eutrophication but are limited in their use to large, slow flowing rivers.

The use of fish as indicators of impacts on river systems is relatively uncommon across Europe. Although it is clearly recognised that fish are important indicators of river condition, they are difficult to sample without specialist equipment and the results are difficult to interpret because of their mobility within the river systems, barriers in the river systems, effects of fishery and stocking etc. Care must be taken in choosing the most appropriate indicators of local conditions and impacts, particularly in the case of migratory Salmonids.
