The use of fish as indicators of accidental pollution is an important consideration in setting up monitoring schemes.

V1.1.3 Key hydromorphological elements

The physical structure and flow dynamics of river systems are very important elements for determining ecological quality. All the biological quality elements vary in accordance with their habitat requirements and the processes associated with the hydromorphological quality elements and flow dynamics are highly influential in determining the basic floral and faunal community composition. Of particular importance are the influences of these elements on substrate, the decomposition of organic matter and the extent of interaction with the riparian zone.

Further work is needed to provide better methods to describe the relationships between the biological quality elements and the morphology, river continuity and hydrological regime.

The influence of groundwater inputs to river systems (or loss to groundwater systems and/or irrigation) is also an important issue to be considered under the Directive, both in terms of maintaining the river system and the potential to cause pollution.

V1.1.4 Key physico-chemical elements

Many of the basic physico-chemical quality elements in Annex V of the Directive are basic measures of river condition and like the physico-chemical elements are important influences on natural river systems. These includes temperature, nutrients, salinity and the pH balance. It is important therefore to include measurements of these elements in relation to their natural as well as potential polluting influences. For example, nutrient concentrations outside the expected range of concentrations are likely to cause eutrophication.

The other main quality elements, which need to be taken account of, are the specific pollutants identified as being likely to cause a failure of the biological quality status. These will vary locally and will need to be determined during the analysis of pressures.

V1.2 Lakes

V1.2.1 Influence of eutrophication on ecosystem structure and function

The key element influencing ecosystem structure and function in lakes and reservoirs is anthropogenic eutrophication. Eutrophication, which in principle is a natural, but very slow phenomenon of lakes, contributes to a number of water quality problems such as phytoplankton blooms, reduced recreational aesthetics, hypolimnetic oxygen depletion, reduced transparency and fish kills. It is important to note that the fundamental processes, such as stratification and internal nutrient loading, occurring in natural lakes and artificial reservoirs are similar. However, differences in morphology, hydrology and water residence times need to be recognised before comparisons can be made.

The figure below Figure 7.1 illustrates the major physico-chemical and biological processed occurring in lakes during stratified and mixed conditions.

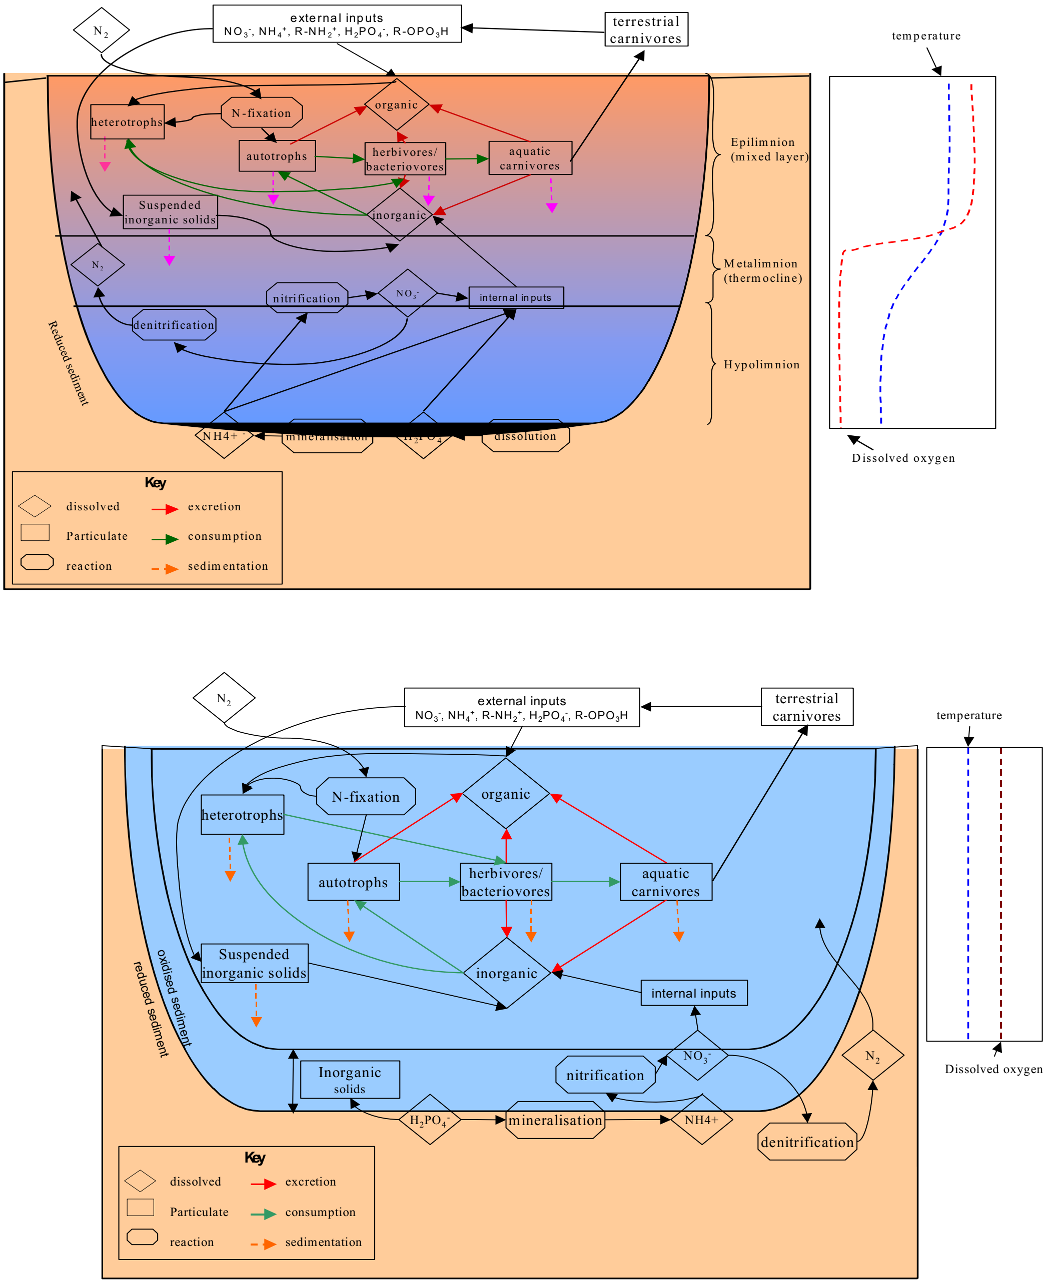

Figure 7.1 **Conceptual model/understanding illustrating the key physico-chemical and biological processes occurring in lakes under stratified and mixed conditions (from Littlejohn 2002).**

V1.2.2 Key biological quality elements

The assessment of phytoplankton diversity, abundance and biomass is of fundamental importance in lakes and reservoirs (Willén, 2000). Phytoplankton growth and distribution is influenced rapidly by physico-chemical changes and excessive blooms of phytoplankton are considered evidence of eutrophication. Chlorophyll-a concentrations can provide a good indicator of phytoplankton biomass and is often a major component of trophic state indices. Attention should, however, be paid to the methods used in analyses. However, due to the number of different methods which can produce variable results as indicated by the findings of the SALMON Project (cf. Premazzi et al., 1999), an important consideration is the standardisation of methodology

Littoral vegetation plays an important role in the regulation of metabolism in lakes and reservoirs. Although the response of macrophytes to pollution have not been previously well documented determination of their composition and abundance are important in defining flow and habitat structure for other biotic elements. Macrophyte communities and associated epiphytic microflora can function as sieves for inorganic nutrients and dissolved organic matter. Large water level fluctuations water level can restrict the development of productive and stabilising littoral flora (Kimmel *et al.* 1990). Therefore, reservoirs (which are the most abundant of lacustrine environments in non-alpine countries like Spain) do not support abundant macrophyte life due to water level fluctuations. This results in a reduction in the nutrient sieving capacity, enabling pelagic processes to assume a greater importance.

Fish have not been frequently used in classification systems due to their behavioral characteristics (e.g. mobility, seasonal upstream or downstream migration and avoidance to pollution). Furthermore, a clear relationship between community structure and ecological quality is not always obvious. For example, stocking programmes can greatly obscure the effects of environmental degradation in that high observed species diversity might be due to the introduction of new fish species. Nevertheless, the composition, abundance and structure of fish communities are useful indicators of long-term ecological impacts as they have long life cycles, are composed of several trophic levels and are relatively simple to identify. Some fish species (as well as mussels) can also be used in monitoring harmful organic substances and heavy metals because they have a high bioaccumulation capacity.

V1.2.3 Key hydromorphological quality elements

Each water body has a unique hydrology that depends on the pluviometric regime and on the morphometry of the river basin. The quantity and temporal patterns of water flow, and hence the residence time, influence the ecology of a water body through nutrient loading, growth of aquatic flora, the maintenance of marginal fish spawning habitat etc. However, natural variability also results from natural and anthropogenic climatic changes.

The quantity and dynamics of flow is greatly influenced by water abstraction and diversion. Furthermore, the addition of water to a lake or river in water supply transfer schemes may be ecologically damaging due to the introduction of water with different chemical and biological characteristics.

Lake morphology, particularly the surface area to depth ratio, is important in the development of littoral zones, to ensure there is adequate sediment substrata available for the establishment of littoral flora. Most European lakes and reservoirs are relatively shallow (mean depth <10m), resulting in a large proportion of the lake or reservoir basin potentially suitable for colonisation by littoral flora. This along with higher sediment deposition rates means that shallow lakes can theoretically support greater numbers of aquatic macrophytes. Wetzel (1990) suggests that based on the evidence of the shallow nature of most of the world's lakes, the global conclusion is that the littoral zone dominates over the pelagic zone.

Increased water residence time leads to greater stability and increased sedimentation of nitrogen and phosphorus and influences the accumulation of sediments and organic matter (Petrere, 1996). Additionally, water residence time governs the time available for biological interactions to occur and influences such factors as sedimentation, resuspension, dilution, diffusion, turbidity and nutrient supply (Soballe and Kimmell, 1987). Small impoundments, such as weirs, generally have low water residence times and the phytoplankton growth and species composition may be influenced by the flushing rate of the system.

Reservoir construction interferes with ecosystems, by creating a physical barrier for fish migration, increasing mean water depth, altering residence times and flushing rates and ultimately impacting on community structure and function (Petrere 1996). Therefore few autochthonous river fishes are found in reservoirs and generally most of the fish fauna has been recently introduced. The introduction of exotic fish species significantly contributes to the destabilisation of fish populations in reservoirs.

V1.2.4 Key physico-chemical quality elements

Different trophic levels create different conditions for lake metabolism, therefore influencing internal nitrogen and phosphorus cycling through altering the redox state of the sediment-water interface. Low primary production in oligotrophic lakes means that oxygen demand is not sufficient to cause complete deoxygenation of the hypolimnion during the stratification period. Alternatively, the flux of organic matter to the sediments may be significant in eutrophic waters increasing the sediment oxygen demand, leading to complete hypolimnetic anoxia.

Anaerobic conditions limit the diversity of hypolimnetic organisms, and can have a detrimental affect on the quality of fisheries. Low levels of dissolved oxygen at critical times of the year hinder the movements of migratory fish, which in turn may affect breeding success. Therefore monitoring temperature and oxygen are key elements for the determination of stratification/mixing regimes, and the level of biological productivity and respiration rates. Oxygen conditions have been used to characterise lake trophy and can be related to nutrient loading (OECD,1982).

Phosphorus, and to a lesser extent nitrogen, are the nutrients limiting algal growth in lakes and hence monitoring is essential to support the assessment of ecological status. Nutrient monitoring should provide an indication of general trophic conditions and enable discrimination of pollution sources (e.g. point and diffuse). Therefore, in order to provide adequate discrimination, monitoring should include the major forms of nitrogen and phosphorus, including dissolved and particulate and organic and inorganic forms. Additionally, the measurement of silicate ($Si\text{-}SiO_3$, $\mu g/L^{-1}$) may be a useful indicator of potential growth of diatoms.

V1.3 Transitional Waters

Aspects and features of the different quality elements to be monitored are summarised in the Tables 3.7-9.

V1.3.1 Biological Quality Elements

NOTE: see section V1.4.1 (coastal waters) of Annex V

Phytoplankton

Particularly relevant is the identification of nuisance or potentially toxic species, if they are typical for the transitional water studied. The main difficulties in using phytoplankton as a quality element for transitional waters with pronounced tides are represented by the extremely high natural spatial and temporal variability of the planktonic communities which may make phytoplankton monitoring a useless exercise in some transitional waters. The use of size fraction and size spectra may overcome the problems of taxonomic identification and intercalibration, but still require a standardisation of methods In shallow environments, the structure of phytoplankton community can be influenced by the resuspension of benthic microalgae, mostly due to wave and wind.

Seasonal monitoring is suited representing the phytoplankton community variability when seasonal patterns are predictable. However, the seasonal frequency applies only for taxonomic analyses. At least monthly samplings for phytoplankton chlorophyll-a should be considered during the vegetation period, weekly sampling would be optimal, fortnightly sampling recommended. Chlorophyll-a analyses give a coarse assessment of the phytoplankton biomass (expressed as $\mu g\ L^-$), therefore parallel sampling for cell identification and counting should be collected and stored. In case of significant month-by-month changes of chlorophyll-a the stored samples might be used for taxonomical analyses. In addition to the chlorophyll-a analysis, the direct water colour can also give important information, namely the coloured waters are symptoms of typical blooms (e.g., red waters for dinoflagellates, etc.).

Macroalgae (seaweeds)

The main difficulties in using macroalgae as a quality element are represented by the ephemeral behaviour of these quality elements undergoing some spatial and temporal variability which bias monitoring, however, to a much lesser extent than in case of phytoplankton. Therefore in some transitional waters, macroalgae and other macrophytes such as angiosperms may be better suited for monitoring the ecological quality than phytoplankton.

The sampling frequency should be suited for representing changes in seaweed communities thus be selected on a region- and type-specific level. During the vegetation period, sampling should be carried out fortnightly to monthly.

Changes in community structure and specific biomasses may be rapid and unpredictable due to the ephemeral characteristics of some of the macroalgae, therefore seasonal samplings are not well suited.

The coverage (as a % of the total system area), changes of this area, the frequency of macroalgal blooms, their size together with the community variability are a good indicator of the state the macroalgae and their environment, and can be used as an early warning systems. Qualitative analyses of new species (new forms) can be also performed by site-trained personnel as an additional warning detection.

Angiosperms (seagrasses)

Optional parameters that countries may wish to use in addition are species abundance (as number of individuals per m^2) and biomass (as g dry weight m^{-2}) as well as depth distribution (lower limit of occurrence). Changes in coverage and composition as well as the occurrence of rare or sensitive species may be used as indicators of human, but also natural impact (e.g. storms, ice winters).

The sampling frequency suited for representing changes in seagrass communities in shallow transitional waters is monthly during the vegetation period. Depending on region and assemblage, it may be sufficient to sample twice during the vegetation period (extensive mapping at a time when species identification is most easy, e.g. during the bloom period, followed by a second survey at the end of the vegetation period).

Benthic invertebrate fauna

Optional parameters that countries may use in addition are biomass (usually expressed as g ashfree dry weight m^{-2}) as well as fractionated biomass (size fractions or body size spectra). However, the reliable determination of macrozoobenthic biomass at a representative station requires a very large number of samples (e.g. 200 replicates per station). Apart from natural small-scale variability, the methodological bias is fairly high due to several steps involved (fresh/wet weight, dry weight, ash-free dry weight). A solution could be to use conversion factors derived from reliable time-series taken in the region/type concerned.

A standardisation of methods is still required and there is a lack of quality assurance protocols. On a temporal scale, the sampling frequency suited for representing changes in benthic invertebrate communities in shallow transitional waters should be selected on a regional/type-specific basis. Sampling should take place at least twice per year (spring and autumn) A recommendable approach for transitional waters in temperate areas (e.g. river Elbe) is fortnightly sampling during spring/early summer (April–June) followed by 2-3 samplings in August/September. In other areas (e.g. Mediterranean), seasonal sampling might be preferable. Recent attempts to apply statistical analyses to the higher taxonomic levels or on species pooled into ecological or trophic guilds have been successful.

Fish fauna

For classifying the ecological status, the limnological classification scheme based on indicator fish species could be used. Sound abundance estimates require long time series due to high variability. In general, the species composition (do typical and specially sensitive species including migrating species and spawning schools[48] occur as to be expected) of transitional waters seems to be most appropriate for WFD purposes; abundance or biomass are not good in these waters because of high variability.

It should be noted that sampling for fish faunal composition and abundance should preferably be carried out at least 2 times per year (spring/autumn) and that for reliable estimates of fish abundance, long time series of at least 10 years are inevitable because of natural variability.

V1.3.2 Hydromorphological Quality Elements

Expertise's suggestion is to consider the hydrological budget a quality element more general than the freshwater flow, which is actually a component of the hydrological budget. Hydrological budget responds to variation of the freshwater flow but also to variation in the sand accumulation vs. sand erosion processes.

Morphological conditions

Refer to same paragraph of Section 1.4.2 (coastal waters).

Depth variations

Refer to same paragraph of Section 1.4.2 (coastal waters).

Structure and substrate of the transitional water bed

Refer to same paragraph of Section 1.4.2 (coastal waters).

Structure of the transitional zone

The structure of the transitional zone can be monitored in terms of structure of the vegetation occurring at the land-water interfaces, as affected by features of the substrate (mud, sand, rock, etc.), of the climatic and hydrologic regimes and of the anthropogenic pressures.

Vegetation coverage, vegetation type and floristic composition are the parameters that can be monitored.

A major problem is that the structure of vegetation is only an indirect indicator of the activity of the transitional zone as a buffering zone for the pressures of the anthropogenic activities in the watershed.

The structure of vegetation can be monitored every three years.

Hydrological budget

The hydrological budget characterizes the different transitional waters, i.e. estuaries, deltas, lagoons, coastal lakes, ports or gulfs, determines the sediment distribution and affects the sensitivity and resilience of transitional water ecosystems. Consequently, the hydrological budget has a major influence on all the quality elements in transitional waters.

Hydrological relevant parameters for an estuary are the volumes entering the estuary during high and low tide (tidal volume). The waterflow (volume and velocity) varies very locally. Subsequently erosion and sedimentation processes are sensitive to anthropogenic measures (LT-process) and extreme events like storm (ST-process). Special attention has to be given to the fish breeding areas between 0 to 5 m water depth and currents below 0.5 m. Monitoring these area's should be included in the program.

Changes in the components of the hydrological budget, due to human activities, are expected to be relatively slow. Therefore, monitoring is recommended every three years.

[48] e.g. of the stickleback (*Gasterosteus aculeatus*)

Monitoring should be performed with data collection on all the freshwater inputs and outputs arranged on a seasonal scale.

V1.3.3 Chemical and Physico-chemical Quality Elements

For all the chemical and physico-chemical quality elements refer to the same paragraphs of section 1.4.3 (coastal waters).

<u>A specific consideration for transitional waters is:</u>

Salinity

It is fundamental to measure the salinity gradient horizontally as well as vertically, especially for the physical delimitation of the transitional zone.

V1.4 Coastal Waters

V1.4.1 Biological Quality Elements

A very important issue when using biological elements as QE is the need of expertise required for taxonomic identification at the species level and the *in-situ* taxonomic resolution limitation.

Appropriately scientifically qualified personnel should carry out the surveys. They should be able to document competence within their specialist field, and participate in ring-testing, when the appropriate routines are available. For investigations spanning several years, priority should be given to continuity in personnel carrying out the recordings.

Phytoplankton

Particularly relevant is the identification of nuisance or potentially toxic species as important assessment parameters. Bloom frequency and intensity is considered an indicative parameter for classification of ecological status.

High natural spatial and temporal variability of the planktonic communities requires frequent sampling to ensure meaningful data for classification or detection of events (blooms). Sampling frequency is determined by the variability, and it is recommended a minimum of monthly sampling with optional increased sampling frequency in seasons with main bloom events. Sampling should be performed together with measurements of chemical and physico-chemical parameters. Seasonal sampling is a minimum frequency.

The minimum sampling frequency required by the Directive is every 6 months; however, available expert knowledge and pilot studies on sampling frequencies could be helpful to set up the most appropriate sampling frequency, number and location of stations on a regional or type-specific level. A selection of region/area-specific phytoplankton indicator species could be useful.

New monitoring programmes for the WFD could build on the existing phytoplankton monitoring programmes for other purposes, as, for example the Shellfish Hygiene Directive (Council Directive 91/492/EEC of 15 July 1991), to ensure best ‘value for money’ in monitoring.

Macroalgae / Angiosperms (Phytobenthos)

It is important to monitor not only their composition and abundance (as requested in the Directive) but also their distributions, extension and variation in time and space (mapping at different needed scales), as it provides important information not only on the health status of the plants’ habitats, but also on the ecosystem stability, as variations may indicate long-term changes in the physical conditions at the site.

Macroalgae are an important region-specific parameter. Macroalgal communities often include a wide range of species/functional groups that may change upon eutrophication e.g. highly diverse algal species can be replaced by opportunistic and stress-resistant seaweeds.

For angiosperms, distribution is the most important parameter because changes are not occurring from month to month. It may therefore be sufficient to monitor angiosperms every 6 months (spring/autumn), once a year or even only once every 3 years, depending on the species.

Supplementary variables essential for interpretation of macrophytobenthos results include: substrate type, depth in relation to sea level or standard datum, slope and bearing, presence of loose sediment, degree of wave exposure, tidal range, Secchi disk depth, and salinity.

Benthic invertebrate fauna

The required parameters to be measured are composition and abundance. Important variables to be considered are also diversity of species and presence of sensitive or higher taxa as well as biomass, the latter being indicative of eutrophication phenomena.

Recent studies in taxonomic classification have shown that looping species into higher taxa (including morphological categories) does not necessarily limit the sensitivity of animal assemblages to detect impacts.

It should be noted that sometimes it is difficult to show a clear correlation between possible changes found in the benthos (e.g. long-term changes in zoobenthos species composition) and eutrophication. Biomass may be a better parameter though not mandatory for WFD monitoring. Therefore it is recommended to include biomass as optional monitoring parameter. Furthermore it should be noted that other factors, e. g. fisheries, may have an overriding effect compared with eutrophication effects. A distinction should be made between acute, direct effects on the benthos (e. g. directly related to dredging or oxygen deficiency and/or toxic blooms) and long-term changes. Both may need different sampling frequencies and spatial coverage.

V1.4.2 Hydromorphological Quality Elements

Morphological conditions

The morphological characteristics of coastal areas are generally subjected to low variability due to natural large-scale bottom dynamics processes or changes in tidal regime and weather patterns.

Relevant for ecological status is the time scale of the changes resulting from human impact in the past. A time scale of 10 to 25 years means that relevant changes in hydro morphological conditions have an impact on ecology. In addition sea level rise makes it necessary to adapt the monitoring frequency and spatial scale to analyse the processes and to find the sand budgets in coastal zone, sheltered seas and estuaries.

Monitoring the trends in depth gradients has to take into account water management measures like dredging and dumping activities and naturally induced variability, under particular weather conditions such as storm events and ice winters/ice coverage, as well as natural coastal erosion and elevation of the land e.g. Baltic.

Depth variations

The topography of the area (shape, bathymetry, slope) influences the biological communities living in it. Depth variations could be important elements to be monitored in areas where disturbances are expected, anthropogenic changes will have relevance for the status classification of the water body.

Structure and substrate of the coastal bed

Changes in morphological conditions and/or nature of the substratum may exert severe detrimental effects on benthic organisms. Differences between communities in coastal zones and estuaries are linked to a coastal typology (see link with CIS WG 2.4):

Possible causes of anthropogenic alterations in structure, substrate and shape of the coastal bed are:

- coastal constructions (dredging, dumping, dams, artificial reefs, etc.); and
- variations in riverine sediment inputs (solid transport regime) due to human impact.

For depth variation and structure and substrate of the coastal bed it may be sufficient to collect the required information once (e.g. a map of the coastal bed) and to record:

- at each sampling carried out after first thorough survey: typical parameters (e.g. nature of substratum) and obvious changes (e.g. visible changes after big storm events); and
- changes due to anthropogenic impact (e.g. dam construction).

A thorough survey should be repeated in regular, but longer intervals (e.g. once per management period or longer, depending on parameter).

Structure of the intertidal zone

As for the structure of the intertidal zone, it cannot be used as a quality element in the Mediterranean and the Baltic ecoregions, given the low amplitude of tides in the Mediterranean basin and in the Baltic Sea.

Thus it has been proposed to introduce the intertidal***/mediolittoral*** term as its ecological relevance is due to the fact that it comprises living assemblages that require or tolerate immersion but cannot survive permanent or semi-permanent immersion (same definition for the intertidal). Thus mediolittoral zone supports diverse and very productive assemblages of algae and invertebrates that can be considered analogues to those of intertidal habitats.

Possible causes of anthropogenic alterations in structure, substrate and shape of the intertidal are:

- coastal constructions (dredging, dumping, dams, artificial reefs, etc.);
- chemical inputs (nutrients) leading to a change in the composition of macroalgal communities; and
- variations in coastal or riverine sediment movements (sediment transport regime) due to human impact.

Mediterranean experts' judgements suggest to focus particular attention on the structure and condition of the mediolittoral and upper infralittoral zones in tideless seas, at least in the Mediterranean, since several species and communities thriving in this area are very good biological indicators, as exposed to a wide range of anthropogenic impact due to their critical position at the interface between the sea and the land.

Tidal regime

Tidal regime in terms of direction of dominant currents and level of wave exposure can be seasonally predictable and are available from most of the National Hydrographic Services. Deviations from the natural pattern in tidal regime derive from direct anthropogenic intervention on the profile of the coastline and may have severe bearings on the stability of the biological assemblages, thus they need to be taken into consideration. Asymmetry in the tidal waves results in positive or negative yearly budgets of sediments.

Due to the low tidal range in the Mediterranean and Baltic Seas, tidal currents play a very minor role, if any. It is the case also in part of North Sea e.g. Skagerrak.

Direction of dominant currents

The direction and intensity (speed) of currents represent the main hydromorphological quality elements influencing the biological elements. They could be important elements to be monitored in areas where anthropogenic disturbance could be relevant for the status classification of the water body.

These parameters assume quite a relevant importance in those ecoregions and specific areas where the tidal range being very low poorly influences the coastal processes.

Mainly changes in hydrodynamics induced by morphological changes will result in relevant ecological effects. Temporal changes (storms, anthropogenic activities) could be balanced in the time scale of 5-6 years. On local scales this could not be the case. Monitoring should take into account these short term-effects.

Wave exposure

Wave exposure (wave height, wind, Fetch-index) varies considerably according to coastal typology (from highly exposed to very sheltered) and meteorological conditions, in the different ecoregions. Parameters to be monitored in case of anthropogenic disturbances are e.g. frequencies of storms, directions, high/low tide surge levels.

V1.4.3 Chemical and physico-chemical Quality Elements

In most of the EC countries, all these parameters (with the exception of specific pollutants) are routinely measured as part of their national monitoring programmes, with a variable frequency (weekly to monthly), using national guidelines or OSPAR/HELCOM standards.

Transparency

Transparency is mainly affected by mineral turbidity, organic pollution (e.g. urban discharges) and eutrophication; it can naturally vary due to local hydrodynamics, river discharge and seasonal plankton blooms.

The transparency parameter is necessary for the determination of the depth of the euphotic layer, where primary production exceeds respiration. Measurement is difficult in “troubled waters”, e.g. the NE Atlantic Wadden Sea with high loads of resuspended sediments.

Thermal conditions

Temperature profiles along the water column can be easily obtained by means of *in situ* autographic instruments. The thermal structure of the water column is a relevant information for assessing mixing/stratification conditions, which strongly influence primary production as well as possibly the development of oxygen deficiency.

Oxygenation conditions

Dissolved oxygen concentration is subjected to high natural variability since its solubility depends on temperature and salinity. Deviation, in absolute value, of % saturation from 100% is indicative of intense primary production and/or organic pollution.

Salinity

Salinity in coastal waters can be subjected to high natural variability due to freshwater inputs and mixing of water masses, and due to tidal currents.

Salinity measures in coastal waters can be used to detect freshwater ingressions from the continent; the dilution rate of nearshore waters varies considerably in different areas and can be used, together with other quality elements to indicate potential pollution.

Nutrient conditions

The concentration of nutrients, together with the concentration of chlorophyll ‘a’, indicator of actual production, provide information on the general trophic conditions.

Natural variability of nutrient concentrations can be relevant on a seasonal basis; in coastal waters, high nutrients concentration, mainly related to riverine inputs, are indicative of eutrophication and/or organic pollution.

In order to enable discrimination of pollution sources, the following parameters should be analysed:

- Total Phosphorous (TP, $\mu g\ L^{-1}$)
- Soluble Reactive Orthophosphate (P-PO4, $\mu g\ L^{-1}$)
- Total Nitrogen (TN, $\mu g\ L^{-1}$)
- Nitrate+Nitrite (N-NO3 + N-NO2, $\mu g\ L^{-1}$)
- Ammonia (N-NH4, $\mu g\ L^{-1}$)
- An additional parameter is silicate (Si-SiO3, $\mu g\ L^{-1}$), which is a growth requirement for Diatoms.
- For a better understanding of nutrient cycling in coastal waters, the following supplementary parameters are recommended:
  - Particulate Organic Carbon (POC-C, $\mu g\ L^{-1}$)
  - Particulate Organic Nitrogen (PON-N, $\mu g\ L^{-1}$)
  - Particulate Organic Phosphorous (POP-P, $\mu g\ L^{-1}$)

Nutrient ratios (N/P/Si) are useful for the interpretation of results and eutrophication status.

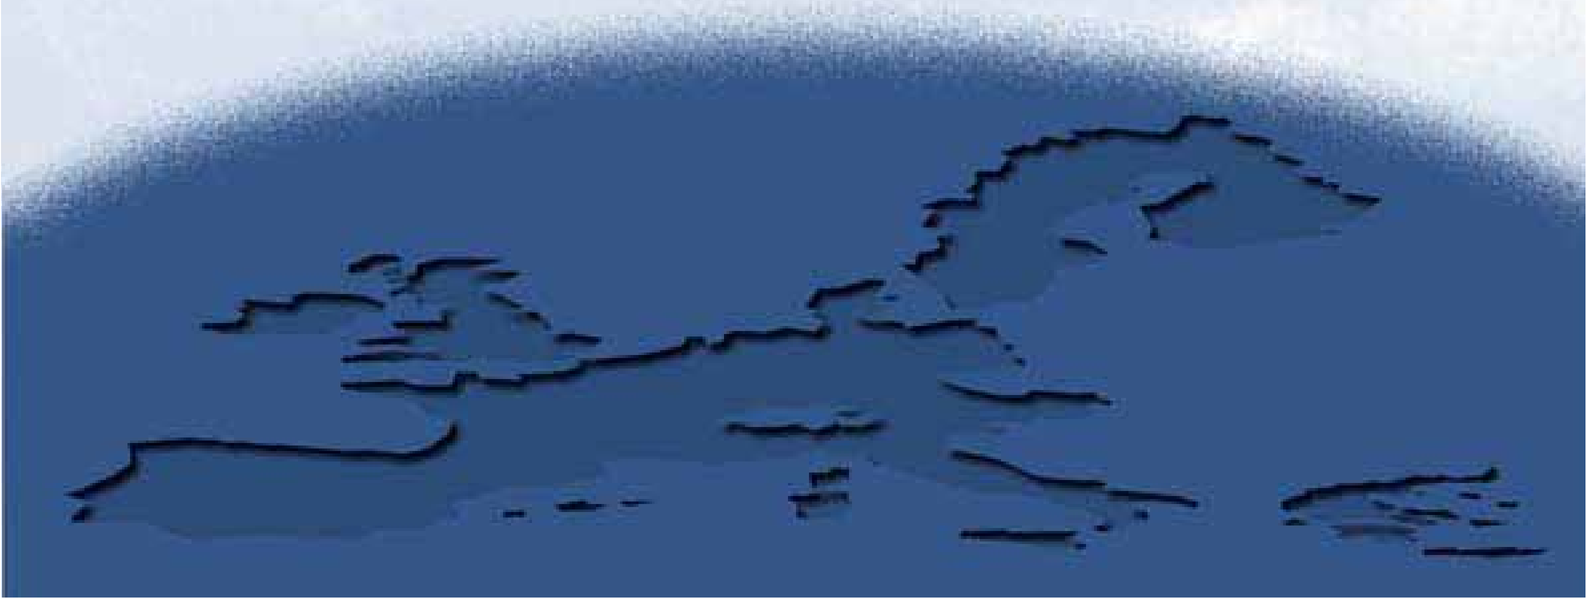
Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 8

Public Participation in relation to the Water Framework Directive



COMMON IMPLEMENTATION STRATEGY FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 8

Public Participation in Relation to the Water Framework Directive

Produced by Working Group 2.9 – Public Participation

Luxembourg: Office for Official Publications of the European Communities, 2003

ISBN 92-894-5128-9
ISSN 1725-1087

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology are therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, an informal working group dedicated to the issues of public participation of the Water Framework Directive has been set up in October 2001, under working group 2.9 (on the Best practices in river basin management planning). The Netherlands, Spain and the Commission are responsible for the secretariat and animation of the working group that is composed of experts from governmental and non-governmental organisations.

The present Guidance Document is the outcome of the informal working group on Public Participation. It contains the synthesis of the output of the group activities and discussions that have taken place since October 2001. It builds on the input and feedback from a wide range of experts and stakeholders that have been involved throughout the process of guidance development through meetings, workshops or electronic communication media, without binding them in any way to its content.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Danish Presidency in Copenhagen (21/22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leaders, the Netherlands and Spain, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

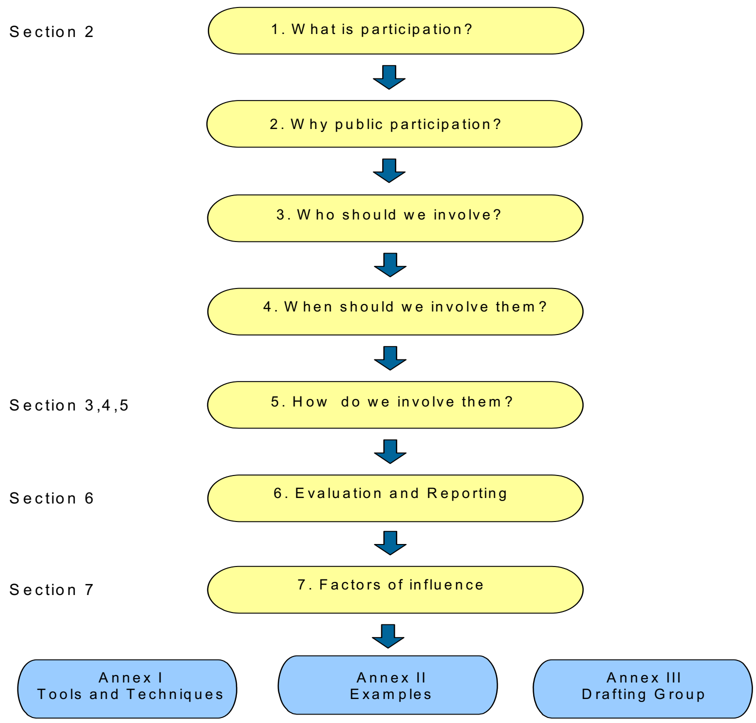
Executive summary

Purpose of this Guidance Document

This Guidance Document aims at assisting competent authorities in the Member States and Accession Countries with the implementation of Article 14 of the Water Framework Directive about Public Participation. This document can also benefit stakeholders and general public by informing them about the public participation process, encouraging them to engage in river basin management planning explaining what can be expected and outlining opportunities. This Guidance is horizontal Guidance since it is of concern to most activities under the Common Implementation Strategy for the Water Framework Directive.

This advisory and non-binding document has been developed by an informal European drafting group of experts and stakeholders under working group 2.9: Best Practices in River Basin Planning in the context of the Common Implementation Strategy for the Water Framework Directive. A list of members of the drafting group and contributing authors can be found in Annex III of this Guidance.

What can you find in this document?



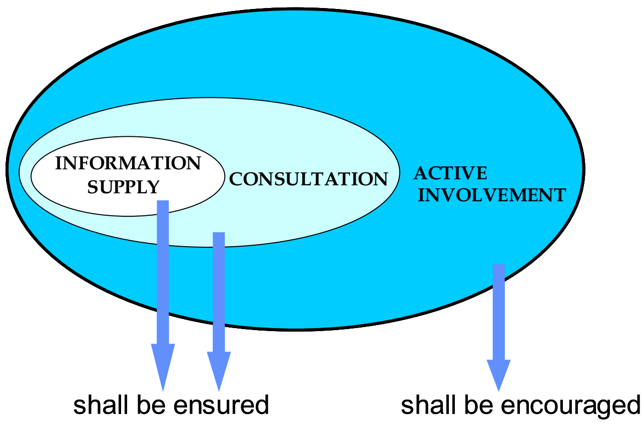
This Guidance starts with creating a *common understanding* regarding the meaning of public participation in the context of the Water Framework Directive (**Section 2**). Public participation can generally be defined as allowing people to influence the outcome of plans and working processes. It is a means of improving decision-making, to create awareness of environmental issues and to help increase acceptance and commitment towards intended plans. Public participation for the implementation of the Directive is recommended at any stage in the planning process, from the Article 5 requirements to the Programme of Measures and the design of the River Basin Management Plan.

After setting out a common understanding of public participation in the context of the Directive, the Guidance gives specific help on how to implement public participation in the different steps of the management process. The general planning steps to be undertaken are indicated in **Section 2.8** and elaborated for public participation in **Sections 3, 4 and 5.**

Although the phrase "public participation" does not appear in the Directive, three forms of public participation with an increasing level of involvement are mentioned:

- Information supply;
- Consultation; and
- Active involvement.

According to the Directive, the first two are to be ensured, the latter should be encouraged. Although the Directive does not require active involvement, this Guidance shows how active involvement can be very useful for reaching the objectives of the Directive. These three forms can be interpreted as being "public participation", although public participation usually covers a wider range of activities than prescribed by the Directive.



Who should we involve? The Directive is prescriptive in the sense that at least stakeholders (i.e. interested parties) should be involved when dealing with active involvement and also the public when dealing with consultation. Background information should be available at any time for anyone. A stakeholder analysis as described in **Annex I** will help to identify the stakeholders "who have something at stake" in the process and could be involved. A stakeholder will generally have an interest in an issue because he/she or it is either affected or may have some influence.

To avoid disappointing the parties involved it is very important to make clear which form of public participation is dealt with and what the role of those involved is. Also it should be borne in mind that Member States are responsible for the public participation process since they are responsible for achieving the objectives of the Directive. A clear signal should be given that *no blue-print exists for public participation* and that the public participation process should be organised and adapted to national, regional and local circumstances. **Annex I** gives examples of *tools and techniques*, which support the process in a practical way. Ingredients for organising a public participation process are given in the main text of this Guidance. **Annex II** gives several *examples* of public participation that are related to different scales and different forms of public participation. Collectively, this information should make it possible to design a tailor-made public participation process at any level in the River Basin District.

With regard to *timing* (**Section 2.6 and 2.8)** public participation should be started early in the river basin planning, today rather than tomorrow in order to establish a good public participation process and allow integration of ideas, comments and input from stakeholders along the way. Moreover, early involvement will most likely prevent the competent authority from ending up with a river basin management plan on which no consensus can be achieved by 2009. The Directive mentions the following deadlines concerning consultation (with a repetitive cycle of 6 years for future river basin management plans):

December 2006 at the latest July 2007	Time table and work programme for the production of the plan, including a statement of the consultation measures to be taken; Comments in writing.
December 2007 at the latest July 2008	Interim overview of the significant water management issues identified in the river basin; Comments in writing.
December 2008 at the latest July 2009	Draft copies of the river basin management plan available; Comments in writing.
December 2009 at the latest	Start implementation of the plan.

The *scale* (**Section 2.7)** at which public participation should take place is not pre-determined. At a local scale the effects of management will be felt more directly and more responses from public and (local) stakeholders can be expected. This input can be aggregated to a higher level to take advantage of local knowledge at river basin or river basin district level. Sometimes the focus should be on a wider area than the one where public participation is undertaken, for example when dealing with measures.

In **Section 3** the significance and practical approach of *active involvement* is elaborated in relation to steps in the planning of the implementation of the Directive. Early active involvement for the identification of the River Basin will raise awareness while involvement in characterisation of the River Basin District will also help to collect data, information and experiences from stakeholders and to identify conflicts or establish common understanding. For the Programme of Measures active involvement is particularly important since it will most likely improve the effectiveness of the implementation and contribute to delivery in the long term.

Section 4 addresses the *3-step consultation* that is foreseen in the Directive (see also table above), trying to indicate practical issues that need to be dealt with when organising a consultation process, either a written or oral consultation process. One of the messages here is the need for clarity about who is being consulted and about what issues and the need for concise information or documents, which will be subject to consultation. Examples of tools for supporting the consultation process can be found in Annex I. Processing comments received and using this input for improvement of the River Basin Management Plan requires a good management plan. Finally it is very important to give feedback to participants.

Access to information and background documents should be secured by the competent authorities. **Section 5** addresses questions like what kind of information should be available, in what way and who will be the one maintaining and disseminating this information. As a minimum the background documents should include all the documents that are summarised in the River Basin Management Plan. Usually on-line information like Internet or e-mail and off-line information like meetings are combined to inform stakeholders and public. One suggestion is to create one central information or knowledge centre in a river basin responsible for information management and dissemination.

During the whole process of public participation *iterative reporting and evaluation* are important tools to make the process transparent for participants. Therefore evaluation should be integrated with the public participation process. In **Section 6** indicators are mentioned that will help reporting and evaluation.

Finally the competent authority (who will often be the manager of the process) should be aware of the fact that any form of public participation requires *capacity building and investment* in order to build relations and understanding between different stakeholders. These and other factors which will help enable a learning approach to public participation are explored in **Section 7**.

A well-managed public participation process is not free of costs and demands time and energy, but it will pay off in the end. Public participation is not an end in itself but a tool to achieve the environmental objectives of the Water Framework Directive. Trust, transparency of process and good management of expectations will help to achieve good participation.

Now just do it!

Table of Contents

Introduction - A Guidance Document: What For?

Look out! What you will <u>not</u> find in this Guidance Document!

The Guidance Document will not provide you with a manual how to exactly perform public participation in your country. Political, organisational and cultural contexts vary a lot from one Member State or Accession country to another and will influence methodologies for public participation. Therefore one blueprint for all States is not possible.

This document focuses on the implementation of public participation in the broader context of the development of integrated river basin management plans as required by the Water Framework Directive.

Public participation is a subject that concerns different steps and phases in the implementation of the Directive and applies to most activities under the Common Implementation Strategy. This Guidance is therefore a *horizontal* Guidance.

To whom is this Guidance Document addressed?

Member States and Accession countries

To create a common understanding and provide guidelines and examples of how to make public participation operational in order to improve the decision making process when implementing the Directive in general, and when developing river basin management plans.

Competent authorities of river basin districts

To support and provide guidance in practice on how, when and at which level to involve the public, water users and stakeholders in order to increase transparency and participation in developing river basin management plans.

Look out! Target group of the document.
This document aims at guiding **the competent authorities in the Member States and Accession countries** in the implementation of Article 14 of the Water Framework Directive.

Stakeholders

To provide a resource in order to support successful participation in water management and successful input into river basin management plans.

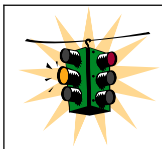
Look out! It also benefits stakeholders and the public! The document:

- explains why stakeholders should engage in river basin management planning and what can be expected by them and the general public: to voice opinions and concerns about future decisions, to ensure that relevant locally-held knowledge finds its way to the right decision platform;
- outlines practical opportunities and approaches for engaging at different levels and at different stages of planning; and
- clarifies, that this is a new process and a new form of partnership, which requires patience and mutual trust.

What can you find in this document?

The document:

- Aims at creating a common understanding with regard to public participation in the Directive and its benefits in order to increase transparency and participation in developing river basin management plans;
- Provides guidelines by explaining the requirements of the Directive with regard to the implementation steps and stages of river basin management planning and by analysing the possibilities the Directive offers; and
- Provides tools, examples and experiences of how to make public participation operational.



Look out! The methodology from this EU Guidance Document must be adapted to national, regional and/or local circumstances.
This is an EU Guidance Document on public participation. It aims to provide general principles and will need to be tailored according to political, organisational, cultural and physical contexts in each Member State and Accession country.

Some Member States have already decided to "translate" this Guidance Document into a national Guidance paper on public participation in the context of the Water Framework Directive.

… And Where?

The role of public participation in the Water Framework Directive

Section 2 *– What is public participation? Which role for public participation in the Directive? Why bother doing public participation? Annex I: Public participation techniques.*

Public participation in the planning steps

Section 2 *– Public participation in the planning steps. Ensuring coherency with the overall implementation process.*

How do we involve them? Tools and techniques for public participation

Section 3 - active involvement of all interested parties. Section 4 – consultation. Section 5 - access to information and background documents. What do you need to do? And what do you need to do by 2004? ***Annex II*** *– Examples of public participation in water management projects.* ***Annex III*** *– Lists and contacts of the Public Participation group*

Reporting the results of public participation

Section 6 *– How to report on and evaluate the processes of public participation in River Basin Management? Section 7 – Developing a learning approach to public participation.*

Section 1 – Implementing the Directive: Setting the Scene

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

December 2000: A Milestone for Water Policy

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the Water Framework Directive.

The Water Framework Directive: new challenges in EU water policy

What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

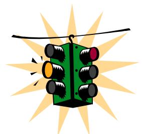
- Prevents further deterioration of, protect and enhance the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

... and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);
- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (Article 2 (22), *Annex V*);
- To make operational the monitoring networks by 2006 (*Article 8*);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*); and
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).



Look out!
Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

Changing the management process – information, consultation and participation
Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

Wetlands
Wetland ecosystems are ecologically and functionally parts of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and

restore the status of water. Relevant definitions are developed in CIS horizontal Guidance Documents water bodies (WFD CIS Guidance Document No. 2) and further considered in Guidance on wetlands (currently under preparation).

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal Guidance paper on wetlands.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fish water Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;

- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** be local, regional or national, for an effective management of all waters; and
- **Integration of water management from different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.

WHAT IS BEING DONE TO SUPPORT IMPLEMENTATION?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

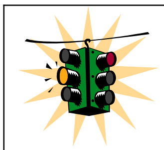
The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance (see *Annex I*). A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision body for the Common Implementation Strategy.

The 2.9 Working Group and drafting group on public participation

A drafting group has been created under working group 2.9 Best Practices in River Basin Planning for dealing specifically with public participation. The main short-term objective of this drafting group was the development of a non-legally binding and practical guidance for supporting the integration of public participation in the implementation of the Water Framework Directive. The members of the drafting group are policy makers, technical experts and stakeholders from European Union Member States and international NGO's (unfortunately no candidate countries to the European Union were involved).

To ensure an adequate input and feedback during the Guidance development phase from a wider audience, and to evaluate earlier versions of the Guidance Document, national consultation rounds have been organised by several Member States. The drafting group has organised an international workshop.



Look out! You can contact the experts involved in the public participation activities
The list of the members of the drafting group with full contact details can be found in Annex III If you need input into your own activities, contact a member from the group in your country. If you want more information on specific examples of public participation in water management projects, you can also contact directly the persons in charge of carrying out these studies.

Developing the Guidance Document: an interactive process

Within a very short time period, a number of experts and stakeholders have been involved at varying degrees in the development of this Guidance Document. The process for their involvement has included the following activities:

- Three workshops of the experts and stakeholder members of the drafting group;
- Some Member States organised national consultation rounds to collect comments on the draft Guidance version 1.1 (270802);
- Organisation of an international workshop to present and discuss the activities and output of the drafting group with not previously involved experts and stakeholders. To discuss the comments of the national consultation rounds (October 2002 – Amsterdam, the Netherlands);
- Interactions with experts from other working groups of the Common Implementation Strategy, via the members of the drafting group on a national basis.

Annex III provides the names of the members of this drafting group and of other contributors, and a list of activities of the Drafting Group.

Follow up activities

The activities of the working group dedicated to public participation will not stop with the endorsement of this Guidance by the Water Directors in Copenhagen (November 2002). The coming about of this Guidance allowed setting up a whole network of experts from several Member States. This network will still continue to follow the implementation of the Guidance and contribute to integrating public participation in the decision making process. Thus, several future activities are been already identified as follows, but other developments could appear in later stages.

From the beginning of 2003 to 2005, the Guidance Documents produced by the different working groups under the Common Implementation Strategy will be tested in a range of pilot river basins through the European Community, to assess the practicability of all the Guidance Documents and the coherence between them. The issues related to 2004 steps will be tested first (2003-2004), the issues related to later steps being tested afterwards. The so-called « horizontal Guidances », will be tested in all the pilot river basins in the first phase. This Guidance on public participation is likely to be tested as such. To help the pilot river basins to test the Guidance on public participation, a specific and more practical format will be elaborated. This format-document will provide a pragmatic approach to the issues that the pilot river basins have to take care of with respect to public participation; it will be prepared for the end of 2002 in co-operation with the working group on Pilot River Basin Testing.

It has to be underlined that the testing exercise will involve a range of stakeholders (and also the general public in certain cases) in the pilot river basins. It will provide the basis for a concrete testing of tools proposed in Annex I and for readjustment of these if necessary.

Section 2 – Introduction to Public Participation in River Basin Management

2.1 The Public Participation provisions of the Directive

Public participation plays a key role in the Water Framework Directive. This Section discusses the different provisions of the Directive. The box below gives the relevant text from the Directive Of these texts Article 14 plays a leading role.

Preamble 14

(14) *The success of this Directive relies on close cooperation and coherent action at Community, Member State and local level as well as on information, consultation and involvement of the public, including users.*

Preamble 46

(46) *To ensure the participation of the general public including users of water in the establishment and updating of river basin management plans, it is necessary to provide proper information of planned measures and to report on progress with their implementation with a view to the involvement of the general public before final decisions on the necessary measures are adopted.*

Article 14

Public information and consultation

1. *Member States shall encourage the active involvement of all interested parties in the implementation of this Directive, in particular in the production, review and updating of the river basin management plans. Member States shall ensure that, for each river basin district, they publish and make available for comments to the public, including users:*

(a) *a timetable and work programme for the production of the plan, including a statement of the consultation measures to be taken, at least three years before the beginning of the period to which the plan refers;*

(b) *an interim overview of the significant water management issues identified in the river basin, at least two years before the beginning of the period to which the plan refers;*

(c) *draft copies of the river basin management plan, at least one year before the beginning of the period to which the plan refers.*

On request, access shall be given to background documents and information used for the development of the draft river basin management plan.

2. *Member States shall allow at least six months to comment in writing on those documents in order to allow active involvement and consultation.*

3. *Paragraphs 1 and 2 shall apply equally to updated river basin management plans.*

(this box continues to the next page)

Annex VII
RIVER BASIN MANAGEMENT PLANS

A. *River basin management plans shall cover the following elements:*

…

9. *a summary of the public information and consultation measures taken, their results and the changes to the plan made as a consequence;*

11. *the contact points and procedures for obtaining the background documentation and information referred to in Article 14(1), and in particular details of the control measures adopted in accordance with Article 11(3)(g) and 11(3)(i) and of the actual monitoring data gathered in accordance with Article 8 and Annex V.*

Look out! Public Participation in relation to the Directive

As indicated by the title, this Guidance elaborates public participation in relation to the Directive and with the corresponding prescriptions. Public participation in general is however a process of which no blueprint exists and which needs to be designed according to the needs with the available means and tools. For the benefit of the results it can be wise to look further than minimum requirements.

Preamble 14 highlights the fact that public participation will contribute to the overall success of the Directive. Preamble 46 emphasises the importance of informing the general public well in order to ensure or rather facilitate their participation in the planning process. According to Annex VII, the river basin management plan should tell where and how background information can be obtained. This plan should moreover summarise the public participation measures taken and should evaluate their results and the impact on the plan.

The key public participation provision of the Directive is article 14. This article prescribes three main forms of public participation:

- Active Involvement in all aspects of the implementation of the Directive, especially – but not limited to – the planning process;
- Consultation in three steps of the planning process;
- Access to background information.

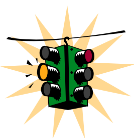
The Member States have to *encourage* active involvement and *ensure* consultation and access to background information.

It may be clear from for instance preamble 14 that active involvement is not the same as consultation. Consultation means that the public can react to plans and proposals developed by the authorities. Active involvement, however, means that stakeholders actively participate in the planning process by discussing issues and contributing to their solution. Essential to active involvement is the potential for participants to influence the process. It does not necessarily imply that they also become responsible for water management.

Look out! The Directive requires more than consultation

In addition active involvement in all aspects of the implementation of the Directive has to be encouraged. Moreover, access has to be given to background information.

Beside the Directive there are other requirements on public participation in other EU legislation, especially in the Directive on Strategic Environmental Impact Assessment (Directive 2001/42/EC). The relationship of the Directive to the SEIA Directive is quite complex and has to be clarified with regard to the programme of measures and the River Basin Management Plan.



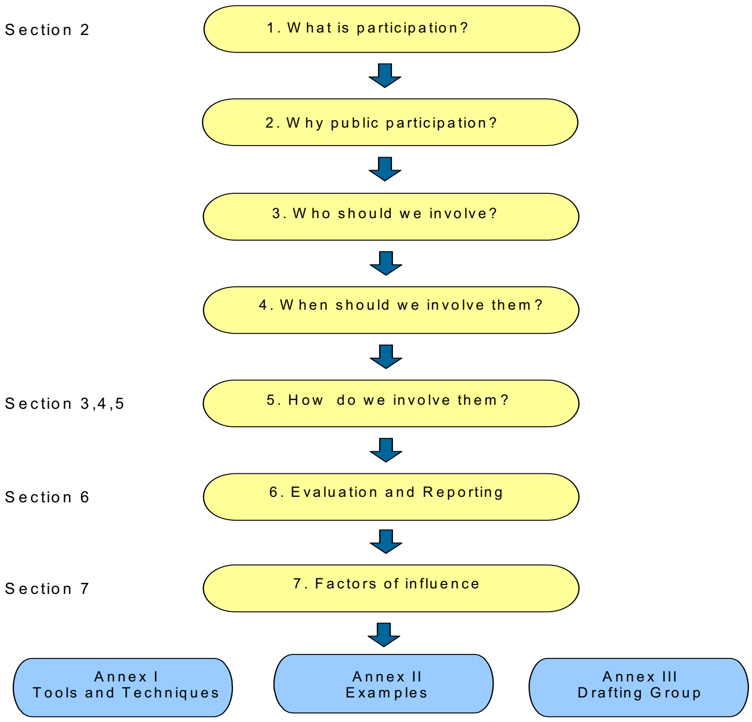
Look out! Public Participation is not only required for the river basin management plan

The programme of measures and individual measures are probably even more important.

The Box below gives an overview (glossary) of the main terms used in the Water Framework Directive and in this Guidance. The different forms of public participation will be discussed in more detail in Section 2.2, and the different types of public in Section 2.4.

Public participation
Allowing the public to influence the outcome of plans and working processes. Used in this Guidance as a container concept covering all forms of participation in decision-making. The Water Framework Directive does not use the term.
Public (or "**general public**")
"One or more natural or legal persons, and, in accordance with national legislation or practice, their associations, organisations or groups" (SEIA Directive (2001/42/EC), Aarhus convention art. 2(4))
Interested party (or "**stakeholder**")
Any person, group or organisation with an interest or "stake" in an issue, either because they will be directly affected or because they may have some influence on its outcome. "Interested party" also includes members of the public who are not yet aware that they will be affected (in practice most individual citizens and many small NGOs and companies).
NGO
Non-governmental organisation
Broad public
Members of the public with only a limited interest in the issue concerned and limited influence on its outcome. Collectively, their interest and influence may be significant.
Consultation
Lowest level of public participation if we consider information supply as being the foundation. The government makes documents available for written comments, organises a public hearing or actively seeks the comments and opinions of the public through for instance surveys and interviews. "Consultation" in art. 14 of the Directive refers to written consultations only. Preamble 14 and 46 and Annex VII refer to consultation in general.
Active involvement
A higher level of participation than consultation. Active involvement implies that stakeholders are invited to contribute actively to the planning process by discussing issues and contributing to their solution.
RBMP
River basin management plan, required by Article 13 of the Directive.

Before discussing active involvement, consultation and information supply in the planning process, guidance will be given on some key participation questions, which all those involved in organising participation, need to consider:

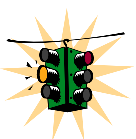


What, Why, Who, When, How questions, addressed in Sections 2-5

2.2 What is public participation?

Public participation can generally be defined as allowing people to influence the outcome of plans and working processes. However, there are different levels of influence.

The foundation for any form of public participation is **information supply** to the public. Strictly speaking, the Directive only requires access to background information and no active dissemination of information. The latter is, however, essential to make the prescribed consultation and active involvement work, as is also mentioned in preamble 46.



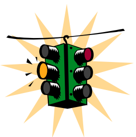
Look out! Public Participation covers a wider range of activities than prescribed by the Directive.

The Directive requires active involvement, consultation and access to information. More may be useful to reach the objective of the Directive (preamble 14).

The first level of real participation is **consultation**. Administrative bodies consult people and interested parties (stakeholders) to learn from their knowledge, perceptions, experiences and ideas. Consultation is used to gather information or opinions from those involved to develop solutions based on this knowledge. Reports, scenarios or plans are presented and people are asked to comment. The process does not concede any share in decision-making, and professionals are under no formal obligation to take on board people's views.

In this Guidance two types of consultation are distinguished: written consultation and oral consultation. Written consultation is the minimum requirement as stated in Article 14(1) i.e. "to publish and make available for comments to the public, including users". Oral consultation is more active and stakeholders have possibilities to have a dialogue or discussion with the competent authorities.

A higher level of participation is **participation in the development and implementation of plans**. Interested parties participate actively in the planning process by discussing issues and contributing to their solution. Still higher levels of participation are **shared decision-making** and **self-determination.** Shared decision-making implies that interested parties not only participate actively in the planning process, but also become partly responsible for the outcome. E.g. water use sectors could be represented in river basin organisations. Self-determination implies that (parts of) water management are handed over to the interested parties, e.g. by establishing water users' associations. Encouraging the first should be considered the core requirement for **active involvement**, the latter two forms are not specifically required by the Directive but may often be considered as best practice.



Look out! Management of Expectations

In order to avoid disappointment, it is very important to make clear towards the public which form of public participation they are dealing with and which role they play. During and after the process feedback should be given to the stakeholders and public.

The different levels of participation are not mutually exclusive. They build on each other: consultation implies information supply and active involvement implies consultation. Moreover, different levels can be useful at different stages. The choice of level depends on aspects like: the timing of public participation and the stage of the planning process, the (political and historical) context for public participation, available resources, objectives or benefits of public participation and the stakeholders identified to be involved.

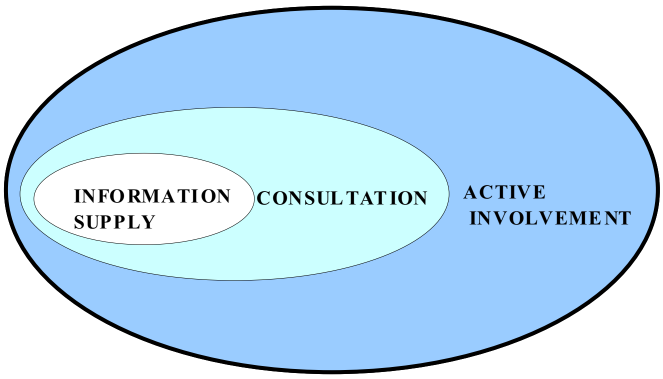


Illustration
Public participation can start with a stakeholder analysis using interviews with selected persons, be followed by public debate where the population is consulted on the identification of significant water management issues, be followed by a consultation of water users representatives (professionals, associations). More examples will be provided in Section 3 and 4.

Look out! Public participation is not necessarily about:
Everybody joining: be selective with actors, do a stakeholder analysis;
Everybody deciding: make clear what everybody's responsibilities are;
Losing control: participation cannot work if the outcome is completely predetermined, yet organise it well;
Achieving consensus at all expense: make clear that it will be impossible to satisfy all wishes hundred percent. Participation will help to explain decisions as they occur and promote ownership of the outcome arrived at.

2.3 Why public participation?

Initially of course to comply with the Directive and to achieve environmental goals and other benefits. Besides these requirements of the Directive it is good to emphasise the fundamental rationale for undertaking public participation, which is to ensure the effective implementation and achievement of the environmental objectives of water management (good status in 2015).

Look out! Public participation is a means to improve decision-making

Public participation is not an objective in itself. Public participation helps to define the rationale, framework, outcomes and validity of decision-making processes.

The main purpose of public participation is to improve decision-making, by ensuring that decisions are soundly based on shared knowledges, experiences and scientific evidence, that decisions are influenced by the views and experience of those affected by them, that innovative and creative options are considered and that new arrangements are workable, and acceptable to the public.

Key potential benefits that can result from public participation are (which are not mutually exclusive):

- Increasing public awareness of environmental issues as well as the environmental situation in the related river basin district and local catchment;
- Making use of knowledge, experience and initiatives of the different stakeholders and thus improving the quality of plans, measures and river basin management;
- Public acceptance, commitment and support with regard to decision taking processes;
- More transparent and more creative decision making;
- Less litigation, misunderstandings, fewer delays and more effective implementation;
- Social learning and experience–if participation results in constructive dialogue with all relevant parties involved then the various publics, government and experts can learn from each other's "water awareness".

Through participation, long term, widely acceptable solutions for river basin planning can be arrived at. This can avoid potential conflicts, problems of management and costs in the long term.

Wise Use of Floodplains project, EU Life Environment (see Annex II)
The WUF Project took place in Somerset, South West England, where it facilitated a creative and positive dialogue on the future management of flood events in the catchment of River Parrett. The aim was to encourage the wise use of water resources in river catchments to benefit people, their livelihoods and their environment. All stakeholders with an interest in the management of water resources in the Parret Catchment were welcomed.
In this project participation has resulted in the following benefits [1]:

- Helped identify long-term sustainable solutions for people, their livelihoods and environment;
- Built up ownership and trust;
- Was an investment as it involved early identification of issues and consensus-building;
- Raised awareness of catchment management issues; and
- Provided a means of accessing local knowledge and expertise.

2.4 Who should we involve?

The Directive uses different terms to refer to the public. With respect to consultation and access to background information simply the term **public** is used. This term is not defined in the Directive, but art. 2(d) of the SEIA Directive (2001/42/EC) gives a definition, which is also applicable to the Directive: "*One or more natural or legal persons, and, in accordance with national legislation or practice, their associations, organisations or groups*". Article 2(4) of the Aarhus convention contains the same definition. In preamble 14 and 46 the Directive also uses the phrases "public, including users" and "general public" respectively without any difference in meaning.

Concerning active involvement the term **interested party** is used. Interested party can be interpreted as meaning any person, group or organisation with an interest or "stake" in an issue either because they will be affected or may have some influence on its outcome. This also includes members of the public who are not yet aware that they will be affected (in practice most individual citizens and many small NGOs and companies). This Guidance will use the term **stakeholder** as synonymous with "interested party".

For practical reasons it is impossible to actively involve all potential stakeholders on all issues. A selection will have to be made. This selection can be based on the following factors:

- The relation of the stakeholder to the water management issues concerned;
- The scale and context at which they usually act, who they represent;
- Their involvement, being governor; user/victim/stakeholder; expert and executer of measures;
- Their capacity for engagement; and
- The political, social, "environmental" context.

Different stakeholders can make different contributions. Some stakeholders can contribute primarily by means of their ideas and the information they possess. Others may have more direct interests such as land or property that may be directly affected. In many cases organisations can represent the individual stakeholders. For every phase of the project the role of the different stakeholders should be reviewed. Some will be more affected by others, represent a larger party, be more active, or have more (financial) resources or knowledge.

Some stakeholders may be more difficult to handle than others, but that shall not influence their identification as stakeholders.

Annex I presents a technique for selecting the relevant stakeholders with a so-called **stakeholder analysis**. This will enable you to prioritise which stakeholders are vital to an issue in a specific phase of the project. Note that in order to ensure transparency and trust, it is important to be able to justify why the final set of stakeholders has been prioritised.

The box below illustrates a typology of possible stakeholders involved in water management. It makes no assumptions about their relative importance.

A typology of possible stakeholders:
Professionals – public and private sector organisations, professional voluntary groups and professional NGOs (social, economic and environmental). This also includes statutory agencies, conservation groups, business, industry, insurance groups and academia.
Authorities, elected people - government departments, statutory agencies, municipalities, local authorities
Local Groups- non-professional organised entities operating at a local level. It usefully breaks down into:
Communities centred on place – attachment centred on place, which includes groups like residents associations and local councils.
Communities centred on interest – e.g. farmers' groups, fishermen, birdwatchers.
Individual citizens, farmers and companies representing themselves. Key individual landowners for example or local individual residents.

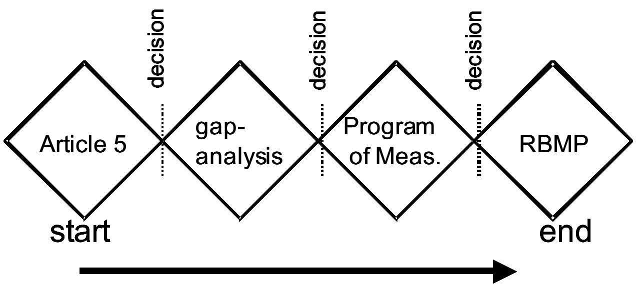
An illustration of governing bodies in Spanish River Basin districts

According the Spanish Water Act and the Regulation on Water Public Administration and Planning (Royal Decree 927/1988), different decision bodies are "governing and managing the river basin districts".
The *Government Board* proposes the plan of activities of the institution, its annual budget and, in general, it is in charge of every matter regarding the direction of the river basin district. At least one third of its members must be representatives of the water users. Representatives of the regional and central administrations form the other two thirds.
The Law also establishes the so called "decision bodies on participation regime" as the *Management Boards.*
The *Management Boards* have to coordinate the management of the different water structures in the sub basins usually defined as "management systems". Actually, they coordinate the water sharing in the basin solving conflicts between users. Members of the Management Boards are users with water rights described in the so called "Waters Register" and include representatives for every town, municipality or company in charge of water supply utilities, representatives of irrigation communities, industrial users and hydropower companies. The totality of the Management Boards according the law is grouped in the so-called "Users assembly". (this example is not presented in Annex II)

2.5 When should we involve them?

This question is divisible into two issues, firstly the matter of timing with regard to the process, secondly the actual necessity to embark on public participation, i.e. is the effort to organise the participation proportionate to the results?

Firstly **timing**. It is important to clearly define the stages of the process and every stage requires a review of the "why" and "who" question. The role and involvement of the stakeholder can differ from stage to stage. When to involve the stakeholders in the process depends on a number of factors. The objective of the project, the history and political setting, but also scale and the kind of stakeholders influence the timing of public participation. Also the stakeholder-analysis (see Annex I) will help to make this more transparent.



Model of a planning process

One may say that the stakeholders should be involved as early as possible, before decisions are taken. Only then the authorities are able to benefit optimally from their insight, experience and knowledge and allow maximum involvement, influence and ultimate acceptance of eventual decisions. It is never *too* early. When involving stakeholders at a very early stage in the process it should be made perfectly clear to the stakeholder what his role is and how his contribution will be handled. Otherwise do not involve them. For example when organising public participation during a reconnaissance study (to identify the sense of urgency of problems and to decide to invest in it or not), you must communicate in advance that the result of this study can be that the foreseen project will not be carried out. The fact is that people will spend energy and time on discussing issues, while the politicians may still decide not to invest in it.

Thus, the degree of participation of stakeholders in the early phases may be different from those in the later phases. Ultimately, timing of public participation has to be assessed on a case-by-case basis. It should be explained to participants how their involvement will be used to avoid false expectations (management of expectations!).

Secondly the **concept of proportionality** with regard to participation. When is the energy (human resources, money) that is put into the process proportionate to the outcome? There is a need to balance costs in terms of time and money and potential benefits. This is relevant for both the organiser of the process and the participants. This will have to be evaluated on a case-by-case basis depending on the form of participation you intend to use and circumstantial factors. Expert judgement and common sense will be your tools to perform a kind of risk analysis for proportionality.

Some questions that might help to consider the proportionality of your specific process are given below:

- In which stage of the process do you want to apply public participation?

- What is the specific problem in this stage and what are the expected activities (refinement of problem definition)?
- Is the outcome of this stage still flexible and open-minded or determined and fixed?
- At what scale do you plan to work?
- What form of participation are you planning to use?
- Which stakeholders are to be involved?
- What are your boundary conditions regarding:
  a) human resources;
  b) finances; and
  c) time.
- What is the political context like with regard to your process (pro/contra/neutral)?
- What is the actual acceptance level towards public participation processes?
- Who will decide in the end?
- Who will be involved from your own organisation in what way?
- Are there ongoing process/research of the same nature?
- How are you going to communicate? (See also Annex I on communication tools)
- What results are to be expected? Is it likely that involvement of stakeholders can positively influence the results?
- What do you want to achieve with public participation?
  - ownership of problem by third parties;
  - commitment of other parties;
  - innovative solutions;
  - acceptance of measures to be taken;
  - raising awareness.

Public and stakeholders should be aware that participation in the planning process will cost both time and money, like administrative cost for the NGO´s, stakeholders and the use of consultants etc.

Illustration from running spatial planning in Sweden
Consultation with the public on overall plans and detailed plans is compulsory in Sweden. Consultation and information are important procedures to realise the plans and to prevent appeal against the plans. Example from one of the municipalities in Sweden shows that up to 25% of the costs and time to produce such a plan, mentioned above, fall on consultation and information just to prevent appeal against the plan and to “get everybody on the train”. This may seem expensive, but appeal against the plans may delay the realisation of the plans to high costs of those involved both authorities and the publics.
In Sweden, no formal costs of the participation process fall on the users – except the time they use for the process.

2.6 The scope and timing of public participation

Note that the Directive tells us that Member States *shall encourage* active involvement and *shall ensure* consultation. In the first case Member States have to make a clear effort to promote and facilitate active involvement, in the second case consultation is an obligation, which has to be performed.

Furthermore the Directive gives no clear boundaries when it comes to the extent of these forms of public participation. This Guidance elaborates the range of possibilities between **minimum requirements** and **best practices** for each topic. It is up to the competent authority, which will – as a representative of the Member State – commission the public participation process, to decide which possibilities will be used in the public participation process. This choice is dependent of several factors such as the available financial means, the scale of the project, the cultural context, the effect on the environment and not in the least the political context. At the same time it should be emphasised that a competent authority should not fear a 'wider' form of public participation: the benefits with regard to improved decision making and the acceptance by the public of (unpopular) measures to be taken can be considerable. Moreover for compliance with the Directive the competent authority is dependent on the willingness of the public to participate in the (consultation) process.

Look out! The Member State is responsible

It should be borne in mind that the member state– and in practice most likely the appointed competent authority – is the final responsible body for achieving the objectives of the Directive. For the public participation process it means that only the member state (competent authority) can decide if it will stay in charge of final decisions or share its responsibility with stakeholders. Of course all without prejudice to the obligations of the Directive.

Article 14(1) 1st sentence deals with the encouragement of *active involvement of all interested parties* in the whole implementation process of the Directive. The success of this involvement will certainly not be met solely via the 3-phased information and consultation procedure pursuant to Article 14(1) 2nd sentence of the Directive ((a) timetable and work programme, (b) interim overview, (c) draft copies). The river basin management plan is to a large extent a summary and justification of all the choices and involvement of the public that has taken place earlier. Starting public participation only in 2006 will not work if the public has not been involved in making these choices. To ensure transparency and acceptance public participation has to start as soon as possible. Besides, the 3-phased procedure of 14(1)(a, b, c) will be successful only if the previous steps of information supply, awareness raising and consultation have been performed before.

Look out! Timing

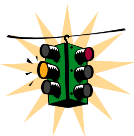
Start public participation as soon as possible and do not wait until 2006.

The timetable for public participation and the steps of the planning process receive attention in Section 2.8. How the three forms of public participation can be applied with regard to the steps of the **planning process** will be further explained in the coming Sections 3, 4 and 5. Firstly the scale issue in relation to public participation will be addressed in this Section.

2.7 The scale issue

The implementation of the Directive will require activities at many different scales: river basin district, river basin, sub basin, water body, national level, national part of an international river basin district, regional and local government level, etc. An important issue is at which scale public participation should be organised.

It follows from article 14 of the Directive that active involvement should be encouraged at all scales where activities take place to implement the Directive. Not only the area where the activities will be implemented should be considered, but the whole area where their impact may be felt. Consultation is required in the planning process for the river basin management plan and therefore at the scale of the river basin district or the national parts of an international river basin district.



Look out! Do not forget the impacted area and people!

When organising public participation on a specific issue, do not focus exclusively on the area where measures may be taken. Consider the whole area that may be impacted.

A public participation requirement at a specific scale does not mean that public participation should actually be organised at that scale. There are good reasons for organising public participation at lower scales. At the local scale the effects of management will be felt most directly and more responses from especially local stakeholders can be expected if public participation is organised at this scale. If for instance in a river basin district just one meeting is held, issues can only be discusses at a general level only and participants would have to travel large distances. Instead, several regional or local public participation meetings could be held, organised either by the competent authority for the whole district or by regional water managers. Of course, the staff requirements and costs would need to be considered.

A possible approach for the scale issue in public participation consists of five steps:

1. Determine which issues should be addressed at which level.

   The competent authorities in each river basin district should, together with the main stakeholders, define and analyse the main issues and their geographical scale. In large international river basin districts international co-ordination will be needed. If it is agreed that an issue should be addressed at for instance the regional level, a similar exercise could be held at the regional level to determine which aspects of the pertinent issue can be addressed at the local level. On top of the geographical scale of the issue, the existing institutional structure needs to be taken into account too, in particular the allocation of tasks and competences;

2. Determine what types of publics can make what types of contribution and what type of public participation is most appropriate for the publics and possible contributions concerned.

   As discussed, different publics may make different contributions in different phases;

3. Organise public participation as close to the public concerned as possible, given budgetary and staffing constraints;

4. Communicate the (first) results as soon as possible across different scales and between relevant units at the same scale.

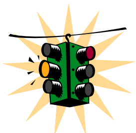
   Much local information and many local concerns and solutions will need to be incorporated, in an aggregated form, in the river basin management plan for the river basin district ("scaling up"). Issues that play at a higher scale should be communicated to and discussed with the local level ("scaling down"). Local information, concerns and solutions may also need to be communicated to upstream and downstream areas and to neighbouring areas outside of the basin (horizontal communication); and

5. Report on follow-up not only in the river basin management plan, but also at the level where public participation was organised.

   In the river basin management plan many details that are of concern for the regional or local level may be lost. The input of the participants needs to be recognised.

In this approach the initiative comes from the competent authority at the district scale. In addition, public participation initiatives can be taken at lower scales and then be "scaled up." River basin management can benefit if there remains room for experimentation.

In principle any level of public participation can be organised at any scale, even at the international river basin district scale. Nowadays many stakeholders are represented by larger international organisations, which is an advantage for the public participation process at large scales. The main issue is to find for each Directive issue the right combination of scale, stakeholders, public participation levels and methods. Stakeholder analysis (Annex I) can be very helpful for this.



Look out! Stakeholder Analysis (see Annex I)

Stakeholder analysis will help you to prepare for public participation at any scale.

The four boxes below give examples of public participation at the local scale and at the national and international river basin district scale. The first example shows, first, that public participation can be organised at the local level while still keeping the process manageable, and secondly, that it is possible to involve the broad public actively. The second, third and fourth example show that also at the national and the international river basin district level active involvement is possible. Annex II gives many more examples of all types of public participation at all scales (see especially the matrix).

Active Involvement of the broad public at the local scale

The Fens Floodplain Project – East of England (Wise Use of Floodplains Project) (see Annex II)

In the Fenlands in Eastern England the Wise Use of Floodplains project, as well as talking to stakeholders and organisations at a strategic level across the floodplain, wanted to talk to local people. In view of budget constraints, the views of communities in two representative villages within the 4,000-km^2 river basin were sampled. A range of local people was involved from school students to adults and retired people. They were invited to make any proposal they wished about making the floodplain more sustainable. A method called "planning for floodplains" was developed. This involved local people putting symbols onto a map based model to indicate the floodplain restoration projects they wanted. 200 different proposals were made in each village (2% of the population). Results of local community involvement were then compared with the views of other stakeholders obtained through other participation techniques (e.g. river basin level workshops, seminars) to assess how well the public proposals matched those of key organisations. The results supported proposals for floodplain restoration from an existing catchment wide project called "Wet Fens for the Future".
The local involvement showed that even just sampling participation in 2 villages in the sub-region can produce useful data to confirm existing proposals or to assess whether it is worth investing in a larger scale participation process.

Active involvement and consultation of stakeholders at the national river basin districts scale

The SDAGE projects, France (see Annex II)

For each of the 10 French large river basins, a management plan has been produced according to the 1992 French Water Act, called SDAGE. In a modified form they will become the river basin management plan according to the Directive. The so-called Basin Committee is responsible for their initial elaboration. This Committee is composed of the representatives of all stakeholders and users in the River Basin District (about 100 members):

- 1/3 local elected officials (i.e. mayors, local communities);
- 1/3 users, consumers, NGOs;
- 1/3 representatives of the State.

The Basin Committee defines the management plan (SDAGE) and co-ordinates the coherence between SAGE Projects (management plans at the sub-basin/local scale). It arbitrates water conflicts, decides on the taxes to be paid by the users and defines action programmes. The SDAGE document was made available to the general public only after its approval, but this will have to change.

Each Basin Committee created a Planning Commission and several Geographic Commissions (implanted at a more local level) in which a number of debates and meetings took place. Hundreds of interested parties were able to voice their opinions in the meetings of these geographic commissions. For example in the Rhone-Mediterranean-Corsica (RMC) Basin, the stakeholders were consulted through 10 geographic commissions, 6 technical committees and 7 socio-professional committees. Besides, the SDAGE Project was submitted to the associations by way of a specific dialogue. 1500 written comments from stakeholders and the general public were received.

National Water Council, Spain

According the Spanish Water Act and the Regulation on Water Public Administration and Planning (Royal Decree 927/1988), the National Water Council (“Consejo Nacional del Agua”), is the highest advisory body on water issues at national level. Three types of members compose the Council: Regular, designated and elected. The first group is formed by “positions” instead specific persons (i.e. the Water Director), the second is formed by appointed representatives that are members of the Council for a non limited period of time and the last one includes members that has to be elected every four years.

Regular members are:

- Chairpersons of the different river basin districts (12).;
- Directors of different Ministries with responsibilities regarding water as Environment, Agriculture, Economy and so on (For instance, the Water Director) (8)..

Designated members are:

- Designated representatives of different Ministries with responsibilities regarding water as Environment, Agriculture, Economy and so on (11);
- Representatives of each one of the Regional administrations (17) ;
- One representative of the Federation of Municipalities;
- One representative of the irrigation users communities;
- One representative of the hydro power companies;
- One representative of the water supply companies;
- One representative of the Commerce Chambers;
- Three representatives of the farmers;
- Two representatives from the limnology field;
- Three representatives of ecological NGOs;
- Three representatives from the University and the research field;
- One expert in irrigation techniques (appointed by the Agricultural Ministry).

Elected members are:
- Elected representatives of the regional administrations that belong to the water river basin district councils (12).;
- Elected representatives of the water users that belong to the water river basin district councils (12)..

According the Law, the National Water Council shall discuss and approve or refuse among others, the following[1]issues:
- The National Hydrological Plan, prior to their consideration by the Government and the Parliament;
- The River Basin Districts Water plans prior to their consideration by the government;
- Projects of regulation to be implemented in the entire Spanish territory affecting the hydraulic public domain;
- Projects and sectorial plans on agriculture, territory, energy or industry if they are considered as being of "general interest" and affect the water planning or the water uses;
- All the issues affecting more than two River basin districts.

It should be taken into account that this situation needs to be assessed and, consequently modified, following the objectives and legal consequences of the Directive.
(this example cannot be found in Annex II)

Active involvement of stakeholders, consultation and access to information at the international river basin district level

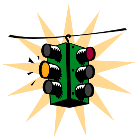
Danube River Commission / Danube Environment Forum (see Annex II)

Planning of the Danube River basin 'occurs' at a range of levels from sub-catchment/communities to international commissions. Participation of stakeholders happens in different ways at different levels in the overall process. The cascade of approaches to public participation from working with communities directly at one level to ensuring that representative organisations are involved at an international level is a good illustration of how public participation can mean different things at different levels, but should have a common set of principles of transparency of process and inclusion.
The co-ordinating body for the international aspects of the Directive in the Danube basin is the International Commission for the Protection of the Danube River (ICPDR). ICPDR is promoting public participation in the planning process through financial support to the ICPDR Information System, including the Danube Watch, as well as operating networks such as the Danube Environmental Forum (DEF), MLIM and AEWS.
Several large international NGOs have observer status in the ICPDR. They can participate in the meetings of the ICPDR, but they have no voting rights in its working groups. They provide significant input to the work of the Commission (for example in the establishment of an Ecological Expert Group). Through their networks, they provide small (national and local) NGOs with direct or indirect access to the international arena.

Key to managing the scale issue in river basin management is communication and co-ordination across scales and between units at the same scale (e.g. upstream and downstream countries or regions). This is very much facilitated by building up formal and especially informal networks across scales and between units at the same scale. Staff members of one competent authority could attend meetings organised by the other relevant competent authorities and vice versa. Moreover, the establishment of a central clearinghouse in each river basin district for public participation could be considered for exchanging the results of and experiences with public participation. Note that public participation at the international

[1] The National Water Council is an advisory body, so, its decisions are not legally binding. However, in practice, there is no record of one decision of the Council that has not been endorsed by the Government

river basin district level encourages the participation process at lower scales within the district. In basins where different languages are spoken sufficient funds for translating the most important documents need to be made available.



Look out! Keep each other informed across scales

Keep each other informed about all public participation processes going on in one river basin district, by formal means but especially informally. Sufficient funds for translating the most important documents need to be made available.

2.8 How do we involve them?

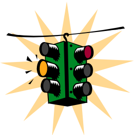
The timetable, which is linked to the program cycle of the Directive, as described in Section 3 is another determining factor in timing public participation. The different planning steps provide different possibilities for public participation. The Directive defines a number of phases and deadlines for its implementation, shown below (enumeration is not exhaustive).

STEP 1 By end of 2003	**Framework** Identification of River Basin Districts Assignment of the Competent Authorities Transposition of the Directive into national legislation
STEP 2 By end of 2004	**Characterisation and Analysis (Art.4)** Characterisation of the river basin district, review of the environmental impact of human activity and economic analysis of water use. Assessment of the likelihood that surface water bodies within the river basin district will fail to meet the environmental quality objectives set for the bodies under Article 4 ('gap analysis' Annex II (1.5)).
STEP 3 By end of 2006	**Planning for establishing programs of measures and outline of river basin management plans** Further characterisation for those bodies identified by the gap analysis as being at risk, in order to optimise the monitoring programme and the programme of measures. Monitoring programmes start
	For Public information and consultation about the RBMP, MS make available for comments a timetable and work programme for the production of the RBMP (MS shall allow at least six months to comment on those documents).
STEP 4 2007	For Public information and consultation about the RBMP, MS make available for comments an overview of the most important water management issues within the RBD (MS shall allow at least six months to comment on those documents).
STEP 5 2008	For Public information and consultation about the RBMP, MS make available for comments a draft copy of River Basin Management Plan (MS shall allow at least six months to comment on those documents).
STEP 6 2009	Final River Basin Management Plan published Programmes of measures shall be established.
STEP 7 2012	**Implementation** Programmes of measures implemented
STEP 8 2015	**Evaluation and updating, derogations** Good water status achieved? Objectives for Protected Areas achieved? Establishing and publishing the next plans and programs Derogations
STEP 9 2027	Final deadline for achieving objectives, following 2 6-year prolongations

In the next Sections the Guidance will describe how the three different degrees of participation can be organised in the different planning steps:

- active involvement (Section 3);
- 3-step consultation (Section 4);
- information supply (Section 5) .

As stated many times before, every process of consultation or active involvement is unique and depending on context and circumstances. Section 7 will help you to reflect on the public participation in your situation.



Look out! Remember communication

The backbone of public participation is two-way communication between the competent authorities, the participants and all other interested parties. Transfer of information between different planning steps is essential. Tools which support communication and interaction such as public meetings, interviews, workshops, websites, etc. are described in Annex I.

Section 3 – Active involvement of all interested parties in the Planning process of the Directive

"Member States shall encourage the active involvement of all interested parties in the implementation of this Directive, in particular in the production, review and updating of the river basin management plans." (Article 14.1, 1st sentence).

3.1 Introduction to active involvement

The purpose of the participatory requirements of Article 14, including active involvement, is to support the effective implementation of the Directive. While this has particular focus on the production, review and updating of the River Basin Management Plans, the encouragement of active involvement of stakeholders in the wider implementation of the Directive also needs to be considered. The potential benefits of greater stakeholder can be summarised as follows:

- RBMPs are likely to be more successful through achievement of "buy-in" to their objectives and delivery by promoting "ownership", acceptability and the co-operation of relevant stakeholders;
- Decision-making is likely to be more efficient through earlier identification and, where possible, resolution of conflicts;
- Solutions are likely to be more sustainable and equitable through the input of a wider range of knowledge and perspectives; and
- In the longer term, relationships between competent authorities and stakeholders are likely to be strengthened.

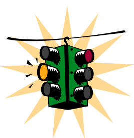
Although "active involvement" has not been defined in the Directive, it implies that stakeholders are invited to contribute actively to the process and thus play a role in advising the competent authorities as described in the spectrum of participation presented in Section 2.2.

It is important to note that there is no single correct approach to the organisation of active involvement. It will require a tailor made process which is context specific. This makes it difficult to be prescriptive in terms of defining an active involvement process. One possible solution would be for the competent authorities to develop a strategy to adapt the common understanding, outlined in Section 2, to the national, River Basin District and local context. In order to secure greater acceptance of the consultation and involvement process amongst stakeholders, the strategy should be published early in the process of implementation.

The ideal for active involvement is inclusiveness but, in practice, the notion of involvement of being open to everyone who has a stake, usually needs to be qualified by "as appropriate" to the particular context due to imposed constraints such as the Directive timetable, technical complexity, and limits on influence etc. Understanding, establishing and communicating clear boundaries for active involvement in the strategy will help keep stakeholder expectations realistic.

Given the above points, this Section presents the broad principles of active involvement: why, what, who and how stakeholders should be involved in the different steps of Directive cycle outlined in Section 2.8.

It is important that this Section is read in conjunction with the Guidance Documents produced by the other Working Groups in the Common Implementation Strategy.



Look out! Active Involvement is not a voluntary exercise
In the first place since Article 14 '*shall encourage*' implies that Member States have to make a clear effort to promote and facilitate active involvement. In the second place since the River Basin Management Plan (Annex VII, element 9) shall give account of the measures taken to inform and consult the public and the changes of the plan that followed from this involvement. In the third place since Preamble 46 tells us "*provide information.... with a view to the involvement of the general public before final decisions on the necessary measures are adopted*".

3.2 Active involvement in the program cycle of the Directive

STEP 1 By end of 2003	**Framework** Identification of River Basin Districts Assignment of the Competent Authorities Transposition of the Directive into national legislation

Why, what and who?

Active involvement in this step will help raise awareness of the introduction of the Directive and the early decisions that will establish the competent authority and spatial outline of the River Basin Districts.
Active involvement in this step is unlikely to be significant, and public participation will be characterised by information supply and consultation via existing national procedures.
Input should be sought from as wide a range of stakeholders as can be reached.

How?

By communication planning (see Annex I) and using the existing national procedures.

Consultation on the Directive Annexes 2 and 5, UK environment agencies (see Annex II)
The technical annexes of the Directive are complex and not easily understood or interpreted. They do, however, provide the basis and instruction as to how the water environment will be assessed, monitored and classified. These tasks inform Objective setting, the development of Programmes of Measures and regulatory regimes. As such it is important that, as far as possible, the principles being adopted, or being considered for adoption, are understood and supported by the range of stakeholders, authorities and organisations potentially affected by these assessment or related activities.

In the summer of 2002 the UK environment agencies issued public consultation documents on "The Guiding Principles on the Technical Requirements of the Water Framework Directive".

The objectives of this exercise were to:

- *Allow stakeholders to input their priorities and concerns as to how technical annex*

interpretation might affect them;
- *Allow stakeholders to comment on proposed WFD technical interpretations and principles;*
- *Provide a framework by which a range of public bodies across the UK could input to the development of a common interpretation and understanding of Directive requirements.*

A number of key lessons are summarised below:
- *It is possible to develop and provide participative opportunities associated with WFD technical processes and issues;*
- *Attempt to involve stakeholders in such issues and processes are appreciated by them and deliver benefits to prospective competent authorities in terms of both transparency and trust and through the valuable and insightful contributions made by stakeholders;*
- *The collaborative working of agencies and public bodies in both Scotland and England and Wales is beneficial in increasing national understanding and co-working relationships;*
- *Similarly the reciprocal involvement of SEPA, EA and EHS in each others drafting processes increased UK wide shared understanding while providing reassurance to stakeholders that common interpretations were being applied and proposed.*

STEP 2 By end of 2004	**Characterisation and Analysis (Art.4)** Characterisation of the river basin district, review of the environmental impact of human activity and economic analysis of water use. Assessment of the likelihood that surface water bodies within the river basin district will fail to meet the environmental quality objectives set for the bodies under Article 4 ('gap analysis' Annex II (1.5)).

Why, what and who?

Active involvement in the characterisation and analysis step will be useful to:
- Raise awareness of the process of characterisation and analysis;
- Collect data, information and views of a range of stakeholders;
- Identify issues and where possible resolve conflicts and manage expectations.

The characterisation and analysis step can be broken down into a number of distinct processes. The delivery of these processes, and ultimately the RBMP which they lead to, will stand a greater chance of success with the involvement of key stakeholders. Some specific detail is offered below for each process.

Review of pressures and impacts: This review forms one of the foundations of RBMP and helps determine which water bodies are likely to be at risk of not reaching ecological status by 2015 (or later) because of the pressures on them. The purpose of stakeholder involvement would be to help determine the pressures and impacts on water bodies and provide input to the identification of waters most at risk.

Economic Analysis: This process will help a) set up a trend scenario which predicts the socio-economic trends for the future, which is essential for the "gap analysis", and b) evaluate current levels of cost recovery and c) analyse the cost-effectiveness of measures between 2004 and 2009. Stakeholder involvement will help to determine a), b) and c). Secondly, involvement is also important since good ownership could mean also better financial support (either directly by the public or by political pressure).

Classification and objective setting: In this process a start has to be made with the definition of the **status of the water bodies** on the basis of the characterisation of water bodies within the River Basin Districts required by Annex II and V. Also **environmental quality objectives** have to be set. When setting the environmental objectives, it is most important to have good ownership of local people, but it has to be guided carefully as capacity building is indispensable (interpretation of Guidance Documents). There is risk of failure of objectives of the Directive by "overriding" economic issues (e.g. clean hydropower and navigation), but there is also a big chance to create awareness and to win the pro-environmental sections of society. This involvement should be organised from bottom (small basin or even water body) to basin districts and whole basin.

Gap analysis: When the current water status and envisaged environmental quality objectives are set, the **gap analysis** can be performed. The first gap analysis is to be performed before the end of 2004, for the purpose of the first RBD characterisation, in order to define the water bodies being at risk of failing to meet the objectives of the Directive for 2015. This first gap analysis will be based mostly on expert judgements and currently available data and information. After 2004, this first gap analysis will be refined on the basis of new data, among them the results from monitoring programmes (operational after end 2006). This new information will be used to update the RBD characterisation to be included in the river basin management plan (Annex 7), involve key-stakeholders in the identification of gaps and set up of trend scenarios. In the case of gaps, this makes them aware of a need for change, and it will help to get their input in the identification of appropriate measures (next step).

Designation of Heavily Modified Water Bodies: Like gap analysis, the designation of heavily modified water bodies is a two step process, with a provisional designation by 2004 and a final designation by 2008 The purpose of stakeholder involvement would be to support the identification of heavily modified water bodies (HMWB), resolve conflicts and contribute to the acceptance of HMWB designation.

The most important stakeholders to be considered at this strategic level of dialogue will be those who can really contribute to delivering solutions (e.g. other government bodies, water companies, wastewater treatment companies), those who have technical expertise and are 'representative' of a particular constituency (e.g. NGOs, research community) and those who pay for action (consumers).

How?

When considering the different processes, active involvement may be undertaken at national, River Basin District and local levels. Involvement at the national level would predominantly be with national government, industry bodies, consumer bodies, national NGOs and technical and academic experts. At the River Basin District and local level, involvement would tend to be with representatives of regional and local government and stakeholders with an interest in a specific River Basin District, river basin or water body.

At each of these levels it may be useful organise involvement using the following methods:

- Bilateral meetings;
- Steering groups;
- Advisory groups.

Possible activities for active involvement are:

1 "Process Start Up" meeting/workshop(s) with key-stakeholders to discuss:
  - The objectives;
  - The working process (how to reach the objectives) and decide on their role;

- The preconditions (Terms Of Reference) for their involvement;
- Availability and relevance of existing data;
- Communication plan.

2 Inventory of knowledge and perceptions on:
- The description of the surface waters and groundwater bodies; what are the major issues (problems)? This can be done through workshops, interviews, panels and fieldtrips with stakeholders.

3 Analysis and structuring, decision making on characterisation;
4 Information supply to all relevant stakeholders.

River Basin Management Plan Maas/sub-basin Niers, (see Annex II)

Pilot project with regard to Article 14 (North Rhine-Westphalia, one of the 16 German Lander)
In the three Niers fora: Municipalities, districts, water companies, water associations, chambers of agriculture, forest authorities, nature conservation NGO's, biological planning units, the Netherlands authorities and stakeholders (all of the relevant region), have been consulted. In round tables with 30 – 40 persons per forum the following activities took place: Information supply, discussion, distribution of relevant materials, exchange of experience, involvement with regard to data collection.

Integrated reconnaissance study on the River Basins of the Rhine and Waal (see Annex II)

Objective:
To give advice to the national government on possible scenario's for future water management
The open interactive process has the following elements:
- a close cooperation with other governmental organisations. In steering committees, the 2 provinces, municipalities, the regional office of PW, VROM and LNV as well as the water boards are represented. They are responsible for the decision making and the advice to the government on further policies. (Before only the regional office of the Ministry developed such studies and gave advice) ;
- an expert group (of government staff (and representatives of NGO's);
- (in a later phase) "working groups" of experts per theme:
    - ◊ water flow, use and land use;
    - ◊ juridical and governmental issues;
    - ◊ communication.
- open communication; from the start the project team showed a positive attitude towards interviews, questions by stakeholders and took care to produce clear reports, and leaflets to inform about the progress and results;
- symposia (IVB). The IVB project has organised two symposia. One for the governors and the other one for NGOs and interested citizens. The aim was to explain about results of the screening study so far, to create understanding and support and to seek reactions and advise on the proposed measures;
- information evenings for the general public with a (DVD) film putting water management in a historical perspective, bringing interests together under the flag of security and illustrating all proposed measures and its consequences;
- The objective is to inform people, provide them the knowledge they need, generate understanding for the necessity and gain insight on the different perceptions and ideas people have. What are the consequences of these measures for the user, inhabitants and local governors?
- "Kitchen table" conferences with the ministry and farmers in the area to discuss possible measures;
- Consultation rounds (interviews) among the parties involved on how to proceed.

STEP 3 By end of 2006	**Planning for establishing programmes of measures and outline of river basin management plans** Further gap characterisation for those bodies identified by the gap analysis as being at risk, in order to optimise the monitoring programme and the programme of measures. Monitoring programmes start. For Public information and consultation about the RBMP, MS make available for comments a timetable and work programme for the production of the RBMP (MS shall allow at least six months to comment on those documents).

NB: The Directive requires consultation and active information supply for the phases from 2006-2009. These subjects are discussed in more detail in Section 4 respectively 5.

Why, what and who?

This step is mainly focussed on planning the potential measures which may be used to achieve the objectives set for different water bodies, and to determine which options would be feasible and effective. Active involvement will help determine stakeholders' views on the potential options, and to elicit other possibilities to be screened which in turn would help determine the final measures selected. The programme of measures should be co-ordinated with other water and land- use planning processes and funding mechanisms. This may have significant financial benefits, in addition to improving effectiveness of the implementation. Also the SEIA directive refers to plans and programmes of measures (see Section 2.1 and 2.4).

The examples on the SDAGE project in France (see Section 2.7 and Annex II) do also illustrate this step.

The most important stakeholders to be considered at this step will be those who can really contribute to delivering the Programme of Measures (e.g. other government bodies, water companies, wastewater treatment companies etc), those who have technical expertise and are 'representative' of a particular constituency (e.g. NGOs, research community) and those who pay for action (consumers).

How?

When considering the different measures, active involvement may be undertaken at national, River Basin District and local levels. Involvement at the national level would predominantly be with national government, industry bodies, consumer bodies, national NGOs and technical and academic experts. At the River Basin District and local level, involvement would tend to be with representatives of regional and local government and stakeholders with an interest in a specific River Basin District, river basin or water body.

At each of these levels it may be useful organise involvement using the following methods:
- Bilateral meetings;
- Steering groups;
- Advisory groups.

The IIVR project, The Netherlands (see Annex II)

The project has chosen for a cooperative style in which the different authorities and nongovernmental organisations (NGO) (and interest groups) work together and have an equal say in the final outcome.

The interaction is organised through:
- a steering committee formed by governors of the different government authorities. They gave

direction to the process and take decisions. The steering committee is supported by the initiative-group;

- an initiative group. This group of experts, government employees and members of NGO's, discussed the content of the planning process;
- consultations of citizens and interest groups. In addition, several sessions were organised during a period of two years to consult citizens and interest groups and give them a chance to share their problem perceptions and generate ideas.

STEP 4 2007	For Public information and consultation about the RBMP, MS make available for comments an overview of the most important water management issues within the RBD (MS shall allow at least six months to comment on those documents)..

See Section 4 and 5.

STEP 5 2008	For Public information and consultation about the RBMP, MS make available for comments a draft copy of River Basin Management Plan (MS shall allow at least six months to comment on those documents)..

See Section 4 and 5.

STEP 6 2009	Final River Basin Management Plan published. Programmes of measures shall be established.

See Section 4 and 5 with respect to the publication of the RBMP.

Why, what and who?

This step is mainly focussed on establishing the Programme of Measures, which will be used to achieve the objectives, set for different water bodies. As stakeholders will implement or be affected by some of the measures, active involvement in this step will help gain commitment to the delivery of the Programme of Measures.

The most important stakeholders to consider at this step will be those who can really contribute to delivering the Programme of Measures (e.g. other government bodies, water companies, wastewater treatment companies, farmers etc) and those who pay for action (consumers).

How?

When establishing the different measures, active involvement may be undertaken at national, River Basin District and local levels. Involvement at the national level would predominantly be with national government, industry bodies and consumer bodies. At the River Basin District and local level, involvement would tend to be with representatives of regional and local government and stakeholders with a role in delivery of the Programme of Measures.

At each of these levels it may be useful organise involvement using the following methods:

- Bilateral meetings;
- Steering groups;
- Advisory groups;
- Workshops and meetings to generate solutions and define measures.

Erne Sustainable Wetlands Project (see Annex II)

In the Erne catchment (cross border Northern Ireland and Ireland) covering over 4,000square km's) the aim was to produce a model for agreeing a vision for management of the river basin (catchment). Active involvement with a range of stakeholders and a range of methods was tried at different geographic levels. It was found that people generally related better to the more local scale.
Methods included questionnaires, community mapping and workshops. Everyone living within the river basin was considered as a potential stakeholder and active involvement was encouraged by a participatory approach of holding workshops open to the public and any interested organisation and going out into public places like town centres.

STEP 7 2012	**Implementation** Programmes of measures implemented.

Why, what and who?

This step is concerned with the implementation of the Programme of Measures. Active involvement in this step will help to maintain the awareness of the measures and contribute to their sustained delivery.

The most important stakeholders to consider at this step will be those who are contributing to the delivery of the Programme of Measures (e.g. other government bodies and industry sectors etc).

How?

When implementing the Programme of Measures, active involvement may be undertaken at national, River Basin District and local levels. Involvement at the national level would predominantly be with national government and industry bodies. At the River Basin District and local level, involvement would tend to be with representatives of regional and local government and stakeholders with a role in delivery of the Programme of Measures.

At each of these levels it may be useful organise involvement using the following methods:

- Bilateral meetings;
- Steering groups;
- Consultation methodologies.

River Tyreså project, Sweden (see Annex II)

Public participation to restore and develop a River basin.
A steering group was set up consisting of politicians from the municipalities. Working groups were formed of representatives of municipalities, county board and from the water users (total 11 persons). The working group has close contact with the sport fishing associations, house-owners associations and many other associations within the catchment area. After the first introductory meeting some interest/issue groups were established: recreation/outdoor life, local history and eutrophication. The working groups have regular meetings once a month with these groups. The public participated also through panel debates. The outcome was a list of measures being implemented resulting in a.o. The establishing of walking paths, improved of the quality of the surface water, protection of an ecological park.

STEP 8 2015	**Evaluation and updating, derogations** Good water status achieved? Objectives for Protected Areas achieved? Establishing and publishing the next plans and programs. Derogations.

Why, what and who?

This step is concerned with the achievement of the objectives. Active involvement in this step will be useful to raise awareness of the achievement of the objectives and facilitate the understanding of the effectiveness of the Programme of Measures.

The most important stakeholders to consider will be those who can really contribute to delivering the Programme of Measures (e.g. other government bodies, water companies, wastewater treatment companies, farmers etc), those who have technical expertise and are "representative" of a particular constituency (e.g. NGOs, academics etc) and those that pay for action (consumers).

How?

When considering the achievement of the objectives, active involvement may be undertaken at national, River Basin District and local levels. Involvement at the national level would predominantly be with national government, industry and consumer bodies, national NGOs and technical experts. At the River Basin District and local level, involvement would tend to be with representatives of regional and local government and stakeholders with an interest in a specific River Basin District, river basin or water body.

At each of these levels it may be useful organise involvement using the following methods:

- Bilateral meetings;
- Steering groups;
- Consultation methodologies.

The Emå River, Sweden (see Annex II)

Catchment area of 4 500 km^2.
Objectives public participation:

- To contribute to sustainable development by encouraging commitment and support from local people as regards restoration of the area and other environmental measures;
- To use knowledge and experience from NGO's and other stakeholders;
- To avoid new and, if possible, solve old conflicts.

Municipalities, county administrative boards, NGO's, etc., cooperated in different working groups from 1994 onwards (from 1997 there were 8 groups). Different associations took part in these working groups such as the Emå River Council, farmers associations, owners of fishing waters, angling associations, local history associations, nature conservation associations, municipalities and tourism enterprises.
Public participation is achieved by holding seminars, information meetings and hearings, circulating documents (e.g. objective documents) for comments, forming working groups (those in the group bring information back to their organisation and vice versa) and distributing newsletters, etc. Minutes from the various meetings were taken and distributed.

West country River Trust (WRT), UK (see Annex II)

The objective of the project is:

- To raise awareness;
- To use the knowledge and experience of stakeholders for the sustainable development of river catchment areas;
- To improve water quality through comprehensive involvement of farmers;
- Participation has largely focused on farmers and key regional stakeholders (e.g. statutory environment agencies, the local water company, other NGOs). The WRT works both as a leader and facilitator in the region to effect change through the development and delivery of action. For instance, WRT has recently used WWF-UK funding to bring together key regional stakeholders in a workshop to begin the process of agreeing a long-term vision for the landscape of the southwest. The workshop has been followed by a questionnaire exercise, which asks stakeholders to identify their priorities for rural land-use. Hence knowledge on local issues, resources in terms of active participation and commitment and willingness to imply changes in their production practices to ensure environmental quality is gained.

The Tubaek stream, Denmark (see Annex II)

The key to the constructive dialogue was:
Public meetings were organised through the farmers union and that meetings took place at the farm – the "kitchen-table model";
Negotiation and signing of voluntary agreements on water management has taken place.

STEP 9 2027	Final deadline for achieving objectives, following 2 6-year prolongations

The six-year programme cycle will remain, including public participation as described before.

Section 4 – Consultation

4.1 Introduction to consultation

Consultation aims at learning from comments, perceptions, experiences and ideas of stakeholders. Unlike active involvement, consultation is only possible after completion of draft plans and other documents, and during the preparation of these documents. Moreover, it is a less intensive form of public participation. Yet, whereas active involvement often is necessarily somewhat selective, consultation allows everybody who is interested to become involved in decision-making. It is a useful complement to active involvement and can function as a kind of check on active involvement, to see if all interests, points of views were represented.

According to Article 14 consultation concerns the following requirements and timetable for consultation (with a repetitive cycle of 6 years for future river basin management plans):

December 2006 (at the latest)	Time table and work programme for the production of the plan, including a statement of the consultation measures to be taken;
July 2007	Comments in writing.
December 2007 (at the latest)	Interim overview of the significant water management issues identified in the river basin;
July 2008	Comments in writing.
December 2008 (at the latest)	Draft copies of the river basin management plan available;
July 2009	Comments in writing.
December 2009 (at the latest)	Start implementation of the plan.

Thus consultation refers to:
- Publishing;
- Making available for comments;
- *For the public*, which is a wider range than stakeholders only.

Further on in this Section the three required consultation phases are discussed separately and something will be said about the timing of consultation.

The Directive specifies that public comments must be provided in writing, e.g. either in paper form, by mail, or via e-mail. Additionally however, other ways of consultation can be considered (oral consultation). So basically, there are two different forms of consultation:

1. *Written consultation*, where people are asked to comment in writing on the proposed analysis or measures (this can include the use of internet);
2. *Oral or active consultation*, where the consult is sought in interviews, workshops or conferences. During these meetings major issues are presented and the invited stakeholders are asked (in small groups) to give their perception, knowledge and ideas on the specific issues (Annex I gives an example of such a workshop). They can also be consulted on the development of measures through questions like: "how to solve these issues?" or "how to proceed with our working process".

Written consultation is regarded as a minimum requirement for implementation of the Directive, oral consultation as best practice. However combinations of these two are often applied.

Code of practice on written consultation for the Directive:

1 Timing for the organisation of consultation, apart from the dates mentioned by Article 14, should be built into the planning process for a policy or service from the start;
2 It should be clear who is being consulted, about what questions, in what timescale and for what purpose, the consultation process is open to anyone;
3 the documents which are subject to consultation (timetable, work programme, significant water management issues, draft copy of river basin management plan) should be as simple and concise as possible (including a summary of 2 pages of the main questions it seeks views on), some summaries for a broader audience should be prepared;
4 the documents should be made widely available, with the fullest use of electronic means and effectively drawn to the attention of all interested groups and individuals;
5 Anyone with an interest has six months respond to the documents;
6 Responses should be carefully and open-mindedly analysed, and the results made widely available, with an account of the views expressed, and reasons for decisions finally taken;
7 Departments should monitor and evaluate consultations, designating a consultation coordinator who will ensure the lessons are disseminated.

4.2 Management of comments

Management of information and comments is important with consultation. There are several available tools for informing the public and at the same time asking them to comment on the plans: fact sheets, newsletters, Internet, brochures, advertisements, articles in magazines, columns in newspapers, exhibitions, open house, info evenings and TV/radio (see description of communication tools in Annex I). The whole area that is potentially affected by the river basin management plan should be covered for example by display in city halls, libraries, local newspapers and actively sent to stakeholders or anybody that is likely to have an interest. Once the information is published you should be prepared to get responses and to act.

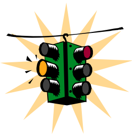
4.2.1 Where to collect responses?

Point 7 in the box above also refers to the question of where comments should be received. For the management plan as a whole, they could be collected centrally, by an (inter)national co-ordination agency, or non-centrally, by the authorities displaying the plan. The Directive contains no provisions regarding collection and processing of comments received from the public.

Comments regarding international management plans can be collected on a national basis, at defined locations. Once collected, comments must be sent immediately to the authorities concerned, in the interest of speedy assessment. Where comments are well founded, the relevant results (such as adaptation of measures plans, etc.) should be collected on a national basis, for the river basin district, and then forwarded to the international agency (if existing) that co-ordinates or facilitates the preparation of an international management plan. In administrative areas that cross boundaries – such as those along the upper Rhine or the Moselle/Saar area – and thus will require sub-plans, co-ordinated processing of comments regarding the relevant areas/sub-plans, by authorities co-operating within the relevant areas, would be a useful way of reducing co-ordination overhead at the international co-ordination agency.

4.2.2 How to analyse the comments?

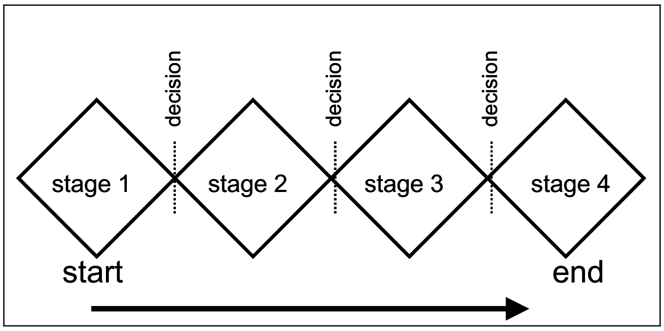
Responses should be carefully and open-mindedly analysed, and the results made widely available, with an account of the views expressed, and reasons for decisions finally taken. It is important that the authority of the area in question is able to respond to the comments and be responsive to the public/stakeholders. They need to be informed on the arguments for decisions taken and the final outcome of the planning process. Also, it should be ensured, that the authority that displays the plan, or the authority that collects comments, is able to forward, to the co-ordination unit and/or the relevant regionally competent authority, comments that refer to parts of the river basin district for which the authority does not have regional competence. When many comments are received it is advisable to categorise the comments. Subsequently the answers, motivations and decisions can be prepared per category in one surveyable document and returned to the public/stakeholder.



Look out! Feed-back
It is important to give feedback to the participants of the consultation. The feedback should contain a motivation and be returned in a reasonable time frame. Remember that in future these consultations need to be organised every 6 years. 'Cherish' the participants: you will need them again!

4.3 How to organise consultation

Dealing with organisation there is the need for a well-organised tailor-made design, using the earlier mentioned planning process diagram:



Stage 1	Starting stage: TOR for your project, indicate clearly the boundary conditions;
Stage 2	Exploring stage: diverge and explore all possibilities/ideas;
Stage 3	Ranking stage: converge and cluster/prioritise the possibilities, make a decision and agreements on further activities;
Stage 4	Implementation and information.

4.3.1 More practically:

- Stage 1 "Process Start Up" meeting/workshop(s) with these groups or groups of key-stakeholders to discuss:
  - The objectives for consultation;
  - The working process (how to reach the objectives of art. 14) and decide on their role;
  - The preconditions (Terms Of Reference) for their involvement;
  - Availability and relevance of existing data;
  - Communication plan;
- Stage 2 Inventory of knowledge and perceptions on:
  - The description of the information to be consulted upon; what are the major issues?
  - Timing of this supply of information; is the time schedule of the Directive practical? Refine the time schedule
  - Who are we going to consult?
  - How are we dealing with the responses; management of information?
  - What tools do we have at our disposal for communication?
  - How do we give feedback;
- Stage 3 Analysis and structuring, decision making on consultation;
- Stage 4 Information supply to all relevant stakeholders.

4.4 Consultation on the timetable and work program (art 14 (1) a)

4.4.1 What tasks to be done?

By the end of 2006 at the latest, the public must be informed and consulted about the timetable and the work programme for production of the management plan and about the planned consultation measures.

4.4.2 How to organise the consultation?

The way consultation is organised depends to a large extent on the geographic scale of management plans.

At *river basin level and Sub-basin level*, both written and oral consultations can be organised. The relevant stakeholders and public in the river basin district should be given an overview of the planned plan-production steps (data collection, assessment, definition of objectives, decision regarding measures) and of the participating authorities and agencies (who is responsible for doing what, and by when). If necessary, information about other options should be provided; for example, regional informational events regarding the Directive could be held. With such overview information, the interested stakeholders and public become aware when they can raise their concerns and proposals.

The public that is consulted does not necessarily have to live in the river basin district concerned, a measure within the district may have effects on areas that are not assigned to the river basin district in question (e.g. adjacent coastal areas, groundwater aquifers). Persons, groups and organisations in these areas also fall under the definition of "public" and consequently they too have to be consulted. Practically this means that at a very early stage the area that may be affected has to be determined and that in the whole area (also if outside of the river basin district) the documents mentioned in Article 14 should be published and made available for comments.

At the *international river basin district level* a useful approach for the written consultation would be to publish internationally prepared papers, all with very similar wording, throughout the river basin district. A form of international co-ordination is needed on making the timetable and work programme including the proposed public participation measures. On the other hand, it is not clear whether such papers will be available on the international level at the time in question. But since only a first general overview is being provided, extensive co-ordination will probably not be required. The data regarding the competent authorities, and a timetable, must be available for all river basin districts by 2006.

Alternatively, the Member States would have to take action independently from each other. In any case, certain content of this information level (such as who does the international co-ordination, who works internationally in support of whom) should be provided in standardised form. Consequently, the relevant discussion on the EU level and in the international river district commissions must be awaited.

Article 14 (1) 2nd sentence, "*Member States shall ensure that, for each river basin district, they publish and make available for comments to the public, including users:*"
The information and documents mentioned in Article 14(1) a) through 14(1) c) must be published and made available. The Directive does not specify what type of publication is required, but we can refer to the Code of practice on written consultation (see Section 4.1).

In discussions in Brussels, the Commission has repeatedly called attention to the Internet, which some Member States have already been using successfully even for larger planning projects. The Internet offers a good opportunity to describe and present transposition of the Directive, which is a complex process, in an understandable way. Using the Internet some questions have to be answered, e.g. the rate of the target audience with a connection to the Internet, whether additional paper versions have to be made available to the part of the public without access to the Internet, if personnel would have to be assigned to guide through a management plan, if internet access of appropriate authorities could be used by the public.

4.5 Consultation on "significant water management issues"

4.5.1 What tasks need to be done?

In the second consultation step, a preliminary overview of the important water management issues for the relevant river basin district and for its river basin(s) (the Directive's use of these terms in Article 14 is not standardised) is to be published by the end of 2007 at the latest. The important issues for the river basin district can be derived from:

- The analysis of the water-quality inventory that is to be completed by the end of 2004;
- The subsequent discussion regarding definition of objectives (taking into account the exceptions provided by the Directive);
- The necessary measures;
- The perceptions, knowledge and experience of the relevant stakeholders.

By the end of 2007, a relatively homogeneous assessment of the key requirements for action should be available throughout the entire river basin district. By this point, assessments should no longer differ, since otherwise any co-ordinated approach would be endangered.

4.5.2 How to organise the consultation?

The examples in the boxes hereafter show different forms of consultation at different geographic scales:

(Inter)national and district level

The International Commission for the Protection of the Danube River (ICPDR) is the co-ordinating body for international aspects of the Directive's implementation. ICPDR is promoting public participation in the planning process, through financial support to the ICPDR Information System, including the Danube Watch, as well as operating networks such as the Danube Environmental Forum (DEF), MLIM and AEWS. NGO observers attend the ICPDR meetings, and provide significant input to the work of the Commission (for example in the establishment of an Ecological Expert Group). Stakeholders are observers to the Commission, which implies full participation, no voting rights.

River Basin level

Water management Plan of the municipality of Örebro, Sweden (see Annex II)

The objective of the consultation is to fulfil the demands about public participation of the Swedish planning and building act concerning consultation in the development of comprehensive plans. A working group and a steering group consisting of a civil servants implement the work. A total of about 70 different authorities and organisations upstream the catchment areas and within the boarders of the municipality have been consulted on a draft plan during a seminar and information meetings. The working and steering group acknowledged their opinions and comments. The adjusted document was sent for a new round of consultations. Farmer- and water protection associations and the university were also involved

4.6 Consultation on River Basin Management Plans

4.6.1 What tasks need to be done?

The centrally important third phase of public information and consultation will begin at the latest at the end of 2008: publication of draft versions of the management plans. The content requirements for plans are described in Annex VII. Such plans, especially those for the larger river basin districts, are likely to consist of extensive documents with maps. At this point, these documents must already be nationally and internationally harmonised, to the maximum possible extent, so that they will clearly show what co-ordinated water management is planned.

4.6.2 How to consult?

National scale
A useful approach could be for the national or international co-ordination unit responsible for the river basin district overall to compile these papers and then provide them to the affected states.

River Basin scale

Consultation on the River Basin Water Plans, Spain

In Spain the development of Water Plans in the river basin districts is made by "Water Councils".

According the Spanish Water Act and the Regulation on Water Public Administration and Planning (Royal Decree 927/1988), the Water Council in each river basin districts has the duty of discussing and proposing the river basin plan to be approved by the Government. At least, one third of the total number of the Water Council members has to be of the representatives of the users.

A river basin Plan in Spain includes, among others, the following contents:
- Water resources assessment;
- Water demands evaluation;
- Criteria for water uses priorities;
- Water resources allocation for current and future uses;
- Basic water quality requirements;
- Measurements for groundwater protection;
- Water infrastructures needs.

4.7 Timing of consultation and international co-ordination

Article 14 (2) "*Member States shall allow at least six months to comment in writing on those documents in order to allow active involvement and consultation*"

For each of the above-described consultation steps, the public must be allowed a period of at least 6 months to comment in writing about the relevant documents. This period is probably reasonable but the over-all time schedule is tight, since results of consultations have to be incorporated within relevant papers, in harmonised form, for the entire river basin district. Especially with regard to consultation regarding draft versions of the management plans, the question arises of how the workload is to be managed. Therefore some consultation steps might be initiated earlier than the final deadlines specified by the Directive. This could save time that would then be available for later work. Therefore, an internationally co-ordinated approach is required, if co-ordinated results are to be presented.

Article 14 (1) requires that the public be consulted regarding the management plan for the entire river basin. This brings up the question of how such consultation should be internationally co-ordinated.

Harmonisation of the timetable plays a central role in this context. In light of the tight deadlines for transposition of the Directive, and the close succession in which the various consultation phases take place, international co-ordination regarding a parallel approach – if at all possible – would seem necessary. Suitable procedures for this should be approved by the relevant international bodies.

Furthermore, the question of what documents must be submitted, a question already mentioned above must also be considered. The key issue in this connection is what an international management plan should look like. Some international river basin district commissions are currently discussing the structure of a management plan for a river basin district. There is concern that too little time will be available to produce such a complex work, especially if it is to be logical and coherent.

Section 5 – Access to information and background documents

Access to information and to background documents covers two aspects:

- Sufficient "Information supply" in the different implementation steps; and
- Access to background documents and information according to Article 14 (1).

5.1 Sufficient "Information supply" in the different implementation steps

In the whole implementation process sufficient information is necessary to enable active involvement of stakeholders and the public in general. The following Section will describe how this can be organised.

Sufficient refers to:

- The different stakeholders and the public;
- The kind of information (progress in the planning process, results and outcome of analysis, proposed measures and plans, arguments in decision making);
- The way information is being provided (in a understandable and easy way, with e.g. announcements where to find information if required). For the public in general, the Internet, brochures and television spots are useful means. The organised stakeholders will most probably get all the relevant information in the steering groups or commit-tees established.

The following examples illustrate how the information supply can be organised. You often see a combination of "on-line" information supply through Internet and mail and off-line meetings and conferences to inform the public of the output of the planning process. Objectives like awareness rising, promoting changes or just to inform people influence the final selection of tools. The availability of budget resources often determines the final choice.

Alcobendas-city, Spain (see Annex II)

The objective of the project is to raise awareness of the population, local authorities and SME's in Alcobendas, a Madrid suburb, on water consumption. A comprehensive package of activities has been implemented, including:

- Exchanging technical and scientific information to encourage the introduction of effective water-saving technologies and programs and water demand management;
- Promoting new regulations;
- Stimulating the water-saving technology market;
- Promoting changes in the productive sectors;
- Increasing public awareness of the need to participate actively in saving water;
- Offering an example of the introduction of effective water saving measures in new homes;
- Publicising the results and methodology so that they can be adapted to other towns.

Activities included press conference, calls and visits by media-rep's, TV reports on water-saving systems, interviews radio stations, and publishing of articles.

Information letters for the implementation of the Directive in Thuringia, Germany (see Annex II)

The objective is to make the persons or organisations interested in water management issues acquainted with the objectives and necessary steps of the Directive and to express their ideas and proposals. At the moment the information letters (six pages) are published twice or three times a year (available in printed form or via internet. At the end of the letters a contact person is named (phone and email) The until now huge demand for the information letters encouraged the Thuringian Environment Ministry to expand this approach in the future. The information letters and the contact to the ministry should be used also as platform with regard to other Thuringian ministries and to other of the 16 German Lander. The information should become intensified and specified, e.g. by information on special issues.

The National Commission for Public Debate, France

A wide range of methods and tools is applied to inform the public

- **"supporting dossier":** provided by the project leader, gives to the public the necessary information to participate - general description of the objectives and the main characteristics of the project, estimation of the economic and social stakes, identifications of the main environmental impacts and evaluation of the economic and social costs of the project - (for example, for the TGV Rhin-Rhône project, 6000 were distributed);
- **"information letters of the debate"** or "lettres du débat: to inform the public on the debate, mobilise it regularly to participate and communicate information on the evolution of the debate " (for the TGV Rhin-Rhône project: 2 700 000 were distributed);
- **public meetings** (TGV Rhin-Rhône project: 10 in different cities);
- **Internet web site:** to have information on the project and the organisation of the public debate (for the TGV Rhin-Rhône project: 6500 visits, 70 per day);
- **Visits** to the headquarters of the specific commission to consult more detailed documents on the project;
- **Question-answer system** (TGV Rhin-Rhône project: 2000 questions received);
- **Prepaid cards**: distributed with the information letters, to ask for further information;
- **mail:** for sending remarks, opinions or thoughts;
- **toll-free number**: to ask for information and questions;
- **E-mail:** from the Internet web site, to ask questions and consult all the answers already given;
- **"contributions"**: mails received at the commission which showed one particular and developed position (TGV Rhin-Rhône project: 85);
- **"stakeholders book"**: selection of some of the observations from the public were published in so-called "stakeholders books" ("cahiers d'acteurs") and distributed (TGV Rhin-Rhône project: 10 books in total);
- **press** (example, for the TGV Rhin-Rhône project: 163 articles published in the regional press, 26 in the national press and 10 press meetings in the 10 cities where the public meetings took place).

For more information, see Annex II.

5.2 Access to background documents and information according to Article 14 (1)

Article 14 (1) "*c) request, access shall be given to background documents and information used for the development of the draft river basin management plan.*"

As a minimum the background documents should include all the documents that are summarised in the river basin management plan (Annex VII). The Article 14 sentence above is referring to an additional right to information, a right that must be exercised via special application. The Directive does not specify to whom such application must be made. There may be one central information- and knowledge centre in a river basin and a national and/or regional centres can be considered (in case of an international river basin). At least these centres should have access to background documents or information. The set-up of these centres and the procedures for providing access to information has to be decided on (see Annex VII A. 11) in the river basins. Background documents can be provided in the form of inventories of pressures and impacts on water bodies or details with regard to the programs of measures or more detailed information on implementation levels under the river basin district level (the public will ask "What consequences will the river basin management plan have for myself or my water uses?"). The Directive does not specify how quickly a request for information should be answered, but taking the Aarhus convention as a reference, one month could be advised.

The possibility of also placing background documents on Internet, and of making relevant reference, should also be considered. This will be a rather small effort, as relevant files have to be prepared anyway for inventories under the Directive.

The Municipality of Örebro's water management plan, Sweden (see Annex II)

Objectives Public participation
To fulfil the requirements for public participation under the Swedish Planning and Building Act of 1987 concerning consultation in the development of overall plans. A working group and steering group consisting of civil servants have been implementing the project.
A total of about 70 different authorities and organisations upstream of the catchment area and within the municipality's borders have been consulted on a draft plan. Their opinions and comments were acknowledged by the working and steering groups. The adjusted document was circulated again for consultation.
Those involved included farming and water conservation associations along with Örebro University.
Consultation was effected by organising seminars, information meetings and hearings and by circulating proposed land use plans for consideration by the parties involved.

The access that must be provided to background materials and information could be seen in connection with the Environmental Information Directive, its transposition into national law and the Aarhus Convention. The Aarhus Convention caused an amendment of the Environmental Information Directive (Directive 90/313/EC) and national laws will have to be harmonised with this amendment by the end of 2006. The materials and information referred to in the framework of Article 14 (1) 3rd sentence are all environmental information within the meaning of the information Directive (both definitions are extensive in scope and also include, for example, measures that could have an impact on environmental media). For this reason, transposition of Article 14 (1) 3rd sentence could employ a cross-reference to national environmental information law and its procedures.

Section 6 – Evaluation, Reporting results of active involvement, public information and consultation measures

Annex VII of the Directive requires that the river basin management plans cover *"a summary of the public information and consultation measures taken, their results and the changes to the plan made as a consequence"* (Annex VII.9) and *"the contact points and procedures for obtaining background documentation and information referred to in Article 14(1) (…)"* (Annex VII.11)

This requirement serves the information of the Commission in its role as "Guardian of the Directive", but can also be used as a tool to improve public participation in the next planning cycle. In that case, reporting is used in an evaluative manner, introducing a learning process. In this Section, both reporting and evaluation are treated.

6.1 Reporting

6.1.1 Why, what, who?

The Directive, as pointed out above, requires reporting on the public participation process. Reporting brings transparency into the public participation process, and gives feedback to the participants on what has happened with their comments. With respect to that, more than an *ex post* tool for supervision of the Commission over the Competent Authority, reporting is a tool for involving the public. Reporting therefore, should not only be directed at the Commission, but emphatically also to the participants involved before. It deserves consideration to report not only at the end of a participative process, but also during the process after participative activities (direct feedback). As stated in the requirements of the Directive, the whole process of participation should be described; from the way information is made accessible for stakeholders and the public, to the effect of the participation process on the River Basin Management Plan.

6.1.2 How?

The requirement from Annex VII, element 9 can be fulfilled by drafting a table with the measures taken and techniques used, the responses received from what sectors, and the implications of the responses for the River Basin Management Plan. It is recommended to take into account the reporting aspects on forehand, when designing a public participation process (this also has to do with 'management of expectations'; what do people expect to happen with their comments?).

It also is recommended to add quality indicators to the report, like:

- 'Facts and figures', description of the public participation plan (objectives and methods, who did you contact and why, how many reached, how many reactions etc.);
- Measuring of 'customer satisfaction' (how do participants judge the information supplied, the possibility to react, the actions following from their participation?);
- Comments per sector (did every sector react; implies stakeholder analysis);
- Proportion between resources for public participation and resources for the rest of the planning process.

The SDAGE projects, Reporting in the Adour Garonne Basin, France (see Annex II)

For each of the 10 French large river basins, a management plan has been produced according to the 1992 French Water Act, called SDAGE. In a modified form they will become the river basin management plan according to the Directive. The so-called Basin Committee is responsible for their initial elaboration. This Committee is composed of the representatives of all stakeholders and users in the River Basin District (about 100 members):

- 1/3 local elected officials (i.e. mayors, local communities)
- 1/3 users, consumers, NGOs
- 1/3 representatives of the State

The Basin Committee defines the management plan (SDAGE) and co-ordinates the coherence between SAGE Projects (management plans at the sub-basin/local scale). After three consultation rounds with 600 stakeholders and 1000 civil servants, a proposal for a river basin management plan for Adour Garonne Basin was finalised. The proposal was put out to a wider public for comments during 50 public meetings and finalised afterwards into a SDAGE, a river basin management plan, for the Adour Garonne Basin.

Reporting

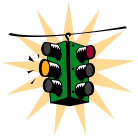
- The comments of the first three consultation rounds are reported in a "registry of comments" which is publicly available;
- Three documents will be published: the final river basin management plan (110 pages), an executive summary (25 pages) and a 4 pages leaflet. The information will be available on a website and can be downloaded from there. Background information is available on demand;
- Every year the Operation Board (under the Basin Committee) publishes an annual report including an executive summary and an informative leaflet, describing the progress of implementation of the plan;
- The SDAGE was made available to the *general* public only after its approval.

6.2 Evaluation

6.2.1 Why, what, who?

Evaluation can improve the quality of the public participation process. Evaluation has been defined as "a process of assessment which identifies and analyses the nature and impact of processes and programmes" (Interact 2001). The essential purpose of evaluation in the context of participatory processes is therefore to assess what they have achieved. Achievement can be assessed against both qualitative and quantitative criteria. And evaluation can examine how particular participation methodologies worked and if they worked well or not. In this way, those involved can assess the "worth" of the exercise, and how things may or may not be done differently in the future. It is vital from many viewpoints that an evaluation is carried out. Not only from the viewpoint of participants who have invested time and effort but also from the viewpoint of the organisers and (if different people) those that have funded a process.

In an ideal situation both competent authority (the organiser of the participation) and participants are involved in the evaluation. Not only to hear from the opinions of participants and stakeholders, but also to include them into the learning process. Further, it is recommended to draft evaluation from the start into the design of the public participation process. On the one hand, objectives should be drawn up in clear terms that actually can be evaluated, and on the other hand, evaluative steps can be build into the participative process in order to 'keep track of the process' and introduce improvements on the way.

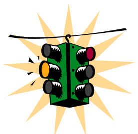


Look out! Evaluation should not be an afterthought
The needs of evaluation should be built into the design of the participation process from the beginning

6.2.2 How?

First: take into account the evaluation aspect when designing a public participation process. This already starts with explicit objectives (preferably quantified), together with timetables for their achievement, included to provide benchmarks against which progress may be assessed. The use of a common framework for evaluation can help ease of comparison where participation has occurred in several places within a river basin.

Outcomes are one of the hardest areas to assess and often outcomes can develop over time and it was too early to evaluate them fully. Outcomes can also be tangible in terms of hard outputs or intangible in terms of process and both are valid reasons for doing participation.



Look out! Evaluate on the basis of the objectives
It will be essential to evaluate public participation against set objectives and review it as the process progresses and plans and programmes are written

A quick evaluation sheet for specific events can be useful and an evaluation form could include questions like:

- Your role/how did you become involved;
- What do you think were the aims of the activity?
- What effect has your contribution made?
- What effect has the activity had on (physical environment, local economy, local organisations)?
- Was the activity worthwhile?
- Ideas for improvements;
- Advice to others holding similar events.

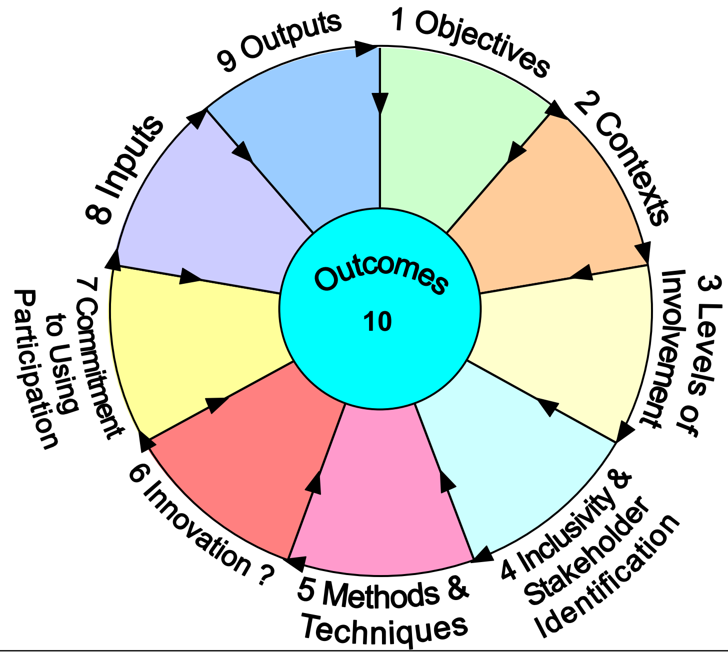
As with most of the issues surrounding participation, there is no right or wrong way to conduct evaluation and the key is to be as inclusive and flexible as possible.

A Framework for evaluation of participation

The following is one suggested basic summary sequential 10-point framework within which to approach the evaluation of the use of various participatory processes within a project or planning process.

Essentially this framework aims to evaluate both the participation 'process itself and the impacts of that process'. It is an adaptation for the EU Wise Use project of work done by Interact – (see references to this Guidance). The user would consider the headings for evaluation starting at 1 – the objectives of the participation and work round through headings 2- 10 culminating in consideration of number 10: the outcome of the participation – that is what was really achieved. Based on evaluation public participation processes and methods may then need to be reviewed.

Summary Framework for Evaluation of Participatory Processes



6.2.3 Evaluation principles:

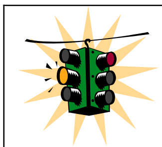
Principle: Try and incorporate time and resources for evaluation of participatory processes into the decision making process itself.
Principle: Carry out evaluation where possible throughout a process, not just once it is completed so processes can be revised and reviewed.
Principle: Make evaluation as inclusive as possible by involving a range of stakeholders (e.g. funders, project staff, participants)
Principle: Use evaluation frameworks where appropriate but also be flexible and allow for other, perhaps less formal evaluation methods.
Principle: Be aware that evaluation will reveal tangible results (e.g. product orientated) as well as intangible ones (process orientated).

Section 7 – Developing a Learning Approach to Public Participation; A key to success

The previous Sections have shown the importance of public participation in the implementation of the Directive. This Section aims to stimulate the reader to contemplate an intended public participation processes. Several factors are highlighted which should be considered for the benefit of the public participation process, but are not prescribed by the Directive. The factors mentioned here could sometimes make the difference between success and failure. Although the text of the Directive does not explicitly require an active participatory approach, the implementation of the Water Framework Directive should be done **together**. The future will also require a more inter-sectoral approach and a broader view on water management, crossing established boundaries and watersheds.

A willingness to improve, trust, transparency and a positive attitude to the process of implementing the Directive in conjunction with other stakeholders and members of the publicis essential for success. Each can learn much from the others. Such a learning approach has increasingly gained attention in, for example, larger commercial companies, which, on the one hand, have to constantly adjust to new expectations and demands of the market, while on the other hand, have to re-organise themselves and adjust their capacities accordingly. Active involvement of the public is indeed comparable to such a situation and subsequently calls for a more dynamic approach to participation and self-understanding among water management authorities.

While many examples have been used to illustrate practical ways in which participation can be undertaken, this Guidance cannot hope to encompass the variety of situations, which will be encountered over the next decade or more, as the Directive is implemented. Yet it will be necessary for competent authorities and other stakeholders to be able to respond to these challenges in a way, which is consistent with the spirit of the Guidance.

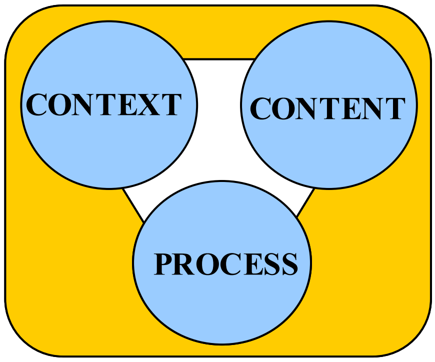


Look out! A dynamic and learning approach will pay off in the future
All, public, stakeholders and competent authorities, at any level, will benefit from increased communication, accumulation of knowledge and sharing of each other's experiences. Lessons learnt in the past will be valuable input for the future.

This Section draws attention to the factors, which underpin a learning approach to participation with three aims in mind. First, to *raise awareness* amongst competent authorities and other stakeholders that there is a need to develop approaches to public participation, which are tailored to local conditions (here 'local' even means the customs and traditions of an international River Basin District). Second, to enable the competent authorities to review and assess their own and others' *current approaches* to public participation. Finally, to enable the competent authorities and other stakeholders to begin to develop a *learning approach* to public participation.

A learning approach means that competent authorities and other stakeholders collectively take responsibility for creating the necessary conditions so that public participation becomes a way of learning about each others perspectives, views and knowledges, thereby providing the basis for negotiation between stakeholders about how best to implement the Directive.

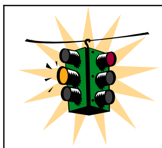
The following Sections illustrate some of the factors, which competent authorities will need to be aware of to assess and inform their own current practices and provide a basis for developing new approaches to public participation in the future. These factors can be grouped under the headings '**context**', '**process**' and '**content**'. Each is explained in turn.



Factors influencing the public participation process grouped in three main groups.

7.1 Context factors

Context refers to the **existing conditions or circumstances** in which the approach to public participation is being developed, since there will always be a 'history' of environmental management before the implementation of the Directive. It is impossible to describe the context of public participation in advance since there will be considerable variations between member states, over time, at different locations and scales and so on. However, the context can significantly influence public participation in terms of process design, content of discussions and outputs. In some instances the context may mean that it is inappropriate to initiate public participation without some change in existing relations between stakeholders. It is therefore necessary to be aware of the starting conditions if processes of public participation are to be successful.



Look out! Existing conditions 'set the scene' for public participation
These conditions evolve from a historical and local context regarding:
- Political culture of decision-making;
- Culture of stakeholder involvement;
- Organisational or institutional practices;
- Budget and resources;
- History of previous attempts to engage stakeholders;
- Environmental conditions;
- The scale of the project.

The strength of a good process is **to recognise the context** in which public participation is being developed and to realise that it may require competent authorities and other stakeholders to accept the need for some or all of the following **changes**:
- Changes in attitude of public authorities to the environment and other stakeholders;
- Organisational changes;
- Political commitment and resource allocation;

- Capacity building and representation of stakeholders;
- Reaching beyond stakeholders to individual citizens and enterprises;
- Demonstration projects to build trust and to learn from experiences.

These factors are explained in more detail.

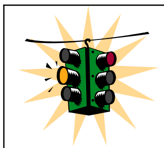
7.1.1 Change in attitude: stakeholders as partners in water management

Many government authorities have realised that the "command-control" resource management systems prevalent in the 1960s and 1970s have had some significant environmental consequences. Sharing the management of natural resources with the people that depend upon them for their livelihood, can help to make their management more sustainable, more efficient, less expensive, and more socially acceptable.

This shift means that the competent authorities may have to change their own organisational perspectives on the value of involving stakeholders in the process of decision-making and implementation. Dominating behaviour by authorities may inhibit participation, while an attitude where authorities realise they need to listen to knowledge, insight and solutions of their partners (stakeholders) in order to be able to provide high quality RBM plans encourages it. For those in powerful positions to adopt a non-dominating, learning attitude may even entail personal change amongst staff. This implies that water managers need to be technical experts *and* process managers. Adopting an attitude, which begins by defining water problems as human problems rather than technical issues, is a good way to begin to appreciate perspectives of other stakeholders.

As a simple way of revealing current attitudes to public participation, we invite reflections on the following questions:

- Why does your organisation (want to) engage in public participation?
- How is this achieved?
- With what results?
- To what extent have either the process or outcomes changed you or your organisation in any way?



Look out! Listen and be open minded
Public participation will not be successful if competent authorities and stakeholders do not respect, listen and learn from the views and perspectives of each other so that over time they become partners in the implementation of the Directive.

7.1.2 Organisational changes

Since public participation often requires a different working approach by competent authorities, it follows that a number of organisational changes may also be necessary. At the most basic, it may be necessary for the competent authority to :

- **Review its current organisational structure** to determine the level and focus of public participation at present and the extent to which its current organisational structure encourages or constrains public participation in decision-making;
- **Review the skills, experience and competencies of staff** to assess whether the competent authority either currently has the competency to engage in processes of public participation or whether it may need additional training;
- **Review the current budget and resources allocated to public participation.**

The need for an organisational review of competent authorities and the findings of the review will vary across the different member states. A review should really be considered since it is often too easy and too simplistic for one organisation to assume that it is *other* stakeholders that need to change when there is conflict. Equally, a review will encourage the competent authorities to determine training needs for staff that may have limited experience of public participation.

The process of public participation may also affect the organisation's practices. These may require the competent authority to ensure some or all of the following become part of the organisations 'way of doing things':

- **Making the results of the planning process more open-ended** (depending on new insights, knowledge, ideas for solutions). Active involvement is characterised by more open-ended processes. Active involvement is by its nature more uncertain and unpredictable in terms of content, scale, financial cost and time;
- **A flexible approach to the contributions of stakeholders**. The timing and tempo of stakeholder involvement may change throughout the process. The competent authority may have to make allowances for this;
- **A flexible approach to financial planning**. As decisions are made in partnership with other stakeholders, there will need to be some provision for open budgets (i.e. not earmarked to certain measures before hand);
- **Retaining a local rather than organisational perspective**. Public authorities working within a certain sector and or institution inevitably orientate towards their own obligations ands objectives and the delivery of these become the key concern. It is important to ensure that the local, broader context is not forgotten. 'Local' in this sense are also the habits and traditions within an international River Basin District.

The challenge of all types of organisations will be to handle these changes. Changes in procedures and structures take their time. However, in the meantime the change in attitude and skills of the motivated employees, actively supported and resourced by senior level management, will help in finding "room for change" within the existing organisational and institutional context.

7.1.3 Political commitment

The starting point for embarking on a participatory approach is a commitment at political level. This commitment has to be based on an understanding and awareness of the new obligations and why active involvement is not only beneficial but also necessary in order to deliver the anticipated water quality objectives as a significant part of promoting sustainable development.

In this regard, political representatives need to be aware of the following:

- The aims of public participation in relation to the development and implementation of the directive;
- The nature of participation, its implications and whether it compliments or replaces previous practices;
- The potential of stakeholders' contribution to water management;
- The need for political commitment to the process *and* the outcome;
- The role and timing of formal decision-making in the process and hence the particular contribution of political representatives;
- Means to reach beyond organisations and institutions to individual citizens;

- Possible consequences of the process. For example will changes in water pricing be more or less acceptable as a result of public participation in the decision-making process?
- Water management is no longer the sole responsibility of government authorities. Network organisations are needed in which government organisations work together with NGO's, business enterprises, interest groups, and experts (universities);
- The commitment from the politicians needs to be transformed into concrete resource allocation ensuring sufficient staff, budget, mandate, ambitious public participation objectives and internal training.

The **Danube River Basin** takes up approx 1/3 of the surface of Europe. Within this scale, linking local and international levels constitute a major challenge. The international cooperation takes place within the framework of the Danube River Commission ICPDR). **(see Annex II)**

Stakeholders e.g. NGOs can apply for observer status to the Commission, which implies full participation, no voting rights. A large number of smaller (national and local) NGOs are connected with this through co-operation platforms, notably the Danube Environment Forum (Assembly of NGOs), and other networks such as the Global Water Partnership CEE. The GEF-financed Danube Regional Project supports the Danube Environment Forum (DEF) by financial means, hereby enabling the NGO-participation in practise.

DEF is an NGO platform with combined local and regional structure, established in 1999 to promote NGO participation in government fora, programmes and initiatives. Within this context, the NGOs have been able to contribute e.g. as follows: facilitating dialogue on trans-boundary River Basin Planning, participating in the establishment of ICPDR Expert Group on River Basin Management and WFD Implementation, development of Issue Paper on WFD and Public Participation, ensuring NGO and public participation in the Danube River management and co-ordination through DEF, providing concrete, local cases for the ICDPR discussions.

7.1.4 Capacity building and representation of stakeholders

To take the steps from some degree of "consultation" towards "active involvement", whatever shape it may take, will be a challenge for the competent authorities and other stakeholders. As noted above, an organisational review will help identify whether those involved (whether the competent authority or any other stakeholder) in the process have sufficient capacity to engage in public participation. The capacity to engage could be dependent on resources, availability of experienced and qualified staff, their knowledge of the situation (e.g. what happens down-stream) and the extent to which those involved are willing to acknowledge the potential for change in the management of the water issues under consideration. This will mean that participants will have to be willing to take co-responsibility for decisions, which emerge from the participation process.

Providing stakeholders with improved access to information and decision-making, will also oblige them to take shared responsibility for utilising their networks and communication channels. Their members and associates should be made aware of some of the implications of the Directive and possible consequences of its implementation, for example about the Programme of Measures.

For example, business sectors that are further involved in the decision-making, and are eventually presented with demonstration projects aiming to identify appropriate water management solutions, will have an obligation to inform their members and encourage them to adopt a new approach to water use. For companies, an analysis of their situation and interests with regard to water management could include questions on the following issues:

- Current water use;
- Current pollution levels/recent pollution permits;
- Current measures to reduce/prevent pollution or other pressures;
- Relative cost levels on water use and wastewater services;
- Current incentives / legislative framework for water use;
- Degree of subsidises in the production process;
- Experiences with EMA / code of conduct / good agricultural practices;
- Awareness level and knowledge of the river basin, particularly down stream.

Equally, NGOs usually have intermittent problems financing their work programmes. Often they depend on various funding schemes offered by national or international donors. These schemes will become particularly relevant in situations where the competent authorities request participation in water management bodies. This problem is particularly relevant for local NGOs and regional branches of national NGOs, being less experienced and having less resource than the central offices, with often only voluntary members.

It will be up to the competent authority to determine how its own organisational approach to public participation can help other stakeholders overcome some of these and similar problems to build the capacity among a wide range of stakeholders to progress the issues. In some cases it may be appropriate for the competent authorities to provide, for example, secretariat support to stakeholder networks, to make information widely available and perhaps to offer training events on specific aspects of the Directive. Equally, the possibility of stakeholders informing and providing 'training' to the competent authority should not be discounted. Capacity building will be a two-way process.

7.1.5 Reaching beyond organisations to the individual citizens and companies

A significant part of a participation strategy should be prioritised to consider reaching beyond organisations and institutions to individual citizens. A large part of the water use as well as water pollution is generated at the level of single households, dispersed settlements, individual companies and agricultural units.

Reaching beyond organisations to individual citizens and companies is crucial for water management, due to the large share of water use and water pollution held by individual households, dispersed settlements, small and medium enterprises and small agricultural units.

7.1.6 Demonstration projects to build trust and to learn from experiences

Demonstration projects will help evaluate and demonstrate the success of public participation in the water management sector and offer the potential for all stakeholders to learn from practical experience. Competent authorities should be encouraged to initiate such projects. These projects could have a wide range of aims:

- Through a "don't talk about it - show it"-approach, to convince target groups to embark on new, different practices with regard to active involvement;
- To create win-win situations: active involvement gives stakeholders the possibility to influence the implementation process with regard to their interests, while the competent authorities will achieve a more widely accepted implementation.

Reducing water consumption in the Graphic Sector, Denmark (see Annex II)
The objectives are:
- To involve stakeholders in the set-up and implementation of demonstration activities;
- To make them "ambassadors" of the new water consumption practices, by showing results and its impact on sustainable water consumption.

The Danish Environmental Protection Agency unit for cleaner production consultancy company, selected companies from the Graphics Sector. The Graphics Business Sector Association were involved comprehensively throughout the entire process shaping the improvements within the daily activities of the companies and testing new equipment, supported economically by the project. With rather limited funding schemes, demonstration activities can successfully be conducted, with the results being extracted for later inclusion in revision of environmental regulation of the sector's environmental impact. Demonstration of concrete opportunities and providing of win-win examples allows for a new business paradigm to spread. Further, through this co-operation the Competent Authorities also get input on how to establish a feasible planning and incentive framework.

7.2 Process Factors

'Process' refers to **the ways in which stakeholders participate** in the implementation of the directive. This is not limited just to the 'delivery' of the directive, but includes the process in which stakeholders engage with each other to negotiate on issues of concern, possible actions and to determine how implementation can be best achieved. Experience has often shown that the quality of the process determines whether wider support for actions and measures is forthcoming.

The quality of the process is dependent on the principles which inform its design. It cannot be overstated that **trust and transparency** are fundamental to mobilising stakeholders to engage with each other and to take on shared responsibility beyond their own immediate interests. The difference between being partners in water management and opponents often rests on a lack of a trust, suspicion of hidden agendas and lack of a co-operative climate for creative solutions. The participation process should encourage:

- Trust;
- Openness;
- Transparency;
- Honesty;
- Respect;
- Inclusion;
- Positiveness.

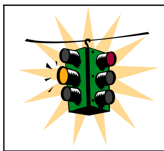
Translating these principles and using them for the design of a participation process is not always easy, since there are many stakeholders, new situations emerging and many aspects of process which need to be considered. However, practical experience suggests that a number of common factors, relating to process design and performance, are key issues for consideration by competent authorities and other stakeholders.

In summary, **processes for public participation should be characterised by some or all of the following:**

- Early involvement of people in setting the terms of reference;
- Developing co-ownership of the process design;
- Opportunities for learning between stakeholders;
- Mutual respect;

- Flexible and 'open' process;
- Iterative and continuous evaluation;
- Independent facilitation;
- Ongoing.

The above list does not include specific recommendations as to *how* to enable opportunities for learning, for example. This is because there is no one method which will work for all in all situations.



Look out! Challenges in the process
The challenge for the competent authority is to take these factors into account while developing and organising the process of public participation in conjunction with other stakeholders.

7.2.1 Early involvement in setting the terms of reference

This is an important consideration and should not be overlooked by competent authorities since one of the most common causes of problems in participation occurs when stakeholders feel excluded from the aims and design of the process. Involving stakeholders in setting the terms of reference can help to build trust and establish dialogue between different interest groups from the outset. The terms of references for the process might include agreement about the following:

- Objectives of the process;
- The general scope of the process;
- The range of stakeholders who are likely to be interested;
- Expectations of those involved;
- Communication protocols;
- Financial resources and allocation;
- Organisational support and contributions as required;
- Timescale and timetabling; and
- The contribution of the process and its outputs to formal decision making.

It is important to remember that the terms of reference can be modified as conditions change, the process gets underway or as new stakeholders are involved for example. This is particularly true of the process objectives, scope and participants.

7.2.2 Developing co-ownership of process design

As with setting the terms of reference, it is important that competent authorities explore with other stakeholders how best to proceed with public participation since there is no single design for participation which will suit every situation. A process based on co-development and co-ownership is likely to build trust, attract greater support from stakeholders and create a mutual willingness to make the process a success. Co-ownership also tends to ensure that the process is more suited to its purpose and maximises the skills and capacities of those involved. It will therefore be necessary for competent authorities to guard against presenting a pre-determined approach without an equal opportunity for participants to contribute to the process design.

7.2.3 Opportunities for learning between stakeholders

The design of the process should help to create opportunities for learning between stakeholders. This goes beyond simply presenting information (such as a lecture or presentation), which tends to be one-way rather than two-way communication. Instead, the design of the process should seek to encourage active dialogue between participants. In some instances, simply the act of bringing people together for the first time results in new insights about the different perspectives, aims, successes and problems of each other's work. This can develop into regular meetings of stakeholders to help establish new partnerships and help alleviate problems before they arise. While dialogue to develop understanding and enable learning between stakeholders is important, the process has to be more than a 'talking shop'. Experience and research suggests that stakeholders are highly motivated by achieving results 'on the ground'.

7.2.4 Mutual Respect

In many instances, stakeholders are not always in agreement with each other and differences of interest and opinions can often be entrenched. The process should encourage stakeholders to respect each other's views. Independent facilitation is often useful in these instances. For some, including competent authorities, this will not be easy to accept particularly if previous encounters have been marked with hostility and strong disagreement. Nonetheless, a learning approach to public participation will only succeed if there is an explicit acknowledgement of difference *and* a commitment to exploring the nature of that difference to identify possible common ground and agreement on how to proceed. The differences are often expressed in a variety of ways such as: disagreement about what the problem is (the identification of the problem); the kinds of information which are considered acceptable (scientific and non-scientific); and ways to proceed and the likely consequences of particular causes of action. The competent authority is likely to be in a central position here and should work to ensure that the invitation to participate and the process of participating builds a sense of mutual respect among all stakeholders by valuing the diversity of interests, views and opinions.

7.2.5 Flexible and 'open' process

This design factor is an important reminder that all stages of the process cannot be pre-determined. A flexible approach to process design is more able to accommodate change and learning as stakeholders engage with each other over time. Equally, an 'open' process is part of building trust between stakeholders. If the process is too rigid and constrains discussion then stakeholders are likely to withdraw support. In agreeing to participate, all stakeholders, including competent authorities, are under an obligation to listen and take note of others concerns. This may mean altering the process design over time.

7.2.6 Iteration and continuous evaluation

Iteration is about inviting participants to review the process, to reflect on what they have achieved so far and whether changes are needed to either process or content. It is part of the continuous evaluation of the process so that learning is incorporated into the process *immediately* and can inform current (rather than just future) ideas, negotiations and so on. This can be very effective, for example, where a new understanding emerges between stakeholders (such as a redefinition of the problem) and shifts the basis of participation onto a new level. Building continuous evaluation into a process can be as simple as identifying time for reflection at any stage – this creates a space in which participants can review what has occurred. The important point is that evaluation is not only just about an ex-post assessment or an evaluation of the outputs. It should be an on-going process.

7.2.7 Independent facilitation

This design factor is not always appropriate since some types of participation are not facilitated. However, independent facilitators can be particularly beneficial when relations between stakeholders are difficult and there is a lack of trust or respect between participants. Using a neutral third party can also help avoid concerns that the competent authority might dominate debates and agendas. Allied to this, it may be necessary for meetings to be held on 'neutral' territory. In any event, consider rotating the location of regular meetings between the different participants. This can keep ideas 'fresh' and new insights and understanding can be gained just by visiting offices of different stakeholders.

7.2.8 Ongoing

While large-scale one-off events have their place in participation, too often they either fail to have a lasting impact on the issues or they fail to generate large-scale ownership and commitment to act. Experience suggests that smaller scale, *ongoing* processes tend to provide more opportunities for stakeholders to establish trust and understanding between each other and are more likely to generate long term momentum. It also ensures that stakeholders who cannot make one particular meeting because of time pressures are not excluded, as they would be if the meeting was simply one-off.

7.3 Content Factors

Many of the **factors relating to content** are closely linked to the design of the process to the extent that many experienced practitioners of public participation often pay more attention to getting the process 'right' in the knowledge that the 'content' tends to follow naturally. As with other parts of this Guidance, it is impossible to be specific about the content of participatory processes. Even so, it is likely that the following factors will be important at some stage in the process:

- Valuing diversity of knowledges;
- Evidence, proof and uncertainty;
- Reporting and communication.

7.3.1 Valuing diversity of knowledges

As more stakeholders are involved, so the diversity of their experiences, views and knowledge is likely to increase. It is important to be aware of, and value, the different types of knowledge which stakeholders draw upon. These might include, for example, scientific expertise, and situated non-expert knowledges – often from stakeholders who live and work in the locality. It is important to realise that expert *and* non-expert knowledges can contribute to a better understanding of the root causes of the problem and lead to a more informed and relevant plan of action. Experience in the water resource sector has shown that generic 'expert' solutions have often been inappropriate for local conditions and have had unintended negative effects. Many of these could have been avoided if scientific expertise had been combined with local knowledge and experience. This is not least likely to be case with regard to defining the reference conditions, where knowledge on historic conditions - being equally distributed with authorities and other parts of society - may turn out to be of crucial importance, e.g. previous physical appearances of rivers and wetlands.

7.3.2 Evidence, Proof and Uncertainty

While valuing diversity is important, it can also create problems for determining what is accepted as 'evidence and proof'. Some stakeholders may insist that only 'scientific' evidence is acceptable as the basis of the decision-making process. Others might want to fill in gaps or qualify this information with their own personal experiences and observations. However, there will be many occasions where no scientific information is available or where considerable uncertainty exists either about the resource base of the consequences or of intended courses of action. There is no easy answer how to proceed under these conditions. However, if the process design is robust, then debates over uncertainty can be aired and decisions taken with this in mind. We suggest that competent authority should try to ensure that decisions are based on all the available evidence by accepting that non-scientific information can be a legitimate form of knowledge about the environment and can be used to compliment and inform expert opinion. In conditions of uncertainty, it will be necessary for the degree of uncertainty to be made explicit.

7.3.3 Reporting and communication

Non-technical summaries, which reflect the perceptions of the stakeholders and the broad public, are important in the reporting of the process. This also includes providing non-technical summaries of the RBD analysis for the local catchment situation. Thus, local stakeholders will be able to identify themselves with specific situations.

7.4 Conclusion

The preamble of the Water Framework Directive includes a very clear statement: active public involvement is most likely the key to success with regard to achieving the desired water quality objectives. This statement reflects several years of accumulated European water management experiences. In simple words: the water users and water polluters need to be turned into part of the solution, not being left outside the considerations as part of the problem. This Guidance has presented a range of recommendations on how to ensure active involvement. It is important, however, to take into account that no blueprint solutions can be provided. Each River Basin District has to find its own way to handle this, taking into account the prevailing cultural, socio-economic, democratic and administrative traditions. Careful planning, e.g. stakeholder analysis, is a particular recommendation, but each competent authority has to accept that a dynamic and learning process based on "trial and error" is the challenge to embark on. Experience show, however, that given sufficient time, it will pay off in the long run.

Annex I - Public Participation Techniques

November 2002

Why, who, when, how?

The first three fact sheets discuss the preparational steps of the participatory process:
1. Stakeholder analysis;
2. Problem and cause analysis;
3. Communication planning.

In the fourth fact sheet, the different communication techniques are listed, from two perspectives:
4. Interaction and communication tools.

The other fact sheets focus on specific techniques. In the future, e.g. after the Pilot River Basin testing, information sheets can be added:
5. Interviews;
6. Active listening;
7. Workshops;
8. Creative sessions;
9. Citizens' Jury;
10. Interactive Geographic Information Systems (Web GIS);
11. Public hearings (see also tool 9. Citizens'Jury);
12. Monitoring and participatory evaluations;
13. Computer tools for processing public comments.

Reference list
This list is currently empty but in future links and references to public participation tools can be added.

1. Stakeholder-analysis

When embarking on an interactive process it is of utmost importance to consider who will be participating in the process. To get an overview of all the relevant stakeholders (or actors) in the field of interest, a so called "stakeholder-analysis" can be performed. This analysis reduces the risk of forgetting an important actor and will give an idea about the different angles from which the subject can be viewed.

Stakeholder-analysis itself is a relatively simple and a methodological exercise. A possible methodology is presented in this Annex along with an illustration. However, it is left to the reader to assess how this can be adapted to her/his own situation and made relevant to the economic analysis process.

Background

A stakeholder can be any *relevant* person, group or organisation with an interest in the issue, either because they will be affected by the subject (victim, gainer) or because they have influence, knowledge or experience with the subject. The analysis will bring transparancy in what stakeholders already exist and which interests they represent. Types of stakeholders are: government, local authorities, non-governmental institutions, political organisations, research institutes, industries, agriculture, households or other businesses.

A stakeholder-analysis is usually performed starting from the contents of a project using the "who?" question (for example: we want to build a house, who knows how to build it?). Be aware that the problem definition must be clear from the beginning and that the problem shall be viewed from as many different angles as possible.

Besides analysing the stakeholders it can be uselful to map the environment of a project to identify external influences. The map could tell something about the interests, motives and relationships of the actors identified, the field of force they operate in and risks. For example: which stakeholders have a positive or negative influence on the project, who has power, who has the biggest monetary interest? Similar mapping can be done for factors influencing the process, often expressed as threats (e.g. weather, financial or human capacities).

Generally, a process consists of several stages (as illustrated in Figure 1). For every single stage, it should be reviewed which stakeholders are relevant to involve in the process and if the stakeholders have the same "rights". The role and involvement of the stakeholder can differ from stage to stage, and the stakeholder-analysis will make this more transparent.

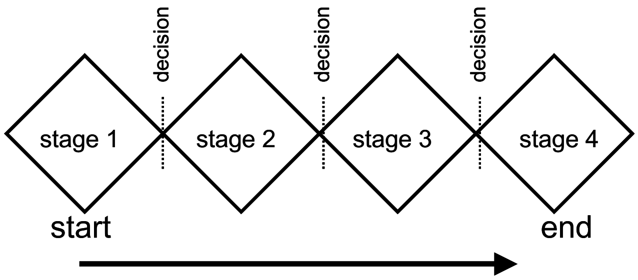


Figure 1: A process represented in diagram form

During the stakeholder-analysis the *degree of involvement* of every stakeholder (per stage) can be labelled as either (see Figure 2):

- *co-operating/co-working*: the stakeholder that will actually participate in and contribute actively to the process (i.e. active involvement);
- *co-thinking*: the stakeholder of which you want input with respect to content, it is a source of knowledge like experts (i.e. consultation);
- *co-knowing*: the stakeholder which does not play an active role in the process but should be informed of its progress (i.e. information supply).

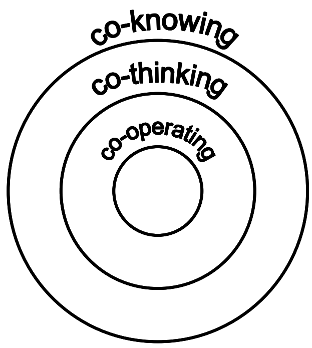

Figure 2: Target scheme to identify degree of involvement of stakeholder

If desired the identification approach can be refined by identifying the type of actor (see Figure 3):

- decision maker: stakeholders which decide about the project;
- user: stakeholders which use the result or are affected by it;
- implementer/executive: the stakeholders that have to implement the results or new policy;
- expert/supplier: stakeholders which put information, expertise or means at the disposal of the project.

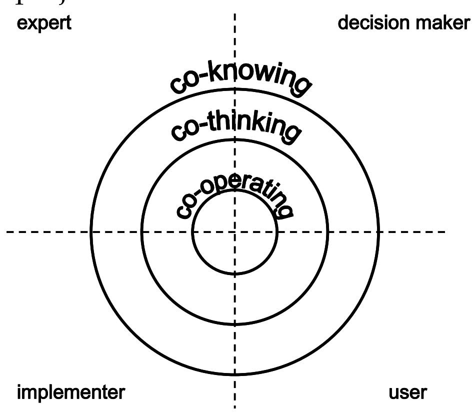

Figure 3: Refined target scheme to identify degree of involvement and type of stakeholder

Important! If the identified stakeholders are going to participate (actively or passively) in the project it is important to give feed-back to the stakeholder and specify clearly their role in order to avoid disappointments: management of expectations.

Stakeholder analysis: a simple methodology

Making the stakeholder analysis operational implies going through a series of steps of questioning and interaction. Although it needs to be adapted and refined to every situation, a simple methodology and series of steps is proposed below.

Step 1 - Define the stage of the process that will be subject to a stakeholder analysis. Putting the subject in question-form makes it usually more accessible and facilitate the identification of key issues/stages. It appears rather wise to invite stakeholders (of which it is obvious that they are involved) to take part in a brainstorming session;

Step 2 - A group of maximum 10 persons (the project team) including a chairman performs a brainstorming session in which as many stakeholders and perspectives or angles linked to the selected stages are mentioned.
Keep it rather general, name groups or organisations, not yet concrete names or people;
Every suggestion is written down without judgement.

Step 3 - Check if the main perspectives/angles can be split up into sub-units/organised in types;

Step 4 – Allocate to the stakeholders identified a concrete name (and address/contact information);

Step 5 - Check the result:

- Did we check all the stages of the process?
- Do we have the ones that benefit and the victims?
- Is the own project organisation included?
- Did we identify the people behind umbrella organisations?

Step 6 - Once the stakeholders are identified, the long list can be ordered by identifying the degree of involvement of each actor in each stage:

- Write down every actor on a Post-it notepaper;
- Draw up the "target"-scheme with circles on a flap over;
- Be clear about the stage in the process that is effectively analysed.

Step 7 - Put the notepapers in the right place in the "target"[2] (Figure 2 and if refinement is desired this can be repeated for Figure 3);

Step 8 - Check if there are no big gaps;

Step 9 - Use the result! e.g. for a communication plan to notify concerned stakeholders. Be very clear with each stakeholder about his expected role and involvement in the process (management of expectations);

Step 10 - The brainstorming session can be continued to identify relationships between stakeholders, their interests and motives and factors that influence the process.

[2] Keep in mind that the degree of influence of the stakeholders is a factor to be considered. It might be useful more closely to involve "big" actors with much influence to ensure commitment and a supporting basis.

Illustration of the stakeholder-analysis

A small case is presented for the illlustration of the methodology. Subject of the case is the pollution at the downstream part of the River Scheldt. The municipalities along the river recognise the problem and and want to improve the water quality, they are initiating this case. The process is described in Figure 4:

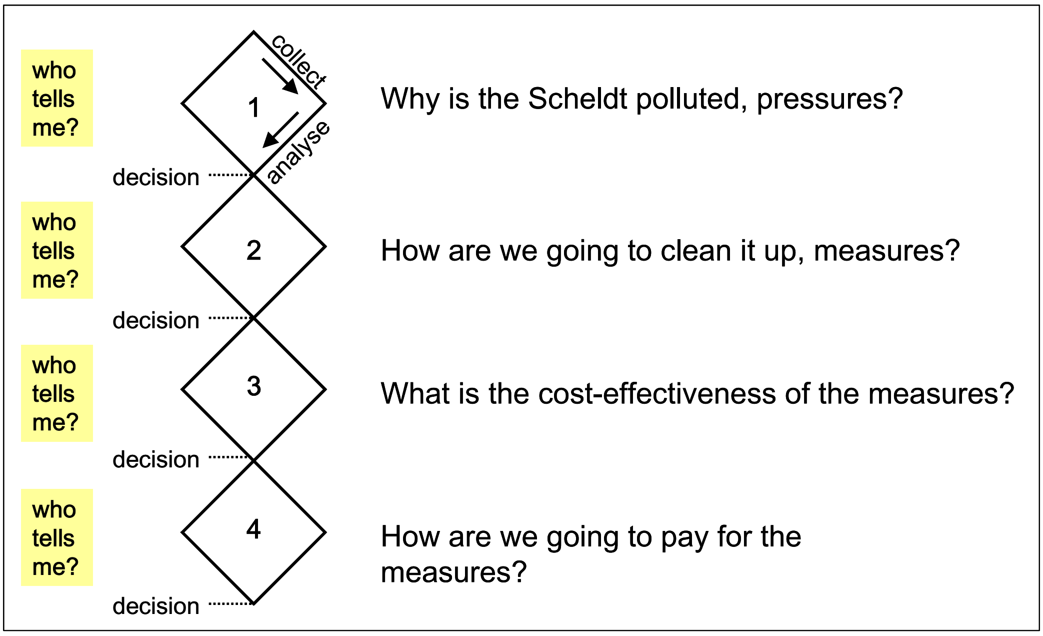

Figure 4: Different stages of a process concerning the pollution of the River Scheldt

Analogous to the presented methodology in the former sub-section, the possible results are presented below for the different steps of the stakeholder analysis and for the stage 1 of the process (i.e. why is the Scheldt polluter, pressures?).

Step 1 - Information is wanted about the pollution in the Scheldt, e.g. "Why is the Scheldt polluted?", who tells me that it is polluted?

Step 2 - The proposed project team will include the municipalities and they have decided to invite also representatives of the harbour of Antwerp and Vlissingen. As many different angles as possible are viewed during a brainstorming session. The output of this session is a (finite) list of stakeholders involved:

ICPS (Scheldt commission)	People in the neighbourhood
Agriculture	Harbours
Recreation	Municipalities
Dredging companies	Shipping traffic
Fisherman	Industries
Government	WWTP

Step 3 – More detailed discussions show that the type "Industries" can be split up into:
- Industries with emission to the air (deposit);
- Industries with discharge to the water.

Step 4 - The list is defined more precisely:

ICPS (Scheldt Commission)	People in the neighbourhood
Agriculture: - farmer A, B, C; - poultry farm D; - pig farm E, F.	Harbours: - Antwerp (B); - Ghent (B); - Terneuzen (NL); - Vlissingen (NL).
Recreation: - anglers; - canoeists; - cyclists.	Municipalities: Antwerp, Ghent, Terneuzen, Vlissingen.
Dredging companies: - company X; - company Y.	Shipping traffic: - EU umbrella organisation for shipping traffic
Fisheries	Industries: - emissions to air: industry G; - discharge to water: industry H.
Government: Belgium (Flandres, Wallonia, Brussels) The Netherlands	WWTP: Antwerp, Ghent, Vlissingen, Terneuzen.

For all stakeholders the contact person/competent authority should be identified and the address/contact information identified.

Step 5 - Checking the result shows that it is unclear which shipping companies are represented by the "European umbrella organisation for shipping traffic", as only shipping companies operating in the Scheldt area are seen as relevant. This will need further checks by the project team. It is also noticed that environmental NGO's are missing from the list of stakeholders identified so far, and the union for the "Protection of the Scheldt landscape" is added to this list.

Step 6 & 7 - The degree of involvement of the stakeholders is expressed by allocating stakeholders into the target scheme (Figure 5). For the first stage of the process (why is the Scheldt polluted, what are pressures?), much information needs to be collected. Thus many stakeholders end up in the second circle (co-thinking) of the target scheme. Some stakeholders are known to have a great socio-economic influence and are asked to co-operate together with the project team (inner circle). The outer border of the figure show the organisations that will be informed about the project.

Step 8 - Check for gaps in Figure 5, refine it.

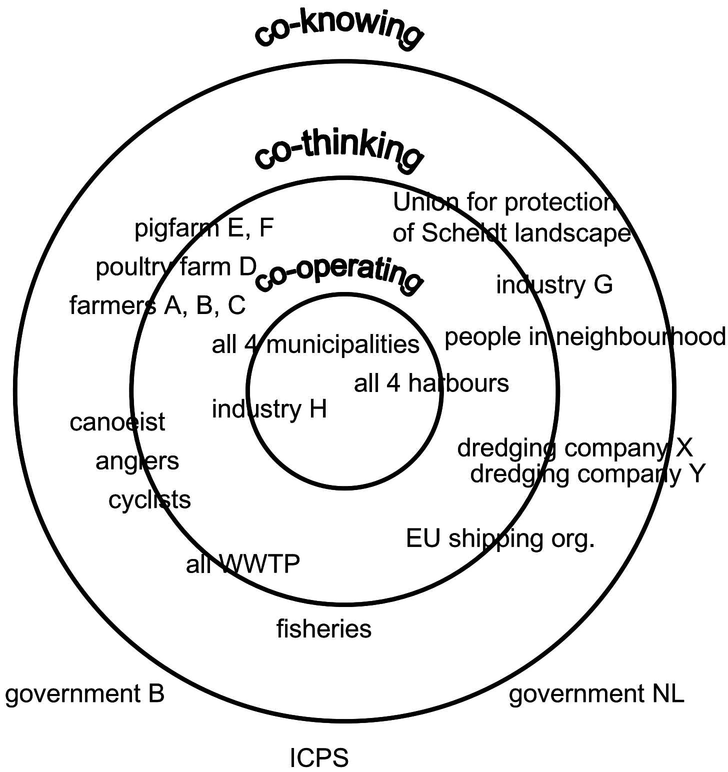

Figure 5: Target scheme with stakeholders who can tell about the pollution of the downstream part of the River Scheldt

Step 9 - The results of the brainstorming session are included into the project plan. Decision is taken that the harbours of Gent and Terneuzen and Industry H that are not yet part of the project team will be approached for co-operation.

Step 10 - The brainstorming session can be continued to refine the target scheme according to Figure 3 and/or to map the environment. Simple questions such as: What is the interest of Industry H?; What is the relationship between municipality A or harbour W? will help increasing the project team understanding of the role and stakeholder relationships.

2. Problem and cause analysis

Objective

Good policy starts with a good and divided analysis of the problems and underlying causes, for which the policy should be developed. For this purpose a problem and cause analysis can be applied. It is a schematic reproduction of a causal complex which is hidden under or behind a problem and it forms the conclusion of the exploration phase.
There will be no good basis to reflect upon the problem until there will be an explicit agreement on the issue as outlined in the analysis. In the first place, the analysis contributes as argumentation to the problem solving strategy. Next to this it will function as a ruling document for the competent authorities at their consideration to what causal level or in what area the most successful actions can be undertaken.

Amplification

In may cases the analysis will get the shape of a 'tree': the most penetrating causes are situated at the bottom, while the symptoms can be found at the top. For this reason the tree is to be read from below to above.

The circles are the recapitulations/summaries of groups of quotes from an anthology (possibly supported by small blocks of literal quotes) or literal quotes.

It is preferred to formulate these recaps as close as possible to the original statements; this will lead to more recognition rather than official formulations.

Procedure

The P&C analysis is to be set up by (a part of) the project team. The persons that have to deal with this should know the situation and context well and have some analytic abilities. It is advisable to call upon a person very well experienced in the making of these kind of analysis schedules.

Make 'in relay' an anthology of the quotes.

In an anthology the quotes have usually already been classified. Sometimes one can get quite far along by indicating the relations between and within the subjects. The analysis phase will require more or less arranging of the quotes, depending on the number of preparations that have already been taken place.

Separate the quotes or groups of quotes that belong together in the anthology. In doing this you should use your common sense. Dare to let loose the work of the anthology, but keep from doing unnecessary double work.

Tape the flap-overs together and put them on the ground. Put the quotes down and start arranging them: put the most thorough, most fundamental causes at the bottom and put the symptoms at the top. By doing this slowly but surely a (number of) schedule(s) will arise. It is not necessary for the whole group to join in this procedure A number of team members can do this by themselves and in a later stage the complete team can compare the 'cause/consequence-trees'. Be aware not to divide the quotes in stacks in a too early stage, as it is important for all team members that they will be able to draw from all quotes available.

Agreement

The P&C analysis will for the first time be submitted to the public for agreement: does everybody agree that this analysis presents a good diagnosis of the problems to which the conductors should take actions?

What does and what does not?

Furthermore a choice needs to be made on which items of the policy route the project team should concentrate. More often the analysis embraces a field to which the project has no influence. For that reason this part drops out, the policy cannot influence this part of the causes. It is important to communicate this conclusion to the public.

Priorities

Priorities can be made for the remaining items, with or without the public, but need to be authorised in all cases by the competent authority. At the conclusion of the exploring phase it needs to become clear on which causal level/in which field successful actions can take place. It should be the ambition to intervene as deep as possible into the causal complex, in order to prevent the symptom contest. However, the deeper and more fundamental the causes, the more difficult it will appear to solve them.

Policy formulation

During the phase of policy formulation the information from the analysis phase can be used as a basis for the shaping of ideas.

Presentation

In a very abstract and analytical way the P&C analysis will give a view of the problems to which the policy should take hold of. It forms the legitimation of choices that are to be made in a later stage of the route. The way of this presentation however will not be appreciated by everybody. Therefore it is advised to use the schedules in a direct way. Or look for an alternative way.

The schedules are adaptable for internal use, as 'evidence' or as input for conversations with some expert groups. For other objective groups images (cartoons, photos, ……….), metaphors, a story or a written text can give better results. It is therefore advisable to write down the problem and cause analysis in an accompanying, summarising text and eventually add the schedules in an enclosure, being a recap of the previous route and as a foundation of the conclusions.

Tips

Pay attention to blind spots: There may lack an important point of view. A number of additional interviews can fill this gap.

The stress for problems and causes may cause quite some resistance: 'how negative this is, while also positive things happen?!' In this case emphasise the objective of the analysis: the searching for the deeper causes of the bottlenecks, not yet for solutions. Essentially for this approach is not to be derived by a vision or being led into a problemsolving direction in an too early stage.

A way to deepen the analysis is the organising of expert meetings.

Be aware of the question or assignment you give at the presentation of the schedules. The question is not: 'Do you agree?', but: 'Is the analysis right. Does it give a good diagnosis of the problems to which the policy shout take action?'

It sometimes appears that the schedules are too rough or over-simplified to get good answers: a way to structure the discussions on the P&C analysis is to nominate tangible topics or conclusions, to which the project team should like to gather more information.

A combination of searching for solutions or policy options are at hand here. Moreover while a natural reaction of people will be: "This all sound very good, but what is your aim to this? Where is the link to what you would like to achieve: the policy objectives?"

3. Communication planning

Objective

Communication is an important instrument in public participation, it is the lubricating oil of the PP-process. The additional schedule can be a first step for the formulation of a communication plan.

Stake

The formulation of a rough communication strategy will take place during the early stages of the route, and preferably during the starting phase. At the entering of every next phase the plan will be adjusted, since the role and the dedication of the actors (and therefore their need for information) can change. The added schedule can be used a working document which can help in providing an overview of all communication activities. Naturally a flexible process also demands flexible communication: a continuous alertness for developments within the project which make communication possible or necessary.

Amplification

The basis of the planning schedule (see Figure 3.1) is the classification of the actors into their category of involvement. At this stage the actors are grouped into four main catagories, all of which ask for another communicative approach:

Co-operators: members of the project team and others who play an active role in the project (i.e. active involvement).
Communication objective: exchange of information on the performance of the activities within the project.
Means: project group meetings, lists of action points, working documents, etc.

Co-thinkers: actors who can, at any moment in the process, be consulted or who contribute in an active way (i.e. consultation).
Communication objective: to inform, interest and stimulate a positive, co-working attitude, and to give continuous back-up of the process steps.
Means: interviews and workshops, newsletters, comment rounds, etc.

Co-knowers: actors who need to be well-informed of the project (i.e. information supply)
Communication objective: informing and giving them the possibility to respond.
Means: a general brochure, intranet site, information meeting, etc.

Deciders: the competent authority (and their advisors), that can make decisions at critical moments.
Communication objective: to inform, and to stimulate, preferably, an active attitude.
Means: reports, presentations, etc.

Along the vertical axes in Figure 3.1 the steps of the process are stated.Here the most important data are implemented. In this way a matrix is being created, in which at any time the the means for every objective group can be filled in.

Procedure

Start making an inventory of the actors after dedication.
Fill in the process structure: which data are important?
Pinpoint in every sector of the matrix what you would like to achieve at that particular moment for each group (co—workers, co-knowers, etc.). What will be the communication objective and what is the main message in that particular phase of the project?

Now fill in the communication means at the proper point of time in the process structure
- take the existing communication means and – channels as a start
- search for combinations of written and oral communication.

Make a plan for each means of communication.

Tips

Appoint one member of the project team to be explicitly responsible for the communication
Adjust the grouping of the actors at the start of every new step in the process. It may be possible that a specific actor has been interviewed during the inventory phase, in this case they need only be informed at a later stage. On the other hand it is possible that a 'co-knower' will become a 'co-thinker' during the next phase of the project.

Make sure that no actor 'is being lost': every person that has ever played a role in the project should remain at least as a 'co-knower'. Radio silence (no feed-back, no response) appears to be an awful let down for actors in interactive processes.

Make use of as many existing communication channels as possible, such as existing consulting networks, internal newsletters, intranet site, etc. An additional newsletter may lead to an overload, while a small article in existing and well-known newsletter may be more appropriate.

It will be possible to set a number of broad communication channels, such as a general brochure, intranet site, a universal report cover, etc. On the other hand, be careful not too widely distrubute reports, anthologies, P&C analyses, etc. It is advisable not to send these kinds of reports to all co-knowers, but enable them to see to a summary. An excess in information will bring the opposite result.

The project team must always be available to respond to questions and suggestions and this interactivity must be done in a transparent way.

It can be useful to give all means of communication within the project its own prospect: a kind of house style, slogan, colour combination or image will make the project recognisable. However, always consider the (substantial) costs versus the benefits. And remember the house style of your own organisation!

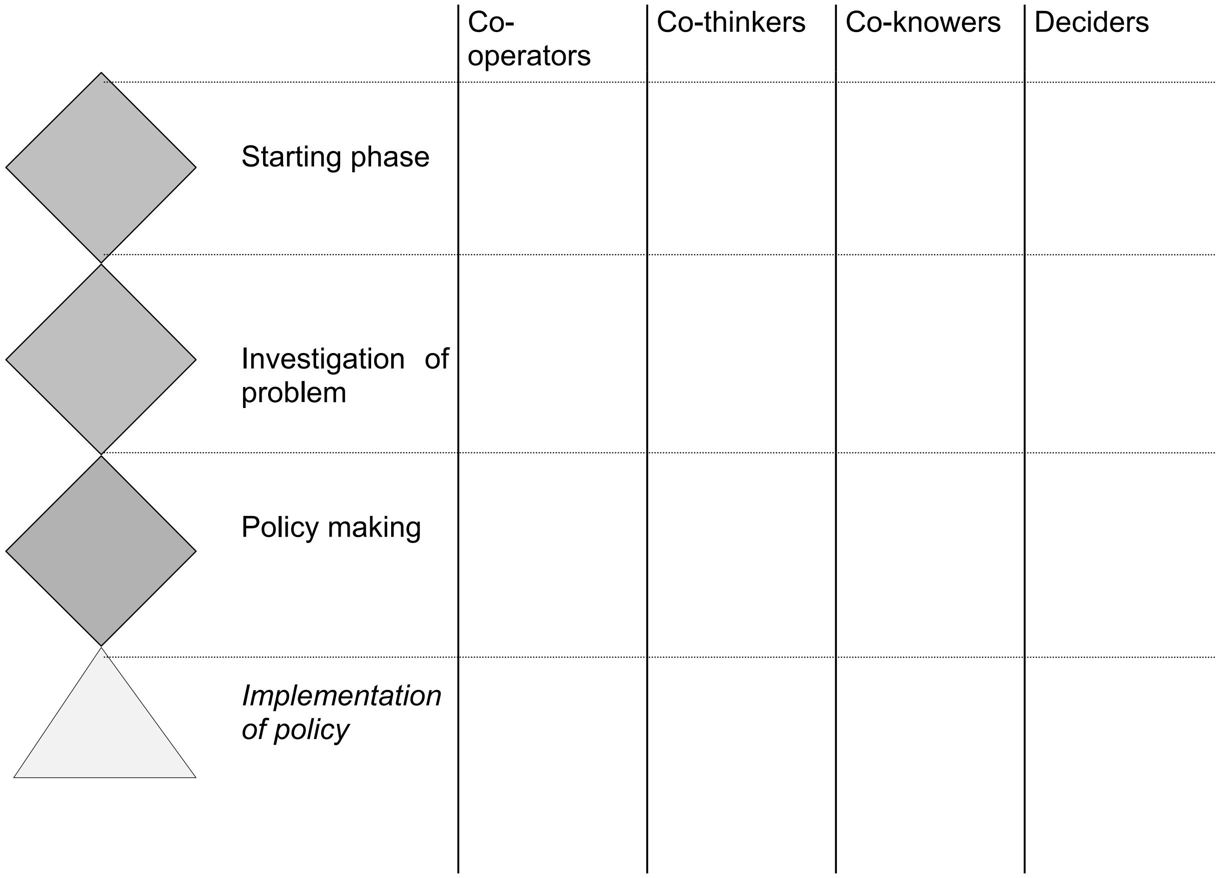

Figure 3.1: Important steps in the policy making process and the involvement of the different categories of actors

4. Interaction and Communication tools

Workshop, sounding board or interview... The interaction and communication with the environment can be designed in several concrete forms. But which means fits the objective? When to choose what? What are the considerations? This inforsheet offers inspiration for a diversity of means. Also it gives some oversight in the multiformity of choices which you need to take while making a proces design or communication plan.

- The first two pages offer a number of criteria that can be of help by choosing certain means;
- Page three offers a “stain chart” with several means, classified after objective;
- Page four and further offer a short description of the different means in alphabetical order.

Criteria: when which means?

What is the aim of the interaction, what do you expect of the parties?

Co-operating: asks for interactive media, such as working meetings, etc.

Co-thinking: asks for “tapping” means, like interviews, discussion groups.

Co-knowing: asks for advising media, like presentations, articles, factsheets.

Using a stakeholder analysis (see first sheet) you can answer this question.

Is it important to pay attention to relationships next to content? If so, choose as little as possible for written communication and as much as possible for personal contact. Do not leave this to third parties but do it yourself.
Is it mainly about communication between project and target group, or also about communication between actors? In the last case, choose group meetings with plenty of time for networking and information exchange.
How much money, time and capacity is available?
Will you use a permanent committee or will you organise a temporary one?
How large are the target groups? The bigger, the more difficult personal communication will be. In that case it is useful to look for liaisons.
Will you ask a selected company, or do you invite everybody to contribute?
Will the information get out of date soon? Do not choose for printed media, but for printing presentations and the internet.

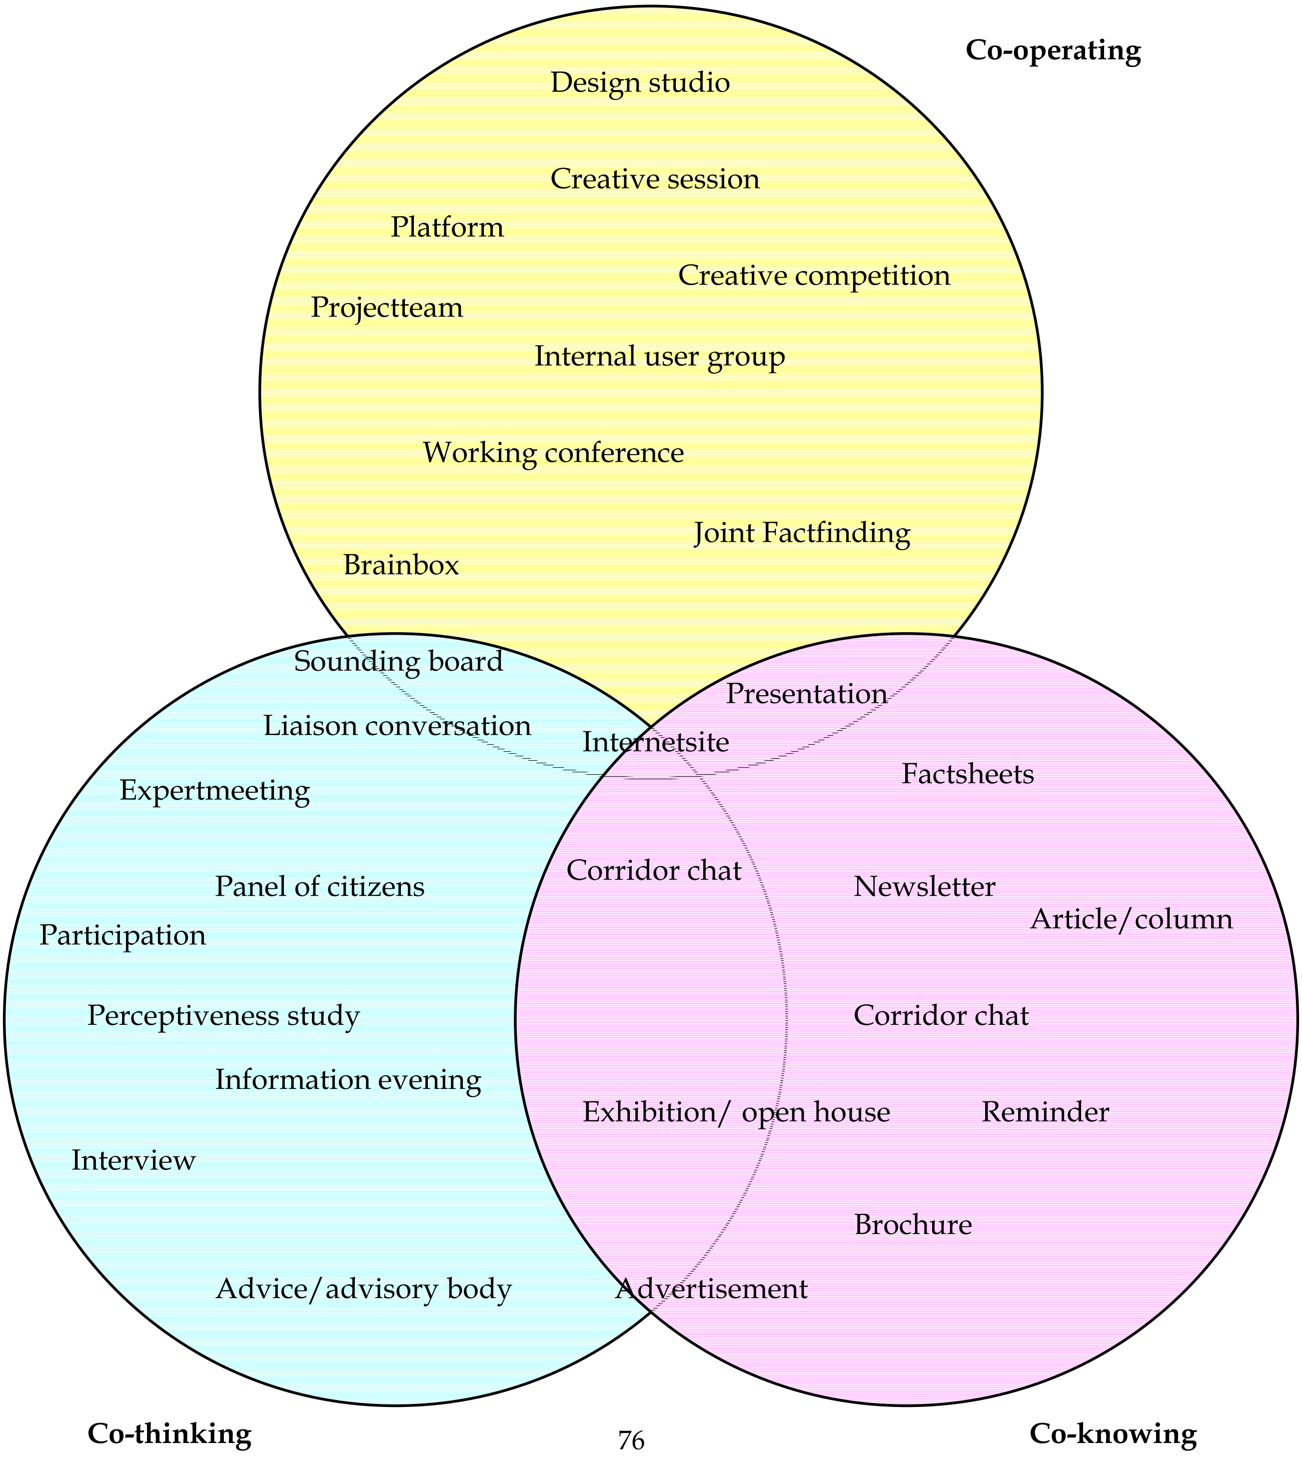
Tips

Do not underestimate the value of showing your face: personal contact will be the best way to establish bonds and to inspire confidence. It also shows that you value the other party.
In general people are bad readers and better listeners. Oral, personal communication is the most effective. Search for the combination: oral supported by written.
Management of expectations: be alwas clear about the status of a certain contact. Tell at the introduction of the day what the objective is and what will happen with the results.
Always state the name of a contact person, or point for reactions, on all communication means.

Do not 'forget' people: once communicating means to continue communicating.
Always provide minutes after a meeting, in which is stated what will happen with the results.
Read also the infosheets in this Annex on Communication Planning and Preparation of Workshops.

Stain chart for forms of interaction and communication

To put into action the different communication means is no hard core science. By presenting them slightly different a co-thinking day can transform into a co-operating day. Often these means are close to each other. The following arrangement gives broad outlines. All means can be found in alphabetical order and with an explanation in the tabel on the next pages.



Interaction and communication ABC

Technique	***Description***	***Look out !*** Advertisement	Certainty that information is presented unchanged at a certain time in a certain medium. Suitable for bringing projects to the attention of for example people living in the neighbourhood of a planned construction project. Can be obligatory in official participation procedures. Can reach a wider public.	Only space for limited information, this can sometimes be understood as "sales talk". Expensive.
Advice/advisory body	An advisory body advises on request of for example the minister or out of their own.	An advisory body cannot be used directly in the project, but can advise in all stages of the policy making process and signalise issues to be put on the agenda or fulfil a canalizing or sounding board function.
Brainbox, electronic meeting, (ballot box)	IT supports participants of a brainstorm meeting, structures information and decision-making. Fast method to collect information with the possibility to give anonymous input.	Experienced facilitator is essential. Combine brainstorming in front of the computer with discussion around the table.
Brochure	Can be used to present a short summary of the project, indicates the most important issues and how to participate. Can be limited to one edition, can be made cheap but also very expensive. Informs many people and restricts misleading information.	Can be interpreted wrongly, contains limited information, no direct feed-back, sometimes hard to disseminate. Quickly out-dated. Always state contact person, telephone number, and e-mail address.
Corridor chat	Individual (informal) approach of people. Good means to ask attention for project, process or aspects from it and in reverse to see if something goes down well. Get an idea what is at stake.	Informal, person-dependent, sensitive to twaddle, does it fit your personal style? info could start to lead a life of its own. Do not forget to update your collegue next door or other departments.

Technique	***Description***	***Look out !*** Creative competition	Establish groups comprising people with different backgrounds. These groups look for innovative solutions in the policy making stage while "competing with each other". This method allows for retaining wider creativity over a longer period due to the different backgrounds. People seek a compromise and a range of different perspectives which prevents the drop-out of solutions in an early stage . (Groups of people of the same background would most likely strive to a uniform solution from the outset).	
Creative sessions	Formulation of groups to find and select solutions. See Section in Annex I "Creative sessions".	
Design studio	To work in small groups (max 5 p.) to elaborate solutions. "Informal" version of creative competition (see above).	
Exhibition, Infocentre, Infopillar, ***Open house, Reading corner, Posterpresentation,*** ***Stand at a fair***	To make accessible to interested parties the knowledge of participants. Gives general information at relatively limited costs, you might reach people who wouldn't participate otherwise. The project is made 'visible'.	One-way communication: gives info but does not receive. Use simple and accessible language, no jargon. Pay attention to anouncement. Give name of a contact person and telephone number.
Expert meeting	Meeting for collection of the commentary/observations of experts on ideas or proposals, or to collect specific information. Make sure that the participants do not feel 'drained' on information only: give them something in return.	Mobilising several experts and finding a date for the meeting can be difficult, invite far in advance. Participating experts can be (business) competitors and may not speak their minds. The panel chairman needs to know the subject well. Besides contents, think about inviting people with experience/empirical knowledge. If the aggregation of new ideas is the objective: do not limit to one and the same sector or discipline.

Technique	Description	Look out ! Factsheets	Give a summarised state of play on ±1 A4. Directed at people who are rather deeply involved in the subject or the proces of the project (co-operators/workers and co-thinkers, sometimes co-knowers). Quick and easy to make, also by having a format on A4 pre-printed which is filled in with up to date information. Relatively cheap.	Possibly requires repeated publishing. It would be good to receive feed-back on the factsheet from the relevant people. However this technique does not offer this possibility. The message should contain tailor-made information, reflecting the needs of the recipient. Always indicate a contact person.
Information evening	Provision of a meeting point to enable networking, a group of co-knowers/co-thinkers is informed.	Do not fill in the programme completely, leave some space. Plan long breaks to give opportunity for informal contacts.
Internal user group	Broad composition of sounding board, specifically for internal projects (in organisation of competent authority).	
Interview, personal or by telephone	A direct way to exchange information. Give people the feeling that someone is listening. Combine a in-depth conversation with a networking function. This can be a valuable investment.	Can be time consuming, reach is limited. Do not tender interviews: doing it yourself is likely to increase the involvement.
Intranetsite, Internetsite, Discussion group on internet, ***Electronic participation and on-line planning***	Gives the possibility to inform and interview people via a computer network or internet. Participation is made easier. The discussion can be protected against other internet users.	Computer infrastructure is the limiting factor. Some experience with computers is required. Target group is unverifiable. Maintenance and updating is labour-intensive. Pay much attention to communication to announce these actions. Discussion group can be a good preparation before a meeting.
Joint factfinding-guiding-group	Group of involved parties and interested parties which guides a process of joint factfinding. Group is involved in the formulation of research questions, selection of research bureau and assessment of interim results. Co-ordinated by initiator with scientific quality check.	

Technique	***Description***	***Look out !*** Liaison conversation, conversation with possible mediators	Conversation in which you address someone about his/her membership of other networks/fora and in which you make agreements about the transfer of information (back and forth). Part of the dissemination of information is outsourced and it offers entrance to neighbouring networks, which can be too far from the subject to involve closely.	Most likely you have to approach these liaisons several times. Often you assume implicitely that people inform their own party. However this hardly ever happens automatically (unless the value of the news is high). Provide with supporting information.
Panel of citizens /focus group	Qualitative research under citizens by means of group interviews, in which the project team/civil servants follow the interviews in a separate room via cameras. During the interview they can ask the interviewer to ask supplementary questions.	Interviews are done by professional agencies. To find out what citizens think is important with regard to issues such as "safety".
Participation	Can be a legal procedure to give citizens a chance to give their opinion about projects and decisions	
Perceptiveness study	Survey which has the aim to identify value judgement of citizens and the estimation of effects of policies or plans from the perspective of the citizen.	
Platform	More or less fixed committee of representatives of organisations, who meet regularly to exchange organised opinions about a certain theme. Can be used as societal thermometer, for competitive cooperation or for policy preparation.	
Presentation	Presentation for formal committees or for a working meeting, etc. You bring the subject to the people which increases the chance that they take note of it.	Timing is very important, even the projectplanning might be adapted to it. Tell clearly in advance why you have come to make a presentation (informative, to probe opinions and what are you going to do with it? will it be used in decision-making?)

Technique	***Description***	***Look out !*** Project team	Projectleader + team, often from the competent authority that take care of the organisation and steering of the project.	If possible involve people in the team that should play a role in the continuation of the project (next projectleader, more regional civil servants).
Reminder	Small present as a thanks, it works as a reminder for the project. A present of daily use keeps people alert at work.	Keep it austere, it might be governmental money. Try to be original, a stale present works contrarily.
Sounding board	Varied group of stakeholders which follows the policy process closely and which advices the decision-makers regularly about decisions to be taken or the progress.	Make good appointments about the status and the input of the sounding board. Take care of a good secretariat and timely information supply
Working conference (with simulation, brainstorm, priority of alternatives, scenario discussion, etc.)	Meeting with a limited amount of participants to deepen the insight in a problem or to map possible solutions. A lot of information exchange, images, arguments. Solutions can be tried.	Good selection of participants, recruitment, preparation, participation and follow-up take a lot of time. Determine the objective well. Is it diverging or converging? Is the input/ contribution of the participants really useful? See to an adequate facilitator and good reporting.

An overview of available tools[3]

The available tools can be grouped into five categories according to the main support of these tools : internet – Web, classical communication tools, groups meetings, visits and field observations, softwares.

They can be also categorised according to the phase(s) of the participation process at which they are the most adapted : starting and organisation phase, actors and context analysis, diagnostic of the current situation, search for solutions, implementation and evaluation.

TOOLS AND TECHNIQUES Categorised by main support and by aim or method.	**PHASES OF THE PARTICIPATION PROCESS**				
	Starting Organisation	**Actors analysis context**	**Diagnostic of the current situation**	**Search of solutions**	**Implementation, evaluation**
INTERNET – WEB					
- Interactive Geographic Information Systems (Web GIS).			*	*	
- Interactive Web Site	*	*	*	*	
- Informative Web Sites Web, polls via internet.	*	*	*		
- Tools for self-evaluation (Web Site, virtual information centre).					*
«CLASSICAL» COMMUNICATION TOOLS					
- Tools for passive information.	*				
- Tools for active information.	*				
- Collection of comments by poll or interviews.		*	*	*	
GROUPS MEETINGS, WORKSHOPS					
- Public audience.			*	*	
- Group for actors analysis.		*			*
- Group for „Participatory Rapid Appraisal“		* *	*		
- Group for „Evaluation of the Citizens Values“	*		*	* *	
- Thematic Round table				*	
- Prospective Conference					
- Workshop for participatory conception of solutions					*
- Participatory follow up and evaluation					

[3] This overview is made on the basis of a study recently ordered by the Water Department of the French Ministry of Ecology and Sustainable Development.

- Visits on the field			*	*	
OTHERS TOOLS (SOFTWARES)					
- Software tools for the management of the comments.			*	*	

Recommendations for the choice of tools

The choice of the tools and techniques for information, consultation and participation depends on the objectives, available resources and the stage of the process.

Some tools result from many years of experience. This can be considered as a quality proof. Firstly a range of techniques and tools which are quite classical but which have proved themselves (numerous implementations, often positively judged) can be used (or testsed).

Anothergroup to take into account comprises emerging tools, which are based on communication technologies, such as the internet and the Web. Some of these new means must be studied in the viewpoint of the participation process which will be put in place for the implementation of the WFD (art 14)..

The use of the formal approach of public audience, even if it seems very efficient, arouses some reserves.

The scale issue appears as essential : it is needed to modulate the objectives according to the scale of the « project ».

5. Interviews

Objective

In public participation the opinion and/or knowledge of the parties concerned play an important part. The question however is how to trace these. A way of "tapping" the environment is to undertake 1-to-1 interviews with a number of the concerned parties. The target of the interviews seems to be easy: getting to know as much as possible on how the interviewed person thinks about the policy item. The right line of questioning can help to achieve this. The following text provides some tips on how to carry out the interview.

Main Issue

During the exploring phase taking interviews can be one of the ways to make an inventory of the opinions of the parties concerned. Besides that it is a good way to make personal acquaintance with the concerned parties. The results are gathered in an anthology, on the basis of which a problem- and cause analysis is made.

Amplification

A number of very open key questions form the backbone of the conversation. The emphasis lies in the identification of problems and causes.

Key questions:
- What kind of developments do you see?
- What kind of problems/bottlenecks do you foresee?
- In your opinion, what are the causes of these problems?
- In your opinion, what is the desirable situation?
- Why is this the desirable situation?
- What can you or what would you like to contribute in order to achieve the desired situation?

Help questions

The situation can arise that the questions are too open or that the lecturer has little to stimulate. In this situation it would be best to rephrase the question. However the essence (developments, bottlenecks, causes) of the question must always be maintained.
For example:
- Think of developments, both long andshort term;
- How do you qualify the problems mentioned: as serious, superficial, etc.?
- Suppose you would look upon your department/field/working area from another point of view/ …….; what kind of problems would you see then?
- When would you feel the policy in this field is being adjusted well and why?
- What would need to be changed?

Procedure

The project team, together with a number of others, will take the interviews themselves. The number of interviews depends of the outcome of the actor's analysis, but can vary from 15 to 100 interviews.

The preparation

Determine – by means of an actors inventory and analysis – which actors are the "co-thinkers". Regular summaries will bring structure to the conversation and helps the listener to check their understanding.

Send invitations in which the motive and the target of the conversation are mentioned:
- inform about the content of the conversation, but not about the actual questions;
- make sure the letter is signed by a high-placed person (the principal);
- make a telephone call after the letters have been sent in order to make a final appointment.

Provide a clear briefing of all interviewers beforehand, including a short training session in active listening.

The interview

Before the interview: Assure yourself and once more briefly recap the context in which the conversation needs to take place.
During the conversation:
- use the question list as a checklist and guiding principle, not as an inflexible must;
- keep track of the time (take one hour as a minimum);
- do not use a tape recorder, but take brief notes in shorthand;
- do not be too formal; treat it more as an informal conversation.

At the end of the conversation:
- check if all questions have been asked;
- ask whether the interviewed person has anything to add;
- write down the person's address;
- inform the person what will be done with the notes (e.g. that they will be treated confidentially and will be summarised in an anthology, which is to be subject to feed-back).

The report

Write up the notes immediatly after the interview; at that time it is still fresh in your memory.

The interview reports are only for your own use: deal with them in a confidential way and make anonymous quotations in the anthology .

Stay as close as possible to the statements of the interviewed person.

Rephrase in case the statements might be unclear for the project team.

Agree to a standard for the processing:
- on the computer;
- reward the statements you found of interest for yourself with a *;
- classify the answers after sequence of the questions.

Tips

Do not contract out the interviews. The interviews give you the opportunity to get acquainted with important contacts in your working field.

Dividing of interviews prevent interviewers taking interviews with their own contacts. Too great an acquaintance can easily result in assumptions being made. (i.e. "oh, you do understand what I mean by this") and there will be a great risk that the interview will give a poor result.

6. Active listening

Objective

The objective of the interviews in the exploring phase seems so easy: getting to know as much as possible on how the interviewed person thinks about the policy item. It however appears to be hard for the interviewers not to enter into the discussion themselves. This can be prevented when interviewers are aware of their own behaviour during these discussions. Some practical tips on listening skills, in order to get the best possible benefit from these interviews:

Main Issue

The below-mentioned guidelines can be used as a basis for a short training for the interviewers in how to listen actively, at the beginning of the exploring phase.

Tips

To do:
Ask open questions.
Ask questions to which the relater can give broad answers, for example questions that start with words like 'how', 'what', 'why', etc.

Summarise.
To summarise regularly will bring structure to the conversation and helps the listener to check whether or not he has understood the issue well: "When I get it well then …'

Ask through.
Questions like 'Do you see any more aspects?' or 'Can you give an example' explore the matter further.

'Humming'.
To 'hum' regularly or to confirm the lecturer ("yes", "indeed") stimulates the lecturer.

Drop a silence.
People have a silence tolerance of only a few seconds. After only four seconds someone will continue speaking. It motivates the lecturer if there are moments of silence from time to time: the lecturer will be stimulated to inform his audience further on the matter in question.

Non-verbal communication.
Regular eye contact, a slightly bent-forward position, approving nods from time to time, etc. demonstrate attention to the lecturer.

Not to do:
Do not ask closed questions.
Questions like: "Do you know the department?", "Do you like apple pie?" can only be answered by the lecturer with yes or no, and therefore will not provide much new information.

Do not ask multiple choice questions.
A variation on closed questions: "Do you or don't you like apple pie?" This kind of question also provides little information.

Do not ask suggestive questions.
Strictly taken, the answer is enclosed in this kind of question: "I take it you do like apple pie? ". The lecturer is being steered in a certain direction when posing this kind of question.

Do not present your own opinion.
The lecturer will be inhibited in telling his story in case you present your own opinion. It will also inhibit the interviewer from listening.

Do not enter into a discussion.
This is the biggest pitfall for listeners, especially when the lecturer mentions an item which is not in line with the interviewer's opinion. However, "yes-no" conversations are conversations with another aim than to gain information.

Do not interrupt.
Let the lecturer tell his story.

7. Preparation of workshops

Workshops – or whatever you call meetings – can be helpful in consulting stakeholders. But only if the contribution to and place in the process is well-considered.

Checklist preparation

1 - Consider the place in the overall process

- In which phase are we?
- Are we in a divergent or the convergent stadium?
- Is there a decision at hand?
- Do we want the people to react or to creatively invent?
- What is the position of the participants in the process?

2 - Determine the problem with regard to the contents

What is the objective of the meeting in terms of contents and relations?
Which questions have to be answered?
Is the group prepared to answer these questions?
Inquire after what is admitted for discussion and what not! Determine the boundary conditions of the conversation: which subjects are no longer under discussion?

Is the objective:

To develop a vision, to collect ideas, then:
pay attention to the human, postpone a judgement.
Decision making, then:
besides diverging also converging and formation of a judgement.
Transfer of knowledge, then:
emphasis on the contents, first establishing a good atmosphere (relations).
Co-operation, then:
build up relations from a common content (e.g. the working process).
Creating a common basis, support, then:
acknowledge and single out anger or resistance, make the boundary conditions for participation explicit.

3 - Explore the situation

The group:

What are the features of the group?
How many people are we dealing with?
What type of people are they?
Do they know each other?
Do they have any antagonism in their previous history?
Are they participating out of free will or is it compulsory?
Are they in a good mood (single out aversions or dislike)?
Have the participants the same level of thinking?

The location:

Is everything present (whiteboard, pens, overhead projector, beamer, etc.)?
Are there enough rooms in case of parallel workshops?
Can you move around the tables/chairs?

How is the atmosphere? It is better to keep the room as close as possible to the usual environment: no energy will be lost on that. A creative brainstorming session asks for a messy space.

Available time and moment:
Consider starting the evening before: evenings allow for informal items in the programme, the social rituals. Next day you can start immediately with the contents.

What type of facilitator fits in?
Meetings with objectives in terms of relations ask for different capacities than meetings which mainly address contents. The one facilitator can't work with lawyers and rather works with farmers, the other one rather works with policy makers. The type of meeting decides the choice of facilitator.

Basis for the programme-structure.
Whatever the objective of the meeting, as a basic rule:
from Abstract to Concrete, and;
from Conceptualisation to Judgement to Decision making.

This brings the following possible basic structure for meetings:

1 Preparation of the atmosphere
    a cup of coffee, etc.

2 Ritual dancing
    introduction round, networking, opening speech of the project leader, etc.

3 Laying eggs
    possible frustrations and dissatisfaction, but people also have to get rid of over-enthusiasm and pride with regard to recently achieved results before they can contribute to the meeting. For example by means of sticking memo's with their comments to a flip-over and spouting knowledge or venting criticism.

4 Warming-up
    a 'creative warming-up', a story teller, a catching presentation, cartoons, etc.

5 Diverge
    make an inventory of ideas, opinions, experiences, etc.
    often in sub-groups.

6 Converge
    combine and cluster of input, draw conclusions.
    plenary feed-back of the subgroups.

7 Planning of actions
    planning of actions with regard to the problems or the further process.

8 Planning of actions
    to agree about actions for the processing of the results of this meeting.

Tips

- Build in mobility in the programme (walking, to get up from the chair, etc.);
- Take into account the famous 'dip' after lunch;

- See to variety; for example between talking and creativity, or by plenary parts and working in sub-groups;
- Consider preparatory interviews with key-figures;
- Make clear agreements about the role of the projectleader/client during the sessions;
- Keep the project team free, so they can orientate on their role with regards to contents. Ask an external facilitator for the supervision of the process.

8. Creative sessions

The phase of the process in which future policy is formulated centralises the search for solutions. Creative sessions with groups of co-thinkers is a good way to generate creative and innovative ideas. Some possibilities:

Programme structure

Generally a creative session consists of two stages:
Diverging: to generate ideas, "fanning out";
Converging: to combine input, search for the leitmotivs, concluding, "bringing together".
(See also infosheet on prepartions of workshops)

A programme for a creative session often contains the following steps:
- Context;
- Clarity about the central question, to give the necessary background information;
- Explanation of working process and time schedule;
- Motivating kick-off;
- Diverging;
- Setting free of new ideas, individually or in a group;
- Inventory of ideas (see below);
- Converging: structuring;
- Look for connection/coherence between ideas, for example by means of clustering;
- Converging: put a name to it;
- Discussion and drawing conclusions, for example by naming or prioritising of clusters;
- Reflection;
- Take decisions about the incorporation of solutions in the process;
- Make agreements about the processing and dissemination of the results.

(co-source: The Institute of Cultural Affairs)

Diverging and converging

All creative sessions have generally the same structure: after a diverging stage (the real brainstorming) follows the converging (analysing and concluding). Several methods can be used. It is important to adapt the method of diverging to the one of converging.
Determine the desired result.
Estimate how widely you can diverge to later on converge to this desired result.
While diverging think about how you want to converge.

Diverging: ways of brainstorming

Some rules of the game are always valid:
- Everything anyone says is OK;
- Postpone judgements;
- Everything will be written down or recorded in another way;
- Everybody has to have his/her say.

Individual brainstorm

Participants write down for themselves a couple of ideas. Then they select the 5-7 best/funniest ones and give it as input into the group. A safe way of brainstorming, appropriate for groups with a 'hindering' hierarchy (i.e. people do not feel free) or if the group contains some participants who start controlling the conversation.

Brainstorming with a mindmap

The simplest way of brainstorming is to have people 'shouting' ideas, experiences, etc. The facilitator writes down everything, for example in the form of a mindmap: the central question or subject in the centre and put around (like a spider) the ideas of the group. Ideas that have interlinkages can be put together at once, and clusters are formed. This method works well with groups that have plenty of ideas and with hardly any hierachic thresholds (people feel free to speak).

'Small' design studio

Participants of the workshops are literally going to cut, paste, sing or dance what they actually mean. Size of (sub)group 5-7 people. Make sure you find a nice space with enough material to tinker with (i.e. old magazines, felt-tips, paper, glue, etc.) in order to stimulate creativity. Duration at least 2 hours. Appropriate for groups which need stimulation to become active, and you will strike new sources of creativity. Excellent for boring and sleepy times of the day like friday afternoon.

Associations

Participants are asked to reason from completely different subjects or things towards the subject which is central for the workshop. This method is often applied in the world of industrial design in order to find innovative solutions. For example: reason from a matchbox to a stadium. Result: an extending soccer field.

But this can also work for questions about organisation or innovative policy solutions. For example by taking the animal world as an example or to benchmark with completely different business areas and to look for differences and similarities. These sessions ask for a relaxed atmosphere.

Searching for images

For sensitive issues (such as the functioning of people or parts of the organisation) it can be useful to ask people about an image or metaphor which they find representative/fitting for themselves or the organisation. Make an inventory of the images and ask what it says about themselves or the organisation; which features are important? Sometimes it can be useful to give a lead for the metaphor, for example an animal or a (type of) car.

Brainbox

A Group Decision Room or Brainbox is a room in which the participants have a computer and are connected with eachother by a network. Everybody can at the same time give input/opinions/ideas (anonymously) and react on each others remarks. In a short time a lot of information will be generated and it stimulates creativity. The software should have the following possibilities: brainstorming, ranking/clustering of ideas, prioritising or voting and discussion. Suitable for both diverging and converging, for large groups with varying backgrounds, complex matters and settled habits of communication. An oral plenary session is necessary to evaluate and make agreements on follow-up.

Converging: clustering and prioritising

Clustering

By putting ideas on yellow Post-it memo's they are easy to move around on a board. Cluster from coarse to fine: firstly make general clusters under one expression (this is about...), later on look for refinements (positive-negative, short term-long term, etc.) and make sentences that summarise the cluster.

Give points, score

Everybody can give points or marks. For example 1x8, 2x4, 4x2 and 8x1 points to a list of items. The result is a kind of thermometer: the options with most points are accepted by definition, also drop-outs will be clear. Discussion can focus on the options with a mean score.

Stickering

Everybody can distribute 10 stickers to the options of his/her choice. The result will be more diffuse than giving points but also less confronting.

Feed-back and discussion

Methods of brainstorming like the design studio and associative exercises do not lead to lists of options which can be prioritised/ranked. In those cases plenary sessions are used for feedback of the results of (sub)groups and an evaluating discussion takes place under the supervision of a chairman.

Tips

Try as much as possible to work in smaller groups; the smaller the group the greater the chance that everybody joins in.
Creative sessions take at least half a day.
It could be useful to hire a facilitator/chairman so the project team can take part themselves.

9. Citizens' Jury

Objective

A citizens' jury (CJ) is a group of randomly selected people, who represent a microcosm of their community, and are paid to attend a series of meetings to learn about and discuss a specific issue and make public their conclusions[4]. Each juror is supposed to represent the public interest and not his/her own self-interest. The idea behind CJs is that given enough time and information, ordinary people can make decisions about complex policy issues. This method aims to strengthen the democratic process by including within it the considered views of a cross section of members of the public.

Amplification

A typical CJ might have the following characteristics[5]:

- The topic for the jury should be of public interest;
- The jurors should be selected on the basis of attitudinal or demographic quotas, or both;
- Jurors are paid to attend the CJ, which typically runs for 2-4 full days;
- The information presented to jurors should come from several points of view;
- A neutral moderator should facilitate all discussion;
- The jurors should respond to a "charge" or question;
- The jury should have review and approve all their findings and recommendations;
- The jurors must be allowed to evaluate the process and make public their views;
- The jurors must believe that their recommendations will have an impact or at least be considered.

The Procedure

A CJ will not be appropriate in all situations. Look at the following questions to decide whether this technique should be used[6].

- Can the issue be distilled into one key question?
- Is the issue complex, with various angles or key issues to be considered?
- Does the issue require background information?
- Is the issue of concern to the community?
- Is the sponsoring body open to change in response to the results of the jury?
- Can the issue be tackled and a conclusion reached in the time allowed?

---

5 based on Crosby (1995: ibid) and James, R.F. (1999). *Public Participation in Environmental Decision-Making - New Approaches*. Paper presented at the Annual National Conference of the Environment Institute of Australia. Hobart, Tasmania.

6 Fife Council (1997). *How to Organise a Citizens Jury.* Corporate Policy. Fife Council. Scotland.

Jury Selection

Jury selection is crucial to the success of the process. Typically juries consist of between 12 and 24 participants who are selected to be representative of the relevant population. Jurors should be selected from the affected population in a fair and open way. Some juries are selected in an entirely random manner, for example by using the electoral register. Others use quotas so that representation from different income, racial or attitudinal groups is ensured.

Selection of Witnesses

The witnesses chosen should represent different points of view and extreme views from one side of the debate should be balanced with opinions from the other side. Typically witnesses are asked to speak for 15 minutes and answer questions from the jury for a further 30 minutes. Witnesses may appear alone in front of the jury, with another witness, or as part of a panel. An ideal jury would have a mix of these formats in order to vary the sessions and maintain the interest of the jurors.

The procedure

In order for a conscientious atmosphere to prevail, the jury must be carefully organised. There is usually one facilitator who chairs the plenary sessions, explains what is to happen in smaller groups session and aids the jury in coming to a decision at the end of the process. The facilitator may or may not have specific knowledge of the issue under discussion, but must, in all cases, be impartial in their words and actions.

The focus of the whole proceedings should allow the jurors to deliberate on the issue at hand, but in order for this to happen careful arrangements need to be in place, and staff are required to ensure the process runs smoothly. Other than the chief facilitator, additional staff are required to help facilitate smaller group sessions; meet, greet and brief the witnesses before their presentation; and take care of housekeeping arrangements.

The facilitator will meet the jurors in an introductory session. This is held before the start the jury to introduce jurors to each other, to indicate what they might expect to happen in the days of the jury and to introduce any staff involved in the process.

During the process a variety of sessions are usually scheduled. As well as sessions where witnesses make presentations to the jury and answer questions, there are usually sessions where the jury discuss issues together or in small groups. They may be given tasks, for example to identify and rank the benefits of a particular issue. This provides variety for the jury, and helps to break down the big task of the jury into manageable pieces.

Decision making

Consensus is the most desirable means by which to come to a final decision or set of recommendations, although this may not always be possible. In order to reach a consensus plenty of time is needed to work through disagreements, but in some cases no matter how much time is allocated a consensus may not be reached. In such situations a voting system may be used. The way in which a jury makes a decision is important, as exploration of minority views is a valuable feature CJs. Such views should always be reported in the final report.

The Report

The final product of a CJ process is a report, detailing the process and recommendations made by the jury. Typically reports contain all details of the process, including witness presentations, reports on discussion sessions as well as final recommendations, and details of any disagreement. In order to avoid bias in the final report a draft copy is sent to all jurors for comment and agreement before it is finalised. This ensures that any misrepresentation is eliminated before the report goes to the sponsoring body.

The report often also contains some evaluation of the process, from the jurors point of view. The evaluation provides a check to the report, and shows how the jurors felt about the process and the relevance of the findings.
Once the report has been finalised it is sent to the commissioning body, and what happens next depends on the jury process and recommendations.

What Happens Next?

One of the most important elements in a jury process is that the jurors feel their opinion is going to make a difference. It is important that the sponsoring body acts on the jury report. This may take the form of a written report, or a workshop, where the appropriate body discusses the recommendations, explains why it will or will not implement them and provides a timetable for further action.

10. Interactive Geographic Information Systems (Web GIS)

Tool implementation objective(s)	Record public reactions on the basis of locational specificity: the interactive Web site, built with a geographic information system (GIS) core, enables associating public comments with geographic positions or spatial coordinates.
Pertinent participation process phase(s)	Public information dissemination, public hearing, co-production of solutions, co-decisions; the tool may be of use during different stages of a process referred to as either "participatory planning" or "participatory physical planning".
Tool description	Having entered its experimentation phase, the tool has been named "LODERWeb" (for Location-Dependent Reaction" Web). A description is available on the site http://cgi.girs.wageningen-ur.nl/cgi/education. This tool (developed using "Mook Technology" and "ARCView IMS") features a set of videos that provide use instructions (via the "Lotus-Screencam" software), which explain how to generate a reaction connected with a specific location.
Implementation	The methodology employed has been set forth in detail in a Ph.D. dissertation written by R. Kluskens of Wageningen University (Geographic Information Center). The implementation of LODERWeb corresponds to step 6 of this methodology (input of citizen reactions associated with specific geographical locations). Step 7 consists of defining "problem zones" based on these reactions and then proposing these zones as a focus of discussion. ("The application of WebGIS in local participatory physical planning: Development of an interactive Web site to inform and consult citizens about physical plans", February 2000).
Eventual variants	Variants are created by the individual plans, and digitised geographical representations may be incited by this tool.
Implementation examples	Application to the design of a fictitious city called Zwuile containing a population of 23,000. This virtual experimental test involves developing a new industrial zone within the city limits.

Source: R. Kluskens (Wageningen University)

11. Public hearings (see also tool 9. Citizens'Jury)

Tool implementation objective(s)	Present the public with the full set of project components, provide a forum for answering all questions; collect opinions in the form of motions filed before the Hearing Commission, and then defended by their respective authors. This procedure satisfies legal requirements and allows officially recording public motions.
Pertinent participation process phase(s)	The entire project, yet most specifically during the diagnosis-building and solution-design phases.
Tool description	A two-step procedure: overall explanation, with questions from the public and responses from experts affiliated with the pertinent institutions (1); followed by the collection of opinions and reports. In the case of the Quebec water project, the hearing lasted a total of 3 days in each of the 17 regions (with 5 or 6 public sessions held each time). 370 motions were filed and heard before the Commission. All pertinent documents could be accessed and consulted simultaneously at 35 "consultation centers" (municipal libraries, town halls, etc.) (2). The Commission's budget amounted to 2 million Canadian dollars ($CAN) and covered the logistics (transportation, lodging) and salaries of the temporary staff hired for the occasion. ($CAN 200,000 were then added to compensate those who filed reports).
Feedback	For the water management hearing held in Quebec: importance of the role played by the Hearing Commission in stimulating public debate; complete transparency, extremely responsive to all participants; inclusion of the full diversity of opinions expressed; legal protection of Commission members. Chief among the difficulties encountered: the procedure tends to overemphasise the opposition, may become repetitive and may be monopolised by a minority interest (for the purpose of grandstanding). According to the International Association of Public Participation, this tool is one to be avoided if at all possible (otherwise, it should be preceded by a series of informal meetings). For this association, the presence of an audience allows freely expressing reactions, but does not incite dialogue and tends to polarise the competing views.
Implementation examples	Water resources management hearing in Quebec (see data sheet).

Sources: A. Beauchamp (Environ-Sage Inc.) - President of the Commission assigned the public hearing on Quebec water management issues, R. Beaudet - Public Hearing Office in Environmental Issues (BAPE), H. Marchand (BAPE)

Notes on the "Public hearings" tool sheet

(1) In the case of the Quebec public hearings, the first phase was actually conducted in two stages. BAPE started by producing a base document that served to frame the approach and initiate discussion. According to some participants, this document "lacked substance" and did not help sharpen the public's comprehension of the stakes involved. The

Environment Ministry then completed this document by drafting a profile of water-related issues specific to each of the 17 jurisdictions engaged in the hearing process. Next, all of the ministries with oversight in the field of water management attended a joint work session in order to file the necessary documents and handle questions from the public. This approach gave rise to a two-level probe:

- A global level dealing with the entire province of Quebec, where water resource protection problems due to private operations lie at the heart of the debate over exporting groundwater or surface water and privatising publicly-owned infrastructure;
- A more local and practical level concerning issues specific to each region: water quality, health risks, groundwater risks related to below ground disposal sites, agricultural production activities, etc.

(2) The Commission was composed of 3 commissioners (including the President), 2 analysts, a planning officer, an information officer and 11 experts.

The complexity of the issues were more pronounced in those territories under convention rule, i.e. the northern regions inhabited by native Inuit and Cris peoples, which are exempt from Article 31 of the law on environmental quality. It thus became necessary to set up a protocol agreement between these territories and the provincial government in order to integrate the BAPE-led consultation.

12. Monitoring and participatory evaluations

Tool implementation objective(s)	Enable a project evaluation to be performed by those most directly concerned (and not exclusively by project sponsors). This tool entails evaluating both the project and its results (plan, etc.) as opposed to merely evaluating the public participation aspect.
Pertinent participation process phase(s)	Evaluation phase.
Tool description	This tool differs from traditional monitoring and evaluation methods for several reasons: - The process has been designed and managed not by the project leaders or an outside expert, but rather by the stakeholders in conjunction with the project team (often assisted by a "facilitator"). - The stakeholders design and adapt the method, collect and analyse the data. - The indicators are defined by stakeholders. A number of supporting materials may be used when implementing this type of monitoring-evaluation: maps (for locating project-induced changes), relational diagrams (among groups, institutions, etc.), and scoring grids (for comparing preferences and results).
Feedback	The success of this approach requires involvement of both men and women, intermediary organisations (including NGOs), interested private companies and those assigned institutional oversight. The application example for this technique in the case of Local Agenda 21 monitoring and evaluation highlights the advantages of this approach in defining the set of monitoring and evaluation indicators (since selected indicators, in some instances, do allow revealing "unsuspected problems").
Implementation examples	"Citizen learning teams" in the United States set up to monitor and evaluate federal programs; Local Agenda 21 tracking in the United Kingdom.

Source: Institute of Development Studies (IDS Policy Briefing No. 12)

13. Computer tools for processing public comments

Tool implementation objective(s)	Procure elements contained within reports and documents filed as part of a public hearing process, in addition to any comments received. Acquire the capability to numerically handle all of these elements in order to analyse and then integrate them into the final report.
Pertinent participation process phase(s)	In the case of Quebec's public consultation, a software application was used during the report-writing phase, following the second public hearing phase.
Tool description	This software is distributed by the Quebec company AGIR, which has developed a new technology in the field of information tracking, one of whose original features pertains to the technique of searching by means of indexed language sequencing. This software is called "Naturel" (Marketing Director: Pierre-Paul Proulx, ppproulx@natquest.com). This tool corresponds to a conventional query-type instrument: digital archives are stored in the form of Word files (PDF files seem to cause problems). The tool builds an index from this databank of documents. The project manager is then able, using keywords, to access the set of documents in which these words have been found by the tool. (The user is directly referred to text passages where the keywords were identified.) The tool also allows for statistical processing (frequency of terminology, number of documents in which a particular keyword appears, etc.).
Implementation examples	At the time of Quebec's public consultation on water management, all 370 reports (14,000 pages of documents) filed in digital format were loaded into a database and queried using the "Naturel" software developed by AGIR.
Feedback	Use of a standard software application, which does not require any modifications to meet BAPE's needs: according to the BAPE project leader, the software is easy to use and does not necessitate any special training - one to be recommended. For further information, contact Stéphane Moreau: stephane.moreau@bape.gouv.qc.ca

Annex II - Examples of Public Participation in water management projects

November 2002

Introduction

This Annex:

- Aims at providing and explaining examples of public participation in water management projects in some Member States and Eastern Europe;
- Demonstrates the range of possible approaches with regard to public participation on different scales and with regard to various issues;
- Aims at motivating competent authorities to try new tools and methods.

The matrix on page 5 will help to find the examples you are most interested in.

The examples are mostly from the past and do not deal especially with the Water Framework Directive (WFD). Others are current examples with regard to the implementation of the WFD, but of course are not finalised yet.

The examples are mostly positive, but some of them show also the difficulties and mistakes that may happen. Therefore the examples are about "lessons learnt"!

The list of examples is in no way exclusive, there are much more examples, of course also from outside Europe. In this context it should be mentioned that there are ongoing or just finalised research projects, which provide more examples and approaches with regard to public participation and WFD:

- French Study comparing public participation tools and techniques in the Netherlands, Denmark and Canada (finalised), for more information contact:
  Ministry of Ecology and Sustainable Development, Water Department - 20 avenue de Ségur - 75 302 PARIS Cedex 07, Madame Coralie NOËL - Bureau de l'économie de l'eau et de la programmation, phone: (00 33) 1 42 19 13 76 - Fax : (00 33) 1 42 19 12 94, E-mail : coralie.noel@environnement.gouv.fr

- Ongoing SLIM (Social Learning for the Integrated Management and Sustainable Use of Water at Catchment level) project in England/Scotland, France, Italy and the Netherlands, for more information contact: http://www.slim.open.ac.uk/

- Ongoing HARMONICOP project (preparation of a "Handbook on PP methodologies" (WFD), comparison and assessment of national PP experiences and their background), for more information contact:
  www.usf.uni-osnabrueck.de/~pahl/projekte/harmonicop

1. River sub basin management plans in Flanders, Belgium

Inspiration points/key points

Integral water management, planning at river basin level, participation in different phases of the process, stakeholders, participatory working groups, interviews, surveys,…

Aim/objective of the project

In Flanders, the water system is managed by several local (a.o. provinces, communities) and regional (Flemish) authorities. Because of different concerns and interests of these authorities on the one hand, and because of the role that stakeholders play in using the water system on the other hand, 11 river basin management plans will be made in a participatory manner. These management plans will include:

- A description of the water system and its surroundings;
- A description of the needs of the stakeholders;
- An analysis of these descriptions, the bottlenecks and expectations;
- A vision on the development of the water system (including goals);
- Programme of measures.

The ultimate goal is to create a more practical level for collecting and analysing information and to ensure more participation from all stakeholders. These sub basin plans will be used as an input for the making of (international) river basin management plans.

Scale/unit of planning

11 river (sub)basins in Flanders

Period: 2001-2006

Objective of Public Participation (Why PP?)

To involve all authorities and come to an agreement on the development of the water system;
To involve all stakeholders and public in general;
To inform the public in order to develop sustainable water management.

Who participated and how (Degree/form of public participation) in what phase of the planning?

A description of the water system and its surroundings: consultation of all authorities, universities and (some) stakeholders in a working group;
A description of the needs of the stakeholders: active involvement of the stakeholders, mostly by interviews with representatives of 12 designated sectors (written enquiries are not efficient);
An analysis of these descriptions, the bottlenecks and expectations: active involvement of authorities and stakeholders (done by several workshops and interviews with key players);

A vision on the development of the water system (including goals): active involvement of authorities and stakeholders;
Programme of measures : active involvement of authorities and stakeholders.

Methods and tools applied

Consultation of stakeholders (key players) by written enquiries, interviews, workshops;
Per sub basin, a working group with representatives from all authorities has been created to evaluate the results;
Website for communication with all stakeholders: www.bekkenwerking.be

Major input of stakeholders

Knowledge; indication of specific problems and solutions; feedback on proposed texts (support or disagreement).

Tangible result

PP is necessary for acceptance of regional planning process as an important tool. Once contacted and convinced, it is much easier to keep everybody focused on the (importance of) making regional management plans.

Lessons learnt

Personal contact with key players of stakeholders is very important and creates added value to the planning process. This personal contact ensures a continuous interest. Thus, it is best to keep them well informed of all stages in the process.

Formal procedures for PP

For the time being, no formal procedures exist. There is however a manual made (that is being continuously updated).

Cost of the project

A minimum of 4 persons per sub basin is required. For the sectoral analysis, support by an external partner is useful (cost: appx 75.000 euro per sub basin)

For more information contact:

Didier D'hont
Ministry of Flanders
Aminal, Water Dept. (E. Jacqmainlaan 20 box 5, 1000 Brussel)
Didier.dhont@lin.vlaanderen.be

Available reports:

www.bekkenwerking.be

2. Regional Planning System, Denmark

Inspiration points

Integration of land-use and water use; public consultation procedures.

Aim/objective of the project

Regional planning in Denmark integrates land-use and water management and provides the framework for agriculture, forestry, assignment of areas sensitive to groundwater, areas assigned for nature corridors, location of large infrastructure and urban development.
The system is linked closely with the EIA requirements as well as all activities related to wastewater treatment planning, drinking water supply and nature restoration.
Thus, the strength of the system is its high degree of integration between land-use and water management.

Scale/unit of planning

Regional planning system, Denmark, up to 5.000 km^2

Period: Since 1970ies

Objective of Public Participation (Why PP?)

PP is provided at consultation level through public hearing procedures.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The number of people attending public meetings, though, is not very high. Stakeholders – organisations, industry, farmers etc. – provide their opinion through letters as well as bi-lateral meetings with the County.

Methods and tools applied

Formal public hearing rounds via electronic media, local and regional press, publications available in public buildings etc.

Major input of stakeholders

Knowledge. Support or disagreement communicated.

Tangible result (effect) of PP?

Opportunity provided for the broad public as well as key stakeholders to influence the process. Acceptance of the regional planning system as the most feasible approach for linking water use and land use.

Lessons learnt

Lessons learned: integration of coastal waters in the regional planning has to take place across watershed boundaries; this is organised through county co-operation structures, but measures may vary from county to county; the Danish Water Action Plan is implemented through the counties, but has still difficulties in addressing non-point sources.

Formal Procedures for PP

Described in the Law on Regional Planning.

For more information contact:

Danish Ministry of Environment
Henrik Dissing, WWF Denmark, h.dissing@wwf.dk

Available reports:

www.mem.dk

3. Tubaek Stream, Denmark

Inspiration points

Involving farmers as partners in water management.

Aim/objective of the project

A 3-year project involving 1 person from the county and 1 from the farmers union aimed at involving all farmers (approx 50) in the 15 km Tubaek Stream in voluntary agreements regarding reducing excessive use of nutrients and pesticides. Through a carefully planned dialogue, a positive and constructive co-operation was established with the farmers, leading to substantial cuts in run-off of nitrogen, full cut of excessive use of phosporous and pesticides. The basis for the voluntary agreements was the existing framework for supporting environmentally-friendly farming, which has its origin in the 2nd pillar of the CAP.

Scale/unit of planning

A 15 km stream and its catchment within the county of Storstroem.

Period: 1998-2001

Objective of Public Participation (Why PP?)

To establish a win-win situation, which involves farmers as partners in water management.

Who participated and how (Degree/form of public participation) in what phase of the planning?

Farmers in a local water catchment together with representatives from county and farmers advisory service.

Methods and tools applied

The key to the constructive dialogue was that public meetings were organised through the farmers union and that meetings took place at the farm – the "kitchen-table model".

Major input of stakeholders

Knowledge on local issues, resources in terms of pro-active participation and commitment. Willingness to imply changes in their production practices to ensure environmental quality.

Tangible result (effect) of PP?

Local farmers accepting environmental objectives, contributing pro-actively in implementation of programs perceiving it as a win-win situation, establishment of relations between farmers and the county build on trust.

Lessons learnt

Lessons learned: farmers can be mobilised for implementing environmentally-friendly practices, provided the dialogue chosen respects the farmer and it meets him at his premises The approach is time-consuming, but prevents conflicts. The results are incorporated into he daily farming activities, hereby creating a win-win situation. The approach builds on existing co-operation structures within the farmers' community.

Storstroems County, Annette Larsen, ajl@npk.stam.dk
Henrik Dissing, WWF Denmark, h.dissing@wwf.dk

Available reports:

Forthcoming.

4. Reducing Water Consumption in the Graphics Corporate Sector, Denmark

Inspiration points

Cooperation with business companies. Knowledge on day-to-day business practices. Co-funding in terms of staff time allocated for demonstration activities. Sharing knowledge with other companies from the sector, which in fact are also their competitors. Cleaner practices in the Graphics Sector.

Aim/objective of the project

Aim: to reduce water consumption and environmental impact from companies in the Graphics Corporate Sector through demonstration activities – the result was an impressive 70-90% reduction in water consumption.

Scale/unit of planning

Company / business sector.

Period: 2000

Objective of Public Participation (Why PP?)

For the corporate sector as such to engage in cleaner practices investments, several barriers must be dealt with: lack of information about their environmental problems and related improvement opportunities (knowledge on benefits), lack of interest / motivation (incentives), lack of access to financing. Demonstration of concrete opportunities and providing of win-win examples allows for a new business paradigm to spread. Further, through this co-operation the Competent Authorities also get input on how to establish a feasible planning and incentives framework.

Who participated and how (Degree/form of public participation) in what phase of the planning?

Danish Environmental Protection Agency unit for cleaner production, consultancy company, selected companies from the Graphics Sector, Graphics Business Sector Association
PP: several companies as well as the Graphics Corporate Sector organisation were involved comprehensively throughout the entire process shaping the improvements within the daily activities of the companies and testing new equipment, supported economically by the project.

Methods and tools applied

Direct involvement of selected companies in concrete activities, elaboration of main results in the evaluation report, dissemination through Danish EPA and Graphics Business Sector networks.

Major input of stakeholders

Knowledge of day-to-day business practices. Co-funding in terms of staff time allocated for demonstration activities. Sharing knowledge with other companies from the sector, which in fact are also their competitors.

Tangible result (effect) of PP?

Significant environmental improvements, positive attitude from the Business Sector to implementation of Cleaner Practices.

Lessons learnt

With rather limited funding schemes, demonstration activities can successfully be conducted with the results being extracted for later inclusion in revision of environmental regulation of the sector's environmental impact. Through this approach, the new regulation is fully in line with what is possible in the sector, while at the same time the organisation can communicate results as well as the future legislative changes in advance to their members. The investments made from the State budget are later saved in costs for wastewater treatment plants.

Danish EPA, +45 32660100, Danish Technological University, Christian Poll, cp@ipu.dk
Henrik Dissing, WWF Denmark, h.dissing@wwf.dk

5. Westcountry Rivers Trust, England

Inspiration points

Environmental charitable trust. Development of catchment management activities.

Aim/objective of the project

The Westcountry Rivers Trust (WRT) is an environmental charitable trust established in 1994/5 to conserve, maintain and improve the natural beauty and ecological integrity of rivers, streams and wetlands. The WRT regards appropriate land management and the restoration of sympathetic flow regimes as central to the recovery of biodiversity. The WRT works both as a leader and facilitator in the region to effect change through the development and delivery of catchment action.

WWF-UK identified the WRT as a partner in 2000. The partnership, still in its early stages, is intended to demonstrate WWF's key policy messages on the ground and to take some of the lessons from WRT's work to national and European level policy arenas. Work on focuses primarily on freshwater conservation, sustainable rural development and other key land use policy areas.

Scale/unit of planning

The Westcountry Rivers Trust focuses its activities in the south-west of England (the counties of Devon and Cornwall). Specific projects are largely focused at the catchment level (e.g. the Tamar 2000 project was focused on the River Tamar catchment).

Period

The Westcountry Rivers Trust has been in existence since 1995. Several projects have undertaken since its formation with varying durations. The Tamar 2000 project was funded by the EU under its Objective 5b scheme – it lasted three years.

Objective of Public Participation (Why PP?)

- awareness raising;
- to use the knowledge and experience of stakeholders for the sustainable development of river catchment areas;
- improved water quality through comprehensive involvement of farmers.

Who participated and how (Degree/form of public participation) in what phase of the planning?

Participation has largely focused on farmers and key regional stakeholders (e.g. statutory environment agencies, the local water company, other NGOs).
The WRT works both as a leader and facilitator in the region to effect change through the development and delivery of action. For instance, WRT has recently used WWF-UK funding to bring together key regional stakeholders in a workshop to begin the process of agreeing a

long term vision for the landscape of the south-west. The workshop has been followed by a questionnaire exercise which asks stakeholders to identify their priorities for rural land-use. Further follow-up activities are planned.

Major input of stakeholders

Vision on the long term development of the landscape.
Priorities for rural land use.
Knowledge on local issues, resources in terms of pro-active participation and commitment.
Willingness to imply changes in their production practices to ensure environmental quality.

Tangible result (effect) of PP?

WRT projects have resulted in:

- Improved river water quality through reduced use of farm chemicals (fertilisers, pesticides etc.). In time this will contribute to enhanced aquatic ecosystems.
- Improved farm incomes: more efficient use of water, improved farming practices and reduced chemical use have resulted in net direct benefits of approximately £2,700 per farm per year in two catchments. Indirect benefits have yet to be measured.
- The implementation of proposed activities with tangible results. For example Salmon is back, being able to swim in the river , etc.

Lessons learnt

One of the most important lessons learned is that farmers are the best people to communicate messages to other farmers. In addition, messages on how to improve rivers and the environment carry more weight if there are clear benefits for farmers.

For more information please contact:

WWF UK, Dave Tickner
Henrik Dissing, WWF Denmark, h.dissing@wwf.dk

Available reports

www.wwf.uk

6. DEFRA Stakeholder Sounding Board, England

Key- words

National stakeholder involvement.

Aim/objective of the project

The terms of reference for the Stakeholder Sounding Board says that it is a forum for stakeholders to:

- provide input to DEFRA (Department for Agriculture, Food and Rural Affairs) thinking on transposition, and related policy issues, of the Water Framework Directive (WFD);
- raise issues relating to the WFD of concern to the group;
- provide input into development of a long-term strategy for the environmental quality of water - what it should cover, in what detail, risks and opportunities.

Scale/unit of planning

National – the Stakeholder Sounding Board considers WFD-related issues for the whole of England. To date, no similar groups have been established in Scotland, Wales or Northern Ireland.

Period

The Stakeholder Sounding Board was established in early 2001 after a request from a group of stakeholder organisations (including WWF-UK). There is no fixed timescale for the group's existence.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The organisations represented on the Stakeholder Sounding Board are:

Government
DEFRA (Department for Agriculture, Food and Rural Affairs)

Statutory agencies
Environment Agency (the government's statutory agency for environmental protection in England and Wales)
English Nature (the government's statutory advisor on, and agency for, nature protection in England)

Private sector
Confederation of British Industry (CBI)
Chemical Industries Association (CIA)
Crop Protection Association (CPA)
Country Land and Business Association (CLA)
National Farmers' Union (NFU)
Water UK (the trade association for UK water companies and water authorities)

NGOs
Royal Society for the Protection of Birds (RSPB)
WWF-UK

Other stakeholders
UK Centre for Economic and Environmental Development (UKCEED)
Office of the National Consumer Council (ONCC)

Participation takes the form of regular meetings (approximately 3 or 4 a year), hosted in turn by different stakeholder Sounding Board members. The meetings are chaired by a senior official from DEFRA. DEFRA also undertakes a secretariat function.

Major input of stakeholders

Individual stakeholder organisations, or small groups of stakeholder organisations, can flag up issues for discussion. They are then invited by the Stakeholder Sounding Board to prepare a paper on the issue. The paper is discussed at subsequent meetings.
DEFRA may also raise agenda items.

Thus, WWF and UKCEED have prepared a paper on public participation; the RSPB and others have prepared a paper on Wetlands and the Water Framework Directive; the RSPB, WWF, Water UK and the NFU are currently preparing a paper on diffuse pollution.

Outstanding issues

It is not clear what status these papers have within the government. Although the papers include recommendations for action by government and other stakeholders, DEFRA have not made clear whether they will act on those recommendations, even if all stakeholder organisations agree with them.

The relationship between the Stakeholder Sounding Board and the UK government's internal technical advisory group on implementing the WFD has yet to be clarified.

Lessons learnt

A national forum that allows stakeholders to input directly into policy thinking is genuinely useful. It allows direct access to government officials and provides a mechanism by which government can assess the most important issues. For relatively little cost and effort this enhances the traditional methods of consultation and individual meetings with each stakeholder organisation.

However, it is important that there is full transparency so that stakeholder organisations can see how their ideas and concerns are considered and acted on (or not) by the Government. At the moment, we are still working on this in the Stakeholder Sounding Board.

7. The Wise Use of Floodplains Project in Somerset, England

Our work was made possible through the award of a 50% grant from the EU LIFE Environment Fund programme.

Inspiration points – this example is inspiring because:

In partnership with other initiatives this project facilitated a creative and positive dialogue on the future management of flood events in a catchment, where previously stakeholder views had been polarised for decades to the extent where the conflict had become notorious in national environmental circles.

Aim/objective of the project

The WUF Project's aim was to encourage the wise use of water resources in river catchments to benefit, people, their livelihoods and their environment. We set out to achieve this by:

1. Generating new options for the sustainable management of flood events across the catchment and annual water levels on the floodplain;
2. Testing public participation methods to find out what were the economic, social and environmental costs and benefits of different options for managing flood events and floodplain water levels.

The project, through its participatory approach helped to find out how the policies of the government and European Union needed to be changed to promote sustainable management of the catchment and its floodplain. Findings were passed to managers of river catchments across Europe to enable their governments to implement the WFD.

Scale/unit of planning

The River Parrett Catchment in the county of Somerset, South West England. It is the largest river system in Somerset covering 1665 km^2, about half of the county area and containing five major rivers: the Parrett, Isle, Tone, Yeo and Cary. The floodplain forms a significant part of the Somerset Levels & Moors: - an area of international importance for wildlife.

Period: January 2000 – March 2002

Objective of Public Participation (Why PP?)

In Somerset, the WUF Project developed new ways of helping stakeholders in the River Parrett Catchment to find sustainable solutions through participation for the management of water, both in flood events and throughout the year.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The Project sought to involve "stakeholders" - anyone or any organisation, at whatever level, with an interest in the management of water resources in the Parrett Catchment. Above all, it offered an opportunity for local concerns to be heard. Since the first participatory workshops started in 2000, a wide range of representatives of communities, local interests and organisations ranging from local to national government-level were involved.

Methods and tools applied

The WUF Project responded to what communities and individuals wanted. Working closely with an existing and (in the United Kingdom) unique forum for local democracy, the Levels & Moors Partnership*, we held participatory workshops to encourage stakeholders to share views and address problems in partnership. Workshops were managed through facilitative leadership: with the help of group management techniques, stakeholders were helped to work together in a non-conflict environment. The WUF Project Officer was the facilitator for all participatory workshops. Contextual information such as new research on the effectiveness of present flood management practices was introduced to help all stakeholders to develop a common understanding of issues.

Participatory working has to be product-orientated to be worthwhile. If a process is not guided by the need to reach a common goal then it will drift and is unlikely to achieve results.

Stakeholders came to agree that no one solution would solve the problems of flood and water management, but that a comprehensive package of measures was needed. Facilitated dialogue provided the bridge to enable a wide variety of interests to work jointly towards a common goal.

To reach the desired goal of integrated flood and water management, a variety of solutions were generated in a series of participatory workshops. These solutions were built into a Parrett Catchment Action Strategy, which sets out what community and organisational stakeholders wanted to be achieved by 2050".

As collaborative working developed between local initiatives, the WUF Project and LAMP managed participatory workshops under an umbrella initiative, the Parrett Catchment Project.

It is estimated that the approximate cost of facilitating the dialogue over two years is approximately €30,000.00 (salary costs of project officer/facilitator). Workshop costs were additional but low at approximately €150 – 180 for each event (hire of the venue and catering for around 40 participants). The overall cost is difficult to estimate accurately, because staff from a variety of organisations donated their time to the initiatives involved. For the LIFE Project, the budget used to commission new research in Somerset was approximately €75,000.00 and partnership organisations provided around €36,000 of in-kind time in support of the Wise Use of Floodplains Project. (Note: all of these figures are provisional.) In conclusion, the total cost of facilitating such a complex dialogue over a two-year period was remarkably low and the gains are far greater than the financial investment.

*LAMP serves 86 parish councils with wetland habitats on the Somerset Levels & Moors, who in turn represent all local community and organisational interests.

Major input of stakeholders at participatory events

We invited 85 representatives of local communities and organisations to our workshops and regularly saw 30 – 40 people at each event. The organisations ranged from the major government agencies to single-issue lobby groups. It was the first time in Somerset that participatory working had taken place on such a scale.

Tangible result (effect) of PP?

A series of 27 facilitated participatory workshops, which began in May 2000, produced:

- A statement of the consensus between all stakeholder interests, which forms the basis for a vision for the future management of the catchment and floodplain;
- Eleven "components" or potential solutions to manage flood events, a combination of which will make up an Integrated Flood Management approach;
- A detailed analysis of the policy, funding, administrative and technical barriers and opportunities involving implementation of the eleven components;
- Appraisal of the social, economic and environmental costs and benefits of each of the components;
- Enhanced understanding among stakeholders of the implications of the conservation management objectives necessary to achieve "favourable condition" of the Special Protection Area (Birds Directive);
- Initiated a productive dialogue on finding a new balance between agriculture and environmental interests to achieve favourable condition of the Special Protection Area and Ramsar sites, while helping agriculture and other rural industries to work towards sustainable management of an internationally important wetland;
- Produced practical sustainability indicators to monitor the effectiveness of changes in water and land management.

Many of these outcomes are continuing to be implemented beyond the end of the Life Project and are resulting in practical land management and integrated catchment management for the area.

Lessons learnt

<u>Positive Lessons</u>

- Make dialogue relevant to people's lives.

In Somerset the project centred on a major environmental issue that affected a wide range of stakeholders.

- Dialogue should be gradual and often.

Frequent small-scale dialogue is better than big one-off events. More flexible processes are better at accommodating changes in views and developing consensus. Continuing dialogue is better at establishing and maintaining trust and helps to manage participants' expectations of outcomes more realistically.

- Maintain the momentum of the process.

Ensure that the next stage in the participatory process can move on from the last one. Discuss issues, generate solutions, appraise them, test them for sustainability and evaluate their effectiveness once implemented.

- Create trust through impartiality.

This was critical to the success of the process in Somerset. It was the first time that water management had been discussed in a neutral public forum. The WUF Project existed between its sponsoring organisations (the LIFE Project partners): it was not seen as part of them. The role of the WUF project officer as an impartial facilitator gave stakeholders confidence that that they were taking part in a truly participative process and independent process.

- Work to invest time.

Constantly remind participants or potential participants of the need to invest time: without commitment the energy of the process will dissipate. Participants have been very committed to the Somerset process: thirty to forty key stakeholder representatives regularly attended workshops.

Negative Lessons:

- Expensive one-off events can bring dialogue to a halt by delivering a "verdict" and may not be appropriate in making progress on a particular issue in a particular context;
- Don't become a discussion forum without a purpose – manage expectation;
- Avoid any one organisation leading a process so that the process does not have the necessary impartiality needed to create trust amongst stakeholders.

8. The Fens Floodplain Project – East of England

Inspiration points

Active involvement can be sampled effectively by involving communities in a few villages within a river basin.

Aim/objective of the project

To involve the community in determining options for floodplain restoration and integrated management.

Scale/unit of planning

Sub- Regional – 2 villages within a river basin.

Period: 1999-2002

Objectives of Public Participation (Why PP?)

To involve local people directly in making floodplain restoration proposals for their local area and to trial new participation and appraisal methods in a few villages to assess how well they reflected wider concerns across the river basin. Participation helped gain a broad understanding of how the public wanted their floodplain developed without the expense of consulting large numbers of people. Results of community participation were compared with the views of other stakeholders obtained through other participation techniques (e.g. workshops, seminars) so as to assess how well the public proposals matched those of key organisations.

Who participated and how (Degree/form of public participation) in what phase of the planning?

A range of local people from school students to adults and retired people in two representative villages. They were invited to make any proposal they wished about making the floodplain more sustainable, socially, economically and environmentally.

Methods and tools applied, plus resources

A method called "planning for floodplains" was developed. This involved local people putting symbols onto a model to indicate floodplain restoration projects they wanted, for example, new wetland nature reserves, riverside cycleways, more boat moorings for tourists. In both villages three main sets of proposals emerged from the groups of symbols on the model such as:

- establishing a wetland nature reserve;
- more boat moorings for tourists;
- constructing cycleways along the riverside.

Training for a project officer and an assistant to run the "planning for floodplains" exercise cost 800 euros each. 20 days of an assistant's time to prepare, run and write up the community sessions cost 5500 euros. Materials cost around 620 euros. 6 days of project officer time were already accounted for in the project budget. This method assumes there is an officer in place to run and manage the process.
Major input of stakeholders
2% of the population in the two villages sampled made 200 proposals.
A model of each village and its floodplain was made available for people to put proposals on over 2 days in public locations such as the library and school.

Tangible result (effect) of PP?

200 different proposals to contribute to sustainable development of the floodplain were made in each village. Most proposals aggregated into 3 main proposals in each village. The results supported proposals for floodplain restoration from an existing project called "Wet Fens for the Future". This was valuable validation of the "Wet Fens for the Future" project for the organisations which had invested in its development.

This validation of the Wet Fens Project has encouraged organisations involved to go ahead with practical floodplain restoration projects aimed at 15,000 hectares over 50 years at a cost of 15,600,000euros. In UK terms this is a large-scale restoration programme.

Lessons learnt:

Positive:

- That even just sampling participation in 2 villages in the sub-region can produce useful data to confirm existing proposals or to assess whether it is worth investing in a larger scale participation process;
- The "Planning for Floodplains" methodology enables any member of the public to indicate easily and quickly the floodplain management proposals they would like to see in their area;
- The Planning for Floodplains method enables public views to be sampled relatively quickly and inexpensively.

Negative

- Lots of time and effort needs to be invested in choosing villages typical or representative of communities in the river basin e.g. in terms of size, location and characteristics. Criticisms can always be made chosen villages are not sufficiently typical. Ideally a project would have as many "samples" as possible;
- The disadvantage of using samples is that statistically they are small numbers of people and therefore may not reflect wider views across the river basin. The results need to be corroborated against the results of other participation methods in the same river basin (workshops/seminars).

Further information contact:

www.floodplains.org or via jac.cuff@virgin.net for the European Environment Bureau.

9. Nõo rural district development of a municipal water supply and sewage system plan, Estonia

Inspiration points

Effective public consultation techniques in preparation of municipal water management plans in rural areas help to develop economically feasible plans and to pull together social and economic objectives of local development with environmental protection objectives.

Aim and scale of the project

Nõo rural district government worked to develop a water supply and sewage system plan using different techniques of public consultations for preparation and development of the plan. The plan included two parts – a part for development of a centralised water supply and sewage system (50% of the inhabitants use the centralised water system) and a part for water use and sewage system for the areas that are not connected to centralised water systems.

The rural district occupies 170 square km, includes 20 villages and is located in Tartu County of Estonia. 4000 people live in the Nõo rural district.

Period: 1998 - 2001

Objective of Public Participation

The local municipality organised consultations with inhabitants of the rural district using different techniques during preparation of its water supply and sewage system development plan.

Who participated and how (Degree/form of public participation) in what phase of the planning?

Local officials; local stakeholders, mostly farmers, and general public – inhabitants of the rural district. Information to the general public was provided through publications in the local newspaper and people had an opportunity to react and comment to the local government. Interviews and meetings/consultations with local stakeholders and public were held that included personal meetings of experts with farmers at farms and group meetings with inhabitants regularly organised by the local government.

Methods and tools applied

At the beginning the local government:

- Informed about a start of preparation of the water management plan in the local (district) newspaper;
- Students of sociology conducted long non-structured interviews with stakeholders and interviews using open-end questionnaires with representatives of public. The study helped to clarify perceptions by local inhabitants of the situation with drinking and waste waters;

- results of the study complimented an assessment of a state of drinking and wastewaters conducted by water engineers.

After the initial assessment was made, the local government:
- Published the results of the studies in the local newspaper and asked for comments through the newspaper to the study. Inhabitants were rather passive in their reaction to the published texts.However, publishing a map of the area with specific information on water quality in wells and location of the wells brought much more interest in the water quality issues from land owners where wells were located. As a result of the publication, the district government environmental department got requests for details on water quality in some of the wells;
- Local government conducted a series of meetings with local people to discuss water quality in the wells and other issues that concerned development of the municipal water management plan.

Major input of stakeholders

The consultations allowed a more detailed and precise mapping of the problems related to drinking and wastewaters in this rural district to be made that might have not been noticed without the public consultation. The last helped to elaborate a more detailed, realistic and economically feasible water management plan.

Result (effect) of the PP

Estonian national water legislation requires that after 31 December 2007, 95% of wastewaters be treated in villages connected with the central sewage system in the rural district. The study showed that this goal is not realistic given low incomes of the population in the area and specific problems with water infrastructure in different parts of the rural district. A tailor-made investment plan is being developed to ensure that the Nõo rural municipality water management plan is economically feasible and realistic. Communication with the local stakeholders also allowed cost-effective solutions for resolving specific water management problems to be developed.

Lessons learnt

Local stakeholders gain awareness about local environmental issues through their practical experiences of using natural resources but also partially this awareness is derived from mass media. For example, the everyday experience of using water from a local well and then reading information about its quality in the media creates awareness and promotes participation. The local newspaper is the main way of obtaining information about the local issues of concern in the district. Local meetings were shown to be important to develop a dialogue between local authorities and the inhabitants.

Surveys and active consultations with local people using different tailor-made approaches are critically important in the process of the development of economically feasible and realistic municipal water management plans, especially in countries in transition, where municipal budgets are very limited and priorities according to social and economic needs of the population have to be defined.

10. Lake Pyhäjärvi: local water management, Finland

Inspiration points

Close co-operation and participation of the local authorities and residents as the basis for lake restoration.

Scale/unit of planning

Local

Period: 1990 – 2000

Objective of Public Participation (Why PP?)

Encouragement of the residents to participate in the development and planning of their local environment and to draw their attention to water and environmental protection in order to reduce the land-derived nutrient load (eutrophication) and improve the water quality of Pyhäjärvi and the rivers Yläneenjoki and Pyhäjoki.

Who participated and how?

Local municipalities, organisations and industry together with local and national authorities founded the Pyhäjärvi Protection Fund (PPF) to guarantee the resources for protection of the lake. In 1996-2000 seven village plans were conducted at the Pyhäjärvi drainage area. The plans are based on the residents' own ideas and the residents themselves are responsible for the implementation of the village plan.

Methods and tools applied

The planning started by contacting the local village associations and organising information meetings for the residents. After the village association had decided to conduct the plan, all the village residents were actively informed about it. Residents selected the planning team (5-6 persons) who innovated and progressed the plan. However, the planning team meetings were open for all the interested residents. The representative of the project mainly worked as an assistant and secretary.

Major input of the stakeholders

The plans are based on the residents' own ideas and the residents themselves are responsible for the implementation of the village plan.

Tangible result (effect) of PP

Since the external nutrient load originates from agriculture, rural waste-waters and air pollution, a multitude of water protection measures have been implemented in the drainage basin since the 1990s, resulting in some reduction of P loads, but the effects cannot yet be seen in lake water quality. The water quality of the ditches running to rivers Yläneenjoki and

Pyhäjoki has improved during the project. Some of the village associations are willing to make new village plans.

Lessons learnt

Village planning brings benefits to both permanent and temporary residents of the villages as well as for the authorities as the interaction and communication between the residents, authorities and the planners increases and it is easier to turn existing ideas into concrete initiatives and to apply funding for further projects. The environmental consciousness of the residents increases and individual residents and the entire village have a better opportunity to get their voices heard. Resident-oriented planning results in a manual of the residents' own ideas, which will be taken into account and committed to.

For more information please contact:

Ventelä, Anne-Mari, Pyhäjärvi Protection Fund, Ruukinpuisto FIN-27500 Kauttua, Finland, fax +358-2-838 0660, email: anne-mari.ventela@pyhajarvi-instituutti.fi;

11. National Water Committee, "Comité National de l'Eau", FRANCE

Elements of inspiration

The diversity of the members of the National Water Committee allows for deep and rich debates. On the basis of a participatory approach, the final advice is established after having reached a consensus. Debating important water-related issues increases the transparency of the national water policy.

Key words

National level ; advisory body ; stakeholders ; debates ; consensus ; transparency.

Background

The National Water Committee was created by the 1964 Water Act, its composition was defined by a 1965 Decree. The advice of the National Water Committee is obligatory for the elaboration of Water Acts, the application texts for Water Acts and the decrees determining the lists of activities subjected to prior authorisation or declaration.

Scale/unit of planning

National – 550 000 km^2 –– 77 members for 60 000 000 inhabitants.

Period

In existence since 1965. 43 plenary meetings in the past 10 years (several meetings per year).

Objective of Public Participation

- To give advice on river basin planning, large development projects and water distribution schemes, problems shared by two or several basins, issues related to water laws or decrees;
- To discuss the preliminary definition of national water policy;
- To propose solutions to the issues related to the water acts of 1964 and 1992.

Who participated and how

Under the Prime Ministers responsibility, the National Water Council is composed of 77 members, divided into 5 clusters :

- 23 water users (chambers of agriculture, fishers' associations, industrialists, associations of consumers or for environmental protection, tourism associations, water suppliers, etc.);
- chairmen of the basin committees;
- competent people (scientists, experts, specialists, etc.);
- 18 state representatives (representatives of the Ministers in charge of water issues);
- 22 elected officials (deputees, department or regional councils, etc.).

Methods and tools applied

Before the meetings, the Committee's Office, hosted by the Water Department of the Ministry of Ecology, prepares information papers and sends them to the Committee members.

During the meetings, a debate takes place for each point of the agenda meeting and any member of the Committee can give his own point of view. The consensus approach is prefered to the voting.

After the meetings, the Committee members can send supplementary comments to the Office, which adds them to the minutes of the meeting. The minutes are examined and approved at the next meeting.

Major input of stakeholders

For example, the National Water Committee gave recently inputs for the draft river basin management plans for Guyana, Martinique and Reunion and for the transposition of the Drinkwater Directive. It will be consulted for the transposition of the Water Framework Directive.

Tangible result (effect) of PP?

The large representation of stakeholders in the NWC improves the dialogue between interested parties and ensures a central function for advice or proposition to the Minister. Comments on the texts are useful and allow a real improvement of them. But above all, the most important result consists in the possibility to organise a real debate on and for water issues.

Lessons learnt

Positive Points

- The National Water Committee has become an important tool for the transparency of water policy;
- It has found a real place and plays a major role in the water policy – related decisions. It has no juridical power but its role is essential : its advice is taken into account when the final decision is taken;
- Concerning draft laws, prior debates within the Committee help to improve the texts and bring a consensus before the presentation to the legislative assemblies;
- Complementarity between co-ordination of measures at national level & planning process at district level.

Negative Points

- Major emphasis on economic uses & interests of water compared to environmental protection.

12. River basin management plans (S.D.A.G.E., "Schémas Directeurs d'Aménagement et de Gestion des Eaux", FRANCE

Elements of inspiration

- Active involvement of stakeholders at basin / sub basin levels;
- Iterative planning process (alternation of writing draft plan and stakeholders consultation);
- Reporting process of stakeholders comments and competent authorities answers.

The success of the dialogue and participation of interested parties will make the success of the SDAGE. To be used by the State services, the municipalities and the users as a reference document, the content of the SDAGE must be well discussed and negotiated, well understood and well accepted.

Key words

River basin scale ; long-term planning ; active involvement ; stakeholders ; iterative process ; reporting ; initial status ; objectives and measures ; reference document ; public information

Background

The French Water Law of the 2nd January 1992 instituted decentralised water planning tools : river basin management plans (the so-called SDAGE) at the level of the 6 large metropolitan river basins and local water management plans (the so-called SAGE) at the level of sub-basins.

Aim/objective of the project

Assess the initial status and main problems, define quality and quantity objectives, guidelines and priority measures. Elaborate the river basin management plan (SDAGE) defining the main orientations of an integrated and balanced management of aquatic environments and their uses and representing a framework for the planning process in the whole River Basin.

Scale/unit of planning

'Regional', river basin level (about 100.000 km^2 – 5 to 15 000 000 inhabitants – 800 to 1500 stakeholders involved.

Period: 1992 - 1997

Objective of Public Participation

- To obtain a reference document for all questions all over the great basin (from flooding to water quality …) defining management objectives, strategy and actions;
- To reach consensus between all categories of users / stakeholders;

- To use the elaboration phase to create a common understanding, a common vision at the scale of the river basin between State services, communities and users;
- To involve people in the definition of the rules of the game : the more people we involve in the process, the more chances we have to see the rules respected.

Degree of PP and stakeholders involved

The Basin Committee is composed of the representatives of all stakeholders and users in the River Basin (about 100 members): 1/3 local elected officials (i.e. mayors, local communities), 1/3 users, consumers, NGOs and 1/3 representatives of the State. The Basin Committee defines the river basin management plan (SDAGE) and co-ordinates the coherence between local water management plans (SAGE). It arbitrates water conflicts, decides on the taxes to be paid by the users and defines action programmes.

Methods and tools applied : Iterative planning and reporting processes:

Each Basin Committee created a Planning Commission and several Geographic Commissions (implanted at sub basin level or for specific issues : inter-regional aquifer or coastal areas) in which a number of debates and meetings took place. Hundreds of interested parties were able to voice their opinion in the meetings of these geographic commissions.

For example, we can describe the planning process used for the elaboration of the management plan of the Adour Garonne Basin to illustrate the stakeholders involvement and the reporting on the results of the consultation.

Basin level: Coordinator Prefect Basin committee (120 stakeholders) Planning board (36 stakeholders) Operation board (District Public Services	Sub basin level (8 in Adour Garonne District): Geographic Commissions (about 1000 stakeholders in a whole)

Step 1: The Operation Board prepared a Draft V0 for the SDAGE, based on experts' knowledge. The diagnosis, main issues, objectives and measures were described at each sub basin level in a "sub basin notebook" with a synthesis for the whole basin level.

Step 2: The Draft V0 was mailed to all stakeholders of the geographic commissions, who could give their comments during a meeting in every sub basin. Consultants made a synthesis of these comments and addressed it to the Operation board.

Step 3: The Draft V0 was improved by the Operation Board taking these comments into account. The Draft V1, containing the SDAGE (70 p) and the "8 sub basin notebooks" (25 p with a lot of maps), were endorsed by the Planning board.

Step 4: The SDAGE and sub basin notebooks were mailed to each stakeholder and presented during another meeting in every sub basin. Stakeholders were asked to mail their comments within 2 months, giving their name and function and explaining the point of the Draft in discussion. The same procedure was conducted specifically with all the Public Services concerned with water policy.

Step 5: All the comments were handled the same way:
a) a draft answer was prepared by the Operation Board;
b) it was endorsed/modified by the Planning board;
c) all the information was reported in a "registry of comments" with a page for every discussed section of the Draft, describing : the issue discussed, all the stakeholders' and civil servants' comments on this issue, the answer of the Operation board and the final decision of the Planning Board;
d) All the registries were made available to the public at the Public Service Office hosting each Geographic Commission.

Step 6: Taking into account about 600 stakeholders' and 1000 civil servants' comments, a new Draft was written (V2 : SDAGE and Sub Basin notebooks) with a new iteration of consultation and reporting of the stakeholders' comments (There were less reactions during this third consultation).

Step 7: The draft V3, endorsed by the Planning board was presented as the « SDAGE draft » for consultation to a wide range of other stakeholders (regional and departmental assemblies, councils of main towns …) and during 50 public meetings. There were very few demands for modification of the project during this step.

Step 8: The draft was endorsed by the Basin Committee and signed by the Coordinator prefect.

Three documents were published for public information: the whole SDAGE (110p), an executive summary (25 p) and a 4p leaflet. A web site was implemented, from which everybody can download all these papers. Sub basin notebooks are available on demand.

Nowadays, the Operation Board publishes an annual report (plus an executive summary and a leaflet accessible on the web), describing what is the state of the basin, compared with the initial objectives. The public can ask questions or react by e-mail.

Major input of stakeholders

- All stakeholders discussed in details all the components of the plan, the preliminary reports and the final report, which were modified in consequence and finally accepted by all;
- A real involvement of the water users in the decision-making process, including 'polluters';
- A lot of exchanges between stakeholders, giving some "social learning" about water management (understanding of the diversity of stakes, better acceptance of the different expectations and water uses);
- For example, as regards the associations concerned with environmental protection, they have been a real stimulus for different issues : management of alluvial plains, hydroelectricity, granule extractions from the rivers, etc.

Tangible result (effect) of PP?

- The river basin management plan (SDAGE) was elaborated and discussed between all categories of stakeholders within the Basin Committee and the Geographic commissions;
- The decentralisation of the Basin Committee through geographical commissions, users & consumers commissions, allows the involvement of local people;

- Associations have been stakeholders in the thinking and the decision-making, which is essential. For example they achieved great progress as regards the protection of wetlands, flood-prone areas, riparian forests, alluvial groundwater, etc.;
- Socially more accepted measures.

Lessons learnt:

Strong points :

- Necessity to implement training and information all along the process;
- Consultation and effective participation of users needs sufficient delays in order to allow the different consultations to actively take place;
- Time is necessary so that the stakeholders of a river basin know and understand each other, speak together, ratify together the diagnosis of the river basin status and think together about the possible solutions to solve the problems identified.

Weak points :

- The SDAGE was elaborated and discussed by representatives: it is a representative and not a direct participation of the public in general;
- The SDAGE document is made available to the general public only after its approval;
- The cost of the project is difficult to assess, but in every basin, a staff of 2 to 5 people was dedicated to the stakeholders involvement and public information for 2 years.

13. The local water management plans (S.A.G.E., "Schémas d'aménagement et de gestion des eaux"), FRANCE

Elements of inspiration:

Active involvement of stakeholders at a local level – capacity building.
The scale of these local management plans (about 1000 km^2) allows them to be closer to people and concrete problems. It gives more place for participation than larger scale plans. This example shows that time and pedagogy are needed to reach a consensus between interested parties. According to the case, interested parties can decide in the final document to apply the existing water law only or to go a little further.

Key words

Local scale ; local wishes ; long-term planning ; active involvement ; stakeholders ; initial status, objectives and measures ; reference document ; public consultation

Background

The French Water Law of the 2nd January 1992 set up decentralised water planning tools : river basin management plans (the so-called SDAGE) at the level of the 6 large metropolitan river basins and local water management plans (the so-called SAGE) at the level of sub-basins. The SAGE is drawn by a Local Water Commission and then submitted to the Basin Committee, local government institutions, chambers of commerce and agriculture and the general public for consultation before being voted by the Local Water Commission and finally officially approved by the State prefect.

Scale/unit of planning

'Local', sub-basin level - about 1.000 km^2 – about 100 stakeholders involved for 100 000 inhabitants

Aim/objective of the project

- To start from a local wish and progress towards a large consensus between users;
- To involve local people;
- To refine the guidelines defined in the SDAGE and to adapt them to local circumstances;
- To be closer to concrete questions and implement concretely the guidelines defined in the SDAGE.

Period: About 5 years

Objective of Public Participation (Why PP?)

- The elaboration of this type of planning document needs a collective approach, based on the local solidarity at the level of the basin or sub-basin. The most important success factor is to create dynamics round the definition of a common project;

- To obtain a reference document for important water issues all over the sub basin (from flooding to water quality…) defining management objectives, strategy and actions, by reaching a consensus between users;
- To use the elaboration phase to create a common understanding, a common vision at the scale of the river basin between State services, communities and users;
- To involve people in the definition of the rules of the game : the more people we involve in the process, the more chances we have to see the rules respected.

Degree of PP and stakeholders involved

Diagnosis, objectives and measures are discussed between all categories of stakeholders within the Local Water Commission (from 50 to 100 members) : ½ local elected officials, ¼ users, consumers, NGOs and ¼ State representatives. The SAGE is the end product of the works undertaken by the Commission, completed by a consultation of all the citizens, who have access to the draft during 2 months.

Methods and tools applied

- A facilitator (a technician or an engineer) is employed at the beginning of the project in order to manage the whole process;
- At the beginning, the facilitator organises information meetings for the members of the Local Water Commission on water issues and the role of the SAGE document. He/she also informs the elected officials and raises the awareness of the different partners and stakeholders within the river basin;
- A lot of meetings of the Water Local Commission take place, in which the people concerned can debate to produce the plan from the beginning to the end of the elaboration process;
- Thus, the members of the Local Water Commission work on a co-ordinated way from one step to the next. Preliminary reports are discussed in detail, modified and finally accepted by all stakeholders: assessment of the initial status of the basin and tendencies, definition of water quality and quantity objectives, determination of the rules for the preservation of aquatic environments and the actions to be planned;
- When the SAGE project is elaborated by the Local Water Commission, it is made available for comments to the general public for 2 months;
- The project can be modified by the Local Water Commission to take into account the comments of the public before adoption by the Prefect;
- After the adoption of the plan, the Local Water Commission follows the implementation of the plan and for this purpose it has 2 meetings / year; and,
- During the whole process, communication tools are used to raise and maintain the motivation of both the stakeholders and the general public (some booklets are regularly distributed to all homes).

Major input of stakeholders

- ll stakeholders discuss in detail all the components of the plan, the preliminary reports and the final report, which are modified in consequence and finally accepted by all;
- Involvement of the water users in the decision-making process, including ‘polluters’;
- At the local level of the sub-basin and in the SAGE preparation, local associations can speak on behalf of the river itself.

Tangible result (effect) of PP?

- A lot of exchanges between stakeholders, giving some "social learning" about water management (understanding of the diversity of stakes, better acceptance of the different expectations and water uses);
- Progress towards a shared culture;
- Decentralisation of the decision;
- Concrete implementation of the existing water law and definition of some supplementary water regulations at the level of the sub-basin;
- Socially more accepted measures.

Lessons learnt:

Strong points :

- With regard to the SDAGE, the SAGE is closer to concrete questions and is at a more adequate scale for participation;
- It is necessary to implement training and information throughout the process;
- It is necessary to have clear ideas on the common objectives, to put in place a solid but also open institutional organisation;
- It is essential to work at an adequate scale and adapt to the context;
- The Local Water Commission is a place for the dialogue between the different stakeholders of the territory. The representiveness of the composition of the Commission is an essential success factor;
- Importance of human resources : the staff must be adapted to the stakes and the context;
- It is essential to maintain the motivation of everybody all along the process and to show the progress realised with the concrete actions made during the whole elaboration of the SAGE.

Weak points :

- Discussions between (local) representatives of the same organisation/authority;
- The asymmetry of information among stakeholders;
- The slowness of the process, mainly for legal, political and institutional reasons;
- The consultation of the general public is only formal, when the draft is already developed and complete;
- The cost of the project is difficult to assess precisely. It needs a facilitator and a secretary for 2 to 4 years, and consultants for the diagnosis and the first draft of plan.

14. The Drôme river management plan, FRANCE

Elements of inspiration

Active involvement of stakeholders at the local level – capacity building.

Key words

Local scale ; local wishes ; long-term planning ; active involvement ; stakeholders ; initial status, objectives and measures ; reference document ; public consultation.

Background

The Drôme river management plan was the first SAGE to be completed, implementing the procedure established by the 1992 Water Act (see previous example).

Aim/objective of the project

- Protect the Drôme valley area characterised by a beautiful countryside and varied heritage value through the rivers of the catchment, their underground water tables, and their dependent wetland ecosystems;
- Solve the priority problems of the catchment which are the quantity management of the water resource and the maintenance of beds and river banks; and,
- Refine the guidelines of other aspects of the water management.

Scale/unit of planning

Local / catchment - 83 municipalities concerned - catchment area of 1,640 km^2. 42,500 inhabitants.

Period: 1994-1997

Technical studies, discussions and local meetings from 1994 to 1997 (3 years).
Consultation and approval in 1997 ; implementation since 1997.

Objective of Public participation (Why PP)

The objective was to protect the river heritage and to ensure a better appreciation of it, taking into account the different water uses and ensuring preventive action against risks. For that purpose, a process of local consultation, negotiation and consensus was implemented to reach agreed objectives regarding water management between the different interested parties and river users.

Who participated and how (Degree/form of public participation) in what phase of the planning?

Active participation of the stakeholders :

- The Local Water Commission for the Drôme river was composed of 44 members : 50% local elected officials, 25% representatives of State services and departments, 25% representatives of local water users groups (agricultural irrigation, gravel extraction, leisure activities, associations, etc);
- The Basin Committee (consulted);
- Local elected officials (consulted);
- Chambers of commerce and agriculture (consulted);
- The State Prefect (final decision).

Methods and tools applied

- Meetings of the Local Water Commission at the level of the basin;
- Sub-basin meetings;
- A specific facilitator (who was also a technician) was in charge of the preparation of meetings, the communication during the whole process concerning the progress of the works, the technical secretariat and the co-ordination of the writing of the SAGE;
- The draft was made available to the general public for comments in public places (for 2 months);
- The Local Water Commission published a journal regularly during the process to inform the population living in the basin of the different activities carried out in the catchment;
- The planning document is now under implementation and the Local Water Commission still publishes regularly this journal.

Major input of stakeholders

About 20 meetings of the Local Water Commission ; Numerous sub-basin meetings ; Consultation of the general public.

Tangible result (effect) of PP

The process has gone through three main steps at which a consensus between all categories of stakeholders and users was reached : assessment of the current situation, definition of management priorities, evaluation of necessary measures to achieve these objectives. The SAGE objectives were translated into 6 actions plans related to : water resources, river channels and banks, water quality, risk management, natural heritage ecosystems, tourism and leisure activities.

Lessons learnt

<u>Positive points</u>

- Agreement on the SAGE was possible through a local will to make public interest a priority;
- The Drôme river was perceived as a linking factor and gave an identity to the whole valley area and to the whole consultation process;
- The consensus obtained on the SAGE document ensures the implementation of the SAGE since 1997, the co-ordination between existing structures and a sustainable presence in this field.

<u>Negative points :</u>

- The asymmetry of information among stakeholders;
- Problem of capacity building for some stakeholders;

- The slowness of the process mainly for legal, political and institutional reasons;
- The consultation of the general public is only formal, when the draft is already developed and complete.

15. National Commission for Public Debate (CNDP), FRANCE

Elements of inspiration

The public debates organised by the CNDP are open to every citizen. At the moment, the CNDP has not adressed any issue related to water management but for each public debate it has organised, a combination of methods and tools for public information and participation were used. The most innovative tool consists in the gathering of the public contributions into comprehensive "stakeholders' books", these documents being distributed to all participants for discussion, in the same way as the documents realised by the project leader.

Key words

Public debates ; early participation ; broad public ; combination of tools ; stakeholders' books.

Background

The National Commission for Public Debate (CNDP) was created by law on the 2nd February 1995 to reinforce the environmental awareness in big development projects (motorway networks, airports, harbours, etc). The Commission is composed of members of the Parliament, local representatives, magistrates, representatives of civil society and experts.

Aim/objective

When it is requested to do so by a petition, the Commission organises itself a 4-month public debate, or it asks the project leader to organise it. The public debate has to deal with the objectives and characteristics of the project, so it means that it takes place at the very beginning of the process. A specific commission, composed of competent people in the field, is put in place to coordinate the debate.

Scale/unit of planning

The projects usually concern several French regions. For example, the public debate organised between March and June of 2000 for the TGV Rhin-Rhône (southern part of the high-speed rail line between East and South) concerned 4 regions : Alsace, Bourgogne, Franche-Comté and Rhône-Alpes, which represents 4,5 million people from Strasbourg to Lyon.

Period: 4 months (possible extension to 6 months in certain cases).

Objective of Public Participation

The public debate can help to reach a consensus on the objective and characteristics of the project and particularly, it can help to identify the potential impacts for the environment and for the inhabitants which may be affected by the project and then to propose to the project leader some measures to reduce these impacts and improve the project.

Who participated and how (Degree/Form of public participation) in what phase of the planning?

For example, for the TGV Rhin-Rhône project, the CNDP was requested by a federation of environmental NGO (France Nature Environnement) to organise a public debate on this project. The special commission was composed of the French Rail Network as the project leader, the "organised public" (representatives, departments'chiefs, economic authorities, etc.), the press, the users and environment protection associations and individuals ("non organised public"). These people represent the very first circle of participants. But the public meetings are open to all citizens and concern thousands of participants.

Methods and tools applied

The methods used to inform the public:

- "Supporting dossier": provided by the project leader, gives to the public the necessary information to participate - general description of the objectives and the main characteristics of the project, estimation of the economic and social stakes, identifications of the main environmental impacts and evaluation of the economic and social costs of the project - for the TGV Rhin-Rhône project, 6000 were distributed;
- Internet web site : to have information on the project and the organisation of the public debate (for the TGV Rhin-Rhône project : 6500 visits, 70 per day);
- "Information letters of the debate" or "lettres du débat: to inform the public on the debate, mobilise it regularly to participate and communicate information on the evolution of the debate " (for the TGV Rhin-Rhône project: 2 700 000 were distributed);
- Visits to the headquarters of the specific commission to consult more detailed documents on the project;
- Prepaid cards: distributed with the information letters, to ask for further information.

The methods used for public participation

- Public meetings (TGV Rhin-Rhône project : 10 meetings in different cities);
- Question-answer system (TGV Rhin-Rhône project : 2000 questions received);
- Prepaid cards + toll-free number : to ask for information and questions;
- Mail: for sending remarks, opinions or thoughts;
- E-mail: from the Internet web site, to ask questions and consult all the answers already given;
- "Contributions" : mails received at the commission which showed one particular and developed position – (TGV Rhin-Rhône project : 85);
- "Stakeholders book" : selection of some of the observations from the public were published in so-called "stakeholders books" ("cahiers d'acteurs") and distributed (TGV Rhin-Rhône project : 10 books in total);
- Press (example, for the TGV Rhin-Rhône project : 163 articles published in the regional press, 26 in the national press and 10 press meetings in the 10 cities where the public meetings took place).

Major input of stakeholders

Essentially through public meetings, questions-answers system, contributions and stakeholders' books.

Tangible results of PP

The public is invited to express itself but the project leader is not legally bound by its answers given to the public. However, the project leader takes into account the opinions of the public who participate in the debate and the project might be modified in consequence. The assessment report of the public debate is made available to the public.

Lessons learnt

<u>Strong points</u>

- Participation of individuals who are given the same importance as the representatives;
- Question-answer system : allows everyone to ask questions, with the assurance of having an answer;
- "Stakeholders book" : innovative tool creating further considerations between stakeholders and public;
- Interest of the public for these types of democratic consulting processes at a time where the project is not totally defined and where there is still place for making modifications;
- Very important role of the regional and local press as a support for information supply to the public;
- Taking into account the lessons learnt, the CNDP will be able to give advice and recommendations to public authorities to favour and develop public participation (Local Democracy Law, 27th February 2002).

<u>Weak points</u>

- Superficial interventions sometimes ; not the same level of participation in all meetings;
- Not enough meetings (reasons of costs, time and availability of stakeholders).

16. Information letters with regard to the implementation of the Water Framework Directive Germany (Thuringia)

Elements of inspiration

This example shows one possibility to inform stakeholders and the broad public continuously about the contents of the WFD and the implementation process.

Key Words

Continuous and current information on the implementation and planning process, stakeholders and broad public.

Background

The WFD is a new approach, also in the 16 Lander (regions) of Germany which have competences concerning water management. Thuringia is part of several river basins and has the task to implement the WFD in the parts of these river basins in its territory. The environment ministry of Thuringia wants to inform stakeholders and also the broader public continuously from the beginning of the implementation process in the region in order to encourage acceptance and provide transparency.

Aim/objective of the project

Early and continuous information is seen as the basis in order to enable and encourage the active involvement of the public as required in Article 14 WFD. The information letters are distributed in order to explain the implementation steps and the work to be done and in order to enable stakeholders and public to be informed, to follow the implementation process and to be prepared when the programme of measures is discussed and when the consultation on the river basin management plan takes place.

Scale/unit of planning

Thuringia (one of the 16 German Lander), national/regional/sub-basin level. Thuringia is part of the river basins of the Elbe, the Weser and the Rhine. The Land covers 16 171,5 km^2 and has 2 449 082 inhabitants.

Period

During the whole implementation process, i.e. at least until 2009. Three information letters have already been published up to October 2002.

Objective of Public Participation (Why PP?)

Not all stakeholders are members in the implementation groups in Thuringia and it is also important to reach the broader public. This can be done by the information letters. The letters provide detailed information on e.g. the content of the WFD with regard to the actual implementation steps (at the moment e.g. with regard to Article 5 WFD (description of the status quo), on pilot projects in Thuringia, information events etc. The public can become acquainted with the objectives and necessary steps of the WFD early in the process and can express ideas and proposals.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The target group are especially the persons or organisations interested in water management issues, but also the broad public. The information letters are particularly intended to inform stakeholders and persons who are not members of the WFD implementation groups in Thuringia. The information letters are sent to the environment ministries of the other German Lander, to all district authorities and to other regional environment, agriculture and planning authorities in Thuringia, all sorts of industrial, environmental, agricultural etc. associations and NGOs in Thuringia and on federal level, political parties in the parliament of Thuringia, but also to private persons, private planning institutions and universities.

Methods and tools applied

At the moment the information letters (six pages) are published twice or three times a year (available in printed form or via internet (www.thueringen.de/tmlnu, see: Europäische Wasserrahmenrichtlinie, only in German). There is a list for the distribution of the printed form (number of copies: 3000) by mail. Additionally there is a big list of Email addresses to which the information letters are sent automatically. Everybody can ask to be inserted in this Email list. At the end of the letters a contact person is named (phone and email) in case of questions or proposals. The information letters are also made available during water management related seminars, workshops etc. organised by Thuringia's authorities or other institutions.

Major input of stakeholders

The WFD implementation process has just started, so there is less input than a huge interest from the stakeholders in as much information as possible.

Tangible result (effect) of PP?

There is a clear interest in information on the WFD and its implementation. The public wants to be informed, even more specified than in the last three information letters. The environment ministry of Thuringia feels encouraged in its approach and plans to expand it in the future.The information letters and the contact to the ministry will be used also as platform with regard to other Thuringian ministries and to other of the 16 German Lander. The information should become intensified and specified, e.g. by information on special issues. Therefore also other authors than from the competent authorities themselves will have the possibility to deliver texts for the information letters.

Lessons learnt

There is already a huge demand for detailed information on the WFD and its implementation which was perhaps underestimated in the beginning. Early and open information and communication is the key for a coherent implementation of the WFD within the given timescales.

17. River Basin Management Plan Maas/sub-basin Niers, Germany (North Rhine-Westphalia)

Elements of inspiration

This example shows one possibility to involve stakeholders on regional level in the implementation of the WFD from its beginning on in order to get hold of their knowledge and in order to discuss the relevant implementation steps and its consequences.

Key- words

Information and consultation of the public, organised public, regional forums, non organised public.

Background

The WFD is a new approach, also in the 16 Lander (regions) of Germany which have competences concerning water management. North Rhine-Westphalia is part of several river basins (e.g. Rhine, Maas) and has the task to implement the WFD in the parts of these river basins in its territory. The Land covers 34.079 km^2 and has more than 18 million inhabitants.

Aim/objective of the project

Pilot project with regard to Article 14 WFD in North Rhine-Westphalia. Involvement of the organised public/the stakeholders in the first implementation phase until 2004 (Article 5 WFD: inventories, review, analysis) on regional level. Information of the broad public in the relevant region with regard to WFD in general (objectives, implementation steps etc.).

Scale/unit of planning

Sub-basin level (the sub-basin of the Niers is divided in three parts in order to have three regional discussion and information forums (upper, middle and lower Niers)). The river Niers is part of the Maas river basin. The Niers sub-basin covers 1382 km^2 mostly in Germany and for a small part in the Netherlands, 715.000 people are living in this area. The environment ministry of North Rhine-Westphalia was interested to create a structure which allows to involve the relevant stakeholders in the implementation process.

Period

For 2 years until 2004 (end of first implementation phase). At the moment it is likely that public participation by regional forums will be continued until the end of the implementation process.

Objective of Public Participation (Why PP?)

To enable information, stakeholders' input and a consensual approach from the beginning of the implementation process on.

Who participated and how (Degree/form of public participation) in what phase of the planning?

In the three Niers forums: Municipalities, districts, water companies, water associations, chambers of agriculture, forest authorities, nature conservation NGO's, biological planning units, the Dutch authorities and stakeholders (all of the relevant region), 30 – 40 persons per forum. Round Tables: Information, discussion, distribution of relevant materials, exchange of experience, involvement with regard to data collection.
Broad public on regional level: Internet site (www.niers.nrw.de), possibility to ask questions.

Methods and tools applied

In the three Niers forums: Meetings at the moment once a year (sufficient for the first implementation phase, later on perhaps more frequent), internet site for each forum (only accessible by password, with all relevant information and discussion material).
Broad public on regional level: One information flyer until now (general information with regard to the WFD), Internet site (www.niers.nrw.de), press reports.

Major input of stakeholders

Stakeholders in the three forums delivered the necessary data for the first implementation phase until 2004 (Article 5 WFD: impacts, pressures etc.). Stakeholders delivered their view on the WFD and the implementation process. At the moment there is mainly a huge demand to get informed and involved.

Tangible result (effect) of PP?

In the three regional forums none of the stakeholders feels discriminated, it is a balance of to give and to take, open and positive discussions, good atmosphere with regard to the next implementation steps.
Experiences could be used for the North Rhine-Westphalia Guidance paper on pp.
The data delivered by the stakeholders are used to fulfil the requirements of Article 5 WFD and as basis for the WFD planning process.

Lessons learnt

Huge interest of the stakeholders to participate in the implementation. Positive reactions because they are involved early and get a lot of useful information. The regional approach and the discussion in smaller groups proved their worth (it was already useful in the past before the WFD with regard to alluvial water programs) , they enable useful discussions and create acceptance and common understanding as a basis for the next implementation steps.

This approach is already used in some other parts of North Rhine-Westphalia and because of its benefits is likely to be taken over in all sub-basins or parts of them in the territory of North Rhine-Westphalia.

On the other hand this approach is a lot of work (preparing and organising the meetings) and requires staff and time.

18. Erne sustainable wetlands cross border Ireland and Northern Ireland

Inspiration points

Erne Sustainable Wetlands was an inspiring example of public participation because it carried out a range of participation methods at a range of scales. This resulted in a shared vision for the area as well as specific projects.

Aim/objective of the project

Erne Sustainable Wetlands aim has been to identify ways of achieving integrated and sustainable, or 'wise use', of water and land resources for the benefit of people and wildlife within the Erne catchment.

The project has achieved its objectives through:
- Development of a framework, or process, to help demonstrate, in practical ways, how the public could be engaged in a decision making process within the catchment;
- Development of a common vision and set of values that sets out the 'desired future condition' for the future of the Erne catchment. It describes stakeholder values for river, floodplain and catchment management for which measurable objectives can be developed subsequently;
- Exploration of issues and management proposals for sustainable management of water and land resources that are practical and have public support;
- Development of criteria and impact indicators to help assess the sustainability and impact of management proposals;
- Application of the Local Sustainability Model to assess economic, social and environmental sustainability of the management proposals;
- Development of a catchment scale, impact assessment methodology;
- Examining how policies need to be changed to promote integrated and sustainable management of the catchment.

Scale/unit of planning

The Erne Project tested participation at three different scales:
- Catchment;
- Sub-catchment;
- Cross-border partnership (c1000 km^2).

Period

The project took place over a two and a half year period, from November 1999 to March 2002.

Objective of Public Participation (Why PP?) Who organised it?

The Project Officer, Janie Crone, trained as a facilitator, developed principles for participation, designed the participatory process and facilitated all the workshops and training events. The participatory process was designed to help demonstrate, in practical ways, how the public could be engaged in a decision making process within the catchment. The process initiated was open and inclusive so that anyone with a management responsibility, stake or interest in the catchment could contribute to discussions, and each workshop started with, in a sense, a blank sheet of paper.

To help encourage informed action, the process involved elements of education, awareness raising, information sharing and training. The project used Participatory workshops and events. Training and capacity building were key elements to: Increase commitment to the process; develop ownership of the process; develop lasting skills at all levels; be cost-effective.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The Erne Sustainable Wetlands participatory process involved different levels of participation at different times. Some of the process (Questionnaires, Community Mapping) was concerned with gathering information and public awareness, while other parts of the process, (themed workshops and prioritising workshop), asked stakeholders, together with statutory and non-statutory organisations, to prioritise and make choices that gave stakeholders an equal role in decision making.

Every person living within the Erne catchment should be considered a stakeholder. A stakeholder is any person, group or organisation who can impact on or be impacted by decisions made about land and water management. The population of the Erne catchment is approximately 150,000 people over an area of 4340 km^2. The population is mainly rural and dispersed with an average density of 29 people per km^2.

The process in the Erne tried as far as possible to include anyone who wanted to get involved. All workshops were publicly advertised through local newspapers, local newsletters, leaflets/posters and direct mailings.

In the time constraints of the project (effectively the bulk of participation had to run from September 2000 to Feb 2001) it would have been impossible to get full participation, and even the 10% (which would have been 15,000) required for a true representative sample, would have been difficult to reach. However, over 150 stakeholder groups, community organisations and development associations were contacted in the course of the project. Each group has a stake in the future of the Erne wetlands through, either, economic considerations, social life of communities or environmental concerns. In terms of inclusivity, therefore, many of the organisations and groups involved represented large numbers of people, for example, the local wildflower group that was involved has a membership of over 400. Also many elected councillors were at the meetings and have representative status. In these terms therefore, though the figures for 'individuals' present would suggest low percentage involvement true representation was much higher.

Methods and tools applied; Include resources used if known (time, money)

Participatory Methods included: Facilitative Leadership, Stakeholder Dialogue, Participatory Appraisal, Community Survey, questionnaires, and the Local Sustainability Model. Members of the community, stakeholder organisations and project Steering Group have been trained themselves in some of these methods.

Indicative costs of some of the methods

- Facilitative Leadership £3098 (pounds);
- Participatory Appraisal Training £3960 (pounds);
- 5-day training programme for 10–16 participants.

Major input of stakeholders

Stakeholders were central to the success of the Erne Sustainable Wetlands project. An early decision in the project was to include stakeholders in the process at a very early stage so that they were involved in shaping the outcomes in a

Tangible results (effect) of PP?

Within the time constraints of a project, it is difficult to give a true estimation of the tangible results of public participation.
There area several measurable results:

- There is more understanding of public participation within statutory and non-government organisations;
- PP has been put on the agenda of many organisations, if only at a discussion level;
- An expectation and momentum has been created within the Erne catchment;
- A long term vision has been created;
- A management model has been created for continued participation.

Lessons learnt

<u>Positive</u>

- The initial process was designed to provide a framework for participation at the scale of the river basin / catchment. The process was successful in achieving its objectives. There was good discussion and debate, and each workshop developed issues into management proposals;

- People relate to the environment immediately around them, and to issues that impact on their lives. Experience of working within a focus area, (between Newtownbutler and Belturbet, an area of c100km^2), has highlighted that:
    - People feel a sense of local ownership and pride;
    - Have a lot of local knowledge;
    - Can often make the link between local actions and local impacts;
    - Feel more able, and have the capacity, to take action at a local level.

This is not to say that the public are not capable of providing valuable contributions to a decision making process at the scale of the catchment. They are, but the process of engagement needs to start at a more localised level to help build capacity and confidence.

<u>Negative</u>

A deeper analysis of the participants of the workshops showed that the process did not attract wide support and participation at community level.

By initiating the process at catchment level, many community stakeholders did not feel they could contribute to discussions because:

- They could not relate their local experiences to a catchment / river basin scale;
- There was often a lack of knowledge and awareness about catchment issues and the ability to make the link between action and impacts;
- They were not always confident about sitting around the table with 'specialists and experts;'
- There was a real feeling that statutory agencies do not listen to the communities needs and it would be a waste of time.

Summary findings

There is a need to build a catchment management structure that people feel confident with and able to participate in. To successfully engage people in a decision making process at river basin / catchment scale requires a structure of localised groups.

19. Integrated Reconnaissance of the river Rhine, Waal and IJssel (so-called RVR and IVB projects), The Netherlands

Inspiration points

Consultation of experts, NGO's and other governmental organisations in a reconnaissance study at River Basin Level.

Aim/Objective of the project

The Dutch government has developed its policy "room for water", but asked the regional offices of the Ministry of Public Works to develop in an open approach, in close cooperation with the other government organisations, to give advice on the possibilities of water management with a waterflow of 16.000m3/s (till 2015) and with a situation of 18.000m3/s or more afterwards (with further climatic changes…) Four projects are initiated of which two RVR and IVB are discussed below.

Scale/unit of planning

Regional level (involving 2 provinces).
Scale 1: 375,000.

Period: 1998-2001

Objective of PP

To use the knowledge and experience of other government organisations for the development of water management options in the coming decades and hence improve the quality of the national policy.

To develop commitment and support for the formulation and implementation of this national policy.

Who participated and how (degree/form of public participation) in what phase of the planning?

The open interactive process is formed by:
- A steering committee;
- A close cooperation with other governmental organisations. In steering committees, the 2 provinces, municipalities, the regional office of PW, VROM and LNV as well as the waterboards are represented. They are responsible for the decisionmaking and the advise to the government on further policies. (Before only the regional office of PW developed such studies and gave advice);
- An expert group (of government staff (and representatives of NGO's).

In the IVB project the project team has been supported (in a later phase) by three "working groups"of experts per theme: 1. waterflow, use and land use 2. juridical and governmental issues 3. communication. The juridical aspects are of large importance as room for water demands a number of changes in the current laws and procedures. The RVR project organised reflection groups with representatives of NGO's).

Open communication

From the start the project team showed a positive attitude towards interviews, questions by stakeholders and took care to produce clear reports, and leaflets to inform about the progress and results.

Symposia (IVB).

The IVB project has organised two symposia. One for the governors and the other one for NGO's and interested citizens. The aim was to explain about results of the screening study so far, to create understanding and support and to seek reactions and advise on the proposed measures.

Information evenings for the general public (IVB)

A (DVD) film putting water management in a historical perpective, bringing interests together under the flag of security and illustrating all proposed measures and its consequences . The objective is to inform people, provide them the knowledge they need, generate understanding for the necessity and gain insight on the different perceptions and ideas people have. What are the consequences of these measures for the user, inhabitants and local governors?
"Kitchen table" conferences with the ministry and farmers in the area. Which measures are possible?
Consultation rounds (interviews) among the parties involved on how to proceed.

The government has based is decision on policy making on the results of the study on "water management in the 21th century" (so-called WB21). This study has also been interactive in a sense that it formulates a strategy by organising:

- Expert meetings focusing on different topics (like agriculture, nature conservation, recreation, shipping, town planning and international aspects);
- Expert meetings and research on different policy instruments;
- Research on the coherence between regional- and the national water systems.

Methods and tools

See above: expert groups; working groups per issue; open communication; interviews; symposia; information evenings; DVD film; "kitchen table conferences"; consultation rounds.

Experience and lessons learnt

Only after a thorough problem analysis and the generation of guidelines for water management, the project organised discussions with NGOs. The idea was that the government should have a sense of direction before other parties become involved in the discussion. The topic is difficult as the problem is security and national interests are at stake.

However, in retrospect, the consultation of other parties and stakeholders would have been useful half-way the process in order to share problem ownership and invite people to generate solutions.

The province is eager to take the role as process manager. They are responsible for the integral area development and fear that the Ministry has a dominant say in the plan development (see reaction minister).

A reconnaisance study becomes more effective if combined with proposals for alternative measures or scenario's. The latter makes conflicting interests but also chances for new solutions clear. For example, the measures as proposed by IVB made the interest of the different parties clear and evoked the development of new alternatives by these stakeholders. The RVR project decided not to come with a plan but provides a kind of toolkit with 1000 measures, without indicating the location of possible measures and its effects. Discussion on what where, when and for whom was postponed and thus agreements among parties was still missing.

The strategy that is currently being developed on water management in the next century was still missing at the start of the study. Hence, pre-conditions and directives were not clear. The IVB project took initiative and developed new pre-conditions which could (with approval of the Hague) could be used in the further development of measures.

Communication towards citizens about progress and results is poor in the RVR project. People do not see the necessity of this study yet.

Projects were implemented (funded by EEC) in the riverbeds while the policy on water management in the coming century is still being developed. This resulted in one project in a confusing situation where the government appeared to be unreliable. In the other project "no-regret" measures were formulated to be financed by these EEC funds.

(Tangible) Result

1. A new style of government

The steering commitee wants to continue its cooperation and appreciates the atmosphere of trust, good relationship and the working together. *"we want to continue this cooperation like wise people that make sense"."it is a form of careful decision making in a phased approach"*
Other government organisations and NGO's like the department of agriculture and nature conservation have gained understanding for the interests of PW and the importance that is being attached to security ("nature is more flexible than security"). Hence, they search for alternative policies like security in "wet nature". The feeling of mutual understanding and trust has grown among the different organisations involved.
NGO's showed new initiatives, e.g. a waterboard developed their own alternative solutions (and published it in a newsletter).
Also farmers came up with constructive alternative solutions for water management in specific areas.

2. Water management issues

General outline for water management in the riverbasin (of the river Rine).

Development of a vision on spatial planning in relation to water management by Provincial Government and Department of VROm in the region.
Different alternatives are developed and the effects of each are indicated.
The question has been answered; within the existing watersystem the river water can be accomodated (16.000 m3/s) through improved maintenance and measures within the system
The weak parts in the watersystem (with respect to security) are indicated in the region
No alternatives, but different measures are developed that can be implemented sequential (IVB):

- In between dikes;
- Flowing through the Biesbosch;
- Green rivers (after 2015);
- No regret"measures are proposed (that are subsidised by EEC) , which can be directly implemented (and shows direct results to those who have been involved);
- "It is no longer a study on civil-technical measures, but an organic process, focussing on security through creating room for water…. Measures need to be flexible in order to anticipate further changes and the effects of measures…..All relevant parties (organisation) share the problemperception and measures!" (project leader).

20. IIVR project, Integrated Planning of the Veluwe Lakes, The Netherlands

Inspiration points

This project shows an example of shared responsibility among several authorities in developing an integral plan. This shows a number of institutional challenges and gives examples of different forms of participation in different phases of the process.

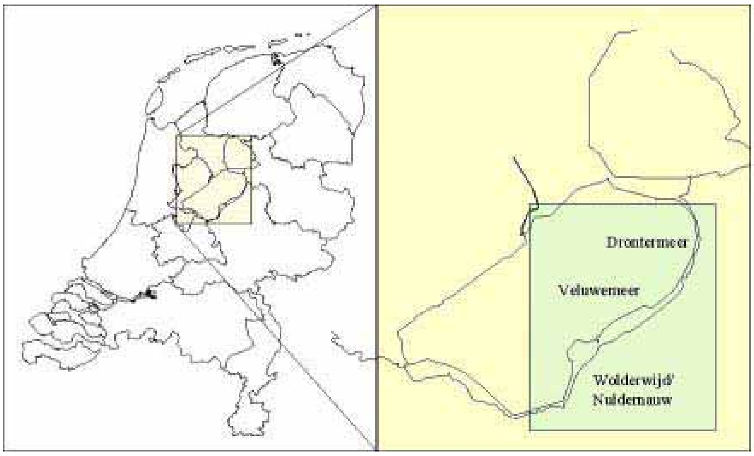
Aim/objective of the project

The Veluwe lakes are managed by several authorities, each with its own policy and instruments to manage the different parts of the water and its border. Besides these local and regional authorities (in total 20), also non governmental issue groups, have their concerns and interests. Hence a situation has occurred where plans are not in line with each other and often have conflicting interests, like those of nature, recreation, fishery and transport by water.

In 1996 an integral planning project was initiated by the Ministry of Public Works and water management (PW) in the region.

Scale/unit of planning

Hundreds of stakeholders, 3 provinces, 10 municipalities, 4 national ministries worked together on a plan for the Veluwe Lakes (about 64 km^2). See Figure below.



Period: 1996-2010

Objective of Public Participation

An open planning approach was chosen with the following objectives:
- To achieve more consistency in existing and future development;
- To develop a high quality plan which is feasible and widely accepted.

Who participated and how (degree/form of public participation) in what phase of the planning?

The project has chosen for a co-operative style (see Section 2) in which the different authorities and non-governmental organisations (NGO) (or interest groups) work together and have an equal say in the final outcome. The interaction is organised through:

- A steering-committee, formed by governors of the different government authorities. They gave direction to the process and take decisions The steering-committee is supported by the initiative-group;
- An initiative group. This groups of experts; government employees en members of NGO's, discussed the content of the planning process;
- Consultations of citizens and interest groups. In addition, several sessions are organised to consult citizens and interest groups and give them an chance to share their problem perception and generate ideas.

A project team facilitates the planning process. This team consists of staff of ministry of public works. However they have a separate office, their own name and logo and work independently. An important motive of the project team for this approach is that citizens should not be burdened by the fact that the government is divided in state, provincial and other government organisations.

In the process the four steps of start, problem inventory, generating solutions and action can be recognised. After each steps decisions are made on how to proceed.

1. Start

- Process plan (1996),
- Developing a terms of agreement with all authorities (1997),
- Organising team and steering committee, task assignment.

2. Exploration of current situation

- Inventory of all problems, issues and first ideas (summer 1997);
- Government Authorities in 3 provinces, NGO and citizens (total 300) participated by attending one of eight sessions. 400 issues came up. During the sessions an atmosphere for brainstorming and an open mind has been stimulated by all kind of exercises;
- Cartoon artists visualised and hence stimulated the discussion (see illustration);.
- Experts participated in the sessions but were asked not (yet) to react;
- Also, non-participants were consulted, to verify the outcome. After the sessions all problems were clustered and analysed with the help of the expert-centre. A report with results has been sent to all participants.
- The steering committee approved the outcome and the continuation of the process.

3. Generating solutions

- Generation of ideas and solutions (summer 1999);
- During sessions with 170 participants ideas and solutions are developed for the problems. Creativity has been stimulated with different tools and techniques (a/o

varying from artist performance, brainwriting techniques to the use of GIS design to indicate the location of problems and solutions). During this session all kinds of knowledge and ideas are brought together and induces citizens, interest groups, project team, experts and authorities to look at solutions from a different point of view. After the sessions the expert-centre analyses and further develops the ideas into "building blocks".

- Inventory of actual situation and on-going projects, a structure analysis and zone map;
- scenario development;
- Impact analysis;
- The effects were indicated per scenario during a 2-day session where experts and users indicated criteria and effects using objective arguments and their own experience and knowledge;
- Decision making by the Steering Committee on the strategy to follow (end'99).

4. (Preparation for) implementation

- Development of a plan indicating what, where, when and by whom have been implemented;
- 8 working groups consisting of members of the intitiative groups and key-persons have developed in 3 sessions of a day a detailed plan for the different aspects like nature, recreation, economic development etc;
- Setting up of a terms of agreement (on the responsibility for the implementation);
- Decision by the steering committee on the implementation of the plan (Nov 2000);
- Implementation of the plan in 3 phases, starting in 2002 . Moments for reflection were planned in order to be able to adjust the plan to new developments and insights.

The results:

- Governors were enthusiastic. They took their responsibility by dividing the costs for implementing the proposed 38 measures;
- The response of all participants in the process has been positive;
- New forms of cooperation have started among government authorities (at different levels), within their offices and with NGO's;
- NGO's have improved the quality of the plans. They introduced new perceptions and arguments and kept others sharp (e.g. by posing questions like what is at the interest of the users?);
- NGO's have broadened their scope and got feeling for the interests of the others parties involved. They formed on their own initiative a new consortium of recreation and nature conservation groups have developed a plan (or vision) indicating their mutual interests as well as disputes (on their own initiative);
- The central office of PW in The Hague appreciated the outcome of the process as it gives an integral plan with an overview of different measures, arguments and priorities. It also shows the (financial) contributions of the other parties involved;
- The plan consisted of long-term measures but also activities that can be directly implemented, which motivates the different parties.

Lessons learnt

Lessons learnt with respect to the process are:

- Take time for the start;

- The start took almost two years, as the authorisation of the project and the co-operation of authorities took time;
- Indicate the pre-conditions and/or a sense of direction before starting interactive sessions with citizens and interest groups;
- The large amount of information gathered during the inventory was another reason for delay. It took a considerable amount of time to process all data and compress it into a number of clusters that could be used in the next step of generating solutions. In retrospect the interactive sessions were too open in a sense that no restrictions, preferences or pre-conditions were indicated. For the citizens it may have been easier if there was a sense of direction (as developed by the steering committee, showing their ambitions and scope;
- Make a tailor-made process design during the start of the process;
- Only half-way, a total process design for plan development has been made. At the start of the problem inventory it was not clear how to proceed with the large number of problems (sometimes even contradicting each other);
- Integrate the interactive planning process in the formal decisionmaking procedures;
- Involve the governors actively and support them in their new role;
- The major role of governors is to provide a clear assignment. They need to be involved in the problem definitions, to make sure they are committed and see the necessity to act;
- Governors do not want to be involved in sessions to generate solutions (they don't feel secure nor capable to do so…). They rather discuss the generated options and directions how to proceed (and choose). Informal meetings help to get a feeling for their political context and their attitudes towards possible solutions. They need time to discuss proposals and generate support within their own organisation. The attendance of governors during public "information-evenings" is positive as they can indicate their role and dilemma's;
- It is the role of the project leader to keep all governors committed to the process and major outcomes;
- Work with an independent project team;
- Although it consisted of staff of the ministry of public works (PW), they have gained the support and trust of the other parties as care takers of their interests. Since there were two different provincial governments involved and the central topic was water, the project team of PW appeared to be the logical process manager. Provincial's authorities have showed a growing interest in the role of process manager (as integral spatial development has become their major concern).

www.iivr.nl (only in Dutch)

21. Waterplan for the municipality of Hilversum, The Netherlands

Inspiration points

It shows an example of consultation of stakeholders in the process of developing an integral water plan for a municipality. Collaboration is based on common sense of urgency.

Aim/Objective of the project

A municipality-waterplan is an integral plan, which indicates the policy on the management and use of water in the city. In the municipality of Hilversum the existing plan did not get the support from all other organisations involved. Moreover, the political situation was even more sensitive as the municipality was in financial problems and in ward under the central government. Also physically the situation was complex. Deep water levels led to a shortage of water, while an old-fashioned water sewage system caused problems of flooding and pollution. Complexity was augmented due to the responsibility of different organisations for water management (the province for deep groundwater; the water board for surface water, bottom and banks; the service for water management and sewage system, for policy preparation and maintenance, while the municipality cares for the water quality below ground surface). Hence, the local governor decided that an alternative approach for the plan development was necessary.

Scale/unit of planning; Municipality

Period; *1995*

Objective of PP

- To de-politicise the situation;
- To create a high quality plan;
- To strengthen new forms of co-operation; and
- To create understanding and support for the integral use of water within the municipality by developing a sustainable plan.

Who participated and how (degree/form of public participation) in what phase of the planning?

- The participatory style was a "consultative" one. When considered necessary the project team consulted interest groups and organisations (in total 25);
- The project team was formed by the Municipality responsible for developing the plan. They were supported by a Steering Committee consisting of members of the other organisations involved; the province, the waterboard, and an institution responsible for clean water. Whenever necessary governors were consulted as well as interest groups.

Methods and tools applied

Participation was organised through:

- Discussion sessions per theme;
- Rounds of information supply;
- Consultation evenings a/o to enable interest groups to give comments and indicate priority;
- To proposed measures.

Tangible Result (effect) of PP

- The solutions were no longer solely found in technical measures like bigger pipes and pumps, but a shift in attention took place towards increasing the human capacity to find solutions for the source of problems;
- A waterplan was developed in combination with a plan for a new sewerage system;
- The high quality plan drew all the attention, while the battle for competence among different organisation was put on the back bench;
- Close cooperation between municipality, waterboard and province in a political sensitive situation with strong competition among parties. They all supported the final plan.

Lessons learnt

- The well structured process helped creating clearity on when and how which persons or organisations could participate;
- The governors gave room to the project leader to manage the process with authority (which was useful in the political sensitive situation);
- The latter requires that both governors and process manager have a good working relationship and keep constantly in touch on when the governor should play what role and the other way around;
- Governors want to be able to choose and need to know the effects of the different alternative solutions.

22. Participation, Consultation and Capacity Building in WFD Transposition Processes; Scottish Environment Protection Agency and Scottish Executive, Scotland

Key words

Scottish Executive, SEPA, transposition, capacity building, key issue/ stakeholder /sectoral workshops

Inspiration points – this example is inspiring because:

During the past 2.5 years a number of events were organised to increase organisational capacity and understanding of the WFD across a range of bodies in Scotland. This process helped inform debate and discussion of key WFD issues and enhanced mutual understanding of issues of agreement or concern. A wide range of public and private organisations actively engaged in and contributed to this process.

Aim/objective of the project

In Scotland many of the component parts of the WFD are not presently in place e.g. water abstraction or impoundment controls, controls on river engineering or an equivalent of River Basin Management Planning. WFD implementation, therefore, presents major challenges to many organisations and stakeholders.

The general aims of the activities undertaken and described were:

- To inform a range of public authorities, NGOs, sectoral interests and other stakeholders of WFD transposition and implementation processes in Scotland, notably around periods of formal public consultation;
- To increase organisational capacity in respect of WFD understanding to allow meaningful input to, and engagement in, key WFD transposition and consultation exercises;
- To inform a range of organisations and interested parties of present interpretations of key WFD issues, and to discuss and debate these;
- To encourage meaningful discussion of WFD issues by interested parties to increase mutual understanding of positions and views;
- By the encouragement of participation in these early WFD stages to build capacity across a range of organisations and interested parties to benefit future RBMP and Characterisation processes and activities;
- Scale/unit of planning.

These information sessions, seminars and workshops were undertaken at a range of different scales and levels of input including:
- National (as part of national preparations for WFD transposition);
- Sectoral (individual sectoral groups were involved in specific events);
- Issue specific (individual WFD issues were identified for specific discussion).

Period: Spring 2000 – Ongoing.

Degree of public participation and stakeholders involved

The information and participation exercises undertaken in Scotland were organised in different ways to allow different sectors, issues and geographic scales to be considered. Ranges of stakeholders were, thereby, brought into the process at different stages and in situations in which they were confident and comfortable.

Stakeholders engaged in the process included

- Local Government;
- "Industry";
- Rural Land Use (agriculture, forestry etc);
- Freshwater Fisheries;
- NGOs;
- Environmental Groups;
- Public and Government Agencies and Departments;
- Other interested parties via inclusive and open events.

Methods and tools applied

This example was essentially a sequence of information session, workshop and conference events undertaken throughout preparations for WFD consultation stages.

In order to be most effective a range of approaches were taken which are summarised below:
- Events were sectoral (to allow key audiences to be met) or;
- Issue specific (to allow key issues to be considered) or;
- Wider events (to allow open discussion and resolution of issues and differing opinions from, for example different sectoral groups);
- Stakeholders participated in all of these event types.

A range of groups made presentations on particular WFD issues and aspects of particular relevance to them. This direct and public involvement reduced the perception that these events were the sole responsibility of individual organisations. Events were organised and managed by different partnerships according to subject matter.

Many events were jointly organised by the Scottish Executive and SEPA. Other partnerships, however, organised different events. e.g. the Scottish Executive and WWF were responsible for the provision of a workshop specifically considering WFD public participation .

By using different approaches to different events to encourage engagement with different groups an extensive WFD public participation process was generated.

Major input of stakeholders

Stakeholders were involved in different ways within the process. Some made presentations reflecting their particular expertise, concerns or responsibilities, some debated technical interpretations of particular WFD areas while others played key roles in managing events. Particularly in the early stages of this process general information on the WFD was required to inform later debate and discussion; initially SEPA and the Scottish Executive fulfilled this role. Facilitated sessions allowed the active involvement of parties not specifically leading or presenting any of the events or topic discussions.

Participating numbers ranged from 30 – 40 for sectoral seminars and workshops to in excess of 100 for more general events or where a sector or issue of particular significance was considered.

The sequencing of events around formal consultation processes and stages allowed the introduction of key consultation questions for debate. In this way the consultation responses of stakeholders could be informed by open debate and discussion of issues and on a greater understanding of WFD implications for themselves and of other groups. An increased mutual understanding of WFD issues was delivered.

Tangible results of public participation exercises

The series of events produced, or helped to produce:

- Increased organisational capacity and understanding of WFD issues;
- Enhanced mutual understanding of respective organisational positions, concerns and interpretations;
- Provided opportunities to resolve issues of concern and to re-assure groups of interpretations;
- Helped inform responses to WFD formal consultation exercises;
- Introduced many of the new WFD concepts and requirements (to Scotland) to key groups at the start of the process;
- Started the WFD process of public participation at an early stage in Scotland and provided a start point on which to build future processes, procedures and trusted relationships.

Project costs

It is not possible to quantify the costs involved in providing the participative and consultative opportunities available within the described process. However, significant staff resource from organisations managing events was allocated from SEPA, Scottish Executive, WWF and others. Additionally, time allocated from a range of stakeholders in attending and presenting at events was significant.

Lessons learnt

A number of key lessons have been learned during and as a result of this process in Scotland. Some of these are summarised below:

It is clear that participative approaches similar to that summarised can be hugely beneficial in building organisational capacity of all bodies involved. It is certainly the case that by opening the WFD debate in Scotland throughout the transposition process more informed and valuable contributions from a wide range of groups were received and generated.

Where the approach taken in Scotland has been particularly successful has been in targeting input both sectorally and at appropriate times within the process, e.g. linked to SE consultation periods. That participative and consultative exercises, processes and opportunities should be focussed and targeted and meaningful in order to deliver most benefit to the overall process is perhaps the key lesson.

The continual and ongoing engagement of stakeholders during the past years has improved and developed the dialogue and relationships between organisations. This continued commitment to engagement in the process is better than single events.

The WFD is an ongoing and iterative process so participative and consultative opportunities must be provided on an ongoing basis to allow continued meaningful engagement in the range of WFD processes.

It is apparent that what is delivered is never enough! There remain calls for a wider and more inclusive approach still to WFD implementation. In many cases these are reasonable expectations and aspirations that SEPA and the other Responsible Authorities must try to meet, address and manage.

23. Ettrick floodplain restoration project by Borders Forest Trust in the Scottish Borders, Scotland

Inspirational points

Several techniques have been used by the Borders Forest Trust (BFT), who manage the project, to ensure meaningful public and stakeholder participation. These include an initial public meeting, the establishment of a local community steering group and a technical (stakeholder) steering group. A citizens' jury was also conducted involving members of the wider community to help guide the process. The project continues to be guided and assisted by the community steering group.

Aim of the project

The aim of the project is to restore floodplain characteristics by removing and ameliorating intensive forest and agricultural practices together with the establishment of large areas of semi-natural habitat to produce a functioning floodplain of national and international quality.

The project has developed a matrix of linked elements along the upper Ettrick Water to create an extended mosaic network of woodland and associated habitats. The restoration work has involved the creation of appropriate riparian scrub, wetland, and woodland on species poor unimproved grassland and areas previously afforested with exotic conifers. The removal of exotic conifers and reinstatement of natural flooding patterns has increased the upper Ettrick's flood buffering capacity and the biodiversity value.

Scale/unit of planning

The Upper Ettrick valley contains tributaries of the main Ettrick River which feeds the River Tweed. The project area is in excess of 2 square kilometres, extends for some 6 kilometres along the main watercourse and has involved a number of private landowners and Forest Enterprise (the State forest managers) in the management of: hay meadows; wetland (rush pasture); willow scrub and alder carr; native broadleaved woodland and species poor grassland.

Period

The project has been running for 5 years from 1998-2002 and will continues to run for the next five years.

Objective of public participation

Borders Forest Trust is a community-based organisation originally formed by community groups and individuals. It is designed to serve communities in the South of Scotland. In the Ettrick project the objectives of the community consultation were:

- To identify public aspirations and fears of environmental projects related to floodplains;
- To encourage greater community involvement and ownership within environmental restoration projects;

- To identify problem issues at an early stage of the project;
- To encourage the sustainability of the project by mobilising the local community;
- To benefit from local knowledge.

Who participates and how?

Stakeholders and the local community participate in the planning and implementation of the project through two groupings. The technical steering group comprises a range local bodies and agencies (such as Scottish Environment Protection Agency, Scottish Natural Heritage, Forestry Commission) who advise on the technical aspects of the project. The local community is provided with a voice via the community steering group where dedicated members have an input to the planning and implementation of the project. The wider community also had the opportunity to participate in the development of the project through a citizens' jury.

Methods and tools applied

At the start of the project the local community was invited to a public meeting where the details of the project were discussed. Community members were invited to volunteer to sit on a steering group. The community steering group meets project managers on a regular basis to discuss progress and feed into the planning and implementation of the project.
A citizens' jury was also held to allow wider members of the community to learn about and feed into the project. The jury was made up of citizens drawn from across the Scottish Borders. Stakeholders from different perspectives such as NGO government agencies etc attended the jury as witnesses, presenting information to the jurors, and answering questions. The jury made recommendations on the benefits of the project and management of the site.

Major input from stakeholders

A technical steering group made up of local stakeholders and government agency representatives also meet project managers on a regular basis to advise on technical aspects of the project.

Stakeholders also participated in the citizens' jury as witnesses. This facilitated dialogue between members of the community, stakeholders, and project managers.

Tangible results (effect) of Public participation?

Tangible results of the participatory nature of the project have included:
- Ensuring the sustainability of project, for example members of the community are keen for the project to continue and have volunteered to work as project wardens;
- The ability to iron out difficulties and allay fears early on in the project timetable;
- Encouraging farmers to manage their land in complementary way; and
- Changes made to aspects of the project. For example, the entry points to, and the access paths within sections of the project area were decided by the Community Steering Group, and are different from the original ideas of the BFT staff involved in the management of the project.

Lessons learnt

Community involvement is an essential component of this floodplain restoration project and has contributed to the design and execution of most elements. Without adequate public involvement and consultation the project would have run into many objections and much hostility. Potential objections were likely to stem from confusion as to the nature of the project and sensitivity of people to practical works associated with flooding.
One of the major lessons learned by BFT was the importance of early positive engagement with communities and an ability to respond quickly and flexibly to areas of concern and misunderstanding.

Formal procedures for public participation

There were no formal requirements for public consultation, however, since the BFT is a community led group, a participatory approach was considered vital for the success of the project. Although many participatory processes were designed within the project plan much of the interaction has been led by the community itself. As the project progressed the public consultation and engagement became less structured and formal, and more dynamic as the community began to take the lead with respect to access planning and project interpretation.

24. Consultation on Technical Annexes II and V of the WFD, Scotland, England and Wales

Inspiration points

In the summer of 2002 the Scottish Environment Protection Agency (SEPA) in Scotland and the Environment Agency (EA) in England and Wales issued public consultation documents on "The Guiding Principles on the Technical Requirements of the Water Framework Directive". These documents outlined the principles and requirements of technical Annexes 2 and 5 following:

An inclusive drafting process and Stakeholder input at the outset of the production process and launch of the consultation documents.

Participative approaches related to the technical requirements of the Directive are difficult to formulate, manage and make meaningful but this example shows how progress can be made on such issues where a will to do so exists.

Aim/objective of the project

The general aims of the consultation exercise were to:
- Help stakeholders understand the technical context provided by Annexes 2 and 5 to the administrative and regulatory provisions required of transposition;
- Allow comment on the proposed principles to be adopted in implementing these Annexes as these provide the basis for allowing the sustainable use of water resources and the efficient achievement of the Directive objectives while delivering real environmental benefits;
- To gather views as to how and when stakeholders would wish to be involved in technical implementation processes.

Scale/unit of planning

The respective SEPA and EA consultation documents were issued on a Scottish and England/Wales scale respectively.

Period

The consultation documents were issued in early summer of 2002 with comments to be provided by August/September 2002. Stakeholder workshops were held at the document launches.

Prior to this stakeholder workshops were held at the process outset (2001) to allow initial input at early formative stages of drafting and highlight issues of concern and interest.

Objective of public participation

The technical annexes of the WFD are complex and not easily understood or interpreted. They do, however, provide the basis and instruction as to how the water environment will be assessed, monitored and classified. These tasks inform Objective setting, the development of Programmes of Measures and regulatory regimes. As such it is important that, as far as possible, the principles being adopted, or being considered for adoption, are understood and supported by the range of stakeholders, authorities and organisations potentially affected by these assessment or related activities.

The objectives of this exercise were to:

- Allow stakeholders to input their priorities and concerns as to how technical annex interpretation might affect them;
- Allow stakeholders to comment on proposed WFD technical interpretations and principles;
- Provide a framework by which a range of public bodies across the UK could input to the development of a common interpretation and understanding of Directive requirements.

Degree of public participation and stakeholders involved

Stakeholder participation was encouraged and facilitated within the stages as below:

- At the launch of the Annex 2/5 process stakeholder workshops were organised and attended by a range of industry and environmental interests as well as other public and non-public bodies. At these events views, concerns and issues were gathered from stakeholders to inform later drafting exercises and to provide a context for later discussion and interpretation debate;
- Document drafting required input from a range of public bodies and agencies to fully gather and capture expertise from across sectors and interests. In Scotland participating organisations included SEPA, Scottish Water, Scottish Natural Heritage and Fisheries Research Services. In addition, the EA and the Environment and Heritage Service (EHS) from Northern Ireland participated in the Scottish process. Similarly, SEPA and EHS participated in the EA led process in England and Wales to help ensure UK wide consistency of content and interpretation;
- At the launch of the Annex 2/5 documents stakeholder workshops were organised and attended by a range of industry and environmental interests as well as other public and non-public bodies. At these events initial responses, concerns and questions raised by the publications were aired and discussed openly;
- A consultation period following the document launch allowed a period for formal stakeholder comment to be provided.

Major input of stakeholders

At the organised workshops the views and concerns of stakeholders were:

- Gathered for inclusion and consideration during the drafting process;
- Highlighted by stakeholders to inform others of these views thereby encouraging debate of these, potentially informing the consultation responses of other consultation respondees and allowing mutual understanding of concerns.

Tangible results of public participation exercises

Consultation periods for these documents have now closed and a wide range of responses received by SEPA and the EA. These will be used to help shape ongoing interpretations of the technical annexes, inform principles to be taken forward during this process and allow the balanced consideration of the concerns of stakeholders.

It is likely that ongoing involvement and input from stakeholders in many aspects of Annex 2/5 and general WFD interpretation will be provided following this exercise and process. It is hoped that SEPA and the EA, supported by arrange of other public organisations, will benefit from the adoption of transparent and inclusive approach to WFD interpretation in the coming years. The Scottish Executive in Scotland and the Department this approach for Agriculture, Food and Rural Affairs in England and Wales supported and allowed this SEPA and EA approach.

Lessons learned

A number of key lessons are summarised below:
- It is possible to develop and provide participative opportunities associated with WFD technical processes and issues;
- Attempt to involve stakeholders in such issues and processes are appreciated by them and deliver benefits to prospective competent authorities in terms of both transparency and trust and through the valuable and insightful contributions made by stakeholders;
- The collaborative working of agencies and public bodies in both Scotland and England and Wales is beneficial in increasing national understanding and co-working relationships;
- Similarly the reciprocal involvement of SEPA, EA and RHS in each others drafting processes increased UK wide shared understanding while providing reassurance to stakeholders that common interpretations were being applied and proposed.

25. Global flood defense plan in river Júcar, Spain

Elements of inspiration

Information to the public in this case has been a two way, iterative process. Authorities of the river basin district not only transmitted information of the results of the floods assessment but at the same time involved representatives of the community in the design phase of the flood control related strategies

Key- words

Floods, risk perception, transparency, co-responsibility.

Aim/objective of the project

Development of a global floods control plan.

Background

Jucar River Authority has carried out different hydrological and hydraulic studies in the river Jucar with the ultimate objective of reducing the damage produced by floods in a plain with a very important social and economic relevance. The objective of the participation process has been mainly to involve stakeholders and public in general on the decisions taken, coordinating measures at river basin, regional and local levels. River Júcar flood plain is about 4000 km^2 with a population of more than one million people.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The public participation process started in 1998 with the creation of an ad hoc committee including water authority members and representatives of the municipalities located in flood prone areas. This committee was enlarged in order to incorporate representatives of ministries belonging to the Spanish central administration, departments of the regional government, NGOs and users associations. A permanent secretariat of the committee allowed the management of the consultancy process and capacity building was provided by the Jucar river authority. In order to present the process to the public in general, several workshops and meetings were organised. Risk maps were presented in a workshop in Valencia in April 2002 after a long consultation process with the affected administrations and public in general. These maps together with other basic documentation have been included in a CD with GIS tools that allows their visualisation and analysis. All this information has been distributed to the public free of charge.

Major input of stakeholders

One key element was to agree that the idea of "zero risk" culture can not be accepted. It has to be admitted that a certain degree of danger is present and thus the acceptable level of risk has to be decided. Flood risk maps can be a good tool to apply these principle serving as the first information source of information in order to look for a compromise between urban development and flood control that means important economical implications.

Tangible result (effect) of PP and lessons learn

- Publishing and distribution of risk maps;
- Identification of priority actions;
- Understanding by the community of the degree of vulnerability and assimilation to what extent they can be affected by floods;
- Increasing the transparency and legitimacy as well as underlining the economic and social relevance of flood control policies.

For more information please contact:

- manuel.menendez@cedex.es (technical studies)

26. Alcobendas - city of water for the 21st century, Spain

Inspiration points

Awareness raising on water consumption and change of attitude towards water consumption.

Aim/objective of the project

To raise awareness of the population, local authorities and SMEs in Alcobendas, a Madrid suburb, on water consumption in order to create a culture of treating water with respect.

Scale/unit of planning

Alcobendas, a satellite town at the outskirts of Madrid, with 90.000 inhabitants.

Period: 2000-2001

Objective of Public Participation

To engage the public in water savings.

Who participated and how (Degree/form of public participation) in what phase of the planning?

A broad range of the inhabitants, authorities and local SMEs.
A wide range of activities, information and media coverage: just for publicising the results (see below),the following was carried out:

- Press conference attended by 30 representatives from press, radio and TV;
- The project office received more than 1.000 calls and visits by media-rep's;
- 4 TV reports on water-saving systems;
- 17 programs on "Olca Alcobendas";
- 14 interviews on other radio stations;
- 113 articles published in various magazines and graphic media;
- A total of 250 journalists were informed about the project.

Methods and tools applied

A comprehensive package including:

- Exchanging technical and scientific information to encourage the introduction of effective water-saving technologies and programs and water demand management;
- Promoting new regulations;
- Stimulating the water-saving technology market;
- Promoting changes in the productive sectors;
- Increasing public awareness of the need to participate actively in saving water;
- Offering an example of the introduction of effective water saving measures in new homes;
- Publicising the results and methodology so that they can be adapted to other towns.

Tangible result

Estimated water savings for Alcobendas: 102.200.000 litres per year.

Lessons learnt

The most important aspect of the "Alcobendas - city of water for the 21st century" is not the savings in absolute terms, but the creation of mechanisms that produce a permanent change of attitude towards saving in the use of water in cities.

27. The Water Forum in the Balearic Islands, Helcom, Spain

Inspiration points

This example is inspiring because is promoted directly by the Environment Council of the Balearic Government and designed and organised by the Development and Ecology Foundation (ecodes), a member of the EEB and a serious and responsible organisation. Also, the perception of the participant stakeholders seems to be very positive regarding the first two initiatives encouraged:
- the Pitiusic and Menorca workshops.

Aim/objective of the project

The main objective of the Water Forum in the Balearic Islands is the participation of citizens in drawing up an analysis of the current situation as regards the management of water and the construction of a basic consensus for water policies in the Balearic Islands. This consensus would contribute greatly to moving the management of water towards a sustainable model, which the population of the islands desires, in this case with reference to the management of hydrological resources.

Scale/unit of planning

Balearic Islands (Eivissa, Formentera, Mallorca and Menorca, 5.016 sqKm), Western Mediterranean, Spain

Period: 2001-2003, as a minimum.

Objective of Public Participation

The main objectives of this initiative are as follows:

- To achieve, in a context of neutrality, communication between business, social and institutional groups without the habitual intervention of the news media;
- To create informal environments for meetings between the leaders of social sectors often involved in confrontation;
- To make sure, in a context of negotiating, that parties receive information on the conflicts from the appropriate technician in the local government;
- To ascertain, without the intermediation of the news media, and without bilateral negotiating tensions, the main concerns of the principal community leaders of the sectors most relevant to the management of water on the three islands;
- To ascertain shortfalls in the focuses of social organisations in relation to the management of water;
- To detect the main sources of conflict, and the position held by the range of sectors in this regard, and the nuances of these confrontations;
- To ascertain points for a basic consensus for water in the Balearic Islands in order to construct a new culture of water in the Balearic Islands.

Who participated and how (Degree/form of public participation) in what phase of the planning?

In 2001, the project aimed at the participation of the full range of stakeholders, including individual citizens, local, insular and autonomous administrations, NGOs, representatives of political parties, land owners, water supply, water treatment and desalinisation technicians, consultants, etc. The aim was for the groups to be as heterogeneous as possible, ensuring the presence of women and old and young people, who still appear to be under represented sectors in the water management field. 32 people were invited to every workshop, and 23 on average attended each of them.

Methods and tools applied

For the first phase (Pitiusic Islands and Menorca workshops in 2001) the Logic Framework method was used. This method consists mainly in discussing within the whole group or 4-5 people the proposals of every participant and their appropriate setting in a certain diagram. The final results are a series of logical trees reached in consensus by the whole group. In this case, the proposals represent the main problems and main solutions for solving them regarding water management in the three islands, Ibiza, Formentera and Menorca.

In Mallorca, during the 2002 phase, the EASW (European Awareness Scenario Workshop) methodology may be applied. This is a more complex group method, following in essence the same path but in a more closed and fixed way. The EASW Initiative was launched by the European Commission DG XIII D in 1994 as a pilot action to explore new possible actions and social experiments for the promotion of a social environment favouring innovation in Europe.

For more information see http://www.cordis.lu/easw/home.html

Both methods require skilled consultants. For the Logic Framework Workshops, one facilitator was in charge, helped by three assistants, also skilled, and, in this case, an abbreviated version was implemented, lasting only a whole day (from 09:00 to 20:30, including lunch and several coffees in between). The usual version usually takes 2 days.

The EASW method requires a larger number of consultants (4 to 6), and cannot be successful if shorter than one day and a half.

Indicative costs

The first phase of the Balearic Forum cost about 30,000 euros.

A EASW workshop costs about 13,000 euros to run.

Tangible result

Until now, some encouraging initiatives have arisen from a few stakeholders who organised themselves to push the Administration on specific topics. For example, in Menorca, a member of Menorca Reserve of the Biosphere and a technician from the Sant Lluís Towhall, were freely assigned by the rest as responsible for asking the insular authorities about the project to organise an Insular Water Administration, against the Balearic existing one.

Despite this initiative not being *a priori* positive for the Balearic Government (who promotes the Forum), it is seen as a good movement within the whole participation process.

28. Co-operation on the Catchment Level in the Emån River Basin, Sweden.

Elements of Inspiration

River Basin wide co-operation to achieve sustainable development by encouraging commitment and support from local people in restoration of the area and implementing environmental measures. Catchment area management.

Key words

Stakeholders, broad public, measures, co-operation.

Background

There are several ongoing conflicts between different stakeholder groups in the Emån river basin. The entire main channel and several tributaries are Natura 2000 areas. This part of Sweden is suffering from decreasing population and low educational levels. River basin co-operation, on a broad scale, is used as a method to achieve the following objectives:

- Better water quality within the Emån watershed;
- Pollution should not restrict the use of the water resources for drinking water production, fishing, bathing, industrial purposes etc.;
- Better environment for Trout and Salmon;
- High environmental values existing within the watershed shall be preserved and developed;
- All natural species shall exist in sustainable populations;
- Economic and environmental sustainability in the region.

Scale / unit of planning

Catchment area of 4 500 km^2.
Population involved – more than 2000 (=2%)

Period: 1994 -- ongoing

Objectives for public participation

In the Emån watershed they are paving the way for environmental sustainability by means of involving the public in water management. The stakeholder association is encouraging voluntary action, commitment and support from the local population and industry in restoration and development of the area. The objectives of the public participation in the different projects are:

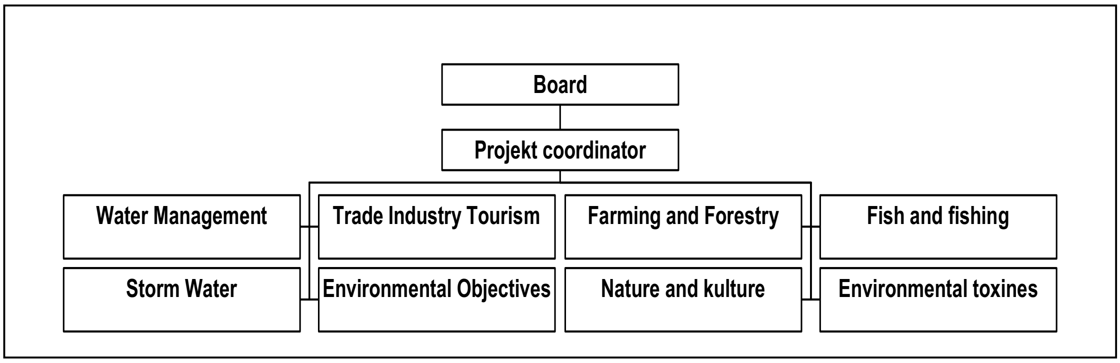
- To make use of the knowledge and experience from NGO's and other stakeholders;
- Avoid or solve conflicts that arise between different groups of stakeholders;
- Increase the awareness of, and knowledge about, the environmental values in the Emån region;
- Increase co-ordination between different enterprises and stakeholders within the watershed;

- Increase interaction between different stakeholders to find strategies for how natural recourses may be exploited from a holistic and sustainable perspective.

The Emån model for public participation - who participated and how?

Eight municipalities, two Regional Administrative Boards, the Emån River Council, The Federation of Swedish Farmers, owners of fishing waters, angling associations, local history associations, nature conservation associations co-operate in the Emån Stakeholder Association. All of the above mentioned have representation on the board of directors. Different task groups perform the work. Each task group has its own chairman and 6 – 15 members representing different stakeholders and with specific knowledge about the tasks at hand.

Different authorities and NGO:s take part in the work in the task groups .



The organisation of the Emån Stakeholder association

Methods and tools applied

Public participation is achieved by holding seminars, information meetings and hearings, circulation of documents (e.g. objective documents) for comments, forming task groups (those in the group bring information back to their organisation and vice versa) distribution of newsletters, press conferences etc. Minutes from the various meetings were taken and distributed. There is always a discussion possibility on the web site.

Major input of stakeholders

Stakeholders have been involved in the planning process, in formulating the environmental objectives and in the negotiation for restoration measures. All stakeholders, including the NGOs have provided input for the information documents and have given their view on all suggested plans of measures.

Tangible results of public participation in the Emån river basin

New fish by pass at the Finsjö hydropower station

The following measures are the result of co-operation between the general public and other stakeholders:

- Two new, well functioning, fish by passes, have reintroduced sea trout (*Salmo trutta*) and Salmon (*Salmo salar*) to 20 kilometres of the main channel. More bypasses are planned further up the river;
- Spawning grounds for stationary stocks of trout have been restored in several sections of the river system;
- A complete inventory and risk assessment of storm water in towns and on the road net. Two storm-water dams are being built in 2002;
- Seventeen working groups of more than 200 farmers have been established to improve water quality and biodiversity;
- One abandoned industrial site has been remediated. 35 000 tons of cadmium- and 9 000 tons of lead-contaminated material has been removed. There are also plans to remediate two mercury-contaminated lakes;
- As from 2002, the water flow from nine hydropower dams is co-ordinated in accordance with a new drought protection plan (flow management plan). Stakeholders have assumed economic responsibility for necessary investments;
- A fishery plan on sub-catchment level has been presented for the whole catchment area.
- Biotope mapping of all rivers and streams (a total length of 800 kilometres) has been performed;
- A plan for nature conservation and cultural history preservation was another result of public participation.

Lessons learnt

- It is important for the general public to derive local benefits and see tangible results of their input and involvement;
- People are more interested in providing input and being involved if the problem concerns their own neighbourhood;
- PP takes a lot of time and involves education and information initiatives as well as the exchange of ideas;
- It is important to create different arenas for participation and discussion;
- It is also important to remember that positive results, big and small, from the PP process must be celebrated;
- The involvement of the media is another important success factor.

Summary

The river basin co-operation started as a means to resolve conflicts. Many people are or have been involved on different levels in the process. The public has been involved in tangible measures. It is, however, difficult to get everybody to participate. Often no more than 10-15 % of the people that are invited to take part in seminars or hearings actually show up. Different forms for participation attract different groups of stakeholders. Therefore there must be several possibilities for communication. The Internet is one good example. Good media coverage is helpful when we want to involve more people in the process. The fact that, in some cases, the stakeholders were involved at the sub-catchment level was useful. It is easier to discuss a problem or a possibility close to people's homes.

The cost of the project

The total budget for the objective 5b projects that were carried out from 1997-2000 was 2,02 million EURO. The cost for public participation during this time may be estimated to 150 000 EURO.

The cost for public participation from 2001-2002 is estimated to about 100 000 EURO most of this cost refers to the work in the farmer project. A smaller portion refers to the planning of fish bypasses, information and lectures in schools and the administration of the Emån stakeholder association.

For more information please contact:

- www.emaprojektet.h.se
- Bodil Liedberg Jönsson
- bod@hultsfred.se

29. The Municipality of Örebro's water management plan, Sweden.

Inspiration points

A total of about 70 different authorities and organisations upstream of the catchment area and within the municipality's borders have been consulted on a draft plan.

Key words

Experiences, long tradition on information and public participation.

Aim/objective of the project

To develop a water management plan as a complement to the municipality's overall land and water use plan. A further aim is to fulfil the regional and national environmental objectives for surface and groundwater.

Scale/unit of planning

The area of the municipality is 1600 km^2 divided into several catchment areas.

Period

Pre-1990 - ongoing.

Public participation objectives

The aim is to get people involved in planning process so they can react and give input, but also to fulfil the requirements for public participation under the Swedish Planning and Building Act of 1987 concerning consultation with the public in the development of overall plans. It is also inspiring that Sweden has had this system for public participation for a very long time and has routines for it.

Who participated and how (degree/form of public participation) in the different planning phases

A working group and steering group consisting of civil servants have been implementing the project.

A total of about 70 different authorities and organisations upstream of the catchment area and within the municipality's borders have been consulted on a draft plan. Their opinions and comments were acknowledged by the working and steering groups. The adjusted document was circulated again for consultation.

Those involved included farming and water conservation associations along with Örebro University.

Methods and tools applied

Consultation was effected by holding seminars, information meetings and hearings and by circulating proposed land use plans for consideration by the parties involved.

Major input of stakeholders

Input from farming associations concerning voluntary versus compulsory measures for farmers. Input from the water conservation associations concerning their present role in monitoring and nature conservation associations regarding species protection measures. Örebro University indicated how sensitive areas should be defined and protected and supported the project by disseminating information to the general public.

Tangible result (effect) of PP?

The steering and working groups met with stakeholders to answer questions and justify their actions. Much of the latter's input is important so that the water management plan can be revised. This will also affect the development of the land-use plans.

Lessons learnt:

It is important for the public to see tangible results and direct benefits from their input and involvement.

Formal procedures for PP

Consultation on advisory overall plans and detailed development plans is compulsory in Sweden under the Planning and Building Act of 1987. The public also has access to reports and documents in the public domain under the Swedish Administrative Procedure Act of 1986.

For more information please contact:

The municipality of Örebro.
stadsbyggnadskontoret@orebro.se

30. The Fyrisån River Water Association, Sweden

Inspiration points

Involvement of many relevant stakeholders in the water association board and the close connection between the association and the public.

Key words

Stakeholders, broad public.

Aim/objective of the project;

To protect and restore the river and provide information for the general public by monitoring water management activities (extraction, aquaculture, etc.) and thus use the river's resources in an economical and sustainable way.

Scale/unit of planning

Catchment area: 2 000 km^2.

Period

1962 – 1983 -- ongoing

Public participation objectives (Why PP?)

To involve relevant stakeholders in the water association board and to get measures done.
To inform the public and hence promote sustainable water management

Methods and tools applied and major input of stakeholders

The association consists of a board and three working groups for monitoring, measures and water management. Members of the water association board and the working groups represent municipalities, industrial plants, irrigation associations, drainage associations, angling association and dam-owners. They represents people from different sub-catchment areas. Many actors such as schools, farmers, NGO's etc., are involved in different projects in sub-catchment areas on the very local level and are supported by the association. Several environmental projects (one of them supported by WWF) have been started and are connected to the water association. The water association has one half-time employee for administrative service and the time for monitoring.

Seminars, information meetings and hearings were held.

Activity days were organised when local people took initiative and helped to restore the lakes by e.g. clearing reeds along the riverbanks to create better conditions for animal life.
Meetings with landowners on the implementation of the proposed measures were also held.

Tangible result (effect) of PP?

The public take initiative and show endurance and are really involved in the job and get measures done. They feel involved. Reconsideration of some of the water permits awarded to avoid too low a water-flow in the lake system.
Restored wetlands by landowners and others. Measures have been implemented at the local level.

Lessons learnt

A positive way of working in the water association is to initiate (small) water projects and ensure the involvement of the public in these projects on the sub-catchment level.
Summary: PP limits the costs of tangible measures. People do various forms of voluntary work within different non-profit associations.

<u>Positive and negative points</u>

The close connections between the board the public through the system with the water association. The board have the main responsibility and everyone know their own role.

Cost of the project?

60 000 euro (excluding administrative costs) for environmental measures and for water analysis.

Formal procedures for PP

Water associations are regulated by the Swedish Water Association Act as legal entities.

For more information please contact:

www.uppsala.se/miljokontoret (in Swedish only), Anders Larsson,
Anders.Larsson@mk.uppsala.se

31. Helcom MLW, Baltic Sea Region

Inspiration points

Trans-boundary co-operation on river restoration, elaboration of sustainable development strategy, coastal catchment planning and management.

Aim/objective of the project

Co-operation at coastal catchment level in 5 large areas on nature conservation, wetlands restoration, water management and community development within the framework of joint demonstration project “Helcom MLW” based on ICZM approach.

Scale/unit of planning

Some of these several thousand km^2 (and linked to the largest river catchments in Europe - Nemunas, Odra, Vistula); 3 of the areas being transboundary.

Period: Ongoing since 1995 (1999)

Objective of Public Participation (Why PP?)

Mobilising of local communities for contributing to international environmental objectives.

Who participated and how (Degree/form of public participation) in what phase of the planning?

The core of PP was the establishment of locally based advisory groups, including in principle all relevant stakeholders in a round-table approach throughout the various stages of the planning process. Combined with various communication efforts directed at the broad public.

Methods and tools applied

Round-table group discussions with all stakeholders. Media, information boards, leaflets, public meetings, consultation on draft plans.

PP include awareness raising activities regarding the role and functions of wetlands (and the areas’ international importance to biodiversity conservation) on one hand, on the other hand particularly support for development of alternative income sources on the other hand.

Major input of stakeholders

Knowledge on local situation, local development context, co-ordination with other relevant programs, ideas for demonstration activities.

Tangible result (effect) of PP?

Local community and several stakeholders committed to continue the process - regrettably halted due to lack of external financing (international donors as well as national funds).

The locally based NGOs (e.g. "Rusne Fund for Nature" and "Kintai Sailing Club" in the Nemunas Delta shared by Lithuania and Russia) has benefited substantially from participation in the process, while at the same time has contributed through disseminating key information to the own networks (e.g. local farmers).

Lessons learnt

Lessons learned: in these areas, poverty is widespread and it is impossible to raise local attention and support for delivering these "environmental services" to the international community without a trade-off in terms of development support.

A local, holistic sustainable development process is imperative for sustaining an adequate contribution and accepts of international environmental objectives. It is possible BUT also time-consuming to establish such a process, and its context must inevitably be in the shape of a trade-off: what does the local community get from the national / international community in return for accepting certain development regulations and restrictions?

The locally based NGOs (e.g. "Rusne Fund for Nature" and "Kintai Sailing Club" in Lithuania) consisting of environment-interested farmers constitutes the core in maintaining at least some type of process following the withdrawal of the project-funded process momentum.

Establishment of a local sustainable development structure will in the long run be imperative for sustaining such a process as well as constituting the local capacity for interactions between international / national environment objectives and local development needs. Further, particularly in resources-weak rural communities (which are of particularly relevance in an Eastern European context) such a structure will also contribute significantly in a broader sense to strengthen local development opportunities and capacity. One such example could be the Solway Firth Partnership in Scotland.

For more information contact:

- Lennart Gladh, WWF Sweden, lennart.gladh@swipnet.se
- Henrik Dissing, WWF Denmark, h.dissing@wwf.dk

32. Danube River Commission / Danube Environment Forum

Inspiration points

Planning at river basin level. Linking between district, basin and local level.

Aim/objective of the project

Dialogue on trans-boundary River Basin Planning, establishment of WG on WFD, development of Issue Paper on WFD, ensuring public participation in the Danube River management and co-ordination through setting up the *Danube Environmental Forum (DEF)*. DEF is an NGO platform with combined local and regional structure, established in 1999 to promote NGO participation in government fora, programmes and initiatives. The DEF network and operation is still under development.

Scale/unit of planning

Planning of the Danube River basin 'occurs' at a range of levels from sub-catchment/communities to international commissions. Participation of stakeholders happens in different ways at different levels in the overall process. The cascade of approaches to public participation from working with communities directly at one level to ensuring that representative organisations are involved at an international level is a good illustration of how public participation means different things at different levels but should have a common set of principles of transparency of process and inclusion.

Period: Ongoing since 1994

Objective of Public Participation (Why PP?)

- Danube Regional Project supports Danube Environment Forum (Assembly of NGOs)
- Linking between district, sub-basin and local level.

Who participated and how (Degree/form of public participation) in what phase of the planning?

- Stakeholders are observers to the Commission, which implies full participation, no voting rights.
- Involvement of international stakeholders, e.g. WWF as observer to the ICPDR. A large number of smaller (national and local) NGOs are connected with this through co-operation platforms, notably the Danube Environment Forum.

Methods and tools applied

Observer status granted to NGO representatives at meetings of the Commission. *The International Commission for the Protection of the Danube River (ICPDR)* is the co-ordinating body for international aspects of the Directive's implementation. ICPDR is promoting public participation in the planning process, through financial support to the ICPDR Information System, including the Danube Watch, as well as operating networks such as the Danube

Environmental Forum (DEF), MLIM and AEWS. NGO observers attend the ICPDR Meetings, and provide significant input to the work of the Commission (for example in the establishment of an Ecological Expert Group).

Major input of stakeholders

- Development of Issue Paper on WFD;
- Participation in several WGs under the ICPDR;
- Providing of knowledge on local issues as well as trans-boundary dimension.

Result (effect) of PP?

International co-operation on sharing of experiences and joint focusing (MS+ACs+nonACs) on river basin planning and WFD implementation.

Lessons learnt

Co-ordination structures are needed in order to provide small (national and local) NGOs direct or indirect access to international river basin co-operation, e.g. through representatives appointed from joint NGO platform. Larger NGOs with international program may play a facilitating role for linking smaller NGOs with the international structures.

Formal procedures for PP in the river basin

NGOs can be granted observer status to the ICPDR.
Considered most feasible way of handling public participation at river basin district level.

For more information contact:

ICPDR Secretariat

Available reports

www.icpdr.org

33. Lower Danube Green Corridor, Bulgaria, Romania, Ukraine, Moldova

Inspiration points

Trans-boundary co-operation on wetlands restoration, role of NGOs, large-scale RBM, involvement of international stakeholders, ensuring coherence with local level participation through pre-project interviews on environmental awareness and social assessments.

Aim and scale of the project

4-country trans-boundary co-operation on wetlands restoration, management and protection aiming at nutrient retention from the Danube River, totally encompassing 700.000 ha (here of some 200.000 ha for wetlands restoration).

Period

Preparations started end of 1990'ies, LDGC officially endorsed in 2000, ongoing - expected to be a multi-year program.

Objective of Public Participation (Why PP?)

Awareness raising among the broad public as well as selected target groups, e.g. local municipalities. Mobilising local community in order to ensure preparedness for utilising new development opportunities.

Who participated and how (Degree/form of public participation) in what phase of the planning?

- NGO-participation in the drafting of the concept and concrete activities;
- Strong local participation in the detailed design at local level anticipated within the framework of a joint overall project steering group;
- NGOs involved in development and implementation of Communications Strategy for the LDGC;
- Involvement of international stakeholders, ensuring coherence with local level participation through pre-project interviews on environmental awareness and social assessments;
- Local NGOs involved in development and implementation of Communications Strategy for the LDGC, a.o. Green Balkans (Bulgaria) and After School Club (Romania).

Methods and tools applied

Travelling exhibition, local events, press and media work, leaflets, meetings with local municipalities and other stakeholders, fundraising with international donors.

Major input of stakeholders

Fundraising, personnel, knowledge, motivation, commitment, international contacts, pictures, creativity, local contacts.

Result (effect) of PP?

Increased public support at local level for the wetlands' restoration activities.

Lessons learnt

Trans-boundary commitment and actions on using wetlands restoration as a measure (nutrient retention) for addressing non-point source pollution, the interviews showed a positive attitude to wetlands restoration while at the same time revealing lack of basic knowledge on wetlands functions leading to the need for a Communications Strategy.
International and local NGOs can play a significant role in mobilising the public for e.g. wetlands' restoration activities.

Annex III - Drafting Group and other Contributors

November 2002

The working process of the drafting group on public participation

Practice what you preach, is what we believe. Therefore the drafting group has organised the development of this Guidance on public participation in a participatory way. The working process until November 2002 is set out below:

Phase 1: Initiation and defining the Terms of Reference	
Interviews with members of the Working Group, EC	
Brainstorm session; drafting the issues paper	October 24 2001
Workshop	March 6,7 2002
Phase 2: Internal writing process "state of the art" concept guidance:	
Bringing existing information together per section	March/May 2002
Collection of examples of public participation in water management projects	
Meeting with WG 2.9 in Madrid	April 15 2002
Development concept 01 during workshop 2	May 21, 22 2002
Adjustment, additional data collection	June 2002
Development of draft Guidance and presentation at meeting WG in Brussels	July 4,5 2002
Phase 3: Consultation and adjustments	
Consultation of experts and target groups per country (including accession countries)	July/Sept 2002
Workshop with experts and target groups from Member States and Accession Countries in Amsterdam	October 7,8 2002
Adjustments and development of draft Guidance	October 2002
Presentation Guidance to the Water Directors	November 2002

From the beginning of 2003 to 2005, the Guidance Documents produced by the different working groups under the Common Implementation Strategy will be tested in a range of pilot river basins through the European Community, to assess the practicability of all the Guidance Documents and the coherence between them. The issues related to 2004-steps will be tested first (2003-2004), the issues related to later steps being tested afterwards. The so called « horizontal Guidances », will be tested in all the pilot river basins in the first phase. This Guidance on public participation is likely to be tested as such.

Another further development of activities could be to establish contacts and exchanges of experiences with the International Association of Public Participation (IAP2) situated in North America, Denver[7]. All the work done for producing this Guidance Document and the results merging from experiences through the establishment of an European experts network could be valorised by providing input concerning the European area, for which currently no data exist.

7 IAP2 was created in 1990 and gathers practitioners of public participation and people interested by this topic. The association has currently 1000 members, essentially North Americans ; it is organised into 18 chapters, among these are 1 Australian and 1 South-African but any European chapter. IAP2 disseminates documents on best practices and methods (see www.iap2.org).

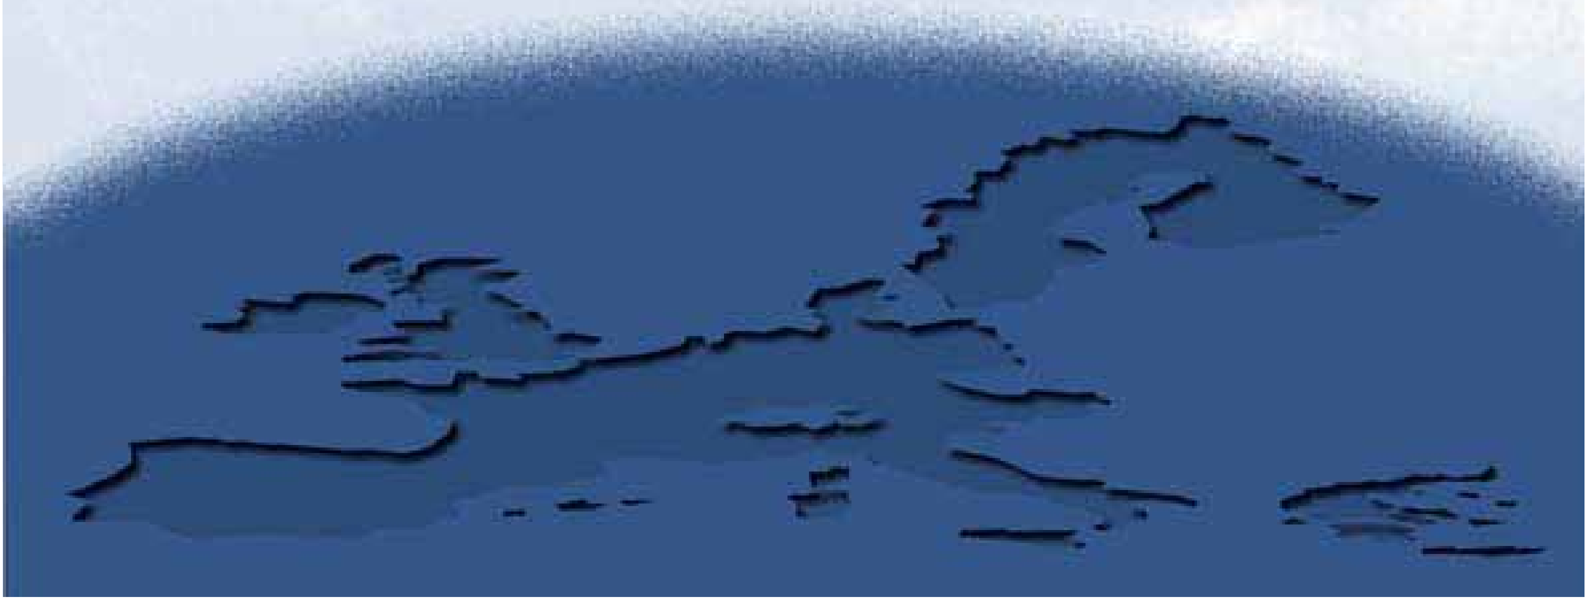
Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 9

Implementing the Geographical Information System Elements (GIS) of the Water Framework Directive



COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 9

Implementing the Geographical Information System Elements (GIS) of the Water Framework Directive

Produced by Working Group 3.1 – GIS

Disclaimer:

This technical document has been developed through a collaborative programme involving the European Commission, all the Member States, the Accession Countries, Norway and other stakeholders and Non-Governmental Organisations. The document should be regarded as presenting an informal consensus position on best practice agreed by all partners. However, the document does not necessarily represent the official, formal position of any of the partners. Hence, the views expressed in the document do not necessarily represent the views of the European Commission.

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology are therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, a working group dedicated to the development of technical specifications for implementing a Geographical Information System (GIS) for the reporting needs of the Water Framework Directive has been established in September 2001, referred to as GIS-WG. The Joint Research Centre (JRC) had the responsibility to co-ordinate and lead this working group, which included representatives from most Member States, some candidate countries, the Commission, Eurostat, and the EEA.

The present Guidance Document is the outcome of this working group. It contains the synthesis of the output of the GIS-WG activities and discussions. It builds on the input and feedback from a wide range of experts that have been involved throughout the process of guidance development through workshops or electronic communication media, without binding them in any way to its content.

We, the Water Directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this guidance during our informal meeting under the Danish Presidency in Copenhagen (21-22 November 2002). We would like to thank the participants of the Working Group and, in particular, the leader, Dr. Jürgen Vogt (JRC), for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a *living document* that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

Introduction - A Guidance Document: What For?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the implementation of its GIS elements in the broader context of the development of integrated river basin management plans as required by the Directive.

To whom is this Guidance Document addressed?

If this is your task, we believe the guidance will help you in doing the job, whether you are:

- ***Preparing the geographic datasets for the preparation of maps required by the Directive;***
- ***Preparing the final maps as requested under the Directive; or***
- ***Reporting the maps and GIS layers to the European Commission as required by the Directive.***

What can you find in this Guidance Document?

The common understanding on terms and on the role of GIS in the WFD

What are a map, a dataset with geographic datatype, a table, and data?
What are the GIS elements of the Water Framework Directive?
Where in the Directive are these elements made explicit or referred to?

The maps and GIS layers requested for reporting under the WFD

Which maps are to be reported to the European Commission and when?
What are the different GIS layers that make up these maps?
What are the level of detail and spatial accuracy expected from the data?
Which is the reference system to use for reporting the data?

How to validate the GIS layers

Which validation procedures should be employed in the validation step?
Which standards should be followed when validating data?

How to document the GIS layers

What are the metadata fields to deliver with each GIS layer?
Which standards are to follow when preparing the metadata?

How to report GIS layers to the European Commission

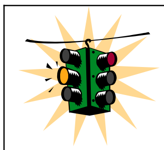
What is the format for transferring layers to the Commission in the short-term?
What is the way forward for the development of a distributed reporting system in the long-term?

How to harmonise data at borders and how to co-ordinate the reporting process

Which aspects should be considered for harmonising data at national borders and at borders of River Basin Districts?
How can a vertical integration between the various GIS layers be ensured?
How should the reporting process be co-ordinated?

How to introduce a European feature coding system

What are the advantages of implementing a European feature coding system?
What is the way forward for implementing a European feature coding system?



Look out! What you will not find in this Guidance Document

The Guidance Document focuses on the thematic content and technical specifications for the GIS layers to be prepared for reporting to the European Commission. The guidance does not focus on:

- *How to make maps out of the various GIS layers (layouts, symbols, generalisation procedures,…);*
- *How to use GIS in the analysis of pressures and impacts;*
- *How to use GIS in the preparation of river basin management plans.*

Historically, georeferenced data have been reported to the Commission in the form of analogue maps. With the introduction of Geographic Information Systems, these maps or the underlying GIS layers can now be reported in digital form.

In the European context experience with digital reporting is limited and standards are still under development. This Guidance Document, therefore, makes suggestions for best practices for the immediate reporting needs of the WFD and at the same time formulates strategies for the long-term needs. The recommendations will have to be tested and further developed over the next few years.

1 Implementing the Water Framework Directive

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

1.1 December 2000: A Milestone for Water Policy

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water quality management that today form the foundation of the Water Framework Directive.

1.2 The Water Framework Directive: New Challenges in EU Water Policy

What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater), which:

- Prevents further deterioration of, protects and enhances the status of water resources;
- Promotes sustainable water use based on long-term protection of available water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

… and what is the key objective?

Overall, the Directive aims at achieving *good water status* for all waters by 2015.

What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (*Article 3, Article 24*);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (*Article 5, Article 6, Annex II, Annex III*);
- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (*Article 2 (22), Annex V*);
- To make operational the monitoring networks by 2006 (*Article 8*);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (*Article 11, Annex III*);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (*Article 13, Article 4.3*);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (*Article 9*);
- To make the measures of the programme operational by 2012 (*Article 11*);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (*Article 4*).

Look Out!

Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation, at the latest by 2006;
- The overview of the significant water management issues in the river basin, at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept of the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering a unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** be local, regional or national, for an effective management of all waters;
- **Integration of water management from different Member States,** for river basins shared by several countries, existing and/or future Member States of the European Union.

1.3 What is Being Done to Support the Implementation?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

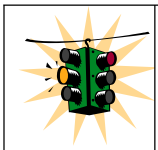
May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding guidance. A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall guiding body for the Common Implementation Strategy.

The GIS Working Group

A working group has been created for dealing specifically with issues related to the implementation of a Geographical Information System. The main objective of this working group, short-named GIS-WG, was the development of a non-legally binding and practical guidance for supporting the implementation of the GIS elements of the Water Framework Directive, with emphasis on its 2003 and 2004 requirements. The members of the GIS-WG are experts from European Union Member States, from candidate countries to the European Union, from Eurostat, form the EEA, from the JRC and from DG Environment.



Look out! You can contact the experts involved in the GIS activities

A list of the GIS-WG members with full contact details can be found in Appendix XI. If you need input into your own activities, contact a member from the GIS-WG in your country. If you want more information on specific scoping and testing in pilot studies, you can also contact directly the persons in charge of carrying out these studies.

Developing the Guidance Document: an interactive process

Within a very short time period, a large number of experts have been involved at varying degrees in the development of this Guidance Document. The process for their involvement has included the following activities:

- *Organisation of* ***four workshops*** *of the 30-plus experts of the GIS-WG;*
- *Drafting and discussing of individual sections in task-groups;*
- *Exchange of documents for discussion and comments through email and the dedicated CIRCA web site;*
- *Inclusion of the opinion of a wide range of experts in the participating countries through their national representatives;*
- *Regular interactions with experts from other working groups of the Common Implementation Strategy through the participation of experts from other working groups in the WFD-GIS meetings, through the participation of WFD-GIS representatives in other WG meetings, or through email contacts;*
- *Set-up of a prototype GIS for testing the feasibility of some of the proposed specifications;*
- *Throughout the development of the guidance, the chairman of the working group attended regular meetings of the Strategic Co-ordination Group and of the Working Group Leaders in Brussels.*

2 GIS in the WFD: Developing a Common Understanding

This Section introduces the general basis for the detailed specifications as outlined in the following chapters. It reflects the common understanding of the working group experts on the purpose and the structure of the GIS elements to be developed as a basis for the reporting obligations under the Directive.

2.1 Terminology

In order to avoid ambiguity in terms, it is important to note that the following terminology will be used throughout this document:

Map: A graphical representation of a section of the Earth's surface. The Directive refers to a number of maps, each one with a specific thematic content (e.g., a map of the River Basin Districts). A map can be made up of one or many datasets with a geographic datatype. Using GIS software, maps can be presented in digital form from which an analogue map can be plotted. In this document, we assume that maps are produced in such a GIS environment and that they are made up of a set of digital datasets with a geographic datatype.

Dataset with a geographic datatype: A collection of data describing similar phenomena that can be represented with reference to the surface of the earth (e.g., the groundwater monitoring stations in a given River Basin District). In this document a dataset with geographic datatype is assumed to be a digital dataset in a GIS. The terms dataset, GIS layer or layer are used as synonyms for a digital dataset with a geographic datatype. The representation can be as pixels, points, lines, arcs and polygons or combinations of these.

Table: Most software systems require the organisation of datasets in one or more tables. In order to make information comparable between organisations, the structure of these tables must be similar.

Data: Tables are made up of digital data. The data will be stored using common typologies like geometry (e.g., points, lines, polygons, networks), strings (e.g., name, codes), numbers (e.g. amount of monitoring stations in a region), or dates (e.g., reporting date).

The relationship between these different levels of information is shown in Figure 2.1.1:

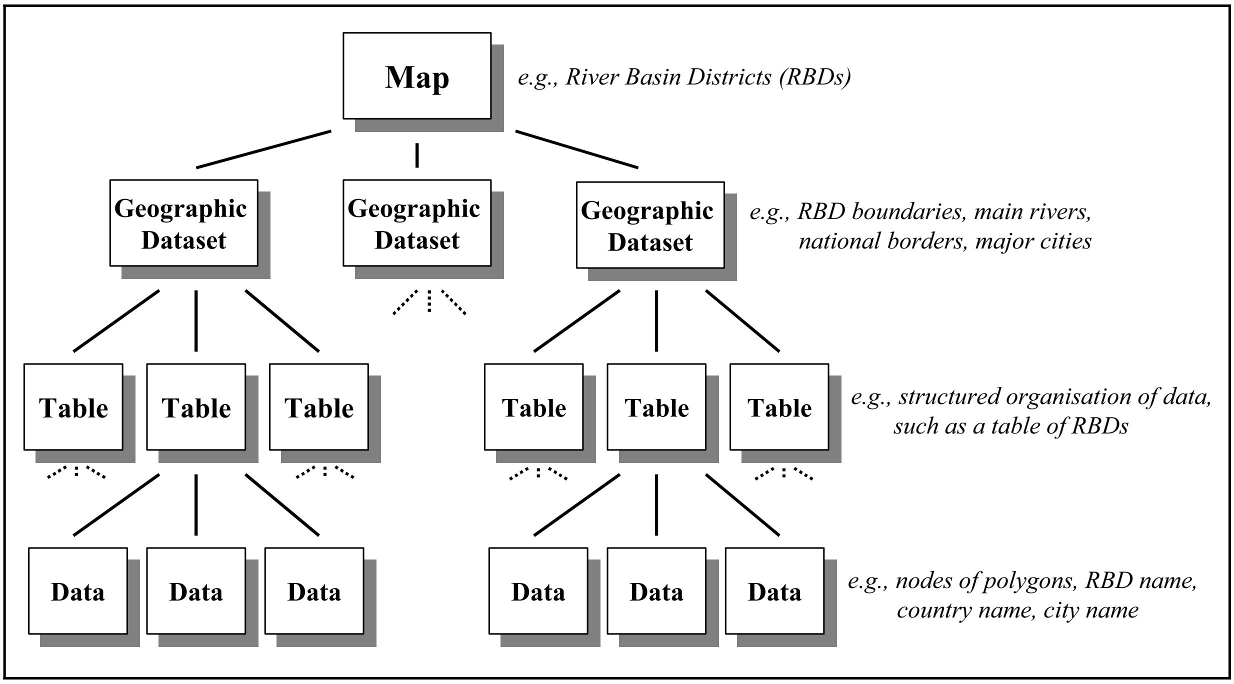


Figure 2.1.1: Relationship between a map, geographic datasets, tables and data.

2.2 GIS Requirements under the WFD and Scope of the Working Group

The WFD requires that Member States report a considerable amount of information in the form of maps. Even though only annex I and annex II of the Directive explicitly state that the respective maps should as far as possible be available for introduction into a GIS, it is obvious that the best way to provide most of the requested information will be in the form of GIS layers. This is due to the fact that most of the data is to be presented in its spatial context and that questions like ‘where are the critical areas?’, ‘how much area is involved?’, or ‘which points are in a designated area?’ can easily be answered when the data are kept in their spatial context and when the background database has the appropriate design.

The provision of (or access to) the requested GIS layers will not only facilitate the reporting of the Member States themselves; it will also facilitate the further compilation and analysis of the information as a basis for the Commission’s own reporting obligations under the WFD. Such development is also in line with current efforts under the INSPIRE (Infrastructure for Spatial Information in Europe) initiative of the Commission and the Member States, aiming at the development of a harmonised European spatial data infrastructure.

Many parties are involved in the implementation of the WFD, ranging from local water authorities to the European Commission. Regarding this wide range of parties, having different practices for water management, different reporting obligations and different levels of technical abilities, this Guidance Document strives to keep specifications as simple as possible, based upon standards where feasible, and according to best current technical options.

While the Directive clearly specifies which information should be provided in the form of maps (see appendix I of this Guidance Document), it gives little information on the technical specifications for these maps. The goal of the GIS working group under the Common Implementation Strategy, therefore, was to elaborate such specifications and to make them available in the form of this Guidance Document. The Guidance Document should help the Member States with the preparation of the GIS layers in such a way that they follow a common and agreed standard. This will not only facilitate the compilation of a European-wide picture, but it will also be a first step towards a more integrated spatial data infrastructure for Europe.

The implementation of the WFD requires the handling of spatial data both for the preparation of the River Basin Management Plans and for the reporting to the Commission. In the first case GIS techniques will be essential for the derivation of various information layers (e.g., on the characteristics of river basins and water bodies, on the chemical and ecological status of water bodies), while in the second case GIS will be the tool for the preparation and delivery of the GIS layers required for the reporting. Considering the limitations in time, the fact that many aspects of the analysis are still under discussion in other working groups, and the immediate needs stemming from the WFD implementation, it was decided that the current focus of the GIS Working Group should be on the WFD reporting obligations.

While this is a short-term goal, it is noted that in the long-term the development of specifications for a system including the possibility to access underlying measurements and statistical data or even for performing the various analyses as required for the preparation of the River Basin Management Plans might be considered. The elaboration of guidelines for these long-term options would, however, require substantial time and effort and is subject to a request by the Strategic Co-ordination Group for the Implementation of the WFD.

2.3 Reporting under the Water Framework Directive

The WFD is specifying which information should be reported in the form of maps and time schedules. This Guidance Document identifies these maps, the various GIS layers that are needed to make up these maps, their content and structure and how to document and to access or transfer them.

The WFD itself falls short in giving more detailed technical specifications with respect to the requested GIS layers. As a consequence, a common understanding had to be achieved on issues such as the contents of the various maps, the scale and positional accuracy of the data, and the reference system and projections to use. Given the fact that the various GIS layers will be part of a European picture, it was further necessary to consider issues such as the harmonisation at boundaries and the use of common identifiers. Recommendations are further given on the standards to be implemented for data exchange and data access and on the content and structure of the metadata to accompany each layer.

Technical possibilities nowadays allow the required GIS layers to be provided in two different ways. One option is to transfer them into a centralised system, where they will be stored, quality checked and analysed. The other option is to leave them at their place of origin (i.e. to store the data sets locally in each river basin district or country) and to guarantee access to these data through common standards and protocols. While the first option is easier to implement, the second option will reduce the burden of transferring data. However, it also asks for detailed technical specifications for the set-up and maintenance of a distributed system, which is more complicated. The GIS Working Group has explored both options. Given the limited time available to prepare the first GIS layers that need to be reported to the Commission in 2004, the Guidance Document gives specifications for a short-term centralised option and indicates the way forward for the implementation of a de-centralised system in the long-term. The GIS Working Group underlines that the preference is for the set-up of a de-centralised system in the long-term. The firm implementation of the outlined data model will strongly support this goal.

Since the GIS layers provided by the various River Basin Districts (or countries) will be collated to a European picture, it was further considered to be of importance to agree on a European feature coding system for river basins, water bodies (according to the definition of the WFD), monitoring stations, and pressures. In the long-term, this system should be smart enough to actively support the spatial analysis of pressures and impacts across Europe. The implementation of such a European feature coding system might prove a complicated task, since all Member States have historically implemented their own feature coding systems, adapted to their specific requirements. In view of this situation, the Working Group proposes the short-term implementation of a system that ensures unique feature identifiers across Europe, allowing to maintain national systems and to link them up to the European level. At the same time, the implementation of a feature coding based on the Pfafstetter system is recommended for countries without a dedicated national system. This approach is seen as a first step towards the set-up of a more intelligent European feature coding system, which will need more in-depth study before a definite proposal can be made.

While the WFD as such does not require the introduction of a European feature coding system, the Working Group considered it to be of major importance in the long-term. The main advantage of a European feature coding system would be the possibility for a more targeted analysis of pressures and impacts at the European level and the facilitation of a further integration of water-related monitoring efforts in Europe.

In order to test the feasibility of the distributed structure proposed for the long-term, the working group further implemented a prototype GIS. This prototype is conceived as a testbed for verifying the practical implementation. Examples from this prototype testing phase will be made available on a dedicated web site. Detailed testing of the specifications given in this Guidance Document is further foreseen in the Pilot River Basins, co-ordinated by Working Group 4.1 (Integrated Testing in Pilot River Basins) of the Common Implementation Strategy.

Finally, the Working Group decided not to include specifications for the map making process in this document. This decision is based on the fact that maps will be made at the River Basin District (RBD) level according to the specific needs of each RBD, and at the European level adequate maps can be made from the individual GIS layers. The Working Group, therefore, recommends that in addition to the maps as specified in the WFD, the GIS layers related to these maps should also be transferred to the Commission. The Commission would then have the possibility to make maps out of the GIS layers as required.

In a more general context, it should also be noted that information, consultation and participation are requirements of the Directive, since it will ensure a more efficient and effective implementation. The *Guidance on Public Participation* will tell more about these forms of participation. In particular WFD Article 14 promotes the active participation of all interested parties in the development of River Basin Management Plans and requires Member

States to inform and consult the public. The latter can most efficiently be done through maps, GIS technology and web mapping.

3 Technical Specifications of the GIS

This Section provides detailed specifications for the development of a GIS, compatible with the WFD reporting needs. It outlines the requested GIS layers, the time sequence for reporting and discusses the general aspects of data quality, data geometry and data documentation.

3.1 Timetable for the Preparation and Delivery of Maps and GIS Layers

The following table (Table 3.1.1) indicates when individual maps or GIS layers have to be made available either internally to a River Basin District (⊗) or externally to the Commission (•).

Table 3.1.1: Time Schedule for Reporting Maps

Actions related to GIS	Related Map (App. II)	Year 20..												
		03	04	05	06	07	08	09	10	11	12	13	14	15
Assigning individual river basins, groundwaters and coastal waters to individual river basin districts (RBD)		⊗												
Provide the Commission a list of the competent authorities for RBD	2		●											
GIS layer containing names of the main rivers and boundaries of the river basin districts	1		●											
Map of the geographical location of the [surface water body] types consistent with the degree of differentiation required under system A	4**		●											
Summary report of the analyses required under art.5 (*)				●[1]										
Summary report of the analyses required under art.8 (*)						●[2]								
Publishing of river basin management plans:								●						
Map of the location and boundaries of surface water bodies	3		⊗					●*						
Map of the ecoregions and surface water body types	4**		⊗					●*						
Map of the location and boundaries of groundwater bodies	5		⊗					●*						
Summary of the register of protected areas (location and description of the legislation under which they have been designated)	11		⊗					●						
Map of the surface water monitoring networks	6				⊗			●						
Map of the groundwater monitoring network	10				⊗			●						
Map of the results of the monitoring programmes for protected areas	12							●						
Map for each river basin district illustrating the classification of the ecological status for each body of surface water	7							●						

Actions related to GIS	**Related Map (App. II)**	**Year 20..**												
		03	**04**	**05**	**06**	**07**	**08**	**09**	**10**	**11**	**12**	**13**	**14**	**15**
Map for each river basin district illustrating the classification of the ecological potential for each body of surface water	7							●						
Map for each river basin district illustrating chemical status for each body of surface water	8							●						
Map of groundwater quantitative status	9							●						
Map of groundwater chemical status	9							●						
Review and updating of the analysis of the characteristics and of the review of the impact of human activity on the status of surface waters and on groundwater whithin a river basin district												⊗		
Review and updating of the river basin management plans														●
Presentation in map form of the monitoring results for the period of the previous river basin management plan														●

⊗ Deadline at Member State level

• Deadline for reporting

(1) 22 March 2005

(2) 22 March 2007

(*) The Directive does not specify whether the "summary report", which has to be delivered in 2005 should contain maps. The Expert Advisory Forum on Reporting will clarify this question. If it is decided that the summary report needs to contain maps, then maps No. 3 and 5 need to be delivered in 2004 instead of 2009. Map No. 4 needs to be delivered both in 2004 and 2009.

(**) Map No. 4 is requested twice: in 2004 according to article 5 and annex II-vi, and in 2009 according to article 13 and annex VII-1.1.

3.2 Overview on the GIS Layers, their Scale and Positional Accuracy

The technical specification of the GIS-layers needed for WFD reporting obligations is based on a detailed analysis of the content of the Water Framework Directive and as far as possible on the documents of the other working groups under the Common Implementation Strategy. All of the maps presented here are explicitly mentioned in the WFD. These maps are translated to GIS-layers, which make up the content of the map. Working with GIS-layers effectively supports the reporting obligations of the Member States and the Commission's needs to access and internally report the information. With the GIS-layers described below and the applied data model, all the requested maps can be made.

The relation between the required maps and the layers is presented in appendix II. GIS-layers are assigned to maps based on the strongest relation. For example, the layer 'River Basin District' is assigned to the map 'River Basin District - Overview'. Some layers can also be part of other maps, which is also indicated. Besides the background layers used for readability of the maps, 15 layers are necessary to make the 12 required maps. Table 3.2.1 presents a summarised view of the maps and layers.

Data collection and map making are the responsibility of the River Basin Districts and the Member States. It is recognised that for data collection an input scale of 1:250,000 or better should be a common goal in the long term. The reporting scale of the maps, however, may either be 1:250,000 or 1:1,000,000 in the short term and should be 1:250,000 in the long term. Only the very general maps No.1 (*River Basin Districts Overview*) and No.2 (*Competent Authorities*) might be reported at smaller scales of up to 1:4,000,000.

To describe the specifications, the GIS-layers are divided in three main groups:

1. Basic information and characteristics of the river basin district;
2. Monitoring network;
3. Status information of surface- and groundwater bodies and protected areas.

The requirements in terms of positional accuracy and input scale and output scale are further described in Section 3.2.4. All the required GIS datasets are vector or point datasets.

Special attention should be given in case of transboundary harmonisation of GIS datasets. In this context, the possibility to use as far as possible already harmonised data is recognised. This is especially true for the case of large international river basins (e.g. the Rhine or the Danube river basin), where the harmonisation work could be substantial. An example of such a database could be EuroGlobalMap at a scale of 1:1,000,000, which is currently under development. For the short-term reporting, this EU-wide database could be an option. In the long term, the scale of reporting may be 1:250,000, as far as an identical and harmonised database (e.g., EuroRegionalMap) is available.

Table 3.2.1: Summary of Maps and GIS –Layers (continued on next page)

Map Name	Layer Code	Layer Name	Feature Type	Availability and Reporting Dates[1]
1: RBD-Overview				
	SW1	River basin district (RBD)	polygon	12/2003 (RBD) 06/2004 (CEC)
	SW2	River basin, sub-basin	polygon	
	SW3	Main Rivers[2]	line	
2: Competent Authorities				
	D7	District of competent authorities	polygon	12/2003 (RBD) 06/2004 (CEC)
3: Surface Water Bodies (SWB) – categories -				
	SW4	Surface water bodies - Rivers - Lakes - Transitional waters - Coastal waters if applicable, indicated as artificial SWB or heavily modified SWB	 line polygon polygon polygon	12/2004 (RBD) 12/2009 (CEC)*
4: Surface Water Bodies (SWB) – types -				
	SW4a	Types of Surface Water bodies	attribute of SW4	12/2004 (RBD) 12/2004 (CEC)* 12/2009 (CEC)*
	D6	Ecoregions	polygon	
5: Groundwater Bodies				
	GW1	Bodies of groundwater	polygon	12/2004 (RBD) 12/2009 (CEC)*
6: Monitoring Network for Surface Water Bodies

	SW5b	Surveillance monitoring sites	point	
	SW5c	Monitoring sites drinking water abstraction points from surface water	point	
	SW5d	Investigative monitoring sites	point	
	SW5e	Reference monitoring sites	point	

(1) RBD: The date when the map or layer needs to be available within the River Basin District.
CEC: The date when the maps need to be reported to the European Commission. Note: The date of December 2009 is the publication date of the River Basin Management Plans. They should be reported to the Commission within 3 months of their publication.
(2) Main Rivers: selection of the rivers from the Water Bodies Layer of map No. 3.
(*) Date of reporting for maps No. 3 and 5 might change to 2004. See also the time schedule in Section 3.1. Map no. 4 needs to be reported in 2004 and 2009 (see also Table 3.1.1)

Table 3.2.1: Summary of Maps and GIS –Layers (continued)

Map Name	Layer Code	Layer Name	Feature Type	Availability and Reporting Dates[1]
7: Ecological Status and Ecological Potential of Surface Water Bodies				
	SW4b	Ecological status	attribute of SW4	12/2009 (RBD) 12/2009 (CEC)
	SW4c	Ecological potential	attribute of SW4	
	SW4d	Bad status or potential causes by (non-) synthetic pollutants	attribute of SW4	
8: Chemical Status of Surface Water Bodies				
	SW4e	Chemical status	attribute of SW4	12/2009 (RBD) 12/2009 (CEC)
9: Groundwater Status				
	GW1a	Quantitative status of groundwater bodies	attribute of GW1	12/2009 (RBD) 12/2009 (CEC)
	GW1b	Chemical status of groundwater bodies	attribute of GW1	
	GW1c	Pollutant trend	attribute of GW1	
10: Groundwater Monitoring Network				
	GW2a	Groundwater level monitoring network	point	12/2006 (RBD) 12/2009 (CEC)
	GW2b	Operational monitoring network chemical	point	
	GW2c	Surveillance monitoring network chemical	point	
11: Protected Areas				
	PA1	Drinking water protection areas	polygon	12/2004 (RBD) 12/2009 (CEC)
	PA2	Economically significant aquatic species protection areas	polygon	
	PA3	Recreational waters	point	
	PA4	Nutrition-sensitive areas	polygon	
	PA5	Habitat protection areas (FFH)	polygon	
	PA6	Bird protection areas	polygon	
12: Status of Protected Areas				
	PA7	Status of protected areas	attribute of PA1-PA6	12/2009 (RBD) 12/2009 (CEC)

(1) RBD: The date when the map or layer needs to be available within the River Basin District.
CEC: The date when the maps need to be reported to the European Commission. Note: The date of December 2009 is the publication date of the River Basin Management Plans. They should be reported to the Commission within 3 months of their publication.

3.2.1 Basic Information

The basic information contains those entities for which the WFD applies. These are the surface water bodies, the groundwater bodies and the protected areas. Furthermore the river basin districts, the river basins and the areas of competent authorities are regarded as basic information.

For the co-ordination of administrative arrangements within river basin districts, and the arrangements within and between Member States, the boundaries of the river basin districts and the competent authorities have to be reported (maps No. 1 and No. 2). The following GIS-layers are required:

- *River basin districts:* The geographical coverage of the river basin district presented as a polygon layer. In cases where the national border is the same as the district border, the national border is leading;
- *River basins and sub-basins:* A polygon layer with the main catchment areas within the river basin district. All the basins and sub-basins taken together fully cover the river basin district. The basins and sub-basins are derived from the hydrological system, whereas the river basin district is designated as the main unit for the management of river basins. While this layer is non-mandatory it provides the basic entities for the river basin management and its delivery is recommended;
- *Main rivers:* A selection from the dataset with surface water bodies, used for general overview purposes;
- *Areas covered by the competent authorities within the river basin district*: A polygon layer with no overlapping features and without uncovered areas and if necessary synchronised with the national border layer and the river basin district layer.

The attributes of these GIS-layers are specified in the description of the data model (see Section 3.3) and in the data dictionary in appendix III.

The environmental objectives of the WFD cover all water bodies as well as areas designated as requiring special protection of their surface and groundwater bodies or for the conservation of habitats and species depending on water. The reporting obligations, therefore, require a general description of the characteristics of the river basin district, including information on surface water bodies, groundwater bodies and all protected areas (maps No. 3, 4, 5, and 11). The requested level of detail of the GIS-layers for surface water bodies and groundwater bodies is based on the essential discussion about the term water body. The outcome of this discussion, presented in the *Horizontal Guidance on the Application of the Term Water Body,* defines which elements should be included in the layer. In the following list we describe the composition of the various layers.

- *Surface Water Bodies*: Surface water bodies are first discriminated into the following categories: rivers, lakes, transitional waters, coastal waters, artificial surface water bodies, and heavily modified surface water bodies. Within each category discrimination is made based on type (according to system A or B). Rivers are represented as line features and lakes, transitional waters or coastal waters as polygons.
- *Groundwater Bodies*: Groundwater bodies are presented as polygon features. The outcome of the Working Group on Groundwater determines the characterisation of the groundwater bodies.

- *Protected Areas falling under specific Community legislation:* they include the following GIS-datasets:
    - Drinking water protection areas (polygons);
    - Economically significant aquatic species protection areas (polygons);
    - Recreational waters (points);
    - Nutrition-sensitive areas (polygons);
    - Habitat protection areas (FFH) (polygons);
    - Bird protection areas (polygons).

Some protected areas may have partially the same geometry as the water bodies, but the main part of the protected areas will have their own geometry. Therefore, the protected areas need to be represented as separate feature layers. The geometric representation of the features is based on the related specific Community legislation.

3.2.2 Monitoring Network

This paragraph deals with the requirements for mapping monitoring stations for reporting and presentation (maps No. 6 and 10). Further information on the requirements for the number of monitoring sites, the size of the related catchment, the sampling frequencies, etc. can be found in the *WFD CIS Guidance Document No. 7 on Monitoring*.

For the purpose of establishing a coherent and comprehensive overview of water status, surveillance monitoring sites will be considered first, since operational monitoring has to be performed in water bodies being at risk of failing to meet the objectives. Modifications of the sites, therefore, are likely.

The monitoring network will serve different purposes according to the water body type:

(i) for surface water:
monitoring the ecological and chemical status and the ecological potential;

(ii) for groundwater:
monitoring the chemical and quantitative status;

(iii) for protected areas:
supplementing those specifications contained in Community legislation under which the individual protected areas have been established;

(iv) for biological reference conditions:
reference conditions can be derived from a spatial network of high status sites (thus more stations per water body may be required);

(v) for drinking water abstraction:
monitoring the chemical and quantitative status.

The location of monitoring points does not statically follow a fixed size of the catchment but depends on sufficient information to assess the overall surface and groundwater status of each catchment, based on knowledge of the environment (region) and on expert judgement. Also stretches of coastal waters, significant international trans-boundary waters and pollutants discharging into the marine environment need to be considered.

The monitoring networks should be delivered in two datasets: one for surface water and one for groundwater. So even if a given monitoring station is used for both surface and groundwater monitoring, it should be considered as two objects. The different kind of monitoring types and purposes are registered in the attributes of the dataset. For surface water these are surveillance monitoring, operational monitoring, and investigative monitoring, or reference sites and sites for drinking water abstraction. For groundwater sites the monitoring types are quantitative monitoring and chemical monitoring. The chemical monitoring sites for groundwaters are further split-up into surveillance and operational sites (see also the data model in Section 3.3). The monitoring network will be presented as point features. The relation between a monitoring station and the represented water bodies is implemented in the data model.

It further needs to be considered that the information on monitoring points (number and location) is dynamic.

3.2.3 Surface Water Bodies, Groundwater Bodies and Protected Areas (Status)

Additionally to what has been mentioned in Section 3.2.2, the maps for status information (maps No. 7, 8, and 9) shall illustrate for a river basin district the classification of the ecological and chemical status of water bodies, colour-coded according to WFD Annex V, 1.4.2. Similarly, this applies to the status of good ecological potential of artificial or heavily modified surface water bodies.

For groundwater bodies or a group of groundwater bodies, both the quantitative and the chemical status shall be shown colour-coded according to the colour scheme given in the WFD Annexes V, 2.2.4 and V, 2.4.5. The status of protected areas shall also be mapped.

The datasets containing the information about the status of the water bodies and protected areas will not be required as separate feature layers but can be delivered as attribute information in tabular format using as a key the unique code of the water body.

3.2.4 Scale and Positional Accuracy

The scale of digital data or, more precisely, the scale of the underlying input data can be regarded as both, an indicator of spatial detail (which level of detail is available for map making), and as an indicator of positional accuracy (what is the possible difference between the true real world co-ordinates and the co-ordinates of the data). The 'spatial detail' determines both the minimum mapping area and the number of co-ordinates used to describe an element. On a large-scale map (i.e. 1:250,000) a river is presented with more points than on a small-scale map (i.e. 1:1,000,000), where, for example, small meanders may not be visible.

While in theory a dataset at 1:1,000,000 scale might contain the same amount of elements (objects) than a dataset at 1:250,000 scale, the latter can present the information in a better way (the positional accuracy is higher and the shapes of the elements are represented with more detail).

The main factor determining the necessary spatial detail of data gathering under the WFD is the size of the smallest feature to be shown on the maps. In the WFD the only direct indication in this context are the size thresholds given for the typology according to system A (WFD Annex II). These thresholds are set to a 0.5 km^2 surface for lakes and to a 10 km^2 catchment area for rivers. Although these thresholds do not imply that all water bodies larger than these numbers need to be reported (see the horizontal guidance on the application of the term “water body”), these figures can be used to estimate the required detail of data gathering or the input scale.

From theoretical considerations of cartography, these thresholds lead to a recommended scale of 1:250,000. On a map with this scale, water bodies with a minimum size of the given thresholds will be clearly visible. A map of 1:1,000,000 scale, to the contrary, will normally not contain lakes with an area of 0.5 km^2 or rivers with a catchment size of 10 km^2. However, digital data with this input scale might contain lakes or rivers of this size, even though they can only be shown as a point or very simple feature.

EuroGlobalMap (EGM) is a dataset that is under development in several Member States. EGM has a scale of 1:1,000,000. As a consequence, not all rivers and lakes larger than the thresholds mentioned above are incorporated in EGM. This implies that, if a Member State wants to use EGM for reporting under the WFD, EGM has to be extended, adding more lakes and rivers. The difference to a 1:250,000 dataset will be that the shape of the objects (rivers, lakes, etc.) will be less detailed or not available at all and that the positional accuracy will be worse. While EGM aims at a positional accuracy of 1000 metres, data layers with an input scale of 1:250,000 generally present objects with a positional accuracy in the order of 125 metres.

Considering both the WFD needs and the practical constraints of data availability, the GIS Working Group recommends that the required positional accuracy for the reporting is set to a minimum of 1000 metres (corresponding to an input scale of approximately 1:1,000,000) in the short-term, while at the same time it is strongly recommended to strive for a positional accuracy of 125 metres (corresponding to an input scale of approximately 1:250,000) in the long-term.

With a minimum requirement of 1000 metres, existing national or European datasets could be used, if amended with the necessary detail. In many cases, problems related to the data policy of such datasets might be less severe than problems related to a stringent requirement of 125 metres of positional accuracy in the short-term. However, in cases where data availability and data policy do not pose a problem, datasets with the highest possible positional accuracy are preferred. In the long-term, these datasets should in any case be the target.

3.2.5 River Basin Management Plans and Summary Reports

Among the various maps, registers, and reports listed as elements of the River Basin Management Plan in Annex VII of the WFD, the following are mentioned:

“*A register of any more detailed programmes and management plans for the river basin district dealing with particular sub-basins, sectors, issues or water types, together with a summary of their results*” (Paragraph 8), and

“*The contact points and procedures for obtaining the background documentation and information referred to in article 14(1), and in particular details of the control measures* *adopted in accordance with Article 11(3)(g) and 11(3)(i) and the actual monitoring data gathered in accordance with article 8 and Annex V*" (Paragraph 11).

These two paragraphs indicate that there is a distinction between "information included in the river basin management plan" (summaries) and more detailed information to be obtained from the national contact point.

In addition, Article 18 of the WFD refers to the Commission's report on progress in the implementation of the WFD based on "summary reports" that Member States submit under Article 15(2).

The above mentioned quotations indicate that a distinction should be made between the rate of detail to be used in reporting to the Commission (small scale) and the rate of detail Member States should have available upon request (large scale).

However, at this moment there is no clear guidance on the level of detail (input scale and spatial accuracy) to be used by Member States in order to fulfil the WFD summary based reporting obligations. This question will be further elaborated in the EAF on Reporting together with the future GIS Working Group.

3.3 Data Model

3.3.1 Purpose of the Data Model

The Water Framework Directive expresses a set of requirements for geographic information. Ultimately, this information will be stored in a number of databases. Data modeling is the first step in database design – it is the blueprint from which the GIS will be built. By modeling, complexity is reduced so that all actors should be able to understand the essence of the system. This provides the basis of development of a common understanding of which objects should feature in the geographic database, and how they should be represented. The model also aims to encourage consistency in data structures to facilitate data sharing.

Key activity 3: Improved Data and Information Management, Project 3.1 – "Development of a Geographical Information System (GIS)" states that "*the data model proposed needs to be defined in such a way that it can accommodate the information resulting from the national obligations of the WFD or that it can be linked to national systems via the coding system.*"

3.3.2 The Unified Modelling Language

The Unified Modelling Language (UML) is a modeling notation that provides tools for modeling every aspect of a software system from requirements to implementation.

UML has become a standard methodology, and is increasingly being applied to the modeling and design of Geographic Information Systems and Databases. In line with the position of the INSPIRE Architecture & Standards Working Group, a UML diagrammatic notation is used here to present an overview of the logical model, together with a detailed data dictionary (Appendix III) describing the attributes of the tables that will be created from the model.

Whilst UML can be applied in many aspects of system design, in the context of the WFD GIS Data Model only a restricted subset of static structure diagrams are used.

3.3.3 Data Model Overview

The data model aims to satisfy the requirements, primarily as defined by the Directive itself, but also based on commonly agreed definitions resulting from discussions in the GIS-WG and other Working Groups. Wherever appropriate, relevant definitions from the Directive itself are given.

Within the model, logically related features are grouped together. Thus, the model extends the basic distinctions in the Directive between "Surface Water" and "Groundwater" and "Protected Areas", adding the "Monitoring Network", "Management/Administration" and "Ecological Status".

Wetlands

Wetland ecosystems are ecologically and functionally parts of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in the WFD CIS Guidance Document No. 2 on *Water Bodies* and further considered in the guidance on *Wetlands (under preparation)*.

Pressures on wetlands (for example, physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can, in appropriate circumstances, offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal guidance paper on wetlands.

Given the role wetlands can play in achieving the environmental objectives of the WFD, it is recognised that it would be important to identify and include wetlands as objects in the GIS, including their key attributes. Wetlands will be related to groundwaters, surface waters and protected areas. As soon as relevant information on the definition and attributes of wetlands are available, the data model should, therefore, be extended accordingly.

The following three figures (Figures 3.3.1 to 3.3.3) show the core components of the model – Water Bodies, Monitoring Stations, Administration and Status:

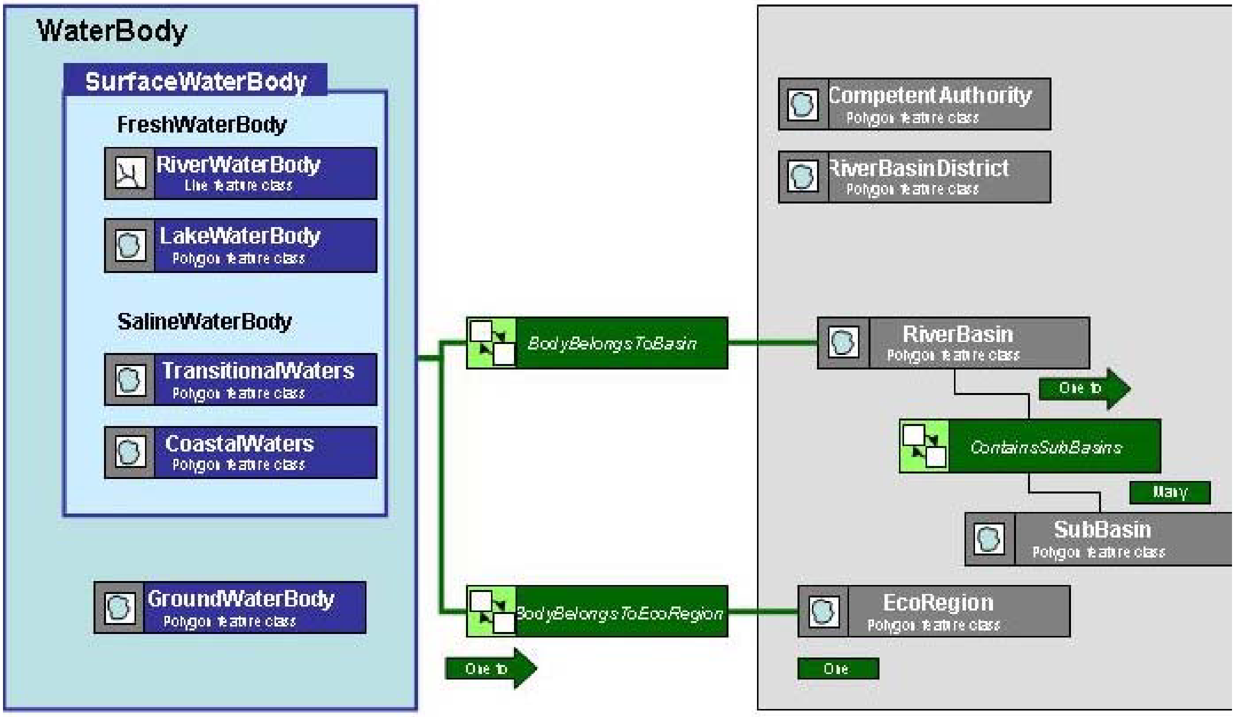

Figure 3.3.1: Water Bodies and Management Units.

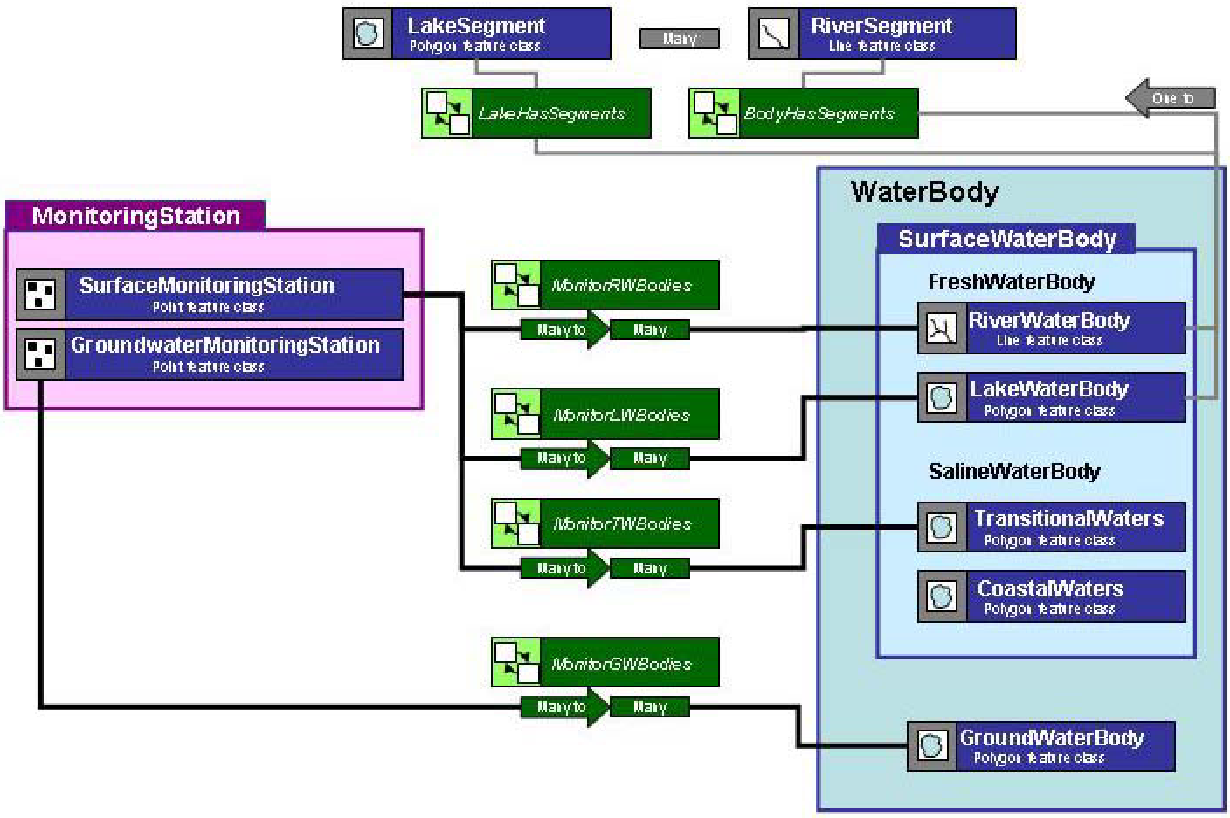

Figure 3.3.2: Water Bodies and Monitoring.

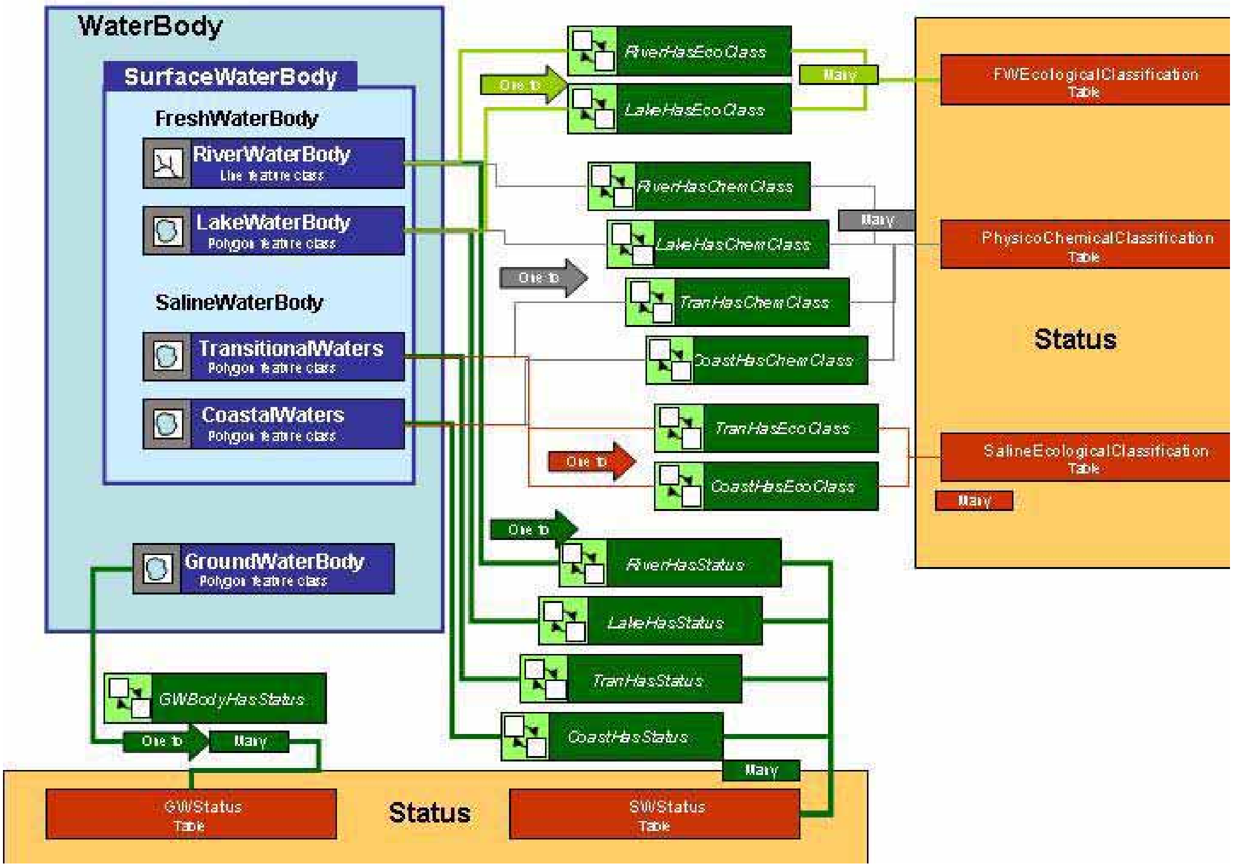

Figure 3.3.3: Water Bodies and Status.

Geometric Representation

In the simple approach presented here, features are represented as simple features only (i.e. points, lines, or polygons). Optionally, the same set of real world features could be modeled as a simple or complex network. Since the main objective of the Directive is reporting, not analysis, this may not be a priority, but should not be excluded at this stage and is discussed further below.

Linear measuring systems are in use in some, but not all, Member States. Instead of explicit x,y locations, data are recorded with reference to relative positions according to a known feature. For example, river segment 2800, kilometer 23.1 identifies a position in geographic space without the use of x,y co-ordinates. Because such measurements refer to relative positions, they can be updated easily without having to edit the underlying geometry of the river network.

Whilst this may become a standard approach in the future, the current release of the model provides a simple feature based approach. Thus, in the case of river lines, any status categorization (for example, poor quality symbolized in red) will apply to the entire line feature, from node to node. The identification and representativity of the segments is therefore crucial, and presents problems if the status values are dynamic. Given that reporting is on a six yearly basis, this problem is not significant. Clearly it is the Member States responsibility therefore to define water bodies, and their segmentation into individual features, according to the following principles:

> To enable "water bodies" to act as **compliance checking units**, their identification and subsequent classification must provide for the accurate description of the status of the water environment.
>
> The Directive only requires sub-divisions of surface water and groundwater that are necessary for the clear, consistent and effective application of its objectives. Sub-divisions of surface water and groundwater into smaller and smaller water bodies that do not support this purpose should be avoided.
>
> A "water body" must be capable of being assigned to a single ecological status class… (source "*WFD CIS Guidance Document No.2 on "Water Bodies"*").

The option of using linear referencing merits further discussion as to the feasibility and desirability of such an approach.

3.3.4 Feature Classes

Feature classes, i.e. those classes in the model which contain explicit geometry, and are thus point, line or polygon features, are as follows. All these classes inherit from the class feature, in that they have geometry and will have a unique internal identifier in the database. Feature classes cannot mix geometry types – they must be exclusively points, or lines, or polygons.

Feature
- SubBasin
- RiverBasin
- RiverBasinDistrict
- CompetentAuthority

Feature — *MonitoringStation*
- SurfaceMonitoringStation
- GroundwaterMonitoringStation

Feature — *WaterBody*
- GroundwaterBody
- *SurfaceWaterBody*
  - *FreshWaterBody*
    - RiverWaterBody
      - RiverSegment
    - LakeWaterBody
      - LakeSegment
  - *SalineWaterBody*
    - TransitionalWaters
    - CoastalWaters

Feature
- ProtectedArea

Feature
- EcoRegion

Inheritance allows classes to be related to parents through generalization. The more specific class inherits attributes from the more general class.

In practical terms, every UML class becomes a table. Every UML attribute in a class becomes a column in a table. Appendix III (Data Dictionary) provides a physical description of the tables and columns, which complements the discussion of each of the classes which follows.

3.3.4.1 General

EcoRegion

Polygon features, with a Name and a unique EcoRegionCode. Two systems are defined according to WFD Annex XI –A for rivers and lakes, and WFD Annex XI – B for transitional waters and coastal waters.

WaterBody

All surface water (SW) and groundwater (GW) bodies inherit from the WaterBody abstract class, which defines the following attributes:

- **EuropeanCode**. A unique identifier at European level, including the 2 character ISO Country Code;
- **Name;**
- **MSCode**. The unique code for the water body defined in the Member State;
- **EcoRegionCode.** The relationship between a water body and its parent EcoRegion is via the EcoRegionCode;
- **InsertedWhen;**
- **InsertedBy;**
- **RiverBasinCode.** The relationship between a water body and its parent RiverBasin is via the EcoRegionCode;
- **StatusYear.**

3.3.4.2 Surface Water

From the Directive definitions, "*Surface Water means inland waters, except groundwater; transitional waters and coastal waters, except in respect of chemical status for which it shall also include territorial waters*."

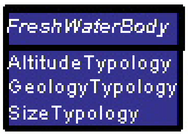
Thus the abstract class SurfaceWaterBody is classified into FreshWater and SalineWater, according to the different sets of attributes.

SurfaceWaterBody

A SurfaceWaterBody abstract feature class defines the following attributes:

- **HeavilyModified** True/False. Heavily modified water body means a body of surface water which as a result of physical alterations by human activity is substantially changed in character, as designated by the Member State in accordance with the provisions of Annex II;
- **Artificial** True/False. Artificial water body means a body of surface water created by human activity;
- **System**. Whether the water body is Type A or Type B.

FreshWaterBody



The abstract feature class FreshWaterBody inherits from the SurfaceWaterBody class, and defines the following additional attributes:

- **AltitudeTypology**. Whether the body is in a high, mid-altitude or lowland area;
- **GeologyTypology**. Basic geological type of the area;
- **SizeTypology**. Size categories will differ between rivers and lakes.

SalineWaterBody

The abstract class SalineWaterBody inherits from SurfaceWaterBody and defines the following additional attribute:

- **SalinityTypology**. Based on the mean annual salinity.

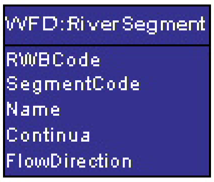
RiverWaterBody

RiverWaterBody means a body of inland water flowing for the most part on the surface of the land but which may flow underground for part of its course. The term RiverWaterBody is used to correspond with the WFD CID Guidance Document No. 2 on Water Bodies, where it is indicated that a single water body may consist of several component river segments. A RiverWaterBody is not therefore required to be a feature class, instead it is a list of the RiverSegment features which make it up. The RiverWaterBody class inherits from the FreshWaterBody abstract class. For the remaining attributes, which are to be completed in the case of a Type B River, the Directive does not give any indication of their definition or allowable values.

A RiverWaterBody is related to its component RiverSegments through the one-to-many relationship *BodyHasSegments*.

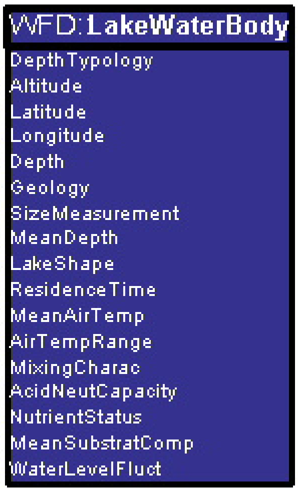
RiverSegment

The Directive does not explicitly state how to identify individual stretches of river (i.e. the concept of river reaches). It defines rivers, as other surface water bodies, as "*a discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal*". As a minimum requirement, river segments should be defined between confluences, and will probably be split additionally at point locations in the Monitoring Network. This is in line with the Horizontal Guidance on water bodies. In this model, river segments are simple line features with nodes at the endpoints.



- **RWBCode** The unique code of the RiverWaterBody to which the segment belongs.
- **SegmentCode** The unique code of the RiverSegment.
- **Name** The locally applicable name for the RiverSegment.
- **Continua** Whether the river segment is a true river reach, or an imaginary *continua* created in order to maintain network connectivity. *Continua* are, for example, imaginary stretches of a river under a lake.
- **FlowDirection** Whether or not the flow direction along the segment is the same as the direction in which it was digitized.

LakeWaterBody



According to the Directive, "*Lake means a body of standing inland surface water*". Lakes are termed as LakeWaterBody in the model to allow for the subdivision of individual lakes into distinct bodies. A LakeWaterBody is not therefore a feature class in itself – it is rather a list of the individual LakeSegments (polygons) which make it up. The LakeWaterBody class inherits from the abstract class FreshWaterBody and defines the following additional attributes:

- **DepthTypology**. Based on the mean depth of the lake.

For the remaining attributes, which are to be completed in the case of a Type B LakeWaterBody, the Directive does not give any indication of their definition or allowable values.

A LakeWaterBody is related to its component LakeSegments through the one-to-many relationship *LakeHasSegments*.

LakeSegment

A LakeWaterBody is composed of one-to-many LakeSegments. A LakeSegment shall be an area (polygon) feature, and should have nodes at inlets and outlets, thus providing connectivity to the RiverSegment (line) features and to any internal "*continua*" segments defined.

- **LWBCode** The unique code of the LakeWaterBody to which the segment belongs;
- **SegmentCode** The unique code of the LakeSegment;
- **Name** The locally applicable name for the LakeSegment.

TransitionalWaters

Transitional waters are "*bodies of surface water in the vicinity of river mouths which are partly saline in character as a result of their proximity to coastal waters but which are substantially influenced by freshwater flows*".

The TransitionalWaters feature class inherits from the abstract class SalineWaterBody and defines the following additional attributes:

- **TidalTypology.** Based on the mean tidal range.

Transitional waters will typically be estuaries, and modeled as polygon features. The use of river segments (as lines), to reach as far as coastal outlets, will maintain the network connectivity (see Coding Systems).

For the remaining attributes, which are to be completed in the case of Type B TransitionalWaters, the Directive does not give any indication of their definition or allowable values.

CoastalWaters

Coastal water means "*surface water on the landward side of a line, every point of which is at a distance of one nautical mile on the seaward side from the nearest point of the baseline from which the breadth of territorial waters is measured, extending where appropriate up to the outer limit of transitional waters*".

The CoastalWaters feature class inherits from the abstract class SalineWaterBody, and defines the following additional attributes:

- **DepthTypology** Based on the mean depth.

For the remaining attributes, which are to be completed in the case of Type B CoastalWaters, the Directive does not give any indication of their definition or allowable values.

For the feature classes which inherit from the abstract class SurfaceWaterBody, a number of attributes are in common (e.g. MeanSubstratComp). In the model these are not passed to the parent class simply to clarify the distinction between Type A and Type B categorization (e.g., the attribute SalinityTypology is a minimum requirement for Type A, both for TransitionalWaters and CoastalWaters, and is therefore presented as an attribute of the SalineWaterBody class. WaveExposure is an example of an optional Type B attribute, and is therefore presented at the feature class level).

3.3.4.3 Groundwater

GroundwaterBody

The GroundwaterBody feature class inherits from the WaterBody abstract class. Body of groundwater means "*a distinct volume of groundwater within an aquifer or aquifers*".

The Directive does not provide standard criteria for the characterization of groundwater bodies, although Member States should provide information on pressures, overlying strata and dependent surface water and terrestrial ecosystems. For groundwater bodies considered to be at risk, further detail on these geological and hydrogeological characteristics can be provided. Information concerning the impact of human activity may also be collected.

The model does not deal with these parameters, but this might be an area that merits increased standardization of the information gathered.

Discussion continues on how such bodies should be delineated, and subsequently represented. For the purposes of the present model, it is assumed that groundwater bodies will be 2-dimensional (i.e. planar) polygon features. Unlike surface water bodies, the delineated boundaries of groundwater will rarely coincide exactly with river basins. Thus the Directive requirement that groundwater bodies must be assigned to a River Basin District will have to be achieved through a relationship in the database, which should be the approach for all water bodies.

The GroundwaterBody feature class defines the following attributes:

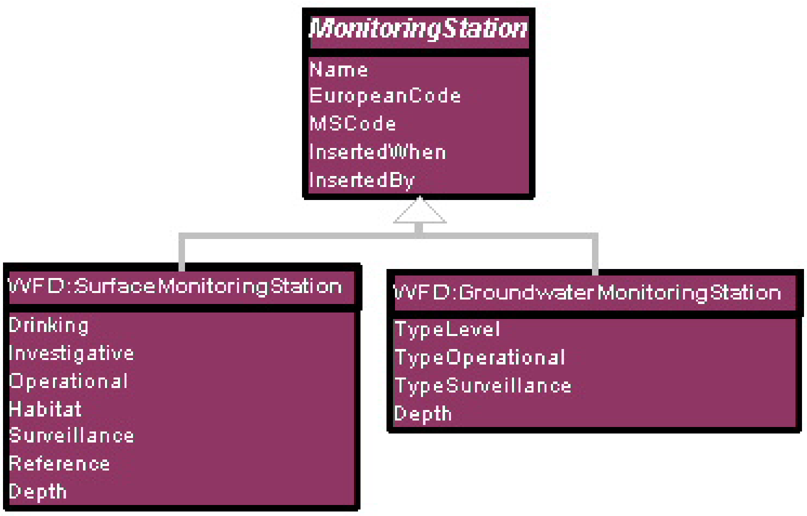
- **Horizon** – For groundwater bodies, reported separately but which are overlying, the horizon attribute provides a distinction of the individual strata.

3.3.4.4 Monitoring Network

Monitoring Stations shall form the basis of the monitoring of water status. The Directive distinguishes between Surface Water Monitoring and Groundwater Monitoring. The monitoring is the basis for subsequent classification of water bodies, but it is not a requirement from a GIS perspective to access the underlying data used to arrive at these status characterizations. Annex V, Article 1.3 states that "*Member States shall provide a map or maps showing the surface water monitoring network in the river basin management plan*". Similarly, Article 2.2.1 states that the groundwater monitoring network shall also be provided as a map or maps.

Thus the model defines an abstract class "MonitoringStation", further subdivided into SurfaceMonitoringStation and GroundwaterMonitoringStation.

MonitoringStation



The abstract class "MonitoringStation" defines the following additional attributes:

- **Name**. If appropriate, a name can be provided for the station;
- **EuropeanCode** A unique code, incorporating the ISO Country Code plus the MSCode below;
- **MSCode** A unique code for the monitoring station.

Monitoring stations are point features. They are further categorised into SurfaceMonitoringStations and GroundwaterMonitoringStations. Since a station may serve multiple functions, it is not appropriate to define distinct subtypes (e.g. a Groundwater station may perform any or all of the functions level (quantity), operational and surveillance monitoring).

The feature class **SurfaceMonitoringStation** inherits from the abstract class MonitoringStation, and defines the following additional attributes to identify the functions it performs:

- **Drinking –** Y/N if the station is a drinking water abstraction;
- **Investigative –** Y/N if the station is an investigative station;
- **Operational –** Y/N if the station is an operational station;
- **Habitat –** Y/N if the station is a habitat monitoring station;
- **Surveillance –** Y/N if the station is a surveillance station;
- **Reference –** Y/N if the station is a reference station;
- **Depth** – Depth in metres.

The feature class **GroundwaterMonitoringStation** inherits from the abstract class MonitoringStation, and defines the following additional attributes to identify the functions it performs:

- **TypeLevel**– Y/N if the station is an operational station;
- **TypeOperational**– Y/N if the station is an operational station;
- **TypeSurveillance**– Y/N if the station is a surveillance station;
- **Depth –** Depth in metres.

Monitoring stations may have multiple functions, as described above, and also may monitor multiple water bodies. They therefore have a many-to-many relationship with WaterBodies, as follows:

The feature class SurfaceMonitoringStation participates in the many-to-many relationships MonitorRWBodies, MonitorLWBodies and MonitorTWBodies.

The feature class GroundwaterMonitoringStation participates in the many-to-many relationship MonitorGWBodies.

3.3.4.5 Status

For each SurfaceWaterBody, ecological and chemical status categories are reported. However, a further level of detail is possible, in which individual ecological, hydromorphological and chemical quality parameters are recorded (Annex V, Article 1.2).

Again, a distinction can be made between Fresh and Saline waters. For each of these elements reported, the StatusDate is recorded.

Status parameters are also reported for groundwater bodies, again with a StatusDate allowing multiple status reports to be made for the same body over time.

All status parameters are linked to the relevant water body via the unique EuropeanCode.

GWStatus

The GWStatus class provides status reports for a given date for a given Groundwater Body, identified by the EuropeanCode. In addition, the following specific quality attributes are defined (see Data Dictionary Appendix III for allowable values):

- **QuantitativeStatus**. For good status, the level of groundwater in the groundwater body is such that the available groundwater resource is not exceeded by the long-term annual average rate of abstraction;
- **ChemicalStatus**. The chemical composition of the groundwater body as determined by pollution concentrations;
- **PollutantTrend**. The long-term trend in anthropogenically induced pollutants;
- **ConfidenceLevel**. The level of confidence associated with the PollutantTrend assessment above (Annex V, Article 2.4.4).

SWStatus

The SWStatus class provides status reports for a given date for a given surface water body, identified by the EuropeanCode. In addition, the following specific quality attributes are defined (see Data Dictionary Appendix III for allowable values):

- **EcologicalStatus**. Ecological status is an expression of the quality of the structure and functioning of aquatic ecosystems associated with surface waters, classified in accordance with Annex V;
- **EcologicalPotential** (for Heavily Modified or Artificial bodies) according to the categories in the *QualityClassification* domain;
- **NonCompliant**. True/False. For those bodies which may be at risk of failing to meet quality objectives;
- **ChemicalStatus** is either Good, or FailingToAchieveGood (Annex V, 1.4.3). Good surface water chemical status means the chemical status required to meet the environmental objectives for surface waters established in Article 4(1)(a), that is the chemical status achieved by a body of surface water in which concentrations of pollutants do not exceed the environmental quality standards established in Annex IX and under Article 16(7), and under other relevant Community legislation setting environmental quality standards at Community level.

FreshwaterEcologicalStatus

The FWEcologicalClassification class is related to a particular water body by the EuropeanCode. This class defines the following attributes (Annex V, Article 1.2.1, 1.2.2):

- **Phytoplankton;**

- **Macrophyto**. Macrophytes and Phytobenthos;
- **BenthicInvertebrates;**
- **Fish;**
- **HydrologicalRegime;**
- **RiverContinuity;**
- **MorphologicalConditions.**

PhysicoChemicalClassification

The PhysicoChemicalClassification class is related to a particular water body by the EuropeanCode. This class applies to all surface water body types, and defines the following attributes (Annex V, Article 1.2.1, 1.2.2):

- **GeneralConditions;**
- **SyntheticPollutants;**
- **NonSyntheticPollutants**.

3.3.4.6 SalineWater Ecological Status

For Transitional and Coastal Waters, the SalineEcologicalClassification class defines the following attributes:

- **Phytoplankton;**
- **Macroalgae**. Merged with angiosperms for coastal waters;
- **Angiosperms**. Merged with angiosperms for coastal waters;
- **Benthicinvertebrates;**
- **Fish;**
- **TidalRegime**. According to the QualityClassification domain;
- **MorphologicalConditions**. According to the QualityClassification domain.

3.3.4.7 Management / Administration

River basin district means the area of land and sea, made up of one or more neighbouring river basins together with their associated groundwaters and coastal waters, which is identified under Article 3(1) as the main unit for management of river basins.

A WaterBody or a MonitoringStation may belong to a single RiverBasinDistrict (even if this may not physically be the case – ref. CIS-WFD Project 2.9 "Guidance on Best Practices in River Basin Management Planning").

SubBasin

Sub-basin means "*the area of land from which all surface run-off flows through a series of streams, rivers and, possibly, lakes to a particular point in a water course (normally a lake or a river confluence)*."

The SubBasin feature class defines the following attributes:

- **Name;**
- **RiverBasinID**. The relationship between a SubBasin and its parent RiverBasin is via the RiverBasinID;
- **SubBasinID**. Each SubBasin shall have a unique code, which should link to the coding used for the river network.

The SubBasin feature class shall be defined as polygons.

RiverBasin

River basin means *"the area of land from which all surface run-off flows through a sequence of streams, rivers and, possibly, lakes into the sea at a single river mouth, estuary or delta*." RiverBasins shall be assigned "*to individual river basin districts"*.

The RiverBasin feature class defines the following attributes:

- **Name;**
- **MSCode;**
- **EuropeanCode;**
- **DistrictCode**. The relationship between a RiverBasin and its parent RiverBasinDistrict is via the DistrictCode;
- **AreaKM2.** Reported area in square kilometres.

The RiverBasin feature class shall be defined as polygons.

An important geometric rule is that river basins shall not overlap.

RiverBasinDistrict

RiverBasinDistricts can be collections of RiverBasins, TransitionalWaters and CoastalWaters. Thus, despite duplication of some geometry, they are defined as a separate polygon feature class. In addition, the following attributes are defined:

- **Name;**
- **MSCode;**
- **EuropeanCode;**
- **CompetentAuth**. The code of the parent Competent Authority.

CompetentAuthority

Competent Authority means an authority or authorities identified under Article 3(2) or 3(3). Because in some cases it is not possible to aggregate RiverBasinDistricts to form the boundary of the CompetentAuthority, they are defined as a separate polygon feature class.

- **Name;**
- **Address;**
- **AuthorityCode.**

3.3.4.8 ProtectedAreas

Annex V of the WFD states that the river basin management plan "*shall include maps indicating the location of each protected area and a description of the Community, national or local legislation under which they have been designated*".

No further specifications are provided by the Directive which might assist data modeling. Activities related to the other Directives and legislation concerning these protected areas may result in further specifications. However, at the present time ProtectedAreas are modeled as simple geometric features, each with a name and, where appropriate, a unique European Code allowing them to be distinctly identified. Whilst certain protected areas may currently be reported as point locations, it is strongly recommended that they are reported as polygon features whenever possible.

ProtectedArea

The feature class ProtectedArea defines the following subtypes:

- **DrinkingWaterProtection;**
- **RecreationalWater;**
- **EconomicSpeciesProtection;**
- **NutrientSensitiveArea;**
- **HabitatProtection;**
- **BirdProtection.**

Each subtype shares the same attributes:

- **Name;**
- **EuropeanCode.**

3.4 European GIS Feature Coding

3.4.1 Introduction

GIS feature coding is the assignment of unique identification codes to each spatial feature that will be referenced by GIS. This assignment needs to be managed to ensure uniqueness at national and international levels. Standard code formats will ease electronic data transfer and enhance the possibility of central querying against distributed storage.

3.4.2 Unique European codes

Unique European codes are provided by the following format

MS$\#_1\#_2\ldots\#_{22}$ where:

MS = a 2 character Member State identifier, in accordance with ISO 3166-1-Alpha-2 country codes, and

$\#_1\#_2\ldots\#_{22}$ = an up to 22 character feature code that is unique within the Member State.

For example:-
a *Groundwater Body in Germany* might have the identifier DE45734
or a *Lake Monitoring Station in Spain* might have the identifier ES67003800958730

Special advice given is that:

- Alphabetical characters should always be in upper case, as systems will be case sensitive;
- Special characters must be avoided, such as '$', '!', '&', 'ë', 'á', etc.;
- Digits should be used where practical to help avoid the above problems.

Use of the MS$\#_1\#_2\ldots\#_{22}$ is the only requirement for unique European feature identification codes. The Data Dictionary in Appendix III allows for these identification codes. Codes of this format should be used for initial and subsequent references to features when reporting to the Commission.

3.4.3 Managing Codes *within* Member States and RBDs

The above mentioned up to 22 alphanumeric string, $\#_1\#_2\ldots\#_{22}$, should be as short as possible to avoid keying mistakes, yet as long as is required to support unique code maintenance at local operational levels. Precise structures are a matter for each Member State to decide upon. However, some guidance is provided here to establish principles that may be adopted to assist code management within Member States.

3.4.3.1 Unique Identification of Coding Authorities

Some features will be identified on a one off basis, by a single agency acting at a national level. Others may be frequently established and identified by multiple organisations. In the latter case, a structured approach can ease the assignment of identifiers locally while automatically forming unique European identification codes. Examples are provided here in order to clarify this point.

There may be a number of authorities, such as counties, regions or Länders, responsible for the establishment of monitoring stations. Each may have sub-authorities such as urban district councils with similar responsibilities. In such a case, it is useful if coding authorities are first assigned unique identifiers at Member State level. For example the initial two digits of a four digit authority code 'AAAA' might be used, e.g., '**40**00', '**17**00' or '**23**00'. The last two digits might be used to identify sub-authorities or regional offices. For example '17**10**', '17**14**', etc. These authorities can then easily generate locally unique codes. A local code becomes nationally unique by the addition of the AAAA code as a header, and internationally unique by the further addition of the MS code. For example, if a monitoring station is locally given the unique identifier of '12345' by coding authority 1700 in Denmark, then that station would be uniquely identified as DK170012345 when reporting to Europe.

This approach is strongly recommended where multiple agencies are, or will be, involved in the ongoing identification of features. Exact coding structures to be used will be a matter for individual Member States to decide upon and these are likely to vary by feature type.

3.4.3.2 Unique Identification Coding at Operational Levels

The above technique can be taken further within coding authorities, where appropriate. For example, if drinking water abstraction monitoring is managed at drinking water scheme level, then a coding authority may first assign unique identifiers to drinking water schemes. The scheme managers can then easily assign unique identifiers to monitoring stations at a local level.

3.4.3.3 Using the River Network for Unique Code Assignments

Once the river network has been uniquely coded, it can be used to assign unique codes to features that are connected to it. This provides another mechanism for assignment of unique codes at a local level without having to cross check against national assignments.

River segment identification codes can be used locally to assign unique codes to:

- river water bodies;
- lakes;
- lake water bodies;
- transitional water bodies; and
- the monitoring stations for all of these.

As explained later, the outlet river segment code should generally be used for hydrologically connected features that are associated with multiple river segments.

For example, monitoring stations can be identified with codes that are an extension of river codes. The first two digits of a 4-digit monitoring station code 'MMMM' might be used. The last two digits could be used at a later stage to allow further stations to be inserted, while maintaining a sequence to the order of stations. Such a sequence would be important for the purpose of visual confirmation of uniqueness.

Thus, for example, if a river segment has 3 monitoring stations, these might be identified as '0100', '0200'and '0300' as we move upstream. If at a later date we want a station between the first and second, then it would have a station code of '0150'. If the river water body code was 'IE54321', then the full unique monitoring station code would be 'IE543210150'.

Practiced variations on this approach include the use of upstream distance. This has the benefit of providing exact location. It has the disadvantage of requiring prior distance analyses and GIS can maintain location in any regard. Again, this is a matter for individual Member States to decide upon and is very dependent of the capabilities and structures of code management organisations.

3.4.3.4 Monitoring Stations

As described above, monitoring stations may be uniquely identified by extending identification codes for river segments or coding authorities. It is very important that monitoring stations retain their initial identification codes regardless of subsequent changes in river water bodies and coding authorities. If monitoring stations were re-coded to reflect such changes, then the link to historic data relating to these stations would be lost.

The extension of feature and coding authority codes provides a mechanism for data validation. This is an added bonus gained from such code extensions. If such validation is used, the database will need to allow relaxation where the monitored features or coding authorities have changed.

However, it must be remembered that the primary purpose for such code extensions is not data validation; it is to help with the management of unique code assignment at local levels.

3.4.4 Structured Hydrological Unique River Identifiers

3.4.4.1 Coding Approach

If rivers are already substantially identified, it may be pragmatic to extend existing coding. However, the number of rivers to be identified may amount to multiples of the number already coded. Codes may also need to be reviewed to achieve harmonisation with Member States involved in shared RBDs. Coding could be as simple as sequential identifiers; however, structured hydrological codes are recommended. This enables rapid manual or automated analyses without the need to refer to GIS. Hierarchical structured coding also tends to ease long-term unique code maintenance.

Many existing river coding systems are reviewed in a document to be found at http://193.178.1.168/River_Coding_Review.htm. The Pfafstetter system is the generally preferred system. Its benefits are addressed at the above web address. Pfafstetter implementation issues are addressed in Appendix IV. However, it is felt that further consideration is required in order to produce a system that adequately caters for rivers, lakes and marine waters in an integrated way.

In the mean time, structured hydrological codes are preferable to random or non-hydrological codes. And thus, where extensive further river coding is expected, a modified version of the Pfafstetter system is proposed as an interim solution pending the possible adoption of a further modified or alternative system.

3.4.4.2 The (Interim) Modified Pfafstetter System

The code takes the form

MS MW N_1 N_2 N_3 N_4, ….

MS = Member State responsible for code assignment (outlet state for cross-border river segments). Use a 2-character Member State identifier, in accordance with ISO 3166-1-Alpha-2 country codes.

MW = Marine Waters identifier. (In accordance with the International Hydrographic Organisation delineation[1], with possible further local sub-divisions per regional marine agreements).

N_1 N_2, .. = Pfafstetter code[2]. This is a series of 1 digit nested codes. These codes are generated by the following process (see Figures 3.4.1 – 3.4.4)

Moving from river exit to source, the 4 most significant rivers are identified and assigned consecutive even numbers (e.g. 2, 4, 6 and 8.). The use of '0' is reserved for closed basins, i.e. with no outlet.

Each significant river has its own catchment. The remaining areas of the overall catchment are the inter-catchments. These are numbered using consecutive odd numbers, starting with '1' being the inter-catchment between the sea and the first significant tributary and ending with '9', being the headwaters or upper catchment area.

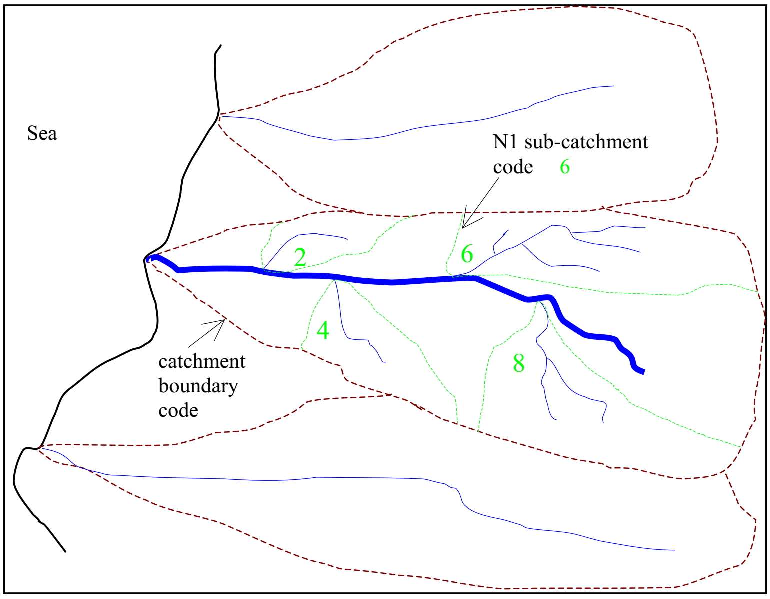


Figure 3.4.1: Pfafstetter numbering of main rivers and tributaries.

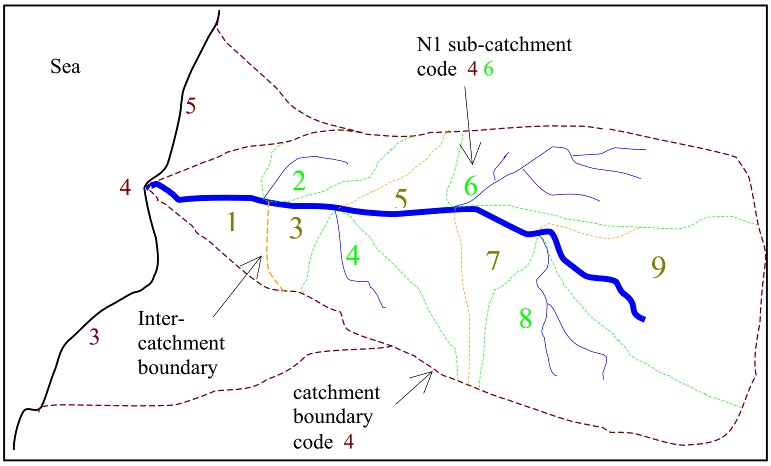

Figure 3.4.2: Defining and numbering the inter-catchment areas

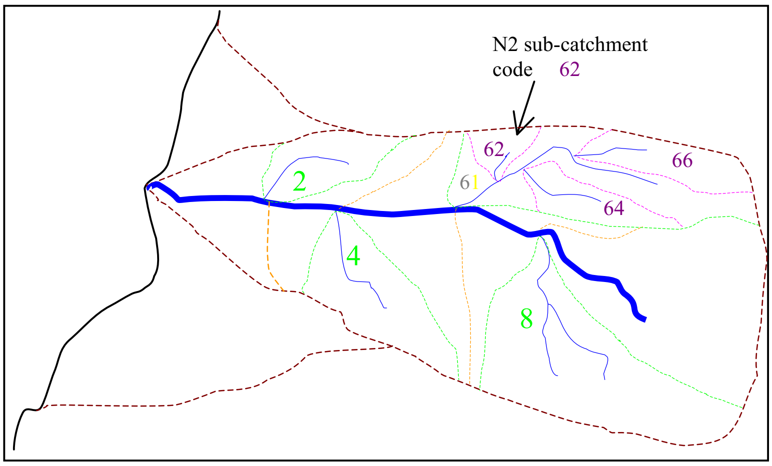

Figure 3.4.3:. Second level tributaries and inter-catchments.

Notes:
1. Use a temporary 2-digit code as IHO decimal codes are not presently suitable. These will need to be mapped to new standard 2-digit codes.

2. Portugal found that between 5 and 9 digits were required for Pfafstetter coding of the river network.

Each catchment and inter-catchment can then be broken down further in the same manner, by the use of N2. This nested process can continue into further levels. If, near the headwaters, four tributaries cannot be found, then the process continues with less catchments and inter-catchments. Alternatively, more detailed mapping is required.

Areas draining directly to sea (with diffused drainage or small rivers), will have odd numbered inter-catchment codes and can use N2 to identify the most significant rivers, then N3 for the most significant tributaries, etc.

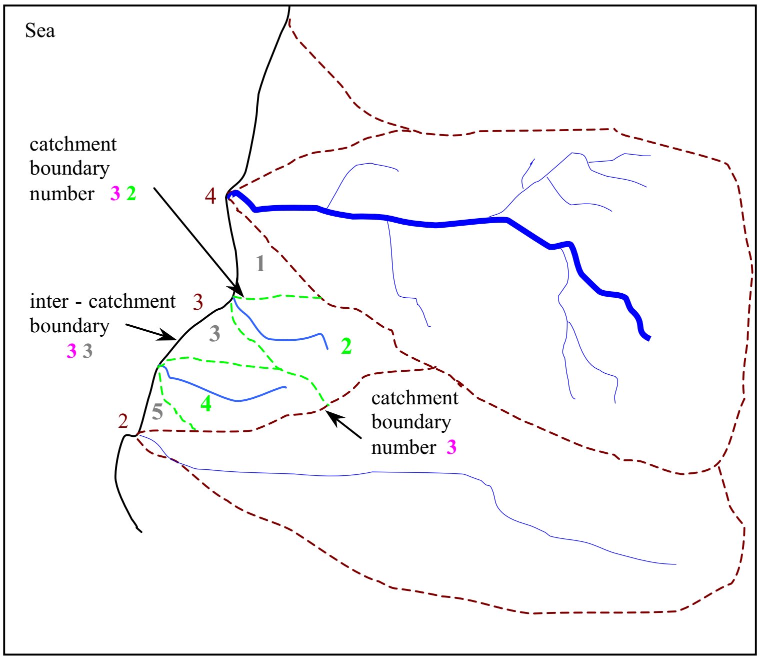

Figure 3.4.4: Sub-division of coastal catchments

The Pfafstetter approach can be used across adjacent Member States in combination with the marine waters code. Pfafstetter codes can be used directly to determine if discharge in a sub-catchment impacts on a potentially downstream channel. This can be achieved without the need for GIS analysis and is demonstrated at http://193.178.1.168/River_Coding_Review.htm.

Practical implementation issues and the impact of lakes on river coding are discussed in Appendix IV.

3.4.5 Structured Hydrological Coding for other Water Bodies

As mentioned already, the modified Pfafstetter system is an interim solution, which requires further study before it is either fully adopted as the recommended hydrological coding system or it is further modified or replaced by an alternative system. Regardless of which system is used, the river network provides a means to

a) assign unique codes to further features, and
b) assign structured hydrological codes to further features.

For example, as demonstrated in Appendix IV, if lakes, transitional water bodies and river water bodies use the same code as the downstream or outlet river stretch, then the assigned feature codes carry some level of hydrological information. This will enable rapid connectivity tests based on codes alone. Coding anomalies will arise on occasion and these will need some level of manual code assignment.

3.4.6 Protected Areas

Protected areas layers are addressed by Natura 2000 which uses a two character Member State identification code followed by a 7-character code to identify SCI's (Sites of Community Importance) and SPA's (Special Protection Areas) within a Member State.

3.4.7 Segmentation

Division of rivers or water bodies into sub-sections requires additional code management. This will not be required for initial reporting, but will be a consideration at river basin district levels. Rivers can be divided into subsections using either the sequential identifiers or the distance approaches referred to when dealing with monitoring stations in Section 3.4.3.3: *Using the River Network for Unique Code Assignments*. Similar strategies need to be put in place for coastal and lake shorelines and sub-regions.

3.4.8 Conclusion

Unique European codes should be generated by placing a 2-character Member State code in front of up to 22 characters unique identifier codes generated within Member States. This is the only requirement for compliance with an agreed common format.

Further advice is provided regarding the structure of codes; but this requires local interpretation and decision making to establish appropriate optimal formats. Member states should initially establish coding structures that suit their particular needs and that support efficient management of unique code.

It is suggested that the following be considered:

- Member states should initially assign identification codes to coding authorities;
- A decision should be made with respect to the use of structured hydrological codes;
- River segment codes should be established for all rivers likely to be used for reporting;
- Coding authority and river segment codes should then be extended to assign further unique feature identification codes at a local level;
- Monitoring station identification codes, generated by such code extensions, should not change once assigned, even if associated authority or feature identification codes do change;
- Agreement should be reached with neighbouring countries regarding harmonised cross-border codes, particularly for river network coding.

Unique European codes of standard format are of a higher priority than structured hydrological codes. However, where computers are used to identify and code features, then for little extra effort, hydrological codes can be assigned. These will facilitate rapid connectivity tests without reference to GIS.

The following tables show some example codes, all of which comply with the MS plus 22 character string format. Suggestions are made with respect to possible coding strategies. However, it will be up to Member States to determine the best approach to adopt for local use and for application in international river basin districts.

3.4.9 Tables of Example Codes

Final code formats should be determined at Member State level, subject to existing data, local practices, organisational structures and long-term code maintenance strategies. The tables below should then be redrafted, at Member State level, to summarise local coding standards.

3.4.9.1 Water Bodies

Water Bodies (GIS Layers)	EXAMPLE ONLY		
River Segments & Catchments (Basins & Sub-Basins) (SW2, SW3 & SW4)	MS $\#_1,\#_2 .. \#_{22}$ or MS, MW, $N_1,N_2,\ldots N_{22}$ (Modified Pfafstetter)	IE12873 a river, GB12874 a catchment	MS = member state, at river section or catchment outlet. Non-Hydrological Approach: $\#_1,\#_2 .. \#_{22}$ = an up to 22 character string. Hydrological Approach: MW = marine waters codes according to a modification of codes for IHO delineations. ($N_1,N_2, N_3\ldots N_{22}$ are nested codes, each consisting of 1 digit With Pfafstetter, rivers use odd numbers, catchments or basins use even.)
River Water Body (SW2, SW3 & SW4)	MS $\#_1,\#_2 .. \#_{22}$	IE12873	For a hydrological approach use the same code as outlet river reach.
Lakes (SW4)	MS $\#_1,\#_2 .. \#_{22}$	SE13873	For a hydrological approach use the same code as outlet river reach.
Transitional (SW4)	MS $\#_1,\#_2 .. \#_{22}$	DE035411	For a hydrological approach use the same code as outlet river reach.
Coastal (SW4)	MS $\#_1,\#_2 .. \#_{22}$	IE10001230	This code may be an extension of a coding authority identification code, or it may relate to IHO marine water delineations.
Groundwater (GW1)	MS $\#_1,\#_2 .. \#_{22}$	GB30002310	This code may be an extension of a coding authority identification code.

3.4.9.2 Water Body Monitoring Points

Points (GIS Layers)	EXAMPLE		ONLY
River Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	GR5730800	MS = Member State $\#_1,\#_2 .. \#_{22}$ = is an up to 22 digit code, but kept as short as possible to avoid keying errors. This code may be an extension of the river segment, catchment or water body code.
Lake Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	GE5730300	This code may be an extension of the lake or lake water body code.
Coastal Water Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	GE100003001230	This code may be an extension of a coastal water body identification code.
Transitional Water Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	IT5730300	This code may be an extension of a transitional water body identification code.
Groundwater Body Station (GW2 & GW3)	MS $\#_1,\#_2 .. \#_{22}$	IT200001500305	This code may be an extension of a groundwater body identification code.

3.4.9.3 Water Usage Monitoring Points

Points (GIS Layers)	**Code Format** EXAMPLE	**Example Code**	**Comments** ONLY
Drinking Water, Groundwater Abstraction Station (SW5 & GW3)	MS $\#_1,\#_2 .. \#_{22}$	LT124000000120	This code may be an extension of a coding authority identification code. Alternatively it might be an extension of the ground water body code. The decision should depend on the member state ongoing code maintenance strategy.
Drinking Water, Surface Water Abstraction Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	ES130001010002	This code may be an extension of a coding authority identification code. Alternatively it might be an extension of the surface water body code. The decision should depend on the member state ongoing code maintenance strategy.
Bathing Point Station (SW5)	MS $\#_1,\#_2 .. \#_{22}$	PT130000100002	This code may be an extension of a coding authority identification code. Alternatively it might be an extension of the surface or coastal water body code. The decision should depend on the member state ongoing code maintenance strategy.

3.4.9.4 Point Pressures – Discharges

Points (GIS Layers)	**Code Format**	**Example Code**	**Comments**
	EXAMPLE ONLY		
Discharges (SW4 & SW5)	MS $\#_1,\#_2 .. \#_{22}$	FR130002500004	This code may be an extension of a coding authority identification code. Monitoring stations could be a further extension again. Discharges may be managed by type, such as Industrial, Treatment Plant, Solid Waste Leachate, etc.

3.4.9.5 Point Impacts

Points (GIS Layers)	**Code Format**		
	EXAMPLE ONLY		
Pollution Incidents (SW5 d)	MS $\#_1,\#_2 .. \#_{22}$	IE130020020123	This code may be an extension of a coding authority identification code.

3.5 Data Validation

This chapter describes the principles for quality assurance related to the GIS layers that are transmitted by the Member States to the European Commission. As pointed out earlier, the working group decided to deliver GIS layers and maps. The focus will be on reporting rather than spatial analysis. Hence the requirements on data quality are less strict compared to spatial analysis requirements. Nevertheless, there are some demands that can be derived from producing good cartography. Additionally, the GIS layers should be in a state that allows using as much as possible automated procedures for quality control. In general the data quality procedures should be applied by the Member States and be reported as part of the metadata. When compiling the national GIS layers, the EC will apply additional procedures that aim at creating homogenous GIS layers within the specifications of this Guidance Document. The framework for applying quality assurance procedures and reporting the results is set by the draft ISO standards on quality principles (19113), evaluation procedures (19114), and metadata (19115).

3.5.1 Data Quality Overview

Every GIS layer should be complemented with overview information on data quality. It consists of descriptions of the purpose, the usage and information on the history (lineage) of the GIS layer. Purpose describes the original objectives for creating the GIS layer, usage illustrates the actual usage(s) of the layer by describing related applications. The lineage gives information on the history of the dataset. It covers the total life cycle of a dataset from initial collection and processing to its current form. The lineage statement may contain the component "source information" that describes the origin of the dataset and the component "process step" that records the events of transformations in the lifetime of the dataset. Lineage also includes information on the process and the intervals to maintain a dataset.

The overview elements on data quality should be transmitted by the Members States and will be continued by the EC when applying further data processing steps.

Table 3.5.1: *Data quality overview*

Element	**Obligation**	**reported by**
Lineage statement Either a general explanation on the history, a more detailed description on the processing steps applied, or a description of the source of the GIS layer.	mandatory	MS, EC

3.5.2 Data Quality Elements

In addition to the general statements on data quality in the overview elements, the GIS layers should include information on selected data quality elements. These are completeness, logical consistency, positional accuracy and thematic accuracy.

Table 3.5.2: Selected data quality elements and sub-elements

Quality Element	Quality Sub-Element
Completeness	Commission Omission
Logical consistency	Conceptual consistency Domain consistency Topological consistency Format consistency
Positional accuracy	Absolute or external accuracy
Thematic accuracy	Classification correctness

3.5.2.1 Completeness

Completeness is assessed relative to the GIS data model specifications, which defines the desired degree of generalisation and abstraction. All features that are described in the specifications should be present in the dataset, more features would lead to a situation of over-completeness. The related attributes should sufficiently describe the feature and the values of the attributes should be filled. Relationships between the features should be established and valid according to the product specifications.

The Member States should report on methods, which they have applied to guarantee the completeness of features in the GIS layers. This refers especially to the number of river basins and sub-basins, the number of main rivers, the surface and groundwater bodies, the monitoring stations, and the protected areas. The completeness of features is normally tested by comparing them to a universe of discourse, i.e. a GIS layer that is considered as being complete. The results of the applied procedures should be reported as part of the metadata by the Member States.

Table 3.5.3: Completeness of Features Elements

Element	Obligation	reported by
Completeness of features in GIS layers	mandatory	MS

3.5.2.2 Logical Consistency

Consistency refers to the absence of apparent contradictions in the dataset, database or transfer file. Consistency is a measure of the internal validity of a database, and is assessed using information that is contained in the database.

Due to the lack of reference data, the most important part of the quality assurance process will be the assurance of the logical consistency of the data. The consistency applies to the features, the attribute-tables as well as to the attributes, and to the relationships. The relationships comprise the defined relationships between feature classes and attribute classes as well as to geometric relationships, e.g. sub-basins are covered by river basins.

Conceptual Consistency

The checks for conceptual consistency should include checking for the existence of the feature classes, the attribute classes, and the relationships that are defined in the model. The next step is to verify the existence and the correct definition of the features, attributes, domains, and relations in the database. Then it should be verified that attribute values exist, where these are defined, and that the relations are valid. The cardinality of the relations should conform to their definition. These quality checks will be applied by the EC when integrating the national GIS layers into the EU geographical database.

In the data model it is expressed that simple features are stored in the feature classes. Consequently it should be verified that the features in the database are consistent with the definition of simple features. This includes, for example, that polygons are closed, that boundaries of the polygons must not intersect, and that holes and exclaves ?? are considered correctly. Quality assurance on the validity of simple features are vital for the consistency of the database and should be applied by the Member States and reported by the EC.

Table 3.5.4: Conceptual Consistency Elements

Element	**Obligation**	**reported by**
Existence of GIS layers, attribute tables, relationships, domains	mandatory	EC
Definition of attribute	mandatory	EC
Existence of attribute values, where mandatory	mandatory	EC
Verification of cardinality of relationships	mandatory	EC
Simple features definition	mandatory	EC

Domain Consistency

In the data model, a number of domains are defined. It should be verified that the definition of the domains is correct. Then it should be checked that the attribute values in the feature and attribute classes are consistent with the domain values. In addition to the existing domains, so-called value range domains should be set up, as soon as the dimensions for the items concerned are defined. The checks on domain consistency should be applied by the Member States and will be verified during the integration process that generates the European database.

Table 3.5.5: Domain Consistency Elements

Element	**Obligation**	**reported by**
Comparison of attribute values with domain definitions	mandatory	EC

Topological Consistency

There are a number of GIS layers and attributes that can be tested for topological consistency. Some of the GIS layers have a country indication. The Member States should ensure that the appropriate country code is used.

The water bodies have an attribute indicating the relation to the EcoRegion GIS layer. The relation between water bodies and its parent river basin district can be verified by overlaying the water bodies with the river basins. The EC will test the correctness of the assignment by overlaying the respective layers.

The Appendix V contains a set of topological rules applicable to the GIS layers. The rules will be tested by the EC when merging the national GIS layers. The correctness should be reported as part of the data quality element topological consistency.

The WFD database will be set up as a collection of data sets provided by the EU countries. It is recommended that the features crossing boundaries should be coherent. This principle should apply to the geometry as well as to the attributes, e.g. the boundaries of river basins should meet at the border. The coding of the basin should be the same. The feature classes which could cover more than one country are in principle all polygon and line features, i.e. water bodies and river basins, sub-basins. This situation will be analysed by the EC when integrating the national GIS layers into a European database.

It is recommended that the hydrographical GIS layers should constitute a network. The directions of the lines should indicate flow directions. Flow lines should connect the incoming and outgoing river lines through a standing water body (e.g., lake). These connecting flow lines are termed *continua* in the data model. The data will be analysed by the EC when integrating the national GIS layers.

Table 3.5.6: Topological Consistency Elements

Element	**Obligation**	**reported by**
Coherence of features crossing country border	mandatory	EC
Country attribute values	mandatory	EC
Indication and verification of water flow	optional	EC

3.5.3 Accuracy

Positional Accuracy

Positional accuracy describes the difference between the location of features in a dataset and the location recognised as being true. The product specification in the Appendix V includes values for the minimum positional accuracy of the different GIS layers. The assessment of the positional accuracy can be done through sampling procedures.

The Member States should include information on positional accuracy and on the validation procedures applied as part of the metadata information. If there is no information on the positional accuracy, we recommend applying the method of the Federal Geographic Data Committee for geospatial positioning accuracy standards[1].

Table 3.5.7: Positional Accuracy Element

Element	Obligation	reported by
Positional accuracy	mandatory	MS

3.5.4 Descriptors of the Data Quality Sub-Elements

The results of the quality assurance for the above mentioned data quality sub-elements should be described using seven descriptors. The descriptors comprise the

- scope;
- measure;
- evaluation procedure;
- result;
- value type;
- value unit; and
- date.

of the data quality sub-element.

Quality measurements are only valid for defined scopes. The scope can be a geographic or a temporal extent, or a certain level of the data hierarchy (i.e. dataset series, dataset, features, or attributes). The scope may even be different within a single dataset, e.g. if the dataset is merged from different data providers.

The data quality measure describes briefly the test that is used for measuring the quality within the defined scope. The evaluation procedure should be described or, alternatively, there should be a reference to where a detailed description of the procedure can be found. This description is very important because it is necessary to understand the result of the applied test. Each test yields a certain result that is part of the data quality report. In order to understand the result, it is necessary to give information on the type of the value and on the unit of measurement. The reporting is completed with the date on which the quality test is performed.

3.5.5 Reporting of Quality Information

The results of the applied quality tests should be reported as part of the metadata. The DIS 19115 provides a defined structure, that follows the logic of the above described data elements, sub-elements and descriptors. The metadata standard distinguishes between data quality information as a report and as information of the history (lineage) of the data. The report comprises information on quality measurements, grouped according to the data quality sub-elements.

[1] see : http://www.fgdc.gov/standards/status/sub1_3.html

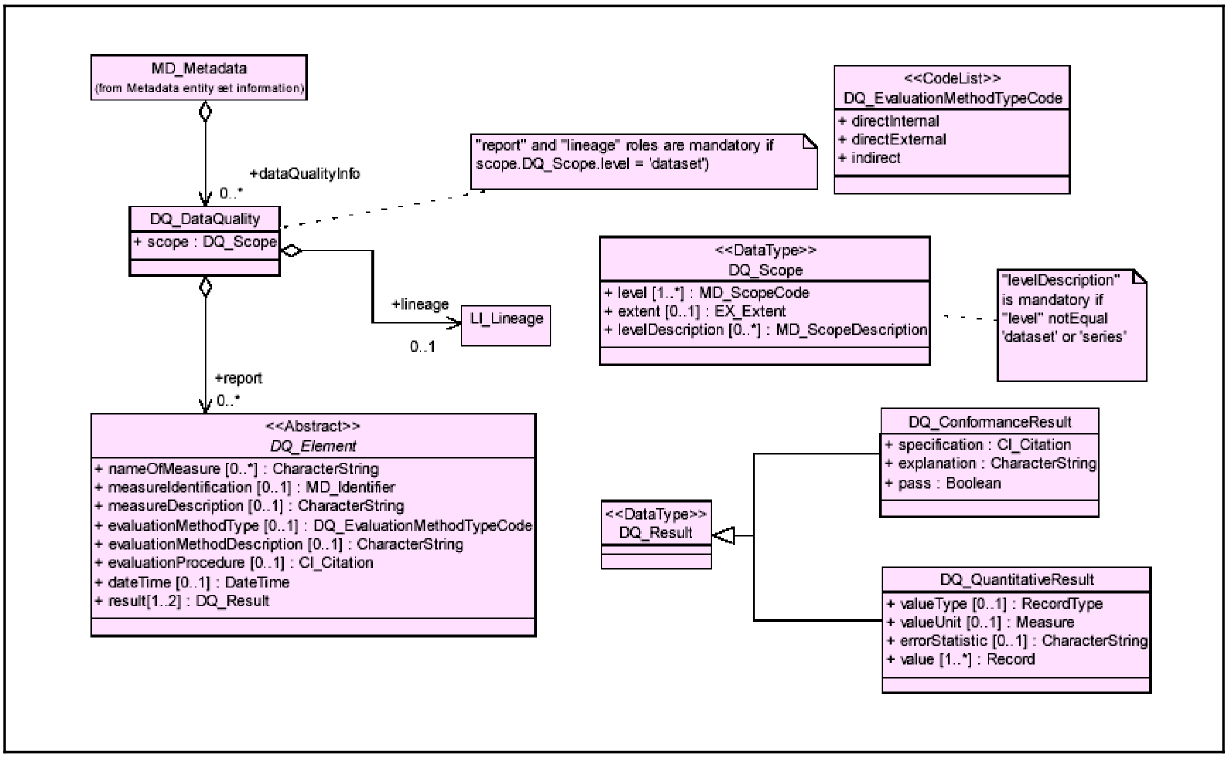

Figure 3.5.1: Conceptual model of metadata description on data quality

Appendix V contains topological rules, applicable to the GIS layers and some examples for reporting on data quality according to ISO 19115. The proposed elements of the DIS 19115 on metadata for reporting on data quality are described in the metadata part in Appendix V.

3.6 Reference System

The use of a common geodetic datum (horizontal and vertical) is a first step towards the harmonisation of geographic information across Europe. The adoption of a common reference system makes it possible to maintain seamless distributed geographic data, assigned to different custodians and avoiding or simplifying the work of geometric harmonisation. A common geodetic datum is particularly important for geographic information system users that require a "seamless" dataset. Furthermore, the fact that spatial data provided by Member States are often insufficiently documented (e.g., the used Datum is unknown or only partially or ambiguously described), is a source of errors when national data are converted to a European system. To avoid these problems, it will be the responsibility of Member States to provide data according to the proposed European datum.

ETRS89[2] is recognised by the scientific community as the most appropriate European geodetic datum to be adopted. It is defined to 1cm accuracy, and is consistent with the global ITRS[3]. ETRS89 is now available due to the creation of the EUREF[4] permanent GPS station network and the validated EUREF observations. It is already part of the legal framework of some EU Member States. Since 1989, ETRS89 co-ordinates, fixed in relation to the European

[2] ETRS : European Terrestrial Reference System
[3] ITRS : IERS Terrestrial Reference System (IERS : International Earth Rotation Service)
[4] EUREF : European Reference Frame

Plate, have regularly shifted from their values expressed in ITRS. However, this shift is well known, monitored by IERS[2] and EUREF, and transformations from one to the other are possible for most part within a 1 cm accuracy [1][2]. Appendix VI contains the full description of ETRS89 following the ISO19111 "Spatial Referencing by co-ordinates" standard [5].

The IAG[5] sub-commission for Europe (EUREF) has now defined a European vertical datum based on the EUVN[6] /UELN[7] initiative. The datum is named the EVRS[8] and is realised by the EVRF2000.

The National Mapping Agencies (NMA) or comparable Institutions / Organisations provided the information for the descriptions of the national Co-ordinate Reference Systems and for the transformation parameters between the national Co-ordinate Reference Systems and the European Co-ordinate Reference System ETRS89. Formulae can be requested from the NMAs or are directly accessible at http://crs.ifag.de/.

We give the following recommendations, partly described in the INSPIRE Architecture & Standards Final Position Paper [4]:

Geodetic framework

- *To adopt ETRS89 as geodetic datum and to express and store positions, as far as possible[9], in ellipsoidal co-ordinates, with the underlying GRS80 ellipsoid [ETRS89;.*
- *To use official formulae provided by NMAs or comparable National Institutions for the transformation between National Co-ordinate Reference systems and the ETRS89;*
- *To document National Co-ordinate Reference systems according to ISO19111;*
- *To further adopt EVRF2000 for expressing practical heights (gravity-related).*

Projection systems

There is a need for co-ordinate reference systems for pan-European applications for many statistical purposes (in which area should remain true) or for purposes such as topographic mapping (where angles or shapes should be maintained). These needs cannot be met through usage of the ETRS89 ellipsoidal co-ordinate reference system alone, and some map projections are required to supplement the ellipsoidal system (because the mapping of the ellipsoid cannot be achieved without distortion, and because it is impossible to satisfy the maintenance of area, direction and shape through a single projection).

[5] IAG : International Association of Geodesy
[6] EUVN : European Vertical Reference Network
[7] UELN : United European Levelling Network
[8] EVRS : European Vertical Reference System
[9] For some data (e.g., cadastral data), the adoption of geographical co-ordinates is not feasible in the short term and projected data should be accepted.

For applications we recommend the following projections [3]:

- for statistical analysis and display: a ETRS89 Lambert Azimuthal Equal Area co-ordinate reference system of 2001 [ETRS–LAEA], which is specified by ETRS89 as datum and the Lambert Azimuthal Equal Area map projection;
- for conformal pan-European mapping at scales smaller or equal to 1:500,000: ETRS89 Lambert Conic Conformal co-ordinate reference system of 2001 [ETRS–LCC], which is specified by ETRS89 as datum and the Lambert Conic Conformal (2SP) map projection;
- for conformal pan-European mapping at scales larger than 1:500.,000: ETRS89 Transverse Mercator co-ordinate reference systems [ETRS–TMzn], which are specified by ETRS89 as datum and the Transverse Mercator map projection.

Within the reporting activity of Water Framework Directive, the use of projected data could be necessary if some raster data (or maps) must be provided. In this case, and if a unique projection system is desirable, the use of ETRS–LCC seems the most appropriate.

3.7 Metadata

The aim of this Section is to clarify the position of the WFD GIS Working Group on geographic information metadata standards, and to provide practical technical guidance for the implementation of metadata.

Metadata is the information and documentation, which makes data understandable and shareable for users over time (ISO 11179, Annex B).

We can distinguish different types of metadata of increasing detail:

- Metadata for Inventory (i.e. internal to an organisation);
- Metadata for Discovery (i.e. necessary for external users to know who has which data, where to find them, and how to access them); and
- Metadata for Use (i.e. a fuller description of an information resource that enables users to make a judgement about the relevance and fitness-for-purpose of the resource before accessing it).

Appendix VII provides more information about standardisation activities in this field as well as more precise specifications for this standard.

Metadata standards are important as they unify the way in which data can be inventoried, discovered, and used. At the time of writing , no international standard on metadata is available. The resolution of the 14th plenary assembly of ISO TC 211 (Bangkok, 24-25 May 2002) has stated that the ISO standard No. 19115 Geographic Information – Metadata will be kept in the status FDIS[10] and the date of publishing of this standard was postponed to December 2002 [1].

[10] FDIS: Final Draft International Standard

However, taking into account the timeframe for the implementation of the Water Framework Directive, it seems reasonable to make the following proposal:

It is proposed to adopt the final draft international standard *ISO/FDIS 19115 Geographic Information - Metadata* and also to suggest some measures for the transition phase in order to minimise the impact on those countries using National or CEN pre-standards (TC 287 ENV 12 657).

It is recommended that in the mean time both the current draft of *ISO/TC211 19115 Geographic Information - Metadata*, and the suggestions of the Dublin Core (DC) metadata initiative for cross-IT searching are used.

Until the ISO 19115 standard is "officially" available and translated in all European languages, existing standards or pre-standards are acceptable. The countries deciding not to adopt ISO 19115 in the FDIS status should, however, adapt their metadata to ISO when the official standard is available. They should at least provide the mapping of the used standards to ISO 19115.

3.7.1 Scope of ISO 19115

The ISO 19115 defines the Scheme required for describing geographic information and services. It provides information about the identification, the extent, the quality, the spatial and temporal schema, spatial reference, and distribution of digital geographic data.

This ISO 19115 is applicable to:

- the cataloguing of datasets, clearinghouse activities, and the full description of datasets;
- geographic datasets, dataset series, and individual geographic features and feature properties.

This ISO 19115 defines:

- mandatory and conditional metadata sections, metadata entities, and metadata elements;
- the minimum set of metadata required to serve the full range of metadata applications (data discovery, determining data fitness for use, data access, data transfer, and use of digital data);
- optional metadata elements – to allow for a more extensive standard description of geographic data, if required;
- a method for extending metadata to fit specialised needs.

3.7.2 Core and Mandatory Elements of ISO 19115

The ISO 19115 consists of 22 core elements of which 12 are mandatory to comply with the international standard. The elements are described in Table 1 in Appendix VII. The mandatory elements focus on the discovery aspect of the metadata (catalogue purposes). Despite information on the metadata itself, they provide information on the title, the category, the reference date, the geographic location, and a short description of the data and the data provider.

The core set expands the mandatory elements with additional information on the type, the scale, the format, the reference system and the data lineage. These elements give rough information on the potential usage of the data.

For shared usage of the WFD spatial data, additional information on the data is necessary. The additional elements should include more detailed information, for example, on data quality or legal aspects of data usage.

3.7.3 Metadata Profile

The ISO 19115 for metadata comprises about 300 elements that exhaustively describe an information resource. Most of these elements are defined as being optional, i.e. they are not needed for compliance with the international standard but are defined for helping users to understand exactly the described data. Individual communities, nations, or organisations may develop a "community profile" of the standard according to their needs by selecting a set of metadata elements to be considered mandatory. A profile consists of the core metadata elements, and an additional set of optional elements that are then declared as a mandatory part of the profile. Additionally, a profile may add elements, i.e. extensions that are not part of the international standard.

The ISO 19115 describes rules for defining community profiles and extensions. A profile must not change names, the definition or data types of metadata elements. A profile must include all core metadata elements of a digital geographic data set, and all mandatory elements in mandatory and conditional sections, if the data set meets the condition required by the metadata element. Relationships between the elements have to be identified. Finally, the profile has to be made available to any user of the metadata.

A profile has to follow the rules for defining extensions. Metadata extensions are used to impose more stringent obligations on existing metadata elements. In addition, an extension can limit or extend the use of domain values for describing metadata elements.

The specific needs of reporting are not fully covered by the ISO 19115 mandatory elements neither by the core elements because they are not sufficient to describe data quality and legal aspects of data usage (see also Appendix VII).

There is agreement in the WFD GIS working group that the creation of a specific metadata profile for the Water Framework Directive is necessary.

The creation of a specific profile for the Water Framework Directive is highly recommended. The profile shall include the core elements and additional elements that are identified as necessary. The profile shall be mandatory for the data provided under the WFD reporting scheme.

The metadata profile to be developed:

- shall follow the rules laid down in ISO 19115 for creating metadata profiles;
- shall include a model for metadata;
- shall define common methods and formats for metadata exchange;
- shall be applicable to data sets and in addition to other appropriate levels of the data hierarchy;
- shall include the core elements and additional elements that are identified as necessary;
- shall include the data quality elements and the legal aspects elements described in Appendix VII;
- shall cover multilingual aspects.

Code lists shall be defined in all official languages of the European Union.

A thesaurus shall be generated to define the relationship between corresponding names in the different languages. Also text presentation should be possible in all European languages. As an alternative the adoption of a common language should be considered.

The metadata profile will be developed under the INSPIRE initiative. National WFD representatives should participate in the definition of the INSPIRE profile. This profile should be available by mid 2003 and should preferably be formally endorsed by CEN.

The metadata profile shall be reviewed in regular time intervals and if necessary adapted to new needs or developments in the GIS field.

In a later stage, the Member States shall also identify a competent authority for co-ordinating the national producers of data, for collecting and for managing the metadata. Metadata shall be kept up-to-date. Whenever data changes occur that might affect the current metadata content, the metadata have to be updated as well.

It is recommended that the metadata shall be implemented within a geographic data service (clearinghouse) on a wide area network and that Member States shall allow access to metadata via catalogues (INSPIRE will define the standard to be used for catalogue services). It is further recommended that a direct link between metadata and the described data should exist.

Acknowledgement

This Section and Appendix VII contain terms and definitions taken from ISO/DIS 19115, Geographic Information – Metadata [1]. They are reproduced with the permission of the International Organisation for Standardisation, ISO. This standard can be obtained from any ISO member and from the Web site of the ISO Central Secretariat at the following address: www.iso.org. Copyright remains with ISO.

Some of the ideas/proposals presented in this Section are drawn from documents produced by European projects like ETeMII [2] and Madame [3], from software manuals [4] and from the collaboration between JRC, Eurostat GISCO and the EEA.

3.8 Standards for Data Exchange and Access

The way data is collected and stored, its quality and coverage will vary from organisation to organisation. In order to reduce the likelihood of data being unusable by the Commission, common exchange formats need to be agreed. This also speeds up the quality assurance issue and makes the data readily available to other Member States. It is not sensible to nominate any one proprietary format as this may limit the software options of the Member States.

There is also the need to explore the options available to allow the enhancement of data delivery in the future. The priority however is the reporting needs in the short term. In this document short term refers to the delivery of data to the Commission in 2004. The longer-term goals are targeted at data delivery in 2009.

3.8.1 Short-Term Data Exchange and Minimum Long-Term Requirements

The **best practice** will be data exchange using Geography Markup Language (GML). GML is an XML encoding for the transport and storage of geographic information, including both the geometry and properties of geographic features. Many of the current commercial GIS packages offer the facility to import data in a GML format. The current versions of most GIS's do not offer the ability to directly export in GML. There are however, several data translators on the market which provide this functionality (an example is "Feature Manipulation Engine", more information at www.safe.com).

Using GML removes many of the problems caused by file conversion by some commercial and non-commercial GIS programmes. This also supports the long-term goal of using OpenGIS or other web based technologies for data transfer. The current version is GML Version 2.1.1. Later versions (as and when they become available) may be used. However the default will be 2.1.1. For further information see http://www.opengis.net/gml/02-009/GML2-11.html.

Conforming to the OGC Simple Features model, GML provides geometry elements corresponding to the following Geometry Classes:

- Point;
- LineString;
- LinearRing;
- Polygon;
- MultiPoint;
- MultiLineString;
- MultiPolygon;
- GeometryCollection.

In addition, it provides a Co-ordinates Element for encoding co-ordinates, and a Box Element for defining extents. The details of the encoding for each of these types of geometries can be found in Appendix VIII.

The **minimum** data exchange standard for vector data will be in a recognised open published standard file format. An example is the 'shape file' format (www.esri.com/library/whitepapers/pdfs/shapefile.pdf) that is compatible with the systems operated by the Commission or their nominated third parties. The exchange format will need to support points, lines and area features. Each feature must also have corresponding attribute data. This format will consist of at least the following:

- *Main file*: This is a direct access, variable-record-length file in which each record describes a shape with a list of its vertices;
- *Attribute file*: This contains feature attributes with one record per feature. The one-to-one relationship between geometry and attribute is based on record number. Attribute records in this file must be in the same order as the Main file. The attribute file is best supplied in a tabular format that can be read by most software packages including text processors. An example of an open standard format is Dbase IV.

The main file and the attribute file must have the same prefix. It is important in the shape file format that the first record in the main file contains the geometrical extent of the whole dataset.

The file must be able to handle integer (signed 32-bit integer (4 bytes)) and double-precision numbers (signed 64-bit IEEE double-precision floating point number (8 bytes)). The floating point numbers must be a numeric value.

The main file should contain a fixed-length file header (100 bytes) followed by variable-length records. Each variable-length record is composed of a fixed-length record header followed by variable-length record content.

The attribute file contains feature attributes. Fields present in the table should reflect the requirements of the data model. Another requirement is that the file name must have the same prefix as the main file. The table must contain one record per shape feature and the record order must be the same order as in the main file.

When non-geometric data are to be exchanged, the recommended standard is the ASCII COMMA DELIMITED format. In this format tabular data are written down per row. Fields are separated by comma (,) and strings are recognised by double quotes (""). Dates are reported in the YYYYMMDD format as a numeric value. The first row contains the fieldnames. The advantage of this format over a fixed position format is its flexibility. Also the use of reserved characters like 'TABs' or '@' tends to fail in user communities crossing various borders and languages.

3.8.2 Long-Term (Data Access)

The proposal for the long-term is to apply state of the art Geographic Information Technology focussing on accessing geographic data through custom internet browsers directly from the Member States.

Currently the technology is based on the Web Mapping (WM) standard for data transfer, focussing on maps as set by the International OpenGIS Consortium. Within the European Commission as well as some Member States this standard is currently successfully applied and appreciated for it simplicity and extendibility. However, the weakness of this system is the fact that it only delivers raster maps and is not feature oriented. There is also a need to ensure that the requirements of the INSPIRE initiative are considered, along with any developments in the technology providing this service.

Any web application requires at least two computer systems. The Client and the Server. The Server delivers data, the Client requests data. Typically a client needs a protocol to request a given selection of data which are available on the Server. In the WM standard, the clients primary interface will be the web browser. The request protocol is resolved in a so-called URL (Uniform Resource Locator). The latter can be specified in a manner as defined in the protocol.

The URL consists of two basic components:

- The URI or the Uniform Resource Identifier, which is commonly known as the web address. On this address (the Server) the software is running that can respond to the request. Example is http://www.opengis.org/cgi-bin/getmap?

- The request part in the WM standard consists of a group of parameters that is typically needed for mapping problems.

Using this standard, an interface be can set up that allows the user to map data from various sources in one interface. The server delivers an image containing the map. The client takes care of the ability to create a user-defined request.

Along with ?compliance to the standard, the following considerations are also important:

- A data source is identified by the URI part of the URL. All other components should be named equal;
- Important in this equality is especially the naming and corresponding standard symbology of the various layers;
- Note that one layer can have more 'styles';
- While mapping data for a giving bounding box with height and width, the client implicitly requests for data at a certain map scale. The symbology should account for this property. For example small rivers should not be displayed when viewing a map on 1:1000,000 scale. When zooming-in these small rivers should appear.;
- All data sources must be mutually consistent in geometric space. Thus a river mapping in Spain should not occur in a data source from France. Most polygon layers may not overlap in space and most line layers must connect both in horizontal space as well as in vertical space. For specific modelling issues it might be necessary that data is sent

from an upstream data source to a downstream data source in order to proceed with correct calculations of cumulated values;

- For ease of use all data will be served by default in geographic co-ordinates. Later versions might explore the various national or regional projection systems;
- In order to allow geometric overlap of various datasets, specific requirements might apply on the large-scale geometric quality of two bordering data sources.

The use of Web Mapping for the delivery of data to the Commission and beyond is hoped to become best practice. It is understood that there may be some technical or political difficulties, which may make this impossible for some Member States. In this case the minimum standard of data exchange to the commission will be GML as described above.

3.8.3 File Naming Conventions.

These are discussed in detail in the introductory Section of the data dictionary (Appendix III). File naming conventions facilitate the creation of automatic procedures to generate and upload datasets. Therefore, they are an asset in themselves.

File naming conventions are important in the short-term solution. They could become trivial in the long term, when the Member States provide an access service for the Commission to their map data instead of sending files out every six years.

4 Harmonisation, Co-ordination and Organisational Issues

This Section highlights some issues on the harmonisation and co-ordination necessary in order to arrive at a seamless product for Europe. It is not possible at this stage to specify the precise steps required for a full harmonisation, both because a preliminary evaluation is required for each layer and then because the process of harmonisation hugely depends on existing data, databases and information services. The precise knowledge of the state of the play is a prerequisite for a cost/benefit analysis as well as a more precise definition of all user requirements.

We propose to adopt the pragmatic approach foreseen in INSPIRE. The long-term vision of INSPIRE is to guarantee the access to information collected and disseminated at the most appropriate level (local, regional, national and European).

However, for the successful implementation of INSPIRE a stepwise approach is proposed. The various steps could partly be carried out in parallel, depending on the WFD user needs and the degree of availability and harmonisation of existing information. All these steps involve actions of standardisation, harmonisation and integration of data and services as illustrated in Figure 4.0.1.

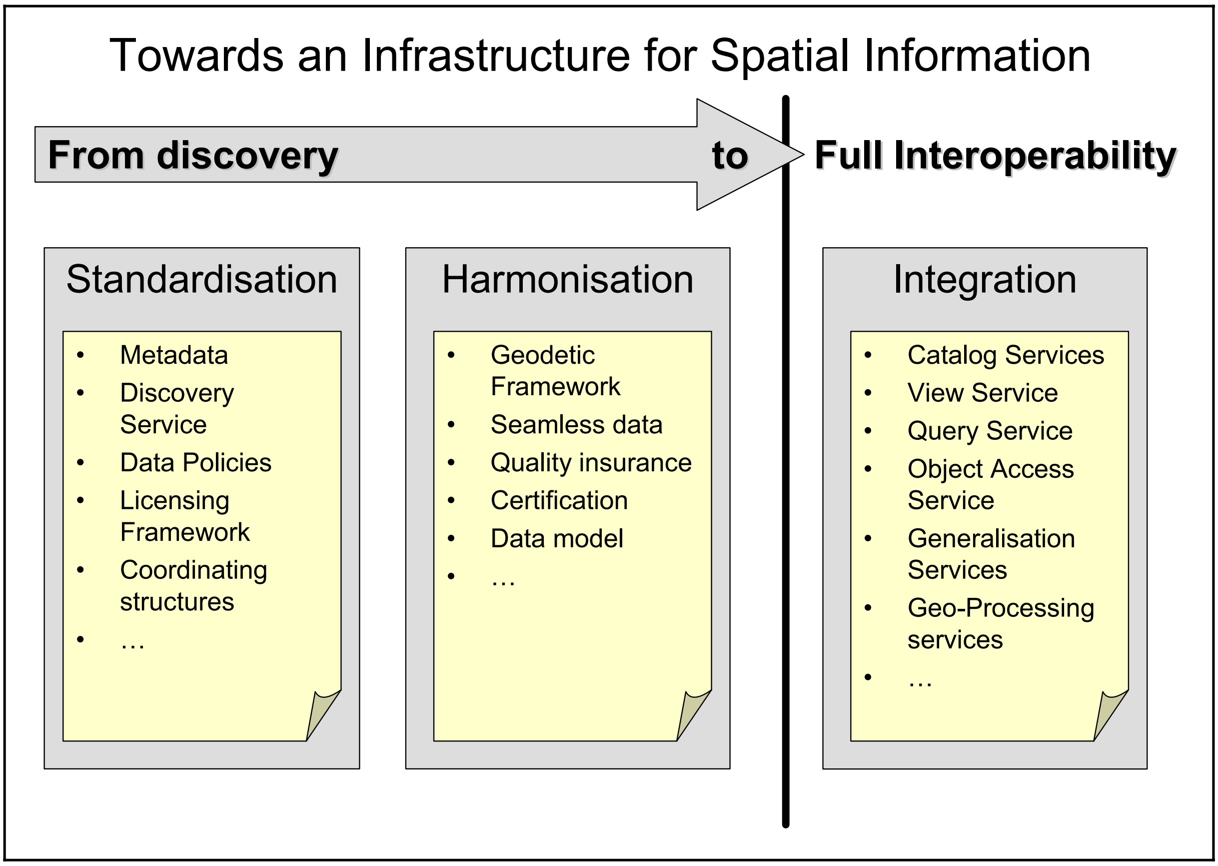

Figure 4.0.1: Towards an Infrastructure for Spatial Information

4.1 Harmonisation

The term harmonisation is used in this Section as the set of measures to be taken in order to develop a European product of comparable quality, starting from information (and services) available in the countries concerned by the WFD.

In this context we make distinction between 3 different European products:

- European seamless data;
- European database (centralised system);
- European federation of spatial data servers (de-centralised system).

The federation of servers is the final goal to be achieved in the long-term. The related harmonisation aspects will be developed under INSPIRE and should be adopted for the second reporting. These will, therefore, not be discussed here.

4.1.1 Geometric Harmonisation of Data

The need to harmonise the geometry is strictly related to the topological consistency within and between different features classes (data quality issues). This means that rivers crossing several countries should be connected and coherent in geometry and that features represented by polygons should not overlap (e.g. river basins, sub- basins and surface water bodies).

Figure 4.1.1 illustrates problems of possible overlapping or void areas in case of non-harmonised river basin district boundaries.

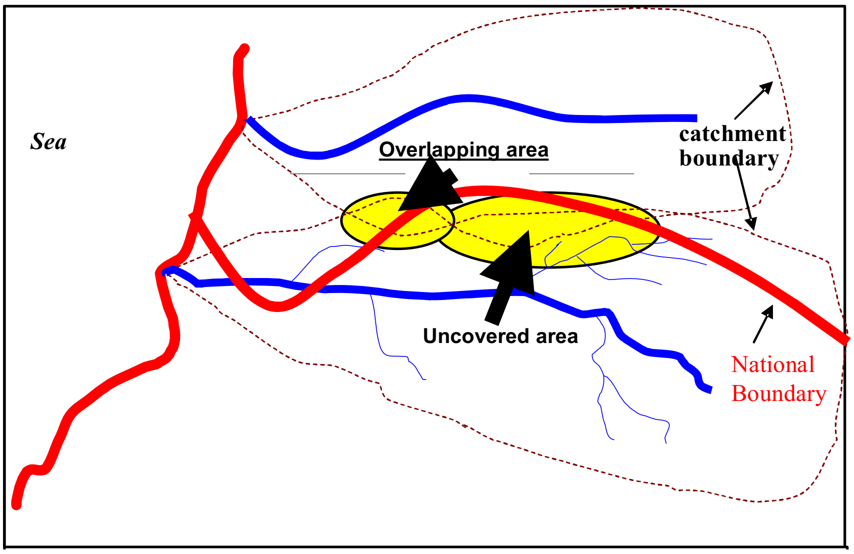

Figure 4.1.1: Possible problems due to the lack of a harmonised geometry

Geometric harmonisation is not a trivial task. We should profit from existing experiences such as SABE [1] (Seamless Administrative Boundaries of Europe) and ABDS [2] (Administrative Boundary Data Services) that show the difficulties to develop a full European operational seamless data set or service.

To obtain a common geometry, the adoption of common standards (e.g., same geodetic reference system, same positional accuracy) is not enough. Two countries should discuss and agree on the geometry to be used in the cross-boarder areas. Under the WFD, this is already foreseen as an obligation for International River Basin Districts.

To prepare a fully connected network we strongly recommend:

- The connection at the borders should be under responsibility of the Member States;
- The tolerance for connection at borders and the related accuracy should be better or equal to 1/10 of the accuracy of the dataset;
- The cartographic generalisation of data should be done at the level of the Member States;
- The use of common political boundaries (e.g., SABE) as well as of a European common layer for a coastline is strongly recommended in order to support the geometric harmonisation in the border areas.

After an evaluation of the two following options for data harmonisation:

1. Agreement on a common geometry at the beginning of the implementation phase; or
2. Harmonisation of the data at each reporting phase,

the GIS Working Group agreed to recommend option no. 1.

The adoption of the option "Agreement on a common geometry at the beginning of the implementation phase" is recommended because:

- it makes it possible to adopt a de-centralised solution in the future (in fact harmonisation is a prerequisite to do it);
- it makes it possible to have a full coherent picture of the European status (same data at European and National level); and
- in the long-term it is saving costs (the initial investment to agree on a common geometry will be recovered by the lower costs of updating and maintenance).

The main disadvantage is the initial effort to co-ordinate the harmonisation process. The following steps are necessary:

1. to agree on common data quality for reporting;
2. to discuss and harmonise the boundaries of trans-national river basin districts, including the connection of the river network;
3. to use/adopt the harmonised boundaries for national purposes;
4. to maintain the agreed boundaries as long as possible;
5. to re-start the process of harmonisation in case of changes;
6. to check that the agreed boundaries are used/maintained.

This level of harmonisation will be under the responsibility of National authorities that should apply, as far as possible, available ISO 19100 [3] series of standards for geographic information. It should be highlighted that all technical and harmonisation proposals strongly support the future implementation of a de-centralised reporting system.

In case of changes between two reporting periods, a harmonised geometry should be guaranteed at each reporting date.

4.1.2 Harmonised European database

The layers provided by the countries under the Water Framework Directive should be initially integrated in a European database (centralised system). This raises the issue whether or not to perform the vertical integration between layers (i.e. the logical and topological consistency between different features classes that refer to each other).

For the purpose of reporting, the vertical integration is not strictly required but for further analysis of the data it is a prerequisite.

The vertical integration requires these preliminary steps:

1. to adopt a common European geodetic framework (ETRS89);
2. to harmonise the geometry of different layers (harmonisation and eventually generalisation is under responsibility of Member States);
3. to connect the layers along the borders (under responsibility of Member States);
4. to adopt/support a European data model;[11]
5. to verify the topological consistency of different layers according to predefined geometric relationships.

It is recommended to use seamless harmonised reference data[12] in order to facilitate the vertical integration. The availability of such data is addressed and specifically perceived as a priority under INSPIRE (when the European Spatial Data Infrastructure will be in place, reference data will be easily available to support the "full" process of vertical integration). Until this happens other European reference data (such as EuroGlobalMap (1:1,000,000), EuroRegioMap (1:250,000) if available, or IMAGE2000) could be used as European reference for the thematic information and to support the vertical integration.

It is recommended to start the process of vertical integration limited to the layers relevant for the Water Framework Directive (excluding background layers). At the same time it is recommended to INSPIRE to consider the background layers of the Water Framework Directive as a priority for the short-term implementation.

4.2 Co-ordination

Co-ordination is a key issue for the implementation of the Water Framework Directive. The responsibilities and tasks of the Co-ordination Body or Task Force will be different in the various phases of the implementation.

It is recommended to establish a close co-operation within international River Basin Districts. This is necessary for a successful implementation.

[11] *Adoption means to use the same data model at National and European level, support means to guarantee the semantic interoperability between the National and the common European data model*

[12] According to the definition of the ETEMII white paper *"reference data is a series of dataset that everyone involved with geographic information uses to reference his/her own data as part of their work"*

4.2.1 1st Phase of Co-ordination (before the end of 2004)

In the first phase, co-ordination will be required to develop more precise specifications in collaboration with INSPIRE and to co-ordinate the harmonisation process.

It is recommended to set-up an office in charge to investigate user requirements and to support the implementation and maintenance of a de-centralised reporting system.

It is also recommended to install a thematic WG on water linked to INSPIRE that should:

1. follow-up INSPIRE developments;
2. contribute to the development of a dedicated metadata profile;
3. ensure a liaison with Framework Directive on Reporting;

5. follow-up of emerging standards for data exchange/access;
6. prepare guidelines for data product specifications;
7. ensure link to the case studies in the Pilot River Basins and integrate feedback into the Guidance Document;
8. prepare for the implementation of a European hydrological coding system, including a link to marine waters through a dedicated sub-group studying the issue;
9. investigate problems related to the analysis of underlying data and/or problems related to the analysis of pressures and impacts (subject to a request of the SCG).

Points 1-7 are related to reporting,
Points 8-9 are related to the access to underlying data and to the analysis of pressures and impacts.

Centralised system

The centralised system can be described as the European repository containing all data and some functionalities to access the information. It could be seen as the system in which the received data should first be harmonised and verified in order to correspond to the pre-defined requirements in terms of consistency (see chapter on data validation procedures).

The tasks for the Custodian of the centralised system will be the following:

1. Design and implement the centralised GIS;
2. Upgrade the centralised GIS to take into account new user requirements (e.g., resulting from the Pilot River Basin testing);
3. Data loading;
4. System maintenance;
5. Data dissemination.

Tasks 1 and 2 are mainly related to the initial stage.
Tasks 3, 4 and 5 are permanent work (heavier at each reporting phase).
Tasks 3 and 5 could be partly or completely automated, if necessary.

It is recommended to set-up an office for receiving, handling and validating data in the short-term (Custodian).

The custodian of the European database should be defined at an early stage in order to start with the system design and in order to define the procedures for data uploading and data access and dissemination.

It is also recommended to enforce the links with other WFD CIS working groups in order to consider the whole set of user requirements in the phase of system design.

4.2.2 2nd Phase of Co-ordination (2005 – 2006)

In parallel with phase 1, several steps should start in order to develop a more comprehensive and de-centralised system in the future. These steps should be co-ordinated and must involve the participation of all countries involved in order to support the implementation of the agreed European data model and to select and test the architecture of the Federation of Spatial Data Servers.

De-centralised system

While the co-ordination for a centralised system mainly implies the work of collection, harmonisation and dissemination of the data coming from Member States, a shared de-centralised architecture requires a strong co-ordination. This includes the checking of the compliance of connected systems with the technical specifications and their availability in operational mode.

The adoption of a de-centralised system implies different rules and responsibilities to guarantee the security and confidentiality of the data.

A de-centralised system in which the data (located on national servers) are directly made available by Member States, which should commit themselves to operationally run the services, is the preferred option in the long-term and is in line with INSPIRE principles.

It is recommended to adopt INSPIRE specifications for the national systems to be connected.

It is recommended to extend the mandate of the co-ordination Office or of the Custodian or to identify a new Agency to cover the additional tasks of the technical co-ordination. The tasks of this co-ordination body will include the checking of the compliance of connected systems with the technical specifications and their availability in operational mode.

5 Practical Experiences from the Prototype Exercise

This Section reports on different tests made in the frame of a prototyping exercise.

5.1 Introduction

The Water Framework Directive concerns a significant group of people involved in preparing maps and digital data to be reported to the European Commission as well as a currently less well defined user community involved in the analysis of these datasets. Both groups are hybrid in their knowledge and feeling at ease with computer technology.

Since both data preparation and analysis require advanced skills of computer technology, the GIS-WG tested some of the aspects discussed in this document in order to get deeper insight into the opportunities and problems to be expected during actual data preparation and analysis.

The prototyping effort has addressed the following topics:

1. Testing the emerging data exchange standards of ISO and OPENGIS;
2. Testing of parts of the common data model;
3. Testing the feasibility of the proposed coding mechanisms.

5.2 Emerging Data Exchange Standards of ISO and OPENGIS

During the GIS-WG meeting in March 2002 the so-called OPENGIS web mapping testbed facility was demonstrated to the GIS-WG. This technique allows generating maps on a remote server that can be visualised in common web-browsers. As a follow-up of this meeting, visual data integration was successfully demonstrated through a collaboration of JRC and Portugal. In this particular case study, a map of Portuguese river data (generated at the Portuguese web server) was overlaid with commune boundaries generated on a web server of the Commission. The example shown in Figure 5.2.1 refers to the Lisbon Area (data were projected using a Cylindrical Projection).

Following this demonstration, the members of the working group agreed that the evolving OPENGIS technology could be seen as a future aim. For the first WFD reporting period, most Member States felt, however, more at ease by sending GIS-layers or maps. Within the user communities of most Member States, the set-up of up-to-date web (map) server technology was not seen as a requirement of the Directive.

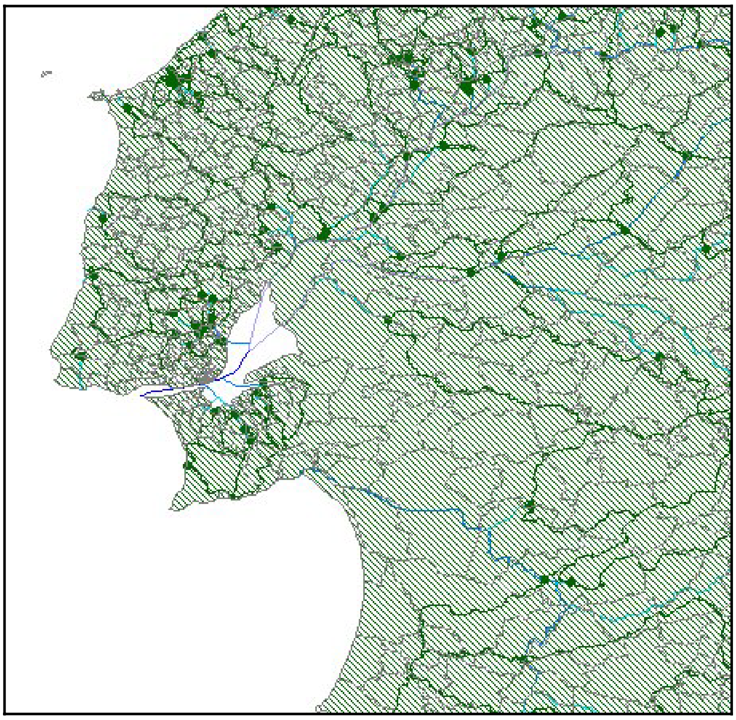

Figure 5.2.1: OpenGIS Web mapping example.

5.3 Testing of Parts of the Common Data Model

In the early discussions of the GIS Working Group, digital maps were seen as the most urgent deliverable. However, in the course of the discussions it became evident that in view of future developments more advanced solutions should be searched for.

Even though the reporting of digital maps has several advantages with respect to the delivery of analogue maps, it still prohibits the automatic analysis of the information provided. To support the latter, a common data model is needed, and the reported data need to be formatted accordingly. Such a data model is proposed in this document. Within the prototype activity, the working group defined an example web page with part of the physical model to be filled in by Member States (see Figure 5.3.1). Such web pages could help the organisations charged with sending in datasets.

By providing empty shapefiles, or ASCII delimited text files with examples, end users can be supported in setting-up the technical part of the dataset preparation. A robust finalisation of such a physical data model, in close conjunction with at least 3 pilot Member States and the presumed data custodian is an obvious recommendation that can be distilled from this activity.

Definition : Area covered by the *competent* authority, the member state part of a river basin district.
Delivered : Once by Reporter except for errors or significant change.
Implementation example : authorities.shp
Entity use in layer preparation : D7, SW1, SW3, SW4
Annex reference : I

Field name	Definition	Field type	Field length	Restrictions
MS_CD	Member state code, code allowing to refer to databases in use in the reporting organization, concatenated with the member state ISO code.	String	6	Mandatory, Primary
NAME	Locally used name, spelled in allowable characters Annex I.i	String	100	Mandatory, Unique
ADDRESS	Address for correspondence Annex I.i	String	200	Mandatory
POLYGONS	Geometric description of the district(s) managed by the competent authority, Annex I.ii	Geometry	resolution 250 meter	Mandatory, not outside territory of member state, exclusive, matching geometrically with the river basins
EU_CD	Code to be given by the data receiving organization	String	5	Feedback in 2005
INS_WHEN	Moment of insertion in the database	Date	8	Mandatory, YYYYMMDD
INS_BY	Acronym of operator responsible of insertion	String	15	Mandatory

Figure 5.3.1: Part of the example web page.

The set-up of a comprehensive inventory of the existing datasets in the Member States is a further recommendation resulting from this exercise. By giving precise guidelines on how to reformat existing datasets, Member States could be supported during data preparation.

The first data reporting will be based on so-called shapefiles and ASCII comma delimited text files. Depending on the evolution of recently introduced standards, one might expect that before 2009, when the larger parts of datasets are to be reported, most standards now mentioned have emerged to best practice.

5.4 Testing the Pfafstetter Coding Mechanism

As a perfection of the data model, it was proposed to develop a robust coding mechanism for the main entities to be reported under the WFD. The analysis of entities like river segments, lakes or catchments could benefit from a coherent coding, valid throughout the continent and its surrounding isles.

The so-called Pfafstetter coding was proposed as a means to obtain a unique numeric code at the level of each entity (e.g., river segment). The advantage of this coding is that it can be derived automatically from a consistent river network. Consequently, a user reading the Pfafstetter code of any segment can immediately understand the position of this segment in relation to other segments of the river network. Pfafstetter codes are based both on the area drained by a segment, and on the position of the segment within the network.

In the frame of the prototyping activity, an algorithm to generate this coding was developed, using the AML language. The algorithm proved that automatic generation is feasible even at detailed level. However, the river network has to be of high internal quality, especially with respect to the so-called topological relations between the segments. In addition for every river segment the area being drained is required before a Pfafstetter code can be determined. The algorithm consists of about 10 pages of AML code.

Next to coding the river segments it became evident that also the landmasses or seas are to be coded in a logical manner, in order to provide a unique code for each river segment. During the working group meeting of October 2002 a landmass coding was demonstrated as an example (see Figure 5.4.1). Note that in this example small islands within 3 km from a landmass have been coded with the same number as the adjacent landmass. It became, however, clear that a consistent sea-coding would be required, in-line with the WFD needs. The recommendation that evolved from this activity is that it is necessary to delineate sea areas in line with established international conventions, and to promote the sea code at the coastal outlet as an identifier to the upstream river network.

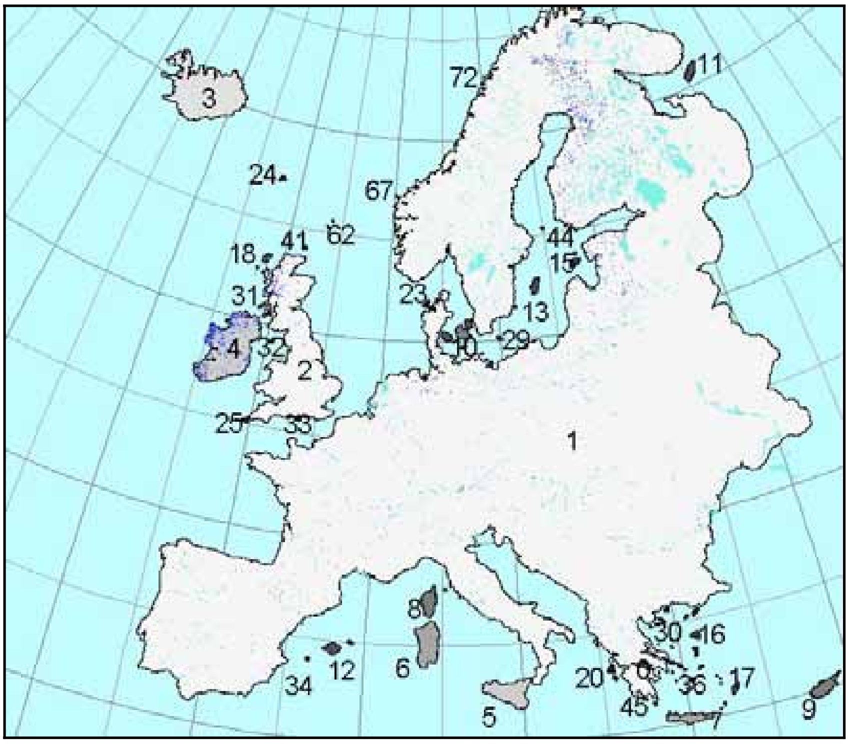

Figure 5.4.1: Example of Landmass coding based on surface area.

Figure 5.4.2 shows an example of the Pfafstetter coding for the river Thames in SE England. The outlet of the Thames in the Centre East of the map is coded '1', while the source in the North West is coded '99'. In line with the landmass coding, the full unique code of the source of the Thames would be 2299. The first '2' standing for the second largest landmass in Europe. The second '2' signifying the southern-most of the 4 largest watersheds on that landmass. The fourth '9' means that the source segment is subdivided one time. If we substitute the landmass code for a sea code, the first '2' in the Pfafstetter code needs to be exchanged for the code of south-western North Sea, for example. Assuming that this sea code would be '42', the full code would become 42299.

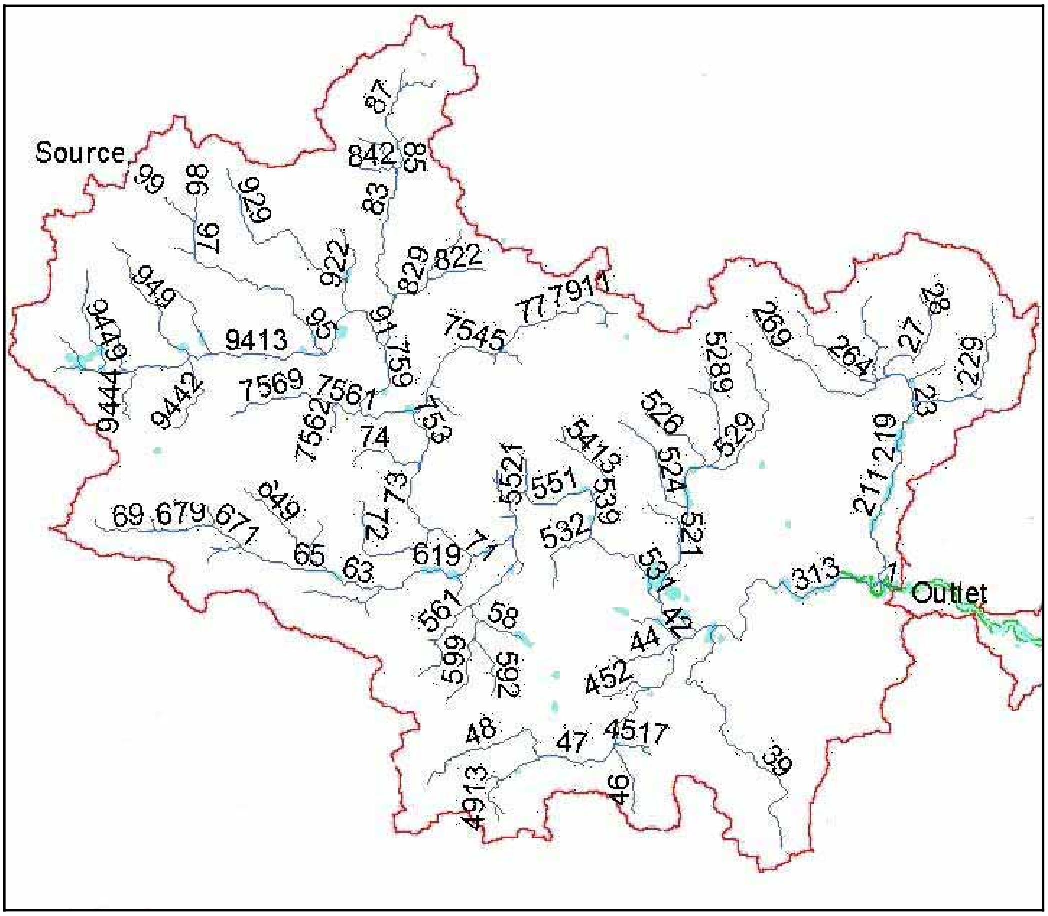

Figure 5.4.2: Example of the Pfafstetter coding of the river Thames and its tributaries.

Besides the Pfafstetter coding, other coding mechanisms are also documented in the literature. During the WG meetings, the Horton/Strahler system has been mentioned as being a valid alternative to the Pfafstetter coding, for example.

Most coding mechanisms assume flowing water along channels from the source to the sea. As a consequence, lakes, groundwater and coastal waters are not well or not at all represented. It became evident that a comprehensive coding of all water bodies covered by the WFD will require some further study, before a definite recommendation can be given.

It should be noted that any code must be regarded as a mechanism to ease analysis and to enhance communication between people about river segments. Computer systems, to the contrary, will always prefer system-generated identifiers that are in most cases logically meaningless and non-transparent to an end-user.

The JRC is about to finalise a new pan-European dataset of river segments, lakes, and catchments, automatically derived from a digital elevation model and ancillary data. This dataset, at a nominal scale of about 1:500,000, will include Pfafstetter codes and will be included in the Eurostat GISCO database. While it is not expected that this dataset can fully fulfil WFD needs, it will be a useful example for a possible implementation and an additional test. It might also help to fill important holes in the WFD generated datasets, such as the area of Switzerland.

5.5 Recommendations Resulting from the Prototype Activity

In the work of the GIS WG, the prototyping activity proved to be an important support to the theoretical discussions. Practical issues concerning data modelling, river coding and standardisation were put to the test, thus contributing to more realistic final recommendations. In a group representing more than 20 countries, cultures and manners, to organise water management, practical examples proved to stimulate discussions and to create a common awareness of the options that are available to everyone.

The coding algorithm, the example web pages for the custodian, and the practical experiences with OPENGIS map serving standards can form a starting point for an organisation yet to be defined. The set up of such an organisation will be a complicated task, not to be underestimated.

The most pertinent recommendations resulting from the activity are the following:

1. To test the proposed data model in collaboration with several Member States as well as with the data custodian;
2. To set-up a comprehensive inventory of the existing datasets currently available in the Member States;
3. To delineate sea areas in line with established international conventions and to agree on international codes for these areas.

6 Conclusions and Recommendations

The Water Framework Directive provides a legal framework for a wide range of actions, aiming to achieve good status for all waters in the European Union by 2015. Many of these actions require the handling of spatially distributed data and as such can potentially benefit from the use of Geographical Information System (GIS) technologies. In addition, the Directive explicitly calls for the reporting of most of the (spatial) information in a GIS compatible format.

Out of the range of possible GIS applications, this Guidance Document gives emphasis to the immediate reporting needs of the Water Framework Directive. As a consequence, it calls attention to the GIS layers to be prepared under the Directive and defines their characteristics (contents, spatial accuracy, time of reporting, etc.). It also underlines short-term and long-term possibilities for data exchange (i.e. centralised vs. de-centralised system), specifies how the GIS layers should be documented (i.e. metadata) and what should be done for harmonising the data across Europe. While the immediate needs of the Water Framework Directive require the set-up of a centralised system for reporting, it is noted that various initiatives at the European level, including the EAF on Reporting, strongly support the future implementation of a de-centralised system. The GIS Working Group, therefore, underlines the preference for the set-up of a de-centralised WFD reporting system in the long-term.

With respect to the level of detail of the data to be reported, the GIS Working Group strongly recommends an input scale of 1:250,000 as the common goal in the long term. However, current limitations in data availability and access require that data with an input scale of 1:1,000,000 can be used in the short-term, if they are complemented with additional objects in such a way that they meet the reporting requirements of the WFD. More detailed specifications with respect to the reporting requirements in terms of summary reporting to the Commission (small scale) and in terms of what Member States should have available upon request (large scale) will be further elaborated in the EAF on Reporting.

In addition, a European feature coding system for water bodies and catchments is proposed. The implementation of this feature coding system will be an important asset in the long-term, since it will allow for a more targeted analysis of the monitoring data and, in turn, will enable the development of a GIS with true analytical capabilities. In fact, feature coding is considered most important since it provides the link between reporting and analysis.

Due to limitations in time and due to the fact that some relevant information is not yet available for all elements of the Directive, other GIS-related aspects of the implementation could not be covered. These aspects include:

(i) the use of GIS in the analysis of pressures and impacts; or
(ii) the potential of GIS in supporting the establishment of River Basin Management Plans (e.g. the modelling of scenarios, the publication of spatial information).

It is further important to realise that also different aspects related to the reporting could not yet be definitely resolved. An example is the development of a specific metadata profile for

GIS layers emerging under the WFD. This is due to the fact that a number of international standards, which should be respected, are still under development.

The GIS-WG also decided not to include specifications on the map making process per se. This concerns not only cartographic details such as the layout, the colour codes, or the font types, but also issues of generalisation according to the map scale. We believe that the cartographic generalisation should be done at the Member State level and that the map production is best done at the level of the individual RBD authority, which will produce specific maps according to the RBD needs. At the European level, maps can be generated from the GIS layers according to the needs of the Commission. We would still recommend the set-up of a platform for exchanging experiences between the Member States and for publishing tools and colour specifications as a support to the map making process at all scales.

In addition, information technology develops at a very fast pace. As a consequence the long-term options could only be roughly outlined. As time progresses these options (e.g. the set-up of a distributed system for data reporting) will have to be further specified in accordance with evolving technical capabilities and standards.

The full implementation of an electronic reporting system will require a clear organisational structure, including the installation of a co-ordination body, capable to formulate clear requirements, to solve problems arising from the variable organisation of water management bodies in Europe, and to respond to technical questions arising from the implementation.

Finally, it should be noted that the specifications given here should be seen in the larger context of both the INSPIRE (Infrastructure for Spatial Information in Europe) initiative and the emerging Framework Directive on Reporting. The developments under these initiatives should be followed closely.

The successful implementation of the Water Framework Directive will require a close collaboration within international river basin districts. In order to ensure a harmonised data set, the GIS-WG strongly recommends using a common layer of national boundaries as well as one coastline. Also the adherence to the proposed data model is seen as an important asset in this direction.

Based on the experiences gained during the lifetime of the GIS-WG, the working group has formulated the following recommendations for the future implementation of GIS aspects under the Common Implementation Strategy:

1. It is recommended to rapidly install the office in charge of short-term receiving, handling and validating the maps and GIS layers requested under the reporting scheme of the WFD (Data Custodian). This body will be able to further co-ordinate the preparation of the requested data.

2. It is recommended to install an office in charge of investigating the user requirements and of supporting the long-term implementation and maintenance of a de-centralised reporting system. This office should enable the further development of the data model and of a European GIS for reporting.

3. It is recommended that a dedicated Thematic Working Group be installed under or linked to the INSPIRE initiative. This working group should:

   (a) follow the developments in the horizontal working groups under INSPIRE and should translate them into further guidance for the implementation of the WFD;

   (b) ensure a close liaison with the upcoming Framework Directive on Reporting;

   (c) contribute to the development of a dedicated metadata profile;

   (d) propose details for the data harmonisation process;

   (e) follow emerging standards for data exchange and access;

   (f) ensure a link to the Pilot River Basins and integrate the feedback from these case studies into the Guidance Document;

   (g) prepare for the long-term implementation of a European hydrological coding system, including a link to marine waters. This could be done through a dedicated small sub-group, studying the issue;

   (h) investigate problems related to the analysis of impacts and pressures and the analysis of underlying data, if so requested by the Strategic Co-ordination Group.

It is the hope of the members of the GIS-WG that the presented specifications will be a valuable support to the practitioners in the Member States, which are responsible for the preparation of the GIS layers and maps required under the WFD reporting scheme. In this sense, the presented Guidance Document could serve as a basis for the development of national Guidance Documents, taking into account the specific needs and circumstances of each Member State.

7 Appendices

Appendix I:The Elements of the WFD Relevant to GIS (original WFD text)

This appendix lists those parts of the Directive which directly or indirectly refer to the reporting of maps or data in a GIS compatible format. The excerpts from articles 3, 5, 13 and 20 as given at the beginning and shown in italics, are given for completeness. They do not directly refer to maps or GIS, but form the basis for the more detailed specifications in the appendices to follow.

Article 3: Co-ordination of administrative arrangements within river basin districts

1. Member States shall identify the individual river basins within their national territory and, for the purpose of this Directive, shall assign them to individual river basin districts. [...] Where groundwaters do not fully follow a particular river basin, they shall be identified and assigned to the nearest or most appropriate river basin district. Coastal waters shall be identified and assigned to the nearest or most appropriate river basin district or districts.

Article 5: Characteristics of the river basin district, review of the environmental impact of human activity and economic analysis of water use

1. Each Member State shall ensure that for each river basin district or the portion of an international river basin district falling in its territory:

- *an analysis of its characteristics,*
- *a review of the impact of human activity on the status of surface waters and on groundwater, and*
- *an economic analysis of water use*

is undertaken according to the technical specifications set out in Annexes II and III and that it is completed at the latest four years after the date of entry into force of this Directive.

[...]

Article 13: River basin management plans

[...]

4. The river basin management plan shall include the information detailed in Annex VII.

[...]

Article 20: Technical adaptations to the Directive

1. Annexes I, III and Section 1.3.6 of Annex V may be adapted to scientific and technical progress in accordance with the procedures laid down in Article 21, [...]. Where necessary, the Commission may adopt guidelines on the implementation of Annexes II and V in accordance with the procedures laid down in Article 21.

2. For the purpose of transmission and processing of data, including statistical and cartographic data, technical formats for the purpose of paragraph 1 may be adopted in accordance with the procedures laid down in Article 21.

Annex I: Information required for the list of competent authorities

As required under article 3(8), the Member States shall provide the following information on all competent authorities within each of its river basin districts as well as the portion of any international river basin district lying within their territory.

[…]

(ii) Geographical coverage of the river basin district - the names of the main rivers within the river basin district together with a precise description of the boundaries of the river basin district. This information should as far as possible be available for introduction into a geographic information system (GIS) and/or the geographic information system of the Commission (GISCO).

Annex II

1.1 Characterisation of surface water body types

Member States shall identify the location and boundaries of bodies of surface water and shall carry out an initial characterisation of all such bodies in accordance with the following methodology. Member States may group surface water bodies together for the purposes of this initial characterisation.

[…]

(vi) Member States shall submit to the Commission a map or maps (in a GIS format) of the geographical location of the types consistent with the degree of differentiation required under system A.

Annex IV: Protected Areas

2. The summary of the register required as part of the river basin management plan shall include maps indicating the location of each protected area and a description of the Community, national or local legislation under which they have been designated.

Annex V:

1. Surface Water Status

[…]

1.3. Monitoring of ecological status and chemical status for surface waters

The surface water monitoring network shall be established in accordance with the requirements of Article 8. The monitoring network shall be designed so as to provide a coherent and comprehensive overview of ecological and chemical status within each river basin and shall permit classification of water bodies into five classes consistent with the normative definitions in Section 1.2. Member States shall provide a map or maps showing the surface water monitoring network in the river basin management plan.

1.4. Classification and presentation of ecological status

[…]

1.4.2. Presentation of monitoring results and classification of ecological status and ecological potential

(i) For surface water bodies […] Member States shall provide a map for each river basin district illustrating the classification of the ecological status for each body of water, colour coded in accordance with the second column of the table set out below to reflect the ecological status classification of the body of water […]

Ecological status classification	Colour Code
High	Blue
Good	Green
Moderate	Yellow
Poor	Orange
Bad	Red

(ii) For heavily modified and artificial water bodies […] Member States shall provide a map for each river basin district illustrating the classification of the ecological potential for each body of water, colour-coded, in respect of artificial water bodies in accordance with the second column of the table set out below, and in respect of heavily modified water bodies in accordance with the third column of that table […]

Ecological potential classification	Colour code	
	Artificial WBs	Heavily Modified WBs
Good	Equal green and light grey stripes	Equal green and dark grey stripes
Moderate	Equal yellow and light grey stripes	Equal yellow and dark grey stripes
Poor	Equal orange and light grey stripes	Equal orange and dark grey stripes
Bad	Equal red and light grey stripes	Equal red and dark grey stripes

(iii) Member States shall also indicate, by a black dot on the map, those bodies of water where failure to achieve good status or good ecological potential is due to non-compliance with one or more environmental quality standards which have been established for that body of water in respect of specific synthetic and non-synthetic pollutants (in accordance with the compliance regime established by the Member State).

1.4.3. Presentation of monitoring results and classification of chemical status

[…]

Member States shall provide a map for each river basin district illustrating chemical status for each body of water, colour coded in accordance with the second column of the table set out below to reflect the chemical status classification of the body of water:

Chemical status classification	Colour code
Good	Blue
Failing to achieve good	Red

2. Groundwater

[…]

2.2.1. Groundwater level monitoring network

[…] Member States shall provide a map or maps showing the groundwater monitoring network in the river basin management plan […]

2.2.4. Interpretation and presentation of groundwater quantitative status

Member States shall provide a map of the resulting assessment of groundwater quantitative status, colour-coded in accordance with the following regime:

Good: green

Poor: red

2.4.5. Interpretation and presentation of groundwater chemical status

[…]

Subject to point 2.5, Member States shall provide a map of groundwater chemical status, colour-coded as indicated below:

Good: green

Poor: red

Member States shall also indicate by a black dot on the map, those groundwater bodies which are subject to a significant and sustained upward trend in the concentrations of any pollutant resulting from the impact of human activity. Reversal of a trend shall be indicated by a blue dot on the map.
These maps shall be included in the river basin management plan.

2.5 Presentation of Groundwater Status

Member States shall provide in the river basin management plan a map showing for each groundwater body or groups of groundwater bodies both the quantitative status and the chemical status of that body or group of bodies, colour-coded in accordance with the requirements of points 2.2.4 and 2.4.5. Member States may choose not to provide separate maps under points 2.2.4 and 2.4.5 but shall in that case also provide an indication in accordance with the requirements of point 2.4.5 on the map required under this point, of those bodies which are subject to a significant and sustained upward trend in the concentration of any pollutant or any reversal in such a trend.

Annex VII: River Basin Management Plans

A. River basin management plans shall cover the following elements:

1. a general description of the characteristics of the river basin district required under Article 5 and Annex II. This shall include:

1.1. for surface waters:
- mapping of the location and boundaries of water bodies,
- mapping of the ecoregions and surface water body types within the river basin,
- identification of reference conditions for the surface water body types;

1.2. for groundwaters:
- mapping of the location and boundaries of groundwater bodies;

2. a summary of significant pressures and impact of human activity on the status of surface water and groundwater, including:
- estimation of point source pollution,
- estimation of diffuse source pollution, including a summary of land use,
- estimation of pressures on the quantitative status of water including abstractions,
- analysis of other impacts of human activity on the status of water;

3. identification and mapping of protected areas as required by Article 6 and Annex IV;
4. a map of the monitoring networks established for the purposes of Article 8 and Annex V, and a presentation in map form of the results of the monitoring programmes carried out under those provisions for the status of:

4.1. surface water (ecological and chemical);
4.2. groundwater (chemical and quantitative);
4.3. protected areas;

[…]

B. The first update of the river basin management plan and all subsequent updates shall also include:

[…]

1. an assessment of the progress made towards the achievement of the environmental objectives, including presentation of the monitoring results for the period of the previous plan in map form, and an explanation for any environmental objectives which have not been reached;

[…]

Appendix II: Table of GIS Datasets and Layers Requested by the WFD

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes (see Data Dictionary for complete list)	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
1	**River Basin District -overview -**			D1, (D3)	annex I, ii) Geographical coverage of the river basin district- the names of the main rivers within the river basin district together with a precise description of the boundaries of the river basin district			1:4,000,000 Larger scale is also possible: 1:2,000,000 or 1:1,000,000		2004
		SW1	River Basin District		art 2, annex I, ii) River basin district means the area of land and sea, made up of one or more neighbouring river basins together with their associated groundwaters and coastal waters, which is identified under Article 3(1) as the main unit for management of river basins.	Name of river basin district, European code	Recommended: 125 metres Minimum: 1000 metres		This layer is required in digital format by the WFD. The boundaries of the river basin district are not only based on catchment boundaries, and are therefore separated from the layer river basin, sub basin	
		SW2	River Basin, Sub-Basin		art 2, annex I, ii) River basin means the area of land from which all surface run-off flows through a sequence of streams, rivers and, possibly, lakes into the sea at a single river mouth, estuary or delta. Sub-basin means the area of land from which all surface run-off flows through a series of streams, rivers and, possibly, lakes to a particular point in a water course (normally a lake or a river confluence)	Name of the river basin district Name of the basin/sub basin National code European code	Recommended: 125 metres Minimum: 1000 metres		Definition as in Art. 2, No. 14 WFD e.g., Mosel (G), Drau/Drawa (A)	
		SW3	Main Rivers		Main rivers of the river basin district used for general overview (selection of rivers from SW4)	Name of river European ID of river	Recommended: 125 metres Minimum: 1000 metres		Not only a selection of the rivers of SW4, but also a generalisation	

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes (see Data Dictionary for complete list)	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
2	**Competent Authorities**			SW1, SW3, D4,				Recommended 1:4,000,000 Larger scale is also possible: 1:2,000,000 or 1:1,000,000	The reporting scale of 1: 1,000,000 can be necessary if the size of competent authorities is small	2004
		D7	District of competent Authorities		annex I Area covered by the competent authority, the Member state part of the river basin district	Name of competent authority Address of competent authority Name of river basin district	Recommended: 125 metres Minimum: 1000 metres			
3	**Surface Water Body - categories -**			D1, D4, (D3), (D5)	annex II - 1.1, 1.2, VII - 1.1 Surface water bodies are first discriminated based on categories - rivers, lakes, transitional waters or coastal waters - or as artificial surface water bodies or heavily modified surface water bodies. Within each category a discrimination is made based on type (system A or B)			Recommended: 1: 250,000 Minimum: 1: 1,000,000	Map of types described in annex II - 1.1 2) Map of waterbodies described in annex VII - A.1.1 3) Map of ecoregion and types described in annex VII - A.1.1	2009 (*)
		SW4	Surface Water bodies - rivers - lakes - transitional waters - coastal waters if applicable, indicated as artificial surface water body or heavily modified surface water body			Category (river, lake, transitional water, coastal water) Name European Code National Code	Recommended: 125 metres Minimum: 1000 metres		Categories are described. This layer is required in digital format by the WFD.	

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
4	**Surface Water Body - types -**			SW4, D1, D4,	annex II - 1.1 - vi Same as map 3			Recommended: 1: 250,000 Minimum: 1: 1,000,000	1) Map of types described in annex II - 1.1 2) Map of waterbodies described in annex VII - A.1.1 3) Map of ecoregion and types described in annex VII - A.1.1	2004
		SW4a	Types of Surface Water Bodies, differentiated for each category			Type, number of values and underlying attributes can be different per category and between River Basin Districts	n.a. (linked to layer SW4)		Differentiation according to type (system A/B) is still in discussion by other working groups, the outcome effects layer SW4. This layer is required in digital format by the WFD.	
		D6	Ecoregions			Ecoregion code Name of Ecoregion	Recommended: 125 metres Minimum: 1000 metres		Ecoregion only required for map described in annex VII - A.1.1, can also be interpreted as an attribute of SW4	
5	**Groundwater bodies**			SW1, SW3, (SW2) D1, D4,	annex II - 2.1, VII - 1.2 Location and boundaries of groundwater bodies			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009 (*)
		GW1	Bodies of groundwater		Location and boundaries of groundwater bodies	Name of groundwater body ID of groundwater body	Recommended: 125 metres Minimum: 1000 metres		European coding - if accessible	

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
6	**Monitoring Network of Surface Water Bodies**			SW4 D1, D4, D5, (D2)	annex V - 1.3, VII - 4 Surface water monitoring network in the river basin management plan, the network contains also the points in the protected areas (map 12)			Recommended: 1: 250,000 Minimum: 1: 1,000,000	Possibly classified by categories	2009
		SW5 a	Operational monitoring sites Inclusive monitoring sites for habitat and species protected areas		annex V - 1.3.2, V - 1.3.5	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres		Inclusive monitoring sites for habitat and species protected areas (annex V - 1.3.5) and intercalibration sites	
		SW5 b	Surveillance monitoring sites		annex V - 1.3.1	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			
		SW5 c	Monitoring sites drinking water abstraction points from surface water		annex V - 1.3.5	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			
		SW5 d	Investigative monitoring sites		annex V - 1.3.3	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			
		SW5 e	Reference monitoring sites		annex II - 1.3 (iv)	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
7	**Ecological Status and Ecological Potential of Surface Water Bodies**			SW4, D1, D4, D8	annex V - 1.4.2 For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in High= Blue, Good=Green, Moderate=Yellow, Poor=Orange, Bad=Red. For heavily modified and artificial water bodies, the classification of the ecological potential is defined in a similar way.			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009
		SW4 b	Ecological status		See above	European code of SW body Ecological status: High, good, moderate, poor, bad	n.a. (linked to layer SW4)		Table related to layer SW4 (Surface water bodies)	
		SW4 c	Ecological potential		Classification of the ecological potential for each body of water (artificial water bodies or heavily modified water).	European code of SW body Ecological potential: Good and above, moderate, poor, bad	n.a. (linked to layer SW4)		Table related to layer SW4 (Surface water bodies)	
		SW4 d	Bad status or potential causes by (non-) synthetic pollutants.		annex V – 1.4.2-iii Those bodies of water where failure to achieve good status or good ecological potential is due to non-compliance with one or more environmental quality standards which have been established for that body of water in respect of specific synthetic and non-synthetic pollutants.	European code of SW body Non-compliant: true or false	n.a. (linked to layer SW4)		Table related to layer SW4 (Surface water bodies)	

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
8	**Chemical Status of Surface Water Bodies**			SW4 D1, D4, D8	annex V - 1.4.3 A map for each river basin district illustrating chemical status for each body of water, colour-coded in Good = Blue, Failing to achieve good = Red			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009
		SW4 e	Chemical status		See above	European code of SW body Chemical status: Good or 'Failing to achieve good'	n.a. (linked to layer SW2)		Table related to layer SW4 (Surface water bodies)	
9	**Groundwater Status**			GW1, SW1, SW3, D1, D4, (D2)	annex V – 2.5, VII – 4.2 Member States shall provide in the river basin management plan a map showing for each groundwater body or groups of groundwater bodies both the quantitative status and the chemical status of that body or group of bodies, colour-coded in accordance with the requirements of points 2.2.4 and 2.4.5. Member States may choose not to provide separate maps under points 2.2.4 and 2.4.5 but shall in that case also provide an indication in accordance with the requirements of point 2.4.5 on the map required under this point, of those bodies which are subject to a significant and sustained upward trend in the concentration of any pollutant or any reversal in such a trend.			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009
		GW1 a	Quantitative status of groundwater bodies		annexes V - 2.2.4, V - 2.5, VII - 4.2 Quantitative status of groundwater bodies: Good: green Poor: red	European code of GW body Quantitative status: Good or Poor	n.a. (linked to layer GW1)		Table related to layer GW1 (Groundwater bodies)	

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
		GW1 b	Chemical status of groundwater bodies		annex V – 2.4.5, V – 2.5, VII – 4.2 Chemical status of groundwater bodies: Good: green Poor: red	European code of GW body Chemical status: Good or Poor	n.a. (linked to layer GW1)		Table related to layer GW1 (Groundwater bodies)	
		GW1 c	Pollutant trend		Groundwater bodies which are subject to a significant and sustained upward trend in the concentrations of any pollutant resulting from the impact of human activity (black dot). Reversal of a trend (blue dot)	European code of GW body Pollutant trend: Upward or reversed Confidence level of the trend	n.a. (linked to layer GW1)		Table related to layer GW1 (Groundwater bodies)	
10	**Groundwater Monitoring Network**			GW1, SW1, SW3, D1, D4, (D2)	annex V – 2.2, V – 2.3, VII - 4 Groundwater level monitoring network; Surveillance monitoring network (chemical); Operational monitoring network (chemical).			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009
		GW2a	Groundwater level monitoring network		annex V - 2.2	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			
		GW2 b	Operational monitoring network chemical		annex V - 2.4	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			
		GW2 c	Surveillance monitoring network chemical		annex V - 2.4	Name of site European code Country name or code	Recommended: 125 metres Minimum: 1000 metres			

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
11	**Protected Areas**				annexes IV, VII - 3 Maps including the following types of protected areas as described with the layers (below)			Recommended: 1: 250,000 Minimum: 1: 1,000,000	Possibly a different map necessary for each layer	2009
		PA1	Drinking water protection areas	GW1 D1, D4, SW1,SW3	(i) areas designated for the abstraction of water intended for human consumption under Article 7;	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres			
		PA2	Economically significant aquatic species protection areas (shellfish)	SW1, SW4, D1,	(ii) areas designated for the protection of economically significant aquatic species;	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres			
		PA3	Recreational waters	SW1, SW4, D1, D4	(iii) bodies of water designated as recreational waters, including areas designated as bathing waters under Directive 76/160/EEC	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres			
		PA4	Nutrition-sensitive areas	SW1, SW4, D1,	(iv) nutrient-sensitive areas, including areas designated as vulnerable zones under Directive 91/676/EEC (Nitrates Directive) and areas designated as sensitive areas under Directive 91/271/EEC (Urban Waste Water Treatment Directive)	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres		Possibly 2 layers	
		PA5	Habitat protection areas (FFH)	SW1, SW4, D1,	(v) areas designated for the protection of habitats or species where the maintenance or improvement of the status of water is an important factor in their protection, including relevant Natura 2000 sites designated under Directive 92/43/EEC (habitats) and Directive 79/409/EEC (Birds).	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres			
		PA6	Bird protection areas	SW1, SW4, D1,	See above	ID or Name of protected area Protected area type	Recommended: 125 metres Minimum: 1000 metres			

Map No.	Map Name	Layer Code	Layer	Other Layers	Definition	Attributes	Positional Accuracy	Reporting Scale	Remarks	Date of Reporting to EC
12	**Status of Protected Areas**			SW1, SW4, D1,	annexes VII - 4.3 Results of the monitoring programmes carried out for the status of protected areas.			Recommended: 1: 250,000 Minimum: 1: 1,000,000		2009
		PA7	Status of protected areas			ID or Name of protected area Status	n.a. (linked to layers PA1 – PA6)		Table related to layers PA1 – PA6	
0	**"Background"**		Divers background layers							
		D1	International borders (NUTS 0)				Recommended: 125 metres Minimum: 1000 metres			
		D2	Corine Landcover							
		D3	Relief/Heights							
		D4	Settlements (selection of NUTS 4)		Only for reference, so bigger settlements					
		D5	Transport							
		D6	Ecoregions				Recommended: 125 metres Minimum: 1000 metres			
		D7	District of competent Authorities				Recommended: 125 metres Minimum: 1000 metres			
		D8	National borders (NUTS 1)							

(*) the date of reporting for maps No. 3 and 5 might change to 2004. See also footnote to Table 3.1.1 in Section 3.1.

Appendix III: Data Dictionary

The Data Dictionary provides a view of the data to be co-ordinated under the WFD as a generic (i.e. not dependent on any specific file format or database technology) representation as files / tables. For the attributes shown in the logical data model, a FieldName (shortened from the verbose description), a text description, a generic fieldtype and length, together with any restrictions (whether Mandatory or Optional, and any specific domains/codes to be used) are provided. Field names are shortened, primarily due to the physical restriction on field name length in commonly used data file formats (e.g. dBase – 10 characters). Fields relating to system B (WFD annex II) are shown in grey.

Classes and recommended file names are given in Table 1 below. File names are made up of a prefix (maximum 8 characters) and a suffix (3 characters). We recommend using a standard prefix for each class. The suffix will depend on the software used (see also Section 3.8).

The aim of the Data Dictionary is to provide a common understanding of the file / table structures that should be used for the WFD GIS data. The classes in the logical UML model which translate to tables are organised alphabetically as follows:

Table 1: Classes and Recommended File Names

Class	Recommended File Name Prefix
CoastalWaters	CWbody
CompetentAuthority	Compauth
EcoRegion	Ecoreg
FWEcologicalClassification	FWeccls
GroundwaterBody	GWbody
GroundwaterMonitoringStation	GWstn
GWStatus	GWstatus
LakeSegment	LWseg
LakeWaterBody	LWbody
MonitorGWBodies	GWmon
MonitorLWBodies	LWmon
MonitorRWBodies	RWmon
MonitorTWBodies	TWmon
PhysicoChemicalClassification	Pchemcls
ProtectedArea	Protarea
RiverSegment	RWseg
RiverWaterBody	RWbody
RiverBasin	Rivbasin
RiverBasinDistrict	RBD
SalineEcologicalClassification	Saleccls
SurfaceMonitoringStation	SWstn
SWStatus	SWstatus
TransitionalWaters	TWbody

CoastalWaters

Attribute	FieldName	Definition	Type	Length	Restrictions
Shape	SHAPE	Geometry (polygons)	Geometry		Mandatory
EuropeanCode	EU_CD	Unique code for a waterbody at EU level	String	24	Mandatory. As per coding guidelines
Name	NAME	Locally used name	String	100	Mandatory
MSCode	MS_CD	Unique code for a waterbody within MS	String	22	As per coding guidelines
EcoRegionCode	REGION_CD	Ecoregion to which a waterbody belongs	String	2	Mandatory. Foreign Key to REGION_CD in EcoRegion
System	SYSTEM	Type of characterization of a waterbody	String	1	Mandatory {A, B}
InsertedWhen	INS_WHEN	Moment of insertion in the database	Date	YYYYMMDD	Mandatory
InsertedBy	INS_BY	Acronym of operator	String	15	Mandatory
RiverBasinCode	BASIN_CD	The code of the parent river basin (see coding system)	String		Mandatory. Foreign Key to EU_CD in RiverBasin
StatusYear	STATUS_YR	Year of reporting of waterbody characterisation	String	4	Possibly can be dropped if duplicates INS_WHEN
HeavilyModified	MODIFIED	Whether the waterbody is heavily modified	String	1	Mandatory {Y, N}
Artificial	ARTIFICIAL	Whether the waterbody is artificial	String	1	Mandatory {Y,N}
SalinityTypology	SALINITY	Salinity category according to Annex II	String	1	Mandatory {F = Freshwater O = Oligohaline M = Mesohaline P = Polyhaline E = Euhaline}
DepthTypology	DEPTH_CAT	Depth category based on mean depth	String	1	Mandatory {S = Shallow <30m I = Intermediate 30-200m D = Deep >200m}
Latitude	LAT	Definition not	Number	8,5	Mandatory if Type = B.

Attribute	FieldName	Definition	Type	Length	Restrictions
		given in WFD. Assume Latitude (in ETRS89) of mathematical centre of waterbody			Can be calculated from supplied geometry
Longitude	LON	Definition not given in WFD. Assume Longitude (in ETRS89) of mathematical centre of waterbody	Number	8,5	Mandatory if Type = B. Can be calculated from supplied geometry
TidalTypology	TIDAL	Not defined – assume same as Transitional Tidal range category according to Annex II	String	5	Mandatory if Type = B {MICRO, MESO,MACRO}
CurrentVelocity	VELOCITY	Not defined			Optional
WaveExposure	WAVE_EXPO	Not defined			Optional
MeanWaterTemp	AV_W_TEMP	Not defined			Optional
MixingCharac	MIXING	Not defined			Optional
Turbidity	TURBIDITY	Not defined			Optional
MeanSubstratComp	SUBSTRATUM	Not defined			Optional
RetentionTime	RET_TIME	Not defined			Optional
WaterTempRange	W_TEMP_RGE	Not defined			Optional

CompetentAuthority

Attribute	**FieldName**	**Definition**	**Type**	**Length**	**Restrictions**
Name	NAME	Locally used name	String	100	Mandatory
Address	ADDRESS	Correspondence Address	String	200	Mandatory
AuthorityCode	AUTH_CD	Unique code for the competent authority.	String	24	To be defined

EcoRegion

Delivered once by Commission

Attribute	FieldName	Definition	Type	Length	Restrictions
Shape	SHAPE	Geometry (polygons)	Geometry		
Name	NAME	Locally used name	String	40	
EcoRegionCode	REGION_CD	Codes as specified by Annex XI	String	2	{1-25} {AT = Atlantic, NO = Norwegian, BR = Barents, NT = North Sea, BA = Baltic, ME = Mediterranean}

FWEcologicalClassification

Attribute	FieldName	Definition	Type	Length	Restrictions
StatusDate	STAT_DATE	Date for which this status assessment is valid	Date	YYYY MMDD	Mandatory
EuropeanCode	EU_CD	Unique code for freshwater body to which this status refers	String	24	Mandatory. Foreign Key to EU_CD in River / Lake
OverallStatus	ECO_STAT	Overall ecological status for the water body	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}
Phytoplankton	PHYTO	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}
Macrophyto	MAC_PHYTO	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}
BenthicInvertebrates	BEN_INV	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}
Fish	FISH	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate

Attribute	FieldName	Definition	Type	Length	Restrictions
					P = Poor B = Bad}
HydrologicalRegime	HYDRO_REG	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}
RiverContinuity	RIV_CONT	Annex V 1.2.1 Rivers only	String	1	Mandatory if waterbody is River {H = High G = Good M = Moderate P = Poor B = Bad}
MorphologicalConditions	MORPH_COND	Annex V 1.2.1 /1.2.2	String	1	Mandatory {H = High G = Good M = Moderate P = Poor B = Bad}

GroundwaterBody

Attribute	FieldName	Definition	Type	Length	Restrictions
Shape	SHAPE	Geometry (polygons)	Geometry		Mandatory
EuropeanCode	EU_CD	Unique code for a waterbody at EU level	String	24	Mandatory. As per coding guidelines.
Name	NAME	Locally used name	String	100	Optional
MSCode	MS_CD	Unique code for a waterbody within MS	String	22	Mandatory. As per coding guidelines
EcoRegionCode	REGION_CD	Ecoregion to which a waterbody belongs	String	2	Mandatory. Foreign Key to REGION_CD in EcoRegion
InsertedWhen	INS_WHEN	Moment of insertion in the database	Date	YYYY MMDD	Mandatory
InsertedBy	INS_BY	Acronym of operator	String	15	Mandatory
RiverBasinCode	BASIN_CD	The code of the parent river basin (see coding system)	String		Mandatory. Foreign Key to EU_CD in RiverBasin
Horizon	HORIZON	Unique identifier for the horizon, where separate, overlying bodies exist	Number	2	Optional
StatusYear	STATUS_YR	Year of reporting of waterbody characterisation	String	4	Possibly can be dropped if duplicates INS_WHEN

GroundwaterMonitoringStation

Attribute	FieldName	Definition	Type	Length	Restrictions
Shape	SHAPE		Geometry (points)		
Name	NAME	Locally used name	String	100	Optional
EuropeanCode	EU_CD	Unique code for a station at EU level	String	24	Mandatory. See coding guidelines.
MSCode	MS_CD	Unique code for a station at MS level	String	22	Mandatory. See coding guidelines.
InsertedWhen	INS_WHEN	Moment of insertion in the database	Date	YYYYMMDD	Mandatory
InsertedBy	INS_BY	Acronym of operator	String	15	Mandatory
Level	LEVEL	Station Type	String	1	Mandatory {Y,N}
Operational	OPERAT	Station Type	String	1	Mandatory {Y,N}
Surveillance	SURVEIL	Station Type	String	1	Mandatory {Y,N}
Depth	DEPTH	Depth in metres	Number	4	Optional

GWStatus

Attribute	FieldName	Definition	Type	Length	Restrictions
StatusDate	STAT_DATE	Date for which this status assessment is valid	Date	YYYYMMDD	Mandatory
EuropeanCode	EU_CD	Unique code for SW body to which this status refers	String	24	Mandatory. Foreign Key to EU_CD in GroundwaterBody
QuantitativeStatus	QUANT_STAT	Annex V 2.2	String	1	Mandatory {G = Good P = Poor}
ChemicalStatus	CHEM_STAT	Annex V 2.3	String	1	Mandatory {G = Good P = Poor}
PollutantTrend	POLL_TREND	Annex V 2.4 Not defined	String	1	Assume : {U = Upward D = Downward S = Static}
ConfidenceLevel	CONF_LEVEL	Annex V 2.4 – not defined	String	1	Assume : {H = High M = Medium L = Low}

LakeSegment

Attribute	FieldName	Definition	Type	Length	Restrictions
Shape	SHAPE		Geometry (polygons)		
LWBCode	LWB_CD	Unique code of LakeWater Body to which this segment belongs	String	24	Mandatory. Foreign Key to EU_CD in LakeWaterBody
SegmentCode	SEG_CD	Unique code for the segment	String	24	Mandatory.
Name	NAME	Locally used name	String	100	Optional

LakeWaterBody

Attribute	FieldName	Definition	FieldType	Length	Restrictions
Shape	SHAPE	Geometry (polygons)	Geometry		Mandatory
EuropeanCode	EU_CD	Unique code for a waterbody at EU level	String	24	Mandatory. As per coding guidelines
Name	NAME	Locally used name	String	100	Mandatory
MSCode	MS_CD	Unique code for a waterbody within MS	String	22	As per coding guidelines
EcoRegionCode	REGION_CD	Ecoregion to which a waterbody belongs	String	2	Mandatory. Foreign Key to REGION_CD in EcoRegion
System	SYSTEM	Type of characterizatio n of a waterbody	String	1	Mandatory {A, B}
InsertedWhen	INS_WHEN	Moment of insertion in the database	Date	YYYY MMDD	Mandatory
InsertedBy	INS_BY	Acronym of operator	String	15	Mandatory
RiverBasinCode	BASIN_CD	The code of the parent river basin (see coding system)	String		Mandatory. Foreign Key to EU_CD in RiverBasin
StatusYear	STATUS_YR	Year of reporting of waterbody characterisatio n	String	4	Possibly can be dropped if duplicates INS_WHEN
HeavilyModified	MODIFIED	Whether the waterbody is	String	1	Mandatory {Y, N}

Attribute	FieldName	Definition	FieldType	Length	Restrictions
		heavily modified			
Artificial	ARTIFICIAL	Whether the waterbody is artificial	String	1	Mandatory {Y,N}
AltitudeTypology	ALT_CAT	Altitude category according to Annex II	String	4	{HIGH, MID, LOW}
GeologyTypology	GEOL_CAT	Geological category according to Annex II	String	1	{C = Calcareous, S = Siliceous, O = Organic}
SizeTypology	SIZE_CAT	Size based on catchment area according to Annex II	String	2	{S = Small 0.5-1km M = Medium 1-10km L = Large 10-100km XL = >100km}
DepthTypology	DEPTH_CAT	Depth category based on mean depth	String	1	Mandatory {V = Very Shallow <3m S = Shallow 3-15m D = Deep >15m}
Altitude	ALT	Not defined			Mandatory if Type = B.
Latitude	LAT	Definition not given in WFD. Assume Latitude (in ETRS89) of mathematical centre of waterbody	Number	8,5	Mandatory if Type = B. Can be calculated from supplied geometry

Appendix IV: Unique Identification Coding Systems

1. Introduction

Many existing river coding systems were reviewed, these are documented at http://193.178.1.168/River_Coding_Review.htm. The historic attention to rivers was driven by the need to assign structure when identifying stream orders and nested sub-catchments. Other feature coding is more straightforward and has been largely ad-hoc.

Recommendations are going to upset established practices for most Member States. The benefits however necessitate that this task be undertaken. The Water Framework Directive demands that we manage and share environment data across national borders. At the core of this is the need to have a common approach to the way we reference components of the observed and managed environment.

The primary objective is to agree unique identification codes, which are harmonised internationally especially in the context of international river basins. The INSPIRE principles are considered with respect to the maintenance of codes by those who can do so most efficiently. Automated coding is also supported where appropriate with the objective of providing unique codes across numerous elements. Automation would in some instances also provide smart codes, which carry additional information about topological connectivity.

A common coding system will a) greatly facilitate the sharing of data across borders, b) form a framework for EU reporting and c) enable efficient electronic reporting at national and EU levels. Any other approach would merely put off the inevitable efficient structure that must evolve. Hopefully by acting now we can realise the benefits early at this crucial stage of implementation of the Water Framework Directive.

2. Required Coding Structure

2.1 Levels of unique identification coding

A. At the highest level, water bodies and river networks need to be identified;
B. These elements may need to be sub-divided. This cannot be fully predicted, as it may arise at a later date due to changes in ecological or physical boundaries. Thus, sub-division coding must not interfere with established primary coding;
C. Status monitoring, pressures and impacts are usually intrinsically linked to water bodies and thus may be developed as extensions of water body coding;
D. Diffused pressures are likely to be linked to many water bodies. Hence, they must be identified with their own codes and related back to water bodies through database links.

2.2 Coding Strategy

The proposed coding structure must adhere to the following:

1. Generation of unique European codes;
2. Establishment and maintenance of codes by those who can do so most efficiently.

It should also addresses the following important issues:

3. Generation of harmonised RBD and European codes where possible;
4. The use of codes that directly carry information, where possible and convenient, particularly where coding is automated. *(Such information can be used to a) directly determine hydrological connectivity, b) validate data and c) determine the organisations responsible for code maintenance.)*

Code maintenance is important and codes must be maintainable in a flexible way by a variety of independent organisations.

3. Local Spatial Features

These include pressures, status and impact monitoring and some water bodies. For example, municipal discharges, industrial discharges, agricultural pressures, groundwater abstraction points, coastal water bodies, etc. These features are generally identified and coded at a very local level and they lends themselves to the INSPIRE principle of data maintenance at one location and by those who can most efficiently do so. While feature codes are not strictly spatial data, but rather data tags, the same principle can be applied.

The recommended approach is:

1. Each Member States is uniquely identified by a 2-character code in accordance with ISO 3166-1-Alpha-2 codes;
2. Each MS, uniquely identifies the agencies or authorities, which manage or monitor local features. (For monitoring stations, the agencies of concern are those that establish them; other agencies may use these stations.
3. Local agencies or authorities assign, to features or monitoring stations, codes that are unique within local administrative areas;
4. Unique European codes are then generated by concatenating the above three elements.

Where there is only one organisation involved in the identification of particular features across the Member State, then step 2 above, identifying the coding agency, can be omitted.

In general a 4-digit code is recommended to identify coding authorities, features and monitoring stations. This can be split into a pair of 2 digit codes to represent local hierarchies and to enable infilling. However, Member States can use any feature coding structures required locally, provided:

- codes have a 2 character header attached prior to reporting at EU levels, which identifies the Member State, in accordance with ISO 3166-1-Alpha-2 country codes;
- the overall identification code does not exceed 24 characters (including the 2 character MS code);
- each identification codes generated is unique within the Member State.

4. Features with Hydrological Connectivity

Rivers are the primary example here, where gravity produces hydrological connectivity and flow direction. The extent of connectivity can reach across multiple Member States. Lakes, coastal waters and transitional waters are hydrologically connected through river networks. Hence it is wise to address rivers at the outset.

4.1 River Coding Approach

If rivers are already substantially identified, it may be pragmatic to extend existing coding. However, the number of additional rivers may amount to multiples of the number already coded. Also, codes may need to be reviewed for harmonisation with adjacent Member States.

River identification is likely to be computer-based. Coding could be as simple as sequential identifiers; however, structured hydrological codes are recommended. This enables rapid manual or automated analyses without the need to refer to GIS. The hierarchical nature of river structures lends itself to systematic nested coding. By using the same coding methodology at each tributary level, we can automatically determine codes and infer river connectivity.

A modified Pfafstetter system is recommended in the absence of alternative hydrological codes. The Pfafstetter system will need to be explored further to see if lakes can be better incorporated. Thus there may be further recommendations regarding its modification or replacement. For now, it is recommended on an interim basis and provides a mechanism to uniquely code river segments while also encapsulating river hydrological structures. Other hydrological coding or non-hydrological coding can be used, provided it uses unique identification codes, of lengths up to 22 characters. Codes of less than 22 characters should not be padded out with leading zeros ('0') for readability and to minimise data entry keying errors.

Both hydrological and non-hydrological identification codes should be preceded by two character codes to uniquely identify the Member State that assigned them.

4.2 River Coding

The main document explains the **MS MW N_1 N_2 N_3 N_4, …** code structure along with Modified Pfafstetter coding**.** Together the MW (Marine Waters) and N_1 N_2 N_3 N_4, … (river segment) components can provide unique hydrologically structured codes that integrate all surface water bodies. Alternatively these components can be replaced by any code not exceeding 22 characters.

4.3 River Coding - Practical Implementation Issues

4.3.1 Trans-boundary River Coding

Where Member States wish to co-operate in the generation of unique codes for trans-boundary rivers, the Pfafstetter system can be used. The highest level Pfafstetter code(s) could be established by the Member State with the coastal outlet. This will reserve the initial digit(s) for coding within each involved Member States, particularly along the main channel. More detailed coding can then be immediately undertaken in the border regions. Each Member State can then proceed with local detailed coding, at their own pace; yet when complete, the full catchment will be coded in a manner that enables hydrological connectivity to be ascertained.

The Pfafstetter approach can be used even where an adjacent Member State wishes to adopt a different coding practice. For example, downstream borders can be considered as marine borders. Catchment contributions from an upstream Member State can be assumed to come from a simplified catchment topology. Regardless of which approach is taken, there will always be a need to agree coding strategies along border regions.

4.3.2 Multiple Harmonisation Agreements

River identification coding may require independent harmonisation with different neighbouring Member States. Care is needed to ensure that multiple harmonisation agreements do not introduce the possibility of non-unique identifiers across different RBDs within the Member State. A number of options are available in this regard:

- A pan European or pan Member State river identifier coding system might be initially developed giving unique codes to all major rivers;
- Unique codes might be assured by the use of the MW code, a marine waters identifiers in accordance with the International Hydrographic Organisation delineation[1], with possible further local subdivisions per regional marine agreements;
- Where rivers drain into the same marine waters, the MS and MW header codes might be immediately followed by the coastal water outlet Member State code.

4.3.3 Impact of Lakes on River Codes

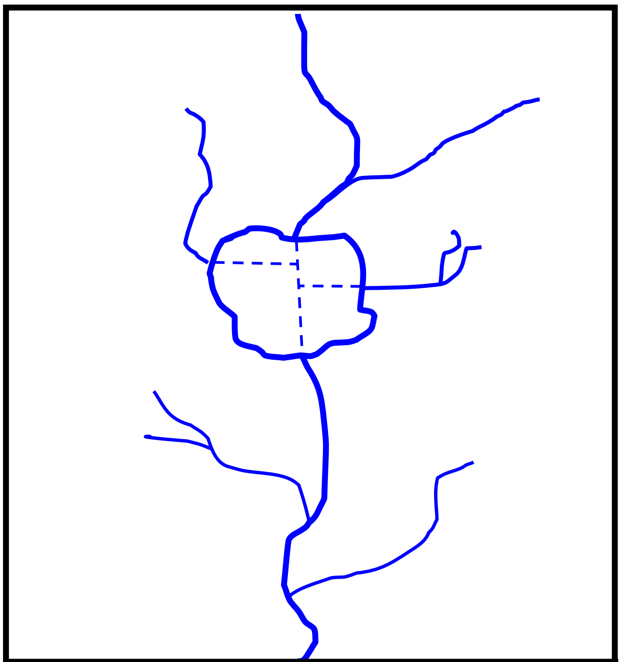

Fig.1. The network is connected manually through the lake. For simple lakes this could be straight lines joining the main channel to the lake tributaries.

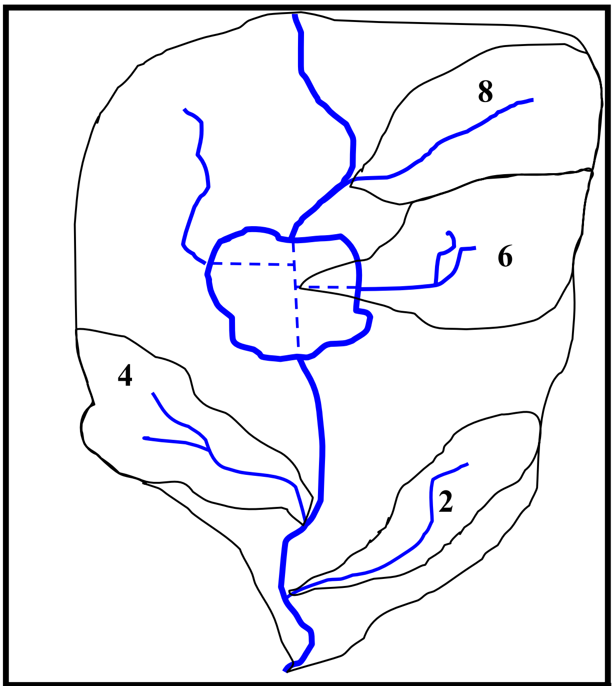

Fig. 2. The major tributaries are identified, while ignoring the presence of the lake.

The easiest way to code river reaches and their basins through lakes is to visualise lakes as wide river channels. This is presented in the Figures 1 and 2.

The river network is connected by simple line-work through the lake. For long curved lakes more extensive line-work is needed. The JRC and various Member States have achieved this with semi-manual procedures. The main tributaries of the resulting network are then coded.

By using a digital elevation model, and effectively ignoring the presence of the lake, we can determine how the sub basin boundaries cross the lake. Interpolation, between the elevation at the imaginary confluence and elevations outside of the lake, will generate a very slightly sloped surface, across the lake, draining towards the imaginary confluence. The lines of steepest gradient will then determine the imaginary watersheds across the lake.

The above method is reliant only on a digitised river network and on a digital elevation model to determine river coding. An undesirable result is that tributary catchments do not enter lakes at a point. This can be seen in Fig. 3 for tributary catchment '6'.

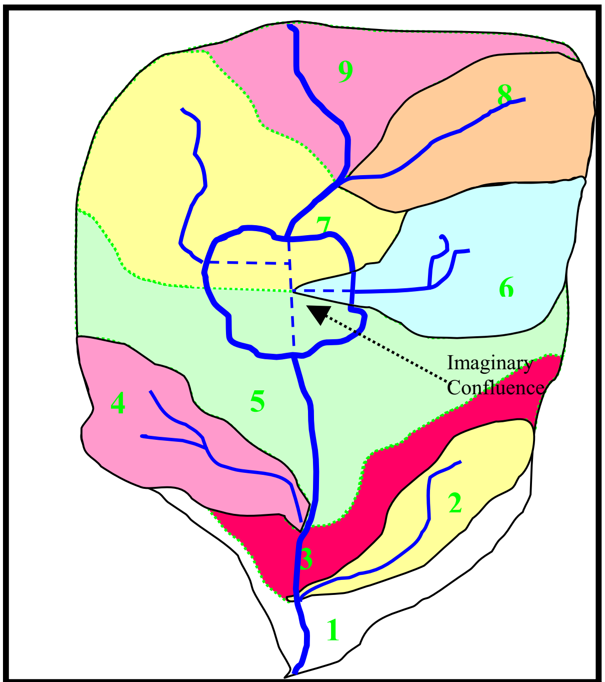

Fig. 3. The inter-basins are identified. Inter-basin boundaries meet, and cross, the lake at points determined by elevation model interpolation (e.g. basins 5 and 7)

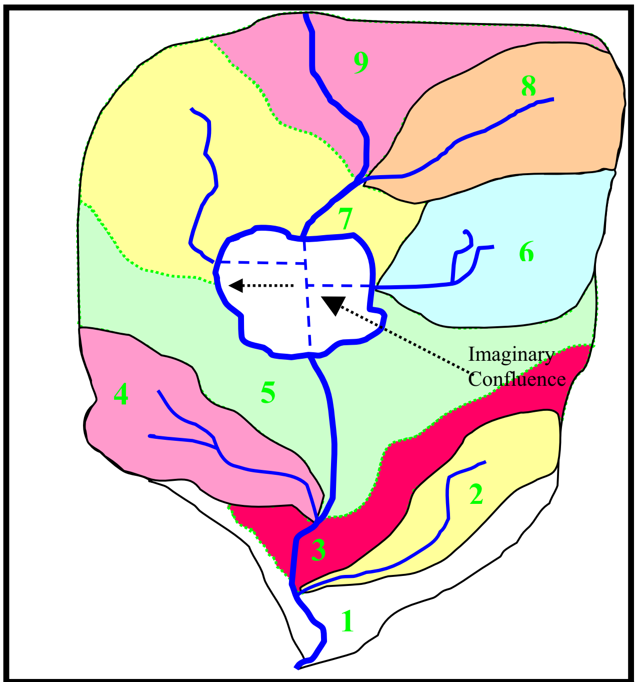

Fig. 4. Alternative approach to tributary catchment 06. Inter-basin boundaries meet the lake at a points determined by elevation model interpolation (e.g. basins 5 and 7).

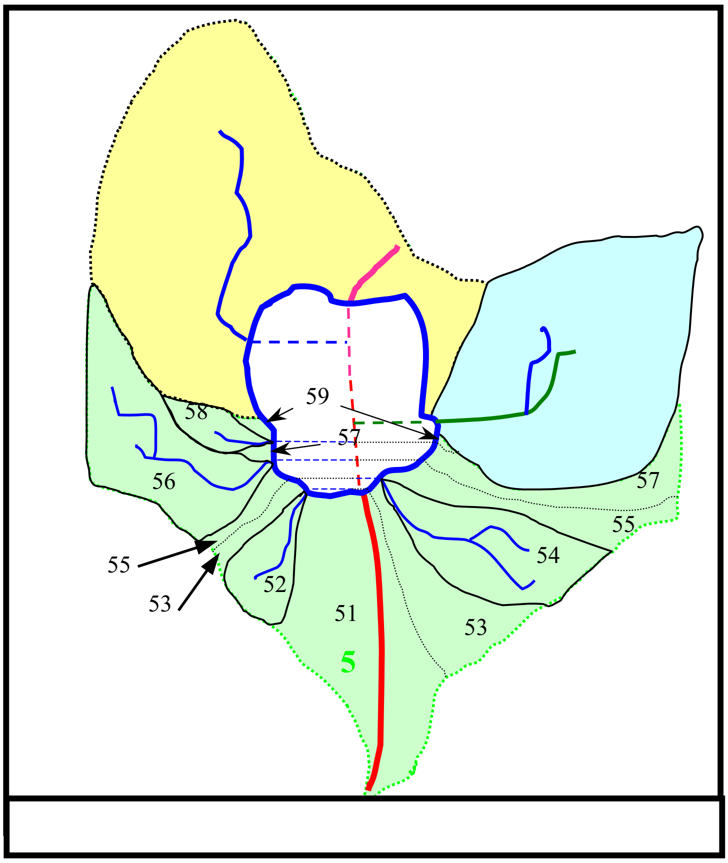
An alternative approach, which takes lakes into account, is shown in Figure 4. This method determines tributary catchments from the tributary and lakeshore intersection. The inter-basin catchments are determined as before, but are truncated at the lakeshore. This approach lends itself better to subsequent further levels of coding of smaller tributaries along the lakeshore and provides a better hydrological breakdown. It is thus the recommended approach.

To proceed with further levels of river coding, the lakeshore can be treated as though it was the river bank of a rather wide main channel. Thus the major tributaries are identified in the inter-basins and a new level of sub-basins and sub-inter-basins is established.

As this process progresses, while tributaries will be neatly identified, inter-basin codes will refer to pairs of disjointed lake shorelines. See Fig. 5.



Hence the inter-basin codes are not suitable for identifying lakeshores, and an independent parallel coding system is needed for that purpose. The system also splits lake-inter-basins, odd numbered catchments in Fig. 5. Tributaries draining into the lake are however coded in a hydrologically sound manner, as can be seen in Fig. 5 for even numbered catchments. Along with the main river channel, these tributaries will generally be the main source of inputs to lakes.

4.3.4 General Anomalies in River Identification Coding

Rivers may disappear into underground systems. The larger flow at a confluence may not come from the upstream contributing catchment with the largest surface area. These and other anomalies will require some level of manual intervention to aid what would otherwise be a largely automated coding process.

4.3.5 Testing the Pfafstetter Coding System

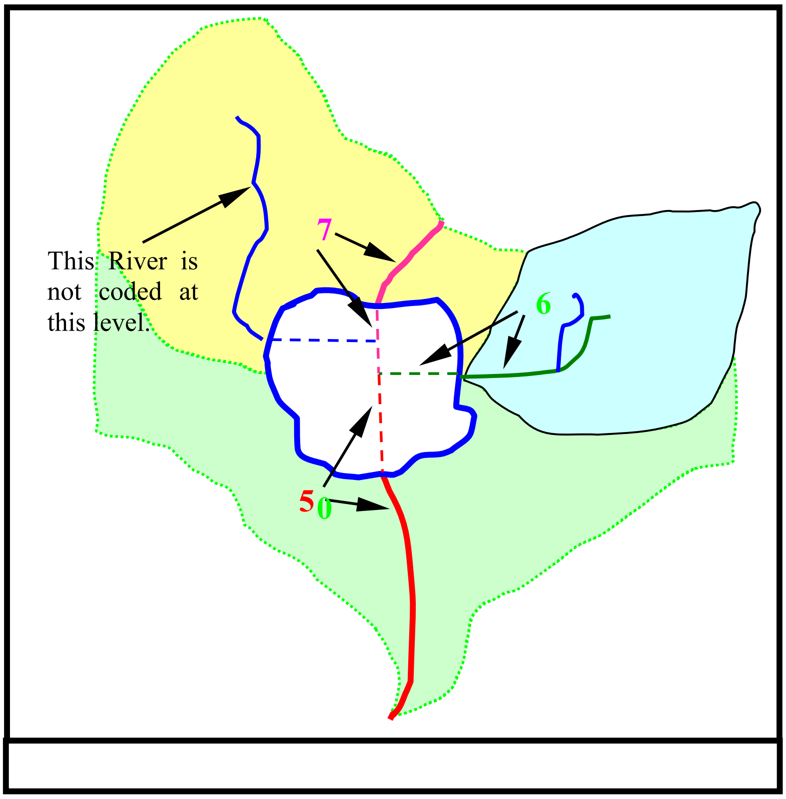
The JRC generated Pfafstetter codes across all of Europe in the prototype GIS. First river channels were identified from digital elevation models. Existing vector maps were used to automatically improve interpolation in flatter regions and to determine lake boundaries. River channels were connected through lakes. The codes generated were in general 6 digits long or less.

5. Lakes

5.1. Lake Coding

River reaches, or continua (imaginary reaches), within lakes, can be coded in the normal manner. A lake will typically be associated with many river reaches (real and imaginary). Fig. 6 demonstrates river codes generated around a lake. At this initial level of coding, there are 3 river reaches involved and the lake intersects each. As rivers and lakes will not usually meet at a drainage catchment boundary, we will not get neat inclusive relationships.

We need to select one code to uniquely represent the lake. The downstream reach code is a suitable candidate for this, as we already know that it is unique. In addition this reach is subject to all lake inputs. Thus, where hydrological river coding is deployed, the use of the downstream river reach code would also provide a degree of hydrological information to lake codes. Numeric upstream / downstream Pfafstetter tests could then be applied.



Shorelines could be identified by a further 2-digit code where even numbers identify the left bank and odd numbers identify the right bank. If additional subdivision is required, then an additional pair of digits can be added. These codes would be assigned manually, to identify administrative, hydrological, ecological and other boundaries. Intervals may be left to facilitate further subdivisions.

An alternative coding structure could be used for lakes and shorelines. Ideally the uniqueness of new lake or shoreline codes should be immediately visible to the person assigning them. Thus extensions of river network coding and the use of sequential identifies are desirable, with allowance for intervals within the sequence.

In summary then:

- Lake codes could use the same format as river inter-basin codes, e.g. '51' in the case of Pfafstetter coding in Fig. 6;
- Hydrological connectivity could be determined directly from lake codes if we use the downstream Pfafstetter or other hydrological river code;
- Lakeshores should use a sequential code format with allowance for later sub-division, such as 2 pairs of digits, e.g. 51-10/00;
- An objective should be to make uniqueness readily visible.

5.2. Dealing with Lake Anomalies

We may encounter:

1. Lakes which have no river outlet;
2. Lakes whose existence or extents are seasonal;
3. A number of small lakes of surface area >0.5 km^2 along a river of catchment size just greater than 10km^2;
4. Other special cases.

These exceptions will require manual intervention to assign reasonable unique codes. In the event that the anomalies are too numerous to achieve this, then use a simple system assigned code (e.g. a unique integer within a RBD or a hydrological area).

6. Transitional Water Bodies

The recommended river coding system will extend to marine waters and will maintain hydrological connectivity relationships. Those river reaches, which are wholly within the transitional waters area, can be assigned database attribute values to identify them as transitional. Around the transitional water body periphery, there will be river reaches, which are partially within transitional waters. Thus, we must rely on database attributes combined with GIS queries to identify the portions of river reaches that lie within transitional water bodies. And hence we can find no inclusive coding system that links directly with river coding.

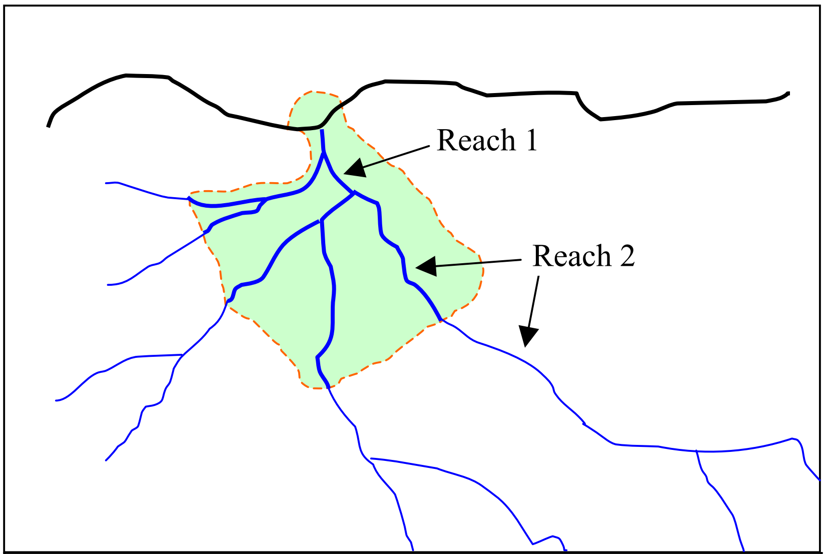


Figure 7. Rivers reaches wholly or partially in Transitional Waters

We can assign some hydrological intelligence to the transitional waters water body code if we use the down stream (outlet) river reach code as the code for the transitional water body. We can thus readily determine the upstream river catchments and lakes, which contribute to the freshwater inputs by referring to codes alone.

7. Coastal Water Bodies

As discussed under river coding sections, unique identifiers for marine waters can be provided internationally by using identifiers in accordance with the International Hydrographic Organisation delineation, with possible further local subdivisions per regional marine agreements. This area needs to be considered in conjunction with the findings of working groups concerned with the typology and classification of transitional and coastal waters.

8. Groundwater Bodies

The following code for **groundwater bodies** are recommended:

- a 2 character Member State Code (ISO 3166);
- an up to 22 character Groundwater Body code.

According to the WFD, groundwater bodies can be classified as single GW-bodies or as a group of GW-bodies. Furthermore GW-bodies can be classified as shallow or deep bodies, the definition of which is still under discussion.

GW-bodies might be divided into sub-bodies for several reasons. The WFD WG 2.8 "Guidance on tools for the assessment and classification of groundwater" has recommended the division of GW-bodies in sub-bodies for statistical purpose. Within the guidance paper, a criterion for monitoring networks is proposed and if the criterion is not fulfilled the monitoring network has to be adapted accordingly or the GW-body has to be sub-divided (http://www.wfdgw.net/).

WG 2.8 also developed a coding system for GW-bodies and sub-bodies. This system suits the statistical tool that was developed for the assessment and classification of groundwater. Within this tool GW-bodies and sub-bodies have different codes and can be addressed separately. Use of this system for GIS coding of GW-bodies would cause problems because the unique code for each polygon is made from two codes that are stored separately. A new unique code for each polygon would have to be introduced and as a consequence three codes would have to be maintained.

In future it might then be necessary to introduce a new code for trans-boundary GW-bodies to be able to assess the total body irrespective of Member State borders.

When assigning GW-bodies to river basins, the borders of river basins may not fit the borders of GW-bodies. The assignment of GW-bodies to river basins can only partly be done geographically. In many cases the assignment will be an administrative decision, handled within a database and will not be geographically reconstructable.

The above issues argue for a simple GW-body code as recommended and a more complex database solution with high flexibility.

9. Sub-Division of Primary Codes

9.1 Division of Rivers and Catchments

After identifying the river reaches that define the topology of the river, it will be necessary to subdivide these reaches for local management purposes. This subdivision will be necessary for river quality monitoring stations, industrial discharge points, ecological boundaries and physical boundaries such as those caused by weirs and changes in river channel geometry. This subdivision is going to be accomplished by manual means.

The need for common standards is determined by the needs for EU reporting but maybe more so by the needs of international RBDs. For example, we may want to divide a first order, and hence long, river reach into sections determined by water quality monitoring points or by sections upstream and downstream of major discharges or urban centres. As this is going to be largely a manual process, it is best to keep the coding simple and extendable.

The recommended approach is to use 2 pairs of digits. The first pair will enable up to 99 initial subdivisions of the reach. The second level would allow further break down of these at a later date. Intervals can be left to allow additional inputs. For example, the first upstream stretch on a reach might be numbered 10/00, the second 20/00. If necessary, the first section could be later subdivided at the top level by introducing 05/00. Lower level subdivision can be achieved by use of the second digit pair, e.g. 10/10, 10/20, 10/30, etc.

Thus if the river reach has a Pfafstetter code of 57, and a section on it is identified as 10/10, then the full section code is given by 57-10/10.

Practised variations on this approach include the use of upstream distance. This has the benefit of providing exact location. It has the disadvantage of requiring prior distance analyses and GIS can maintain location in any regard.

Which approach to take is a matter for individual Member States to decide upon. It is very dependent of the capabilities and structures of code management organisations. The primary objective must be to provide a mechanism for manual assignment of identification codes that allows immediate assurance of uniqueness by visual inspection.

When sharing GIS data, these sections should be provided as GIS line-work with this code attached to each element as its identifier.

9.2. Division of Lakes, Coastal, Ground & Transitional Waters

9.2.1. Division of Lakes

Subdivision of lakeshores has been discussed in Section 6.1. Lake regions, such as bays, etc, might be coded in a similar fashion, using initially 2 digits with a further 2 digits for subdivisions at a later date.

If '51' is a lake identifier, then:

- Lakeshores could use a format such as 2 pairs of digits, e.g. 51-10/00;
- Lake sub-regions could use a format such as 2 pairs of digits, e.g. 51-12/00.

Again, any unique coding mechanism can be adopted by Member States, but is strongly recommended that codes be easily reviewed visually.

When sharing GIS data, lakeshores and lake sub-regions should be provided as GIS line-work with this code attached to each element as its identifier.

9.2.2. Division of Coastal, Transitional & Groundwaters

Division of Coastal, Transitional and Ground Waters could take the same approach of assigning 2 pairs of digits, which allows for further sub-division. Any unique coding mechanism can be adopted by Member States, but is strongly recommended that codes be easily reviewed visually.

10. Pressures, Status and Impacts

10.1. Introduction

10.1.1. Coding Structure

This Section particularly lends itself to approach outlined in Section 3 'Local Spatial Features'. Hence unique European codes are generated by concatenating:

- a 2-character unique Member States code;
- a unique identifier for the local coding authority;
- a unique code for the feature administered by that coding authority.

10.1.2. The Impact of Laboratory Information Systems

All monitoring data is going to be processed through laboratory data management systems. Such databases are going to merge river monitoring samples with drinking water, bathing, landfill, lake, ground water, treatment plant, industrial discharge and other sample data. All samples taken are going to enter such databases in sequential order as they arrive at the laboratory. For feature codes to remain unique, within laboratory databases, it will be necessary to also identify the sample type.

The focus of such laboratory systems is on the laboratory process and not on the subsequent usage or ordering of the data. Sample type codes will also aid the subsequent separation of data into its GIS topics.

These additional sample type codes should be maintained within laboratory systems only, in an additional field alongside the feature coding field. To keep codes simple within GIS, it is not proposed that these laboratory tags be appended to proposed GIS codes.

For example, a river station would have a laboratory code such as 'RS'. This will be used to identify the type of sampling station at which the sample was taken. This will ease data displays, data reporting and data exports. But most of all, it will greatly assist electronic data transfer associated with the extensive pools of data that exist in laboratory systems.

It must be appreciated that such laboratory systems will be the data engines for much of the subsequent GIS thematics. Hence, we need to put in place practices that will ease the data flows to and from such systems. To do this, we need to identify the laboratory codes that will achieve this. Recommended laboratory codes are listed below.

10.1.3. Laboratory System Supplementary Codes

The following codes are suggested as possible identifiers within laboratory systems. These are database attributes, rather than identification codes, but they are required in combination with monitoring station codes for unique identification within laboratory system. They would thus provide a standard approach for direct access to such data from GIS.

'RS' for river stations.
'*LS*' for lake stations.
'CS' for coastal stations.
'TS' for transitional water stations.
'GW' for ground water stations.
'DW' for Drinking Water along with
- *'GWA'* to indicate Ground Water Abstraction, or
- *'SWA'* to indicate Surface Water Abstraction.

'BP' for bathing water stations.
'PI' for pollution incident samples.
'*DP*' refers to a sample taken at a Discharge Point (effluent). For monitoring of receiving waters at *Upstream* and *Downstream* locations, this should be replaced by '*DU*' and '*DD*' respectively. 'DP', 'DU' or 'DD' should be combined with
- '*IND*' to indicate an Industrial discharge, or
- '*COM*' for a Commercial discharge, or
- '*INS*' for a Institutional discharge, or
- 'AGR' for an Agricultural discharge, or
- 'PAV' for a Paved area discharge, or
- 'CSO' for a Combined Sewer Overflow, or
- 'WWT' for a Wastewater Treatment plant discharge, or
- 'WSP' for a Water Supply Plant discharge, or
- 'LFL' for Landfill Leachate.

10.2. Water Body Monitoring Stations

Transitional or Lake water body monitoring stations identification codes might be simple extensions to the overall water body code or the codes for the river segments that occupy the transitional water body. Either method will provide a mechanism for quick assignment of unique codes at a local level.

Thus if an Irish river stretch is identified as IE5441, and a station on that by 03/00, then the full station code is given by:

IE54410300.

In the example shown in Fig. 8., the transitional water body code would be '541'. Monitoring stations could be an extension of the water body code, '541'. Alternatively, as shown, they might be extensions of the river segment codes.

In laboratory databases, the code or attribute 'TS' (transitional station) might be associated with the code 'IE54410300' and 'RS' with 'IE5410450'.

Otherwise, monitoring stations might gain their unique identification codes as extensions of identification codes for local code assigning authorities. Other practical approaches to unique code maintenance may be possible. Visual confirmation of uniqueness and flexibility for all involved organisations should be incorporated into whatever approach is adopted.

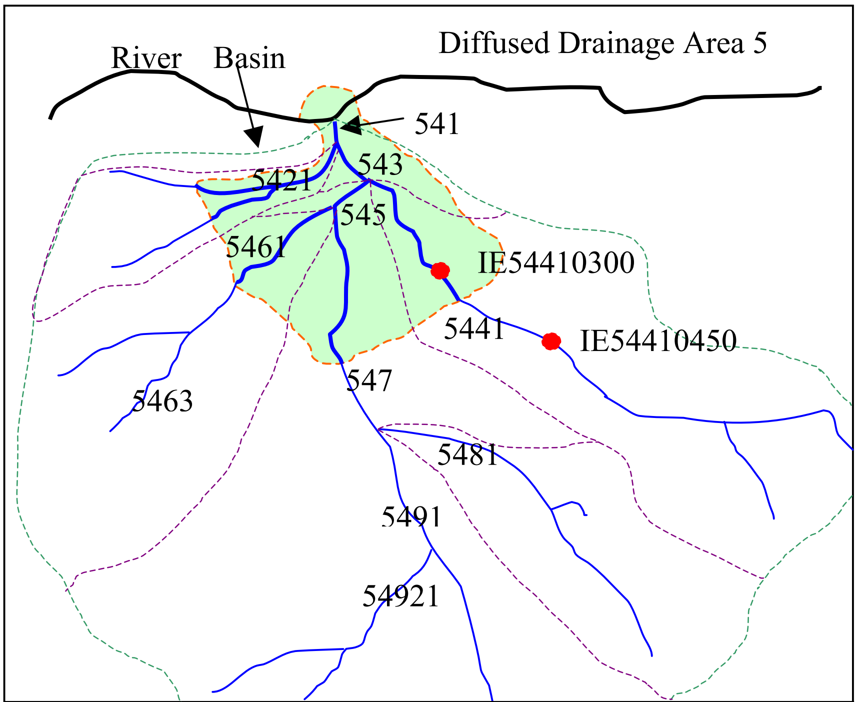

Figure 8. Rivers reaches wholly or partially in Transitional Waters

11. Introducing River Basin Districts

RBD competent authorities are not going to take on the regulatory functions of existing agencies. Thus other agencies are going to remain the primary source of feature identification. Hence it may cause confusion to try to introduce RBDs into the unique codes to be generated. It is suggested that the relevant RBD be identified through database fields and GIS.

12. Working within a Member State

Obviously the Member State component of codes, i.e. 'MS', can be dropped when using data at a local level, provided this information is added on to codes when required to be unique at a European level.

13. Additional Features

The chapter outlining recommended GIS layers identifies additional layers. These include administrative areas, background mapping and protected areas. These are covered by the general rule of supplying codes in the MS$\#_1\#_2\ldots\#_{22}$ format.

Protected areas layers are addressed by Natura 2000 which uses a two character Member State identification code followed by a 7-character code to identify SCI's (Sites of Community Importance) and SPA's (Special Protection Areas) within a Member State.

14. ISO 3166-1-Alpha-2 Country Names and Code Elements

The latest list can be acquired at:

http://www.din.de/gremien/nas/nabd/iso3166ma/codlstp1/en_listp1.html

Once feature codes are assigned, codes should not change. Hence, new country names and country codes should only impact on future feature coding. However, alternative arrangements may be agreed with adjacent Member States and the Commission.

Topological rules for GIS layers

River basins

must not overlap
must not have gaps
must be covered by extent of river basin districts
must not overlap with coastal waters
must not overlap with transitional waters
boundary must be covered by river sub basins
must cover features of river sub basins
must contain at least one river
must touch the coastline

River sub-basins

must not overlap
must not have gaps
must be covered by extent of river basin districts
must not overlap with coastal waters
must not overlap with transitional waters
must contain at least one river

River basin districts

must not overlap
must not have gaps
must cover features of river basins, surface water bodies, groundwater bodies, monitoring stations

Districts of competent authority

must not overlap
must not have gaps
must cover features of basin districts

(Main) Rivers

must not have dangles (exceptions are sources and mouths)
must not overlap
must not intersect (nodes at intersections)
must not touch interior
must be covered by boundary of river basins
mouths must touch river basin boundaries
must not overlap with coastal waters, transitional waters
must not intersect with river (sub) basins (nodes at intersections)
outlet of each feature must touch coastline

Lakes

must not overlap
must not overlap with coastal waters, transitional waters
must be covered by districts of competent authority, river basin districts

Transitional waters

must not overlap
must not overlap with coastal waters, rivers, lakes, river basins
must be covered by districts of competent authority, river basin districts

Coastal waters

must not overlap
must not overlap with transitional waters, rivers, lakes
must be covered by districts of competent authority, river basin districts
must touch transitional waters, river basins

Groundwater bodies

must be covered by districts of competent authorities, river basin districts

Monitoring stations

must be covered by area of districts of competent authorities, river basin districts

National boundaries on land and coastlines

must cover features of national delivery of river basins
boundary must be covered by national delivery of river basins

Non-quantitative data quality information

Data quality component	ShortName	Value
Purpose	idPurp	The Communes dataset is a general purpose geographic database for supporting different GIS applications of the European Commission.
Usage	specUsage	**Usage #1** Mapping of population statistics An important reason of the creation of the GISCO commune boundaries database is the use of these data in combination with the SIRE data in a Geographic Information System. Typical usage is the presentation of SIRE statistics in all kinds of maps. An illustrative example is the presentation of population statistics. **Usage #2** Structural Funds Another important usage of the GISCO commune boundaries database is the definition, validation, storage and monitoring of regions eligible for structural funding. In general complete municipalities are eligible, but in some cases they are only partly eligible. In Sweden, for example, a differentiation is made between the 'mainland' part of a municipality and the islands. Mainland and islands are eligible for different funds. Because in Sweden the original dataset of administrative boundaries did not include the islands explicitly, it is not possible to store and present eligibility for structural funds in a proper way only on the basis of administrative boundaries. **Usage #3** Degree of urbanisation Within the framework of the Labour Force Survey, municipalities are classified according to their 'degree of urbanisation'. Three classes of degree of urbanisation are defined on the basis of the algorithm below: densely populated, thinly populated and an intermediate class.
Lineage	dataLineage	**Source**: As a basis for the 1997 data set of the Commune boundaries for the European Union the SABE database of MEGRIN is used. The SABE database is compiled from official NGI sources. The source data are of the best available semantic quality and of the application scale the closest to 1:50,000 for each country. For the 1:1,000,000 scale coverage the 200 m resolution data from MEGRIN have been used. **Process Step**: Acquisition of SABE data sets. **Process Step**: Coding the CMFTTP **Process Step**: Structuring of data coverage according to overall database design requirements. - Integration of coastlines for SE, NO, FI, NL, HR, PL: Overlay the commune cover with the Scole (coastline). - Integration of lakes through an overlay of the commune cover with the lakes. - Topological quality. Sliver polygons were removed manually. Most sliver polygons were detected in those countries where the coastlines and lakes were integrated. **Process Step**: Appending all country coverages to one coverage. **Process Step**: Conversion to standard GISCO projection system: Lambert Azimuthal projection. **Process Step**: To make a unique coding the SHN code was combined with the country code, SHN = 031003 and ICC = PT makes CMRGCD97 = PT031003. Process Step: The NUTS 3 codes were filled with information from the NUEC1MV7 coverage. This was carried out by taking the commune points and overlaying them with the NUTS coverage. All points that

did not have a match with the NUTS coverage were removed. Then the point coverage was linked to the polygon coverage and the NUTS field in the polygon cover could be filled. All communes that did not have a NUTS code were coded manually. Lakes have been coded with 'LAK', e.g. in Italy lakes are coded 'ITLAK' as NUTS 3 code.
The CMRGCD could only be coded with NUTS level 5 codes for countries that have a link to the SIRE database. These are: AT, BE, DE, DK, ES, FI, IE, IT, LU, PT, SE. For all other countries the CMRGCD was coded with the lowest available NUTS code plus a number of X to fill the complete field.
The Eastern European countries were coded with NURGCD = 'EUCON' and CMRGCD = 'EU00000CON'. Lakes are coded according to the same principal 'EULAK' and 'EU00000LAK'. Within the Italian borders there are two communes that have been coded in a special way, i.e. the Vatican City (CMRGCD = VA00000CON) and San Marino (CMRGCD = SM00000CON).
Process Step: For those countries where a link exists to the SIRE database the name field (CMRGNM) could be filled with names from SIRE. For all other countries the name field has been filled with data provided with the SABE boundaries. These names are delivered as lower case and they contain special characters. According to the GISCO naming conventions the names had to be converted to UPPER case and all special characters were replaced with their **replace characters???**

Appendix VI: Reference System

ETRS89 Ellipsoidal Co-ordinate Reference System (*ETRS89*)

The European Terrestrial Reference System 1989 (ETRS89) is the geodetic datum for pan-European spatial data collection, storage and analysis. It is based on the GRS80 ellipsoid and is the basis for a co-ordinate reference system using ellipsoidal co-ordinates. The ETRS89 Ellipsoidal Co-ordinate Reference System (ETRS89) is recommended to express and to store positions, as far as possible.

Table 1 gives a full description of the ETRS89 Ellipsoidal Co-ordinate Reference System (ETRS89), following ISO 19111 Spatial Referencing by Co-ordinates.

Relationship between ellipsoidal and Cartesian co-ordinates

The co-ordinate lines of the ellipsoidal co-ordinate system are curvilinear lines on the surface of the ellipsoid. They are called parallels for constant latitude *(φ)* and meridians for constant longitude *(λ)*. When the ellipsoid is related to the shape of the Earth, the ellipsoidal co-ordinates are named geodetic co-ordinates. In some cases the term geographic co-ordinate system implies a geodetic co-ordinate system.

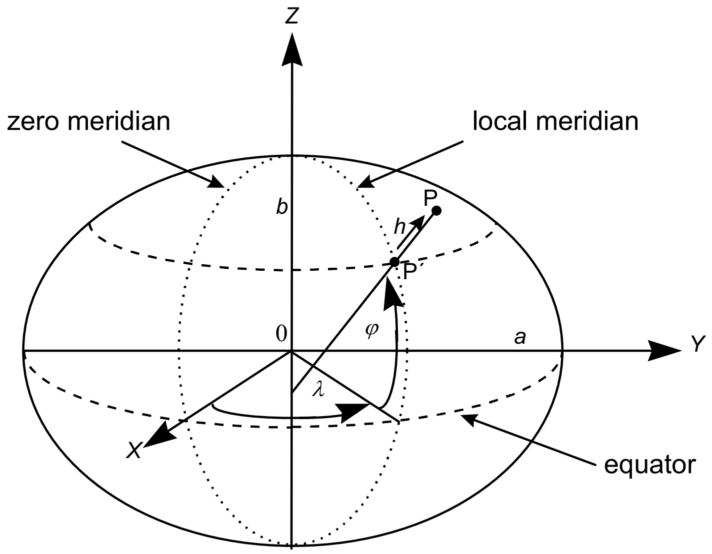

Figure 1 — Cartesian co-ordinates and ellipsoidal co-ordinates

If the origin of a right-handed Cartesian co-ordinate system coincides with the centre of the ellipsoid, the Cartesian *Z*-axis coincides with the axis of rotation of the ellipsoid and the positive *X*-axis passes through the point $\varphi = 0$, $\lambda = 0$.

Table 1 – ETRS89 Ellipsoidal Co-ordinate Reference System Description

Entity	Value
CRS ID	ETRS89
CRS alias	ETRS89 Ellipsoidal CRS
CRS valid area	Europe
CRS scope	Geodesy, Cartography, Geoinformation systems, Mapping
Datum ID	ETRS89
Datum alias	European Terrestrial Reference System 1989

Co-ordinate system axis direction	up
Co-ordinate system axis unit identifier	metre

Appendix VII: Detailed Specifications for Metadata

1. Main metadata standardisation initiatives

Metadata is the information and documentation, which makes data understandable and shareable for users over time (ISO 11179, Annex B). We can distinguish different types of Metadata of increasing detail: Metadata for Inventory (i.e. internal to an organisation), Metadata for Discovery (i.e. that is necessary for external users to know who has what data, where to find it, and how to access it), and Metadata for Use (i.e. a fuller description of an information resource that enables users to make a judgement about the relevance and fitness-for-purpose of the resource before accessing it).

At the time of writing this report, no international standard on metadata is available. The European Committee on Standardisation (CEN) Technical Committee 287 developed a pre-standard on GI metadata in 1997, and the Federal Geographic Data Committee (FGDC) in the USA works at a national level on GI metadata standards.

Based on the experience of various standardisation bodies, the International Standardisation Organisation (ISO) is developing in its Technical Committee 211 a family of standards related to geo-spatial information, including one for metadata, ISO 19115. The resolution of the 14th plenary assembly of ISO TC 211 (Bangkok, 24-25 May 2002) has stated that the ISO standard No. 19115 Geographic Information – Metadata will be kept in the status FDIS and the date of publishing this document was postponed to December 2002.

In addition to the standardisation activities described above, other initiatives have emerged that gained wide support. One is the Dublin Core (DC) international initiative. It is not intended specifically for GI but focuses on the Discovery aspect of metadata related to multimedia in general. It helps discover information resources across disciplinary or sectoral domains.

Another relevant standard is ISO/IEC 11179, *Information technology — Specification and standardisation of data elements*. ISO/IEC 11179 is an international standard for formally expressing the semantics of data elements in a consistent manner, and is used as a base for many other standards, including DIS 19115.

Some organisations have already started to implement metadata, either in a proprietary "standard", or by adopting the recommendations of some national or international consensus process. Examples are the pre-standard of CEN/TC287, or the GISCO data dictionary. It is therefore desirable that appropriate migration mechanisms are set-out that allow to convert existing metadata into ISO 19115. Existing conversion, also called "mapping", exists between CEN/TC287 metadata elements and ISO 19115 and Dublin Core elements.

Recently the EC, EFTA and the European Committee for Standardisation (CEN) agreed to finance a project that will lead to an official mapping between Dublin Core elements and those of ISO 19115 (GI Metadata). The work, which takes form as a CEN Workshop Agreement (CWA), will result in three deliverables: the mapping (a draft of which is expected to be available by December 2002), a Guidance Document, and a spatial application profile. More information is available from http://www.cenorm.be/isss.

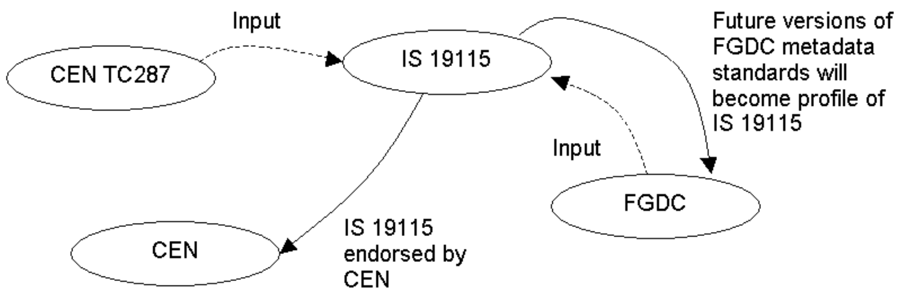

Figure 1: The CEN and FGDC (pre-)standards on metadata have given an important contribution to the creation of DIS 19115 (dashed lines).
No reference to Fig in text

2. ISO and the International Standard ISO 19115

ISO (the International Organisation for Standardisation) is a world-wide federation of national standards bodies (ISO member bodies). The International Standard ISO 19115 Geographic information - Metadata was prepared by Technical Committee ISO/TC 211: Geographic Information/Geomatics. ISO 19115, for example, highlights:

"*Digital geographic data is an attempt to model and describe the real world for use in computer analysis and graphic display of information. Any description of reality is always an abstraction, always partial, and always just one of many possible "views". This "view" or model of the real world is not an exact duplication; some things are approximated, others are simplified, and some things are ignored. There is seldom perfect, complete, and correct data. To ensure that data is not misused, the assumptions and limitations affecting the creation of data must be fully documented.*

Metadata allows a producer to describe a dataset fully so that users can understand the assumptions and limitations and evaluate the dataset's applicability for their intended use.

As geographic data producers and users handle more and more data, proper documentation will provide them with a keener knowledge of their holdings and will allow them to better manage data production, storage, updating, and reuse". (ISO 19115).

The creation of standard Metadata will:

- *"Provide data producers with appropriate information to characterise their geographic data properly.*
- *Facilitate the organisation and management of metadata for geographic data.*
- *Enable users to apply geographic data in the most efficient way by knowing its basic characteristics.*
- *Facilitate data discovery, retrieval and reuse. Users will be better able to locate, access, evaluate, purchase and utilise geographic data.*
- *Enable users to determine whether geographic data in a holding will be of use to them.*

This International Standard ISO 19115 defines general-purpose metadata, in the field of geographic information." (ISO 19115).

3. Scope of ISO 19115

The ISO 19115 defines the schema required for describing geographic information and services. It provides information about the identification, the extent, the quality, the spatial and temporal schema, spatial reference, and distribution of digital geographic data.

This International Standard is applicable to:

- the cataloguing of datasets, clearinghouse activities, and the full description of datasets;
- geographic datasets, dataset series, and individual geographic features and feature properties.

This International Standard defines:

- mandatory and conditional metadata sections, metadata entities, and metadata elements;
- the minimum set of metadata required to serve the full range of metadata applications (data discovery, determining data fitness for use, data access, data transfer, and use of digital data);
- optional metadata elements – to allow for a more extensive standard description of geographic data, if required;
- a method for extending metadata to fit specialised needs.

Though this International Standard is applicable to digital data, its principles can be extended to many other forms of geographic data such as maps, charts, and textual documents as well as non-geographic data.

4. Terms and definitions

data type	specification of the legal value domain and legal operations allowed on values in this domain *EXAMPLE:* Integer, Real, Boolean, String, Date, and SG_Point *NOTE:* A data type is identified by a term, e.g. Integer
dataset	identifiable collection of data *NOTE:* A dataset may be a smaller grouping of data which, though limited by some constraint such as spatial extent or feature type, is located physically within a larger dataset. Theoretically, a dataset may be as small as a single feature or feature attribute contained within a larger dataset. A hardcopy map or chart may be considered a dataset.
dataset series	collection of datasets sharing the same product specification
metadata	data about data
metadata element	discrete unit of metadata *NOTE* 1: Equivalent to an attribute in UML terminology. *NOTE* 2: Metadata elements are unique within a metadata entity.
metadata entity	set of metadata elements describing the same aspect of data *NOTE* 1: May contain one or more metadata entities. *NOTE* 2: Equivalent to a class in UML terminology.
metadata section	subset of metadata which consists of a collection of related metadata entities and metadata elements

5. Metadata profile

The ISO 19115 for metadata comprises about 300 elements that exhaustively describe an information resource. Most of these elements are defined as being optional, i.e. they are not needed for compliance with the international standard but are defined for helping users to understand exactly the described data. Individual organisations may develop a profile of the standard according to their needs. A profile consists of the core metadata elements, an additional set of optional elements that are then declared as mandatory part of the profile. Additionally a profile may add elements, i.e. extensions that are not part of the international standard.

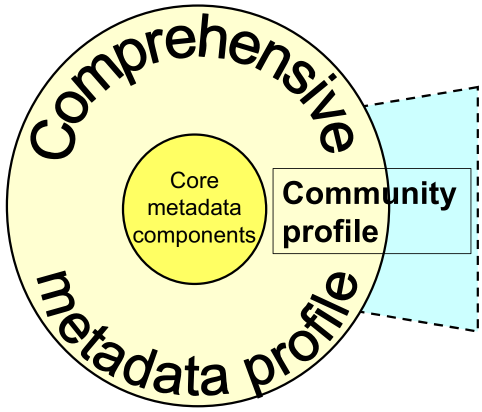

Figure 2: Metadata community profile
No reference to Fig in text

The ISO 19115 describes rules for defining community profiles and extensions. A profile must not change names, the definition or data types of metadata elements. A profile must include all core metadata elements of a digital geographic data set, all mandatory elements in mandatory sections as well as in conditional sections, if the data set meets the condition required by the metadata element. Relationships between the elements have to be identified. Finally, the profile has to be made available to any user of the metadata.

A profile has to follow the rules for defining extensions, too. Metadata extensions are used to impose more stringent obligations on existing metadata elements. In addition, an extension can limit or extend the use of domain values for describing metadata elements.

6. Core and mandatory elements of ISO 19115

The ISO 19115 consists of 22 core elements of which 12 are mandatory to comply with the international standard. The elements are described in Table 1. The mandatory elements focus on the discovery aspect of the metadata (catalogue purposes). Apart from?? information on the metadata itself, they provide information on the title, the category, the reference date, the geographic location, and a short description of the data and the data provider.

The core set expands the mandatory elements with additional information on the type, the scale, the format, the reference system and the data lineage. These elements give rough information on the potential usage of the data.

Table 1: Core metadata elements for geographic datasets (ISO/DIS 19115)

Information about the Metadata

1. Metadata language (C)	(MD_Metadata.language)
2. Metadata character set (C)	(MD_Metadata.characterSet)
3. Metadata file identifier (O)	(MD_Metadata.fileIdentifier)
4. Metadata standard name (O)	(MD_Metadata.metadataStandardName)
5. Metadata standard version (O)	(MD_Metadata.metadataStandardVersion)
6. Metadata point of contact (M)	(MD_Metadata.contact > CI_ResponsibleParty)
7. Metadata date stamp (M)	(MD_Metadata.dateStamp)

Information about the Dataset

8. Dataset title (M)	(MD_Metadata > MD_Identification.citation > CI_Citation.title)
9. **Dataset reference date (M)**	(MD_Metadata > MD_Identification.citation > CI_Citation > CI_Date.date and CI_Date.dateType)
10. Dataset responsible party (O)	(MD_Metadata > MD_Identification.pointOfContact > CI_ResponsibleParty)
11. Geographic location of the dataset (by four co-ordinates or by geographic identifier) (C)	(MD_Metadata > MD_DataIdentification.geographicBox or MD_DataIdentification.geographicIdentifier)
12. Dataset language (M)	(MD_Metadata > MD_DataIdentification.lauguage)
13. Dataset character set (C)	(MD_Metadata > MD_DataIdentification.characterSet)
14. Dataset topic category (M)	(MD_Metadata > MD_DataIdentification.topicCategory)
15. Spatial resolution of the dataset (O)	(MD_Metadata > MD_DataIdentification.spatialResolution > MD_Resolution.equivalentScale or MD_Resolution.distance)
16. Abstract describing the dataset (M)	(MD_Metadata > MD_Identification.abstract)
17. Distribution format (O)	(MD_Metadata > MD_Distribution > MD_Distributor > MD_Format.name and MD_Format.version)
18. Additional extent information for the dataset (vertical and temporal) (O)	(MD_Metadata > MD_DataIdentification.extent > EX_Extent)
19. Spatial representation type (O)	(MD_Metadata > MD_DataIdentification.spatialRepresentationType)
20. Reference system (O)	(MD_Metadata > MD_ReferenceSystem)
21. Lineage statement (O)	(MD_Metadata > DQ_DataQuality > LI_Lineage.statement)
22. On-line resource (O)	(MD_Metadata > MD_Distribution > MD_DigitalTransferOption.onLine > CI_OnlineResource)

- An “M” indicates that the element is mandatory.
- An “O” indicates that the element is optional.
- A “C” indicates that the element is mandatory under certain conditions.

Each of the ISO 19115 elements is further defined using a set of the following 7 attributes:

1. **Name.** A unique label assigned to a metadata entity or to a metadata element.
2. **Short name and domain code.** Short Name for each element.
3. **Definition.** The metadata element description.
4. **Obligation/Condition**. A descriptor indicating whether a metadata entity or metadata element shall always be documented or not. It may have values Mandatory, Conditional,

or Optional. Condition specifies an electronically manageable condition under which at least one metadata entity or a metadata element is mandatory.

5. **Maximum Occurrence.** Specifies the maximum number of instances the metadata entity or the metadata element may have.
6. **Data Type.** Specifies a set of distinct values for representing the metadata elements; for example, integer, real, string,
7. **Domain.** Specifies for each metadata element the values allowed or the use of free text.

7. Metadata information on data validation according to ISO 19115

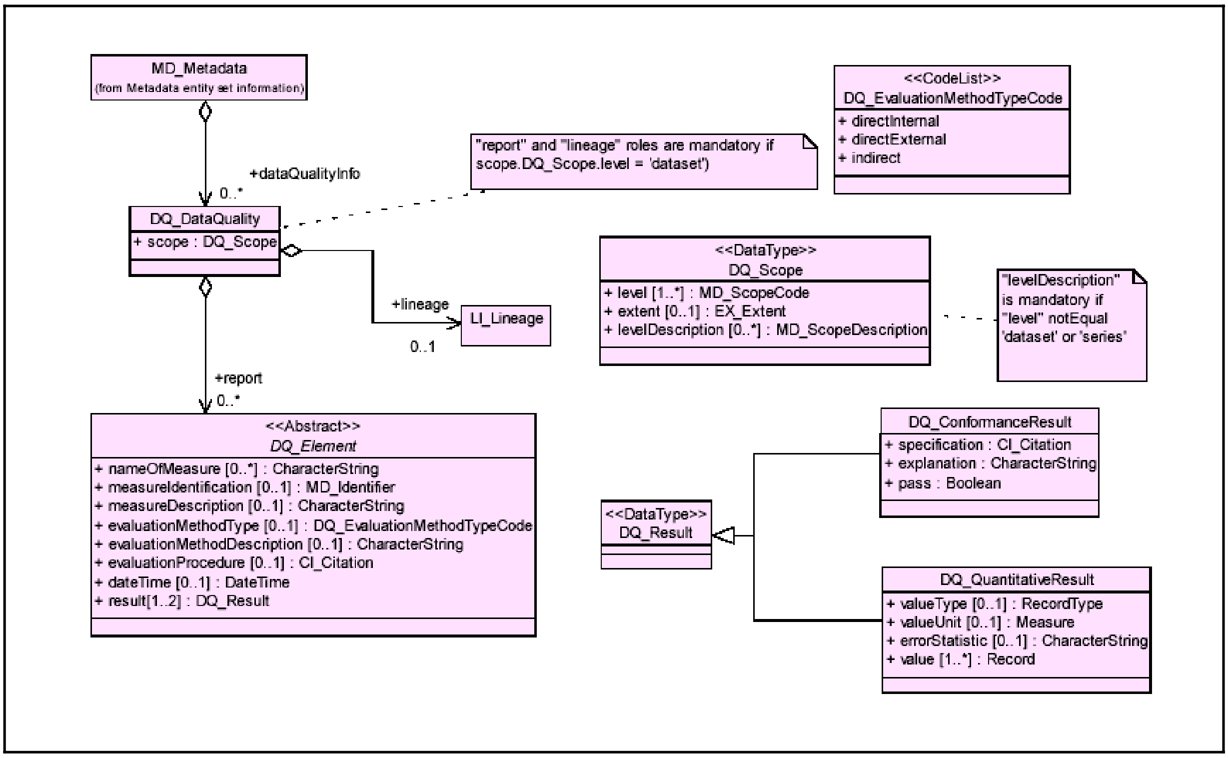

Figure 3: Conceptual model of metadata description on data quality

Bit difficult to read

Table 2: Elements to be integrated into the metadata profile

Name	**Description**	**ShortName**	**Obligation**	**Values**
MD_Identification		*Ident*		
Purpose	Rationale for creating a dataset and information on intended use; part of data quality overview elements	idPurp	O	
MD_USAGE		*Usage*		
SpecificUsage	Description of the application(s) for which the dataset has been used	SpecUsage	O	
DQ-DataQuality		DataQual	M	
Scope		dqScope	M	
Level	Hierarchical level of the data specified by the scope	scpLvl	M	
Extent	Information about the spatial extent, if test refers to spatial features	scpExt	C / scpLvl = dataset or series or feature or featureType	
EX_GeographicExtent		*GeoExtent*		
Ex_BoundingPolygon		*BoundPoly*	*C / if EX_GeographicBoundingBox and EX_GeographicDescription are empty*	
Polygon	Sets of points defining the bounding polygon	polygon	M	
EX_GeographicBoundingBox		*GeoBndBox*	*C / if EX_BoundingPolygon and EX_GeographicDescription are empty*	
westBoundLongitude	Western most co-ordinate, expressed in longitude in decimal degrees in ETRS89	westBL	M	
eastBoundLongitude	Eastern most co-ordinate, expressed in longitude in decimal degrees in ETRS89	eastBL	M	
southBoundLatitude	Southern most co-ordinate, expressed in longitude in decimal degrees in ETRS89	southBL	M	
northBoundLatitude	Northern most co-ordinate, expressed in longitude in decimal degrees in ETRS89	northBL	M	
EX_GeographicDescription		*GeoDesc*	*C / if EX_BoundingPolygon and EX_GeographicBoundingBox are empty*	
geographicIdentifier		*geoID*		
code	Identifier used to represent a geographic area		M	
DQ_Scope		*DQScope*		
levelDescription		*scpLvlDesc*	*M*	*dataset,*

				series, ...
LI_LINEAGE		*Lineage*		
statement	General explanation of the data producer's knowledge about the lineage of the dataset	statement	C / DQ_Scope.level = "dataset" or "series" and source and processStep not provided	
processStep		*prcStep*	*C / statement and source are not provided*	
description	Description of an event in the creation process for the data specified by the scope, including related parameters or tolerances	stepDesc	M	
source			*C / statement and procStep are not provided*	
description	Detailed description of the level of the source data used in creating the data specified by the scope	srcDesc	M	
REPORT		*dqReport*		
DQ_Element	*The following information applies to one of the data quality elements or sub-elements.*	*DQElement*	*M / all tests specified in the handbook*	
nameOfMeasure	Name of the test applied to the data	measName	M	
measureIdentification	Code identifying a standard procedure as described in the handbook	measID	C / if measDesc, evalMethType, evalMethDesc not provided; ID according to Handbook	
measureDescription	Description of the measure being determined	measDesc	C / if measID not provided	
evaluationMethodType	Type of method used to evaluate quality of the dataset	evalMethType	C / if measID not provided	1=directInternal, 2=directExternal, 3=indirect
evaluationMethodDescription	Description of the evaluation method	evalMethDesc	C / if measID not provided	
dateTime	Date on which data quality measure was applied	measDateTime	M	
result	*Value (or set of values) obtained from applying a data quality measure (quantitative result) or the outcome of evaluating the obtained value against a specified acceptable conformance quality level (conformance result)*	*measResult*	*M*	
DQ_ConformanceResult		*ConResult*	*C / if DQ_QuantitativeResult not provided*	
specification	*Citation of product specification or user*	*ConSpec*	-	

	requirement against which the data is being evaluated			
title	Name by which the cited resource is known	ResTitle	M	
explanation	Explanation of the meaning of conformance for this result	conExpl	M	
pass	Indication of the conformance result	conPass	M	1 =pass, 0 = fail
DQ_QuantitativeResult		*QuanResult*	*C / if DQ_ConformanceResult not provided*	
valueType	Value type for reporting a data quality result	quanValType	M	
valueUnit	value unit for reporting a data quality result	quanValUnit	M	
Value	Quantitative value or values, content determined by the evaluation procedure used	quanVal	M	

Elements in **bold** are mandatory. Elements in *italics* are abstracts.

Explanation

The table (Table 2) describes the elements, that have to be integrated into the metadata profile for providing non quantitative quality information as well as information on applied data validation procedures as described in the part on data validation.

General information on the scope

The first part of the metadata documentation defines the scope to which the data quality information applies. The hierarchical level of the scope can be selected from a code list. If the information given is related to spatial features, then the geographic extent of the spatial features has to be specified. This can be done by means of a bounding polygon, a bounding rectangle or a geographic locator. All co-ordinates should be expressed in the ETRS89 co-ordinate reference system.

Lineage description

Non quantitative quality information is described as lineage of the dataset. For the description of lineage, there are three different alternatives. The first option is to include general information that summarises the knowledge of the data producer on the dataset. The second option is to give a detailed description on the data sources that were used to compile the dataset. The third option consists of an explanation of the processing steps that were applied to the dataset.

Quantitative quality information

Quantitative quality information is included in a report. The metadata profile distinguishes between reports on conformance testing and tests that yield a quantitative result. A quantitative result may be a value for the spatial accuracy of a dataset. A maximum acceptable error of distortion could be used as a threshold to determine whether the derived value is acceptable or not. The first information is related to a quantitative result, the second gives a conformance result.

The first item consists of information on the measurement that was applied to the data. Either there is an identifier that relates to the identifier in the handbook on data validation, or a description of the measurement has to be included. Depending on the type of test, conformance or quantitative result, either information on the conformance, i.e. title, explanation and result, or information on the measured values, i.e. type of value, unit and the value itself, have to be added to the metadata.

8. Metadata information on constraint information according to ISO 19115

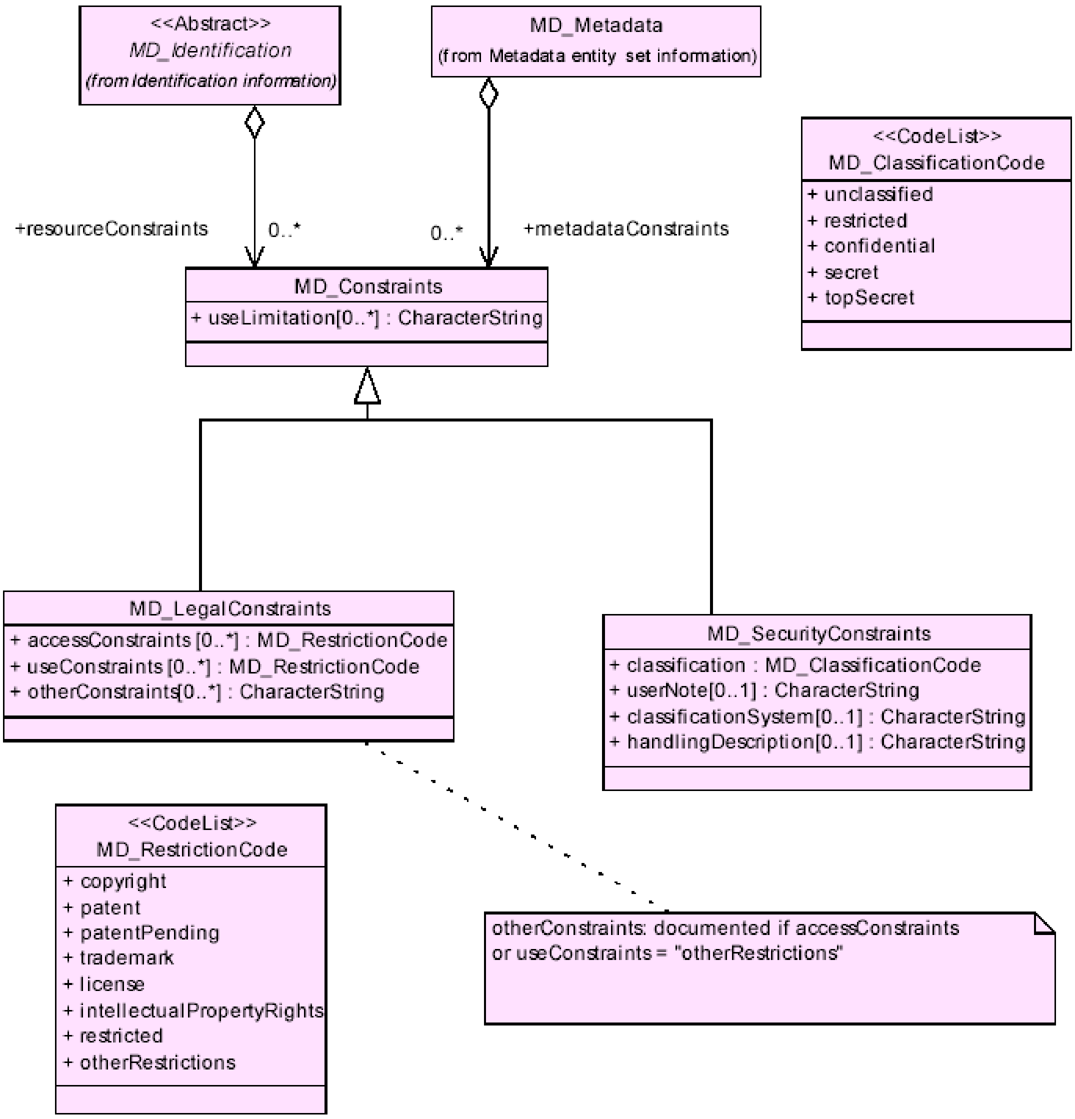

Figure 4: Constraint information

Table 3: Elements, to be integrated into the metadata profile for providing legal and security information.

Name	Description	ShortName	Obligation	Values
MD_Constraints	restrictions on the access and use of a resource or metadata	Consts	M Use obligation from referencing object	
UseLimitation	limitation affecting the fitness for use of the resource. Example, “not to be used for navigation”	useLimit	M	
MD_LegalConstraints	restrictions and legal prerequisites for accessing and using the resource	LegConsts	M	
AccessConstraints	access constraints applied to assure the protection of privacy or intellectual property, and any special restrictions or limitations on obtaining the resource	accessConsts	M	
useConstraints	constraints applied to assure the protection of privacy or intellectual property, and any special restrictions or limitations or warnings on using the resource	useConsts	M	
otherConstraints	other restrictions and legal prerequisites for accessing and using the resource	othConsts	C / accessConstraints or useConstraints equal “otherRestrictions”?	
MD_SecurityConstraints	handling restrictions imposed on the resource for national security or similar security concerns	SecConsts	M	
Classification	name of the handling restrictions on the resource	class	M	
UserNote	explanation of the application of the legal constraints or other restrictions and legal prerequisites for obtaining and using the resource	userNote	M	
HandlingDescription	additional information about the restrictions on handling the resource	handDesc	O	

Elements in bold are mandatory. Elements in italics are abstracts.

Explanation

The table (Table 3) describes the elements, that have to be integrated into the metadata profile for providing legal and security information.

Appendix VIII: Detailed Description of the GML Specification

Co-ordinates Element

A co-ordinate list is a simple list of co-ordinate tuples. The separators used to parse the co-ordinate list are encoded as attributes of the <co-ordinates> tag. In the example below, the co-ordinates in a tuple are separated by commas, and the successive tuples in the <co-ordinates> are separated by whitespace. A co-ordinate list is not a geometry in the Simple Features sense, merely the co-ordinate content. All tuples in the string must have the same dimension. A co-ordinate list is given by the following grammar.

```
<decimal>::='.'
<D>:=[0-9]
<cs>::=","
<ts>::=whitespace (see XML 1.0 [XML]
<co-ordinate>::='-'<D>+(<decimal><D>+)?
<ctuple>::=<ctuple>|<coordinate><cs><ctuple>
<coordinatelist>::=<coordinatelist>|<ctuple><ts><coordinatelist>
```

```
Note that the value of decimal, cs, and ts are determined by the GML
encoding of <co-ordinates>. The grammar is illustrated for default values
of decimal, cs and ts.
```

To find the co-ordinates of any Geometry class instance we introduce the co-ordinate property. We think of this as a function on the Geometry class instance that returns the co-ordinates as a co-ordinate list. The co-ordinate property has the associated DTD fragment:

```
<!ELEMENT co-ordinates (#PCDATA) >
<!ATTLIST co-ordinates
decimal CDATA #IMPLIED
cs CDATA #IMPLIED
ts CDATA #IMPLIED>
```

Note that the default for decimal is '.', for cs is ',' and for ts is whitespace.

<u>Example</u>

```
<co-ordinates decimal="." cs="," ts="whitespace">
1.03,2.167 4.167,2.34 4.87,3.0 1.06,2.3
</co-ordinates>
```

Point Element

The Point Element is used to encode instances of the Point geometry class. Each Point Element encloses a single co-ordinates element, the latter containing one and only one co-ordinate tuple. A Point geometry must specify a SRS in which its co-ordinates are measured. This is referenced by name. Thus the Point element has an srsName attribute. However this is defined to be optional. This is to allow the Point element to be contained in other elements which might have already specified a SRS. Similar considerations apply to the other geometry elements. The Point element also has an optional ID attribute. The DTD fragment for the Point element is as follows:

```
<!ELEMENT Point (co-ordinates) >
<!ATTLIST Point
ID CDATA #IMPLIED
srsName CDATA #IMPLIED>
```

LineString Element

A Line String is a piece-wise linear path. The path is defined by a list of co-ordinates that are then assumed to be connected by straight line segments. A closed path is indicated by having coincident first and last co-ordinates. At least two co-ordinates are required. The DTD fragment is as follows:

```
<!ELEMENT LineString (co-ordinates) >
<!ATTLIST LineString
ID CDATA #IMPLIED
srsName CDATA #IMPLIED >
```

LinearRing Element

A Linear Ring is a closed, simple piece-wise linear path. The path is defined by a list of co-ordinates that are then assumed to be connected by straight line segments. The last co-ordinate must be coincident with the first co-ordinate. At least four co-ordinates are required (the three to define a ring and the fourth duplicated one). Since a LinearRing is used in the construction of Polygons, which define their own SRS, it has no need to define a SRS. The DTD fragment is as follows:

```
<!ELEMENT LinearRing (co-ordinates) >
<!ATTLIST LinearRing
ID CDATA #IMPLIED >
```

Polygon Element

A Polygon is a connected surface. Any pair of points in the polygon can be connected to one another by a path. The boundary of the Polygon is a set of Linear Rings. We distinguish the outer (exterior) boundary and the inner (interior) boundaries. The Linear Rings of the interior boundary cannot cross one another and cannot be contained within one another. There must be at most one exterior boundary and zero or more interior boundary elements. The ordering of Linear Rings, whether they form clockwise or anti-clockwise paths, is not important. A Polygon is encoded via the DTD fragment:

```
<!ELEMENT Polygon (outerBoundaryIs, innerBoundaryIs*) >
<!ATTLIST Polygon
ID CDATA #IMPLIED
srsName CDATA #IMPLIED >
   <!ELEMENT outerBoundaryIs (LinearRing) >
   <!ELEMENT innerBoundaryIs (LinearRing) >
```

Appendix IX: Glossary of Terms

Term	Definition
Accuracy	Closeness of agreement between a test result and the accepted reference value (RDM)
Altitude	Elevation above or below a reference surface (RDM)
Architecture	The models, standards, technologies, specifications and procedures involved in using digital information
AST – INSPIRE	Standards and Architecture – INSPIRE Working group
Attribute	A defined characteristic of an entity type (e.g. composition) (RDM)
Attribute value	A specific quality or quantity assigned to an attribute
Background (Layer)	Display of an orthoimage in the background of other spatial data providing information on the context (RDM)
Bathing Directive	Directive 76/160/EEC
Birds Directive	Directive 79/409/EEC
Catalogue (1)	A mechanism for making third parties aware of available material. A clearinghouse directory. (ISF)
Catalogue (2)	Distributed service to locate geospatial data based on their characteristics expressed in metadata (ISF)
Catalogue services	Also called Clearinghouse. Cf. *Catalogue (2)* (AST - DERM)
CEN	REFCOND: European Committee for Standardization
Class	A set of objects that share the same attributes or characteristics
Clearinghouse (1)	A decentralised system of servers on the Internet which contain metadata (FGDC)
Clearinghouse (2)	A central agency for the collection, classification and distribution especially of information (RDM)
Completeness-attribute	The degree to which all relevant attributes of a features have been encoded (RDM)
Completeness - data	A measurable error of omission and commission observed between the database and the specification (RDM)
Completeness - model	The agreement between the database specification and the abstract universe (RDM)
Completeness - value	The degree to which values are present for all attributes
Concatenating	Combining two or more keys
Conformal projection	A projection on which all angles at each point are preserved. (RDM)
Conformance	Consistency with pre-stated capabilities and specifications
Conformance testing	Testing of a candidate product to determine the extent to which it satisfies the conformance requirements (RDM)
Consistency	Refers to the absence of apparent contradictions in a database. (RDM)

Co-ordinate(s)	Pairs of numbers (abscissa and ordinate) expressing horizontal distances along orthogonal axes (RDM)
Dangling node	Node connected to one line element only. Typically sources and outlets of river segments are dangling nodes.
Data	A formalised collection of facts, concepts or instructions for communication or processing by humans or by computer
Data dictionary	A catalogue of all data held in a database, or a list of items giving data names and structures
Data element	A logically primitive item of data
Data layer	Cf. *Layer*
Data model (1)	The result of the conceptual design process. A generalized, user-defined view of the data related to applications
Data model (2)	A formal method of describing the behaviour of the real-world entities. A fully developed data model specifies entity classes, relationships between entities, integrity rules and operations on the entities
Database	3.1 GIS: A collection of related data organised for efficient retrieval of information (RDM)
Dataset	3.1 GIS: A collection of data on a common theme or having similar attributes (RDM)
Dataset with geographic datatype	3.1 GIS: georeferenced digital dataset
Datum	A model of the earth's shape used for Geodetic calculations (RDM)
Delivery	The process of transferring possession from one individual or organisation to another
Digital Elevation Model (DEM)	A digital representation of a topographic surface (RDM)
Directive	Legal instrument binding as to the result to be achieved. Usually requires additional legislation at MS level
Dissemination	The publication of data to multiple users
Distribution	The process of moving products from supplier to consumer
Domain	Identifies valid values for a data element in the metadata standard definition (RDM)
Dublin Core	Metadata standard promoted by the Dublin Core Metadata Initiative (www.dublincore.org)
Elevation	Vertical height above a theoretical earth's surface base
Elevation	Cf. *Altitude*
Ellipsoid	The three-dimensional shape obtained by rotating an ellipse about its minor axis. (RDM)
Entity	A real world object that cannot be further subdivided into similar objects. (RDM)

Exclave	Polygon related to another polygon without having an explicit geometric relationship
Feature	A point, line or polygon in a spatial database that represents a real-world entity (RDM)
FGDC	Federal Geographic Data Committee (www.fgdc.gov)
Field	In database applications describes a space in which data of the same type is entered
Fish water Directive	Directive 78/659/EEC
Geographic Co-ordinates	A measurement of a location on the earth's surface expressed in degrees of latitude and longitude
Geographic data	The locations and descriptions of geographic features; the composite of spatial and descriptive data (RDM)
Geographic datatype	Category of geometric representation of geographic features (e.g. points, lines, polygons)
Geographic feature	Abstraction of a real world phenomenon associated with a location relative to the Earth (AST)
Geographic information	Information that is referenced to the earth's surface, whether by co-ordinates or by identifiers such as addresses
Geoid	The equipotential surface of the Earth's gravity field, which corresponds most closely with mean sea level and extends continuously through the continents.
Geometry	The scientific study of the properties of and relations between measures of points, lines and surfaces. In a GIS geometry is used to represent the spatial component of geographic features
Georeferencing	The process of determining the relation between the position of data in the co-ordinate system and its map location (RDM)
GIS	A system for capturing, storing, checking, manipulating, analysing and displaying data which are spatially referenced to the Earth (UK Department of the Environment, 1987)
Grid	An array of equally sized square cells arranged in rows and columns referenced by geographic x,y location (RDM)
Habitats Directive	Directive 92/43/EEC
Harmonise/harmonisation	Be in line with, in accordance with, in conformity (AST)
Horizontal	Tangent to the geiod or parallel to a plane that is tangent to the geiod (RDM).
Horizontal/vertical	Horizontal means different user sectors; vertical means the global to local axis (ISF)
INSPIRE	Infrastructure for Spatial Information in Europe (http://egeols222.egeo.sai.jrc.it/inspire/)
ISF - INSPIRE	Implementing Structures and Funding - INSPIRE Working Group
Integration	The bringing together of previously segregated or separated units

Interoperability	The ability of two or more systems to operate in conjunction with each other (cf. RDM & IEEE 90). Semantic interoperability cf. Semantics
Lambert Azimuthal Equal Area	An azimuthal projection that sacrifices shape and distance but preserves area (RDM)
Lambert Conic Conformal	A projection of the earth's surface on a tangent cone normally based on two standard parallels (RDM)
Latitude	The angular distance along a meridian north or south of the equator expressed in degrees, minutes and seconds
Layer	A collection of similar features in a particular area referenced together for display on a map (RDM)
Level	The area over which unified specifications will apply, i.e. pan-European, national or local (RDM)
Line	A set of ordered co-ordinates that represent linear features with no area (RDM)
Location	Identifiable part (place) of the real world (RDM)
Long term	Usually held to be more than two years
Longitude	The angular distance east or west from a standard meridian such as Greenwich to the meridian of any place
Map	A graphical representation of a section of the earth's surface displayed on a planar surface
Map projection	Cf. Projection
Medium term	Usually held to be 6 months to 2 years
Member State (MS)	One of the (currently) fifteen members of the European Union
Metadata	Description of the characteristics of a set of data
Metadata element	One of the items that collectively form a metadata structure (OeE)
Metadata record	A full set of structured relevant metadata describing one information resource
Model	An abstraction of reality used to represent objects, processes or events. (RDM)
Nitrates Directive	Directive 91/676/EEC
Node	A zero-dimensional object that is the topological junction of two or more links or an end point of a link (RDM)
Object	The representation of a real-world entity with properties and relationships with other objects (RDM)
OpenGIS	Transparent access to heterogeneous geodata and geoprocessing resources in a networked environment (RDM)
Parse	Handling over of parameters from one transformation to another
Point	A zero-dimensional abstraction of an object represented by a single x,y co-ordinate (RDM)
Policy	A set of obligations, prohibition or permission rules that either constrain or enable action (AST)

Polygon	An irregular two-dimensional figure enclosing a pre -defined area or an area of common characteristics
Positional accuracy	The accuracy of the spatial component of a database. (RDM)
Precision	A measure of the statistical uncertainty equal to the half width of the C% confidence interval. For any one monitoring exercise, the estimation error is the discrepancy between the answer obtained from the samples and the true value. The precision is then the level of estimation error that is achieved or bettered on a specified (high) proportion C% of occasions.
Projection (1)	The technique used to convert the three-dimensional reality of the earth's surface into a two -dimensional image
Projection (2)	A mathematical model that transforms the reality of the earth's surface to a two-dimensional representation
Protocol	A conventional and accepted method of fulfilling a task
Prototype	A non-operational system for testing purposes
Quality	An essential or distinguishing characteristic necessary for cartographic data to be fit for use (RDM)
Quantitative status	Expression of the degree to which a body of groundwater is affected by direct and indirect abstraction *cf.* Art 2(28) 'good quantitative status'
RDM -INSPIRE	Reference data and metadata – Inspire working group
Reference data	Data necessary to identify the position of physical features in relation to other information in a geospatial context
Reference system	A method for identifying and relating different positions on the earth's surface
Scale	The relation between the dimensions of features on a map and the objects they represent on the earth (RDM)
Scale – large	> 1:25,000 with resolution range < 2.5m (RDM)
Scale – medium	1:25,000 to 1:250.000 with resolution range 10m
Scale – small	< 1:250.000 with resolution range > 100m (RDM)
Schema	Visual representation and simplification of complex relationships and dependencies.
Semantics	The meaning of words
Short term	Usually held to be up to six months
Spatial accuracy	Cf. *Positional accuracy*
Spatial data / information	Identifies the geographic location and characteristics of features and boundaries on the earth (RDM)
Spatial data set	Cf. data set with *geographic datatype*
Spatial Data Infrastructure	The relevant base of technologies, policies and institutional arrangements that facilitate data availability and access
Spatial resolution	The ground dimensions of the pixels making up the digital image (RDM)
Specification/s	A detailed description of construction and performance

Standard(s)	Includes the ISO 19100 series of standards, OGC, CEN and others
Symbology	Visual representation, simplification and classification of objects
Tabular	Data arranged in tables or lists
Topology	Properties of geometric forms remain invariant when the forms are deformed or transformed (RDM)
Transformation	Set of sequentially applied computer instructions yielding a change of one or more parameters.
Transverse Mercator	A projection resulting from projecting the sphere onto a cylinder tangent to a central meridian (RDM)
Type specific reference conditions.	2.3 REFCOND: Reference conditions (see separate definition) representative for a specific water body type.
Tuple	Unique set of parameters in a relational database.
Typology	The study and interpretation of types
Urban Waste Water Treatment Directive	Directive 91/271/EEC
Vector	Ordered list of co-ordinates used to represent linear features
Vertical	At right angles to the horizontal; includes altitude and depth (RDM)
Web mapping	The provision of map based information services on the Internet

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

In the context of this strategy, the project "Development of a protocol for identification of reference conditions, and boundaries between high, good and moderate status in lakes and watercourses" was launched in December 2000 and named REFCOND. During 2001 the REFCOND project was widened to an informal working group included in the Common Implementation Strategy (working group 3.2). The final document to be produced was also changed from a more formal and binding protocol to a non-legally binding Guidance Document. Sweden is the lead country with responsibility of the co-ordination of the working group that is composed of ecologists and technical experts from governmental and non-governmental organisations. The Swedish Environmental Protection Agency (SEPA) has the responsibility for the administration and management and the Swedish University of Agricultural Sciences, as sub-contractor to SEPA, has the responsibility for the scientific project management.

The present Guidance Document is the outcome of this working group. It contains the synthesis of the output of the REFCOND group activities and discussions that have taken place since December 2000. It builds on the input and feedback from a wide range of experts and stakeholders from EU Member States and candidate countries that have been involved throughout the process of guidance development through meetings, workshops, conferences or electronic communication media, without binding them in any way to its content.

"*We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance through written procedure during April 2003. We would like to thank the participants and, in particular, the Swedish leaders of the Working Group, for preparing this high quality document.*

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive. This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work. Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation."

Table of contents

Introduction - A Guidance Document: What for?

To whom is this Guidance Document addressed?

This document aims at guiding experts and stakeholders in the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "the Directive"). It focuses on the implementation of the Annexes II and V with special emphasis on inland surface waters and methods and principles for the establishment of reference conditions and class boundaries between high, good and moderate ecological status. If this is your task, we believe the Guidance will help you in doing the job, whether you are:

- *Establishing reference conditions and ecological status class boundaries for inland surface waters yourself or participating in the process as a stakeholder;*
- *Leading and managing experts undertaking the ecological status analysis;*
- *Using the results of the ecological status analysis for taking part to the policy making process; or*
- *Reporting on the ecological status analysis to the European Union as required by the Directive.*

What can you find in this Guidance Document?

Purposes and timing (Section 1)

- *What is the role of the key elements in the REFCOND Guidance Document within the implementation process of the Directive?*
- *The timetable of the Directive - When are Member States expected to deliver something that requires that reference conditions and class boundaries have been established?*

Common understanding of concepts and terms (Section 2)

- *What are the key elements of the Water Framework Directive relating to reference conditions and ecological status classes?*
- *Where in the Directive are these elements made explicit or referred to?*
- *Which is the common understanding of the concepts "reference conditions" and "high ecological status", "good" and "moderate ecological status", "surface water bodies, "wetlands", "water body types" and "classification of ecological status" incorporating the Directive's terminology and requirements?*

Principles and methods for establishing reference conditions and ecological status class boundaries (Section 3)

- *Which are the key steps in the suggested approach for establishing reference conditions and ecological quality class boundaries?*
- *Which infrastructure is needed for a successful implementation of the suggested approach?*
- *How can differentiation of water body types be done in order to support the establishment of reference conditions and the intercalibration exercise?*

- *How can ecological criteria and pressure criteria be used in site selection and for setting class boundaries?*
- *What benchmark should we use to determine very minor and slight disturbance in terms of pressure criteria?*
- *What methods can be used to establish reference condition values and what are the strengths and weaknesses of different methods?*
- *How can reference conditions and quality class boundaries be validated?*
- *How can " sufficient level of confidence about the values for the reference conditions" be dealt with?*
- *How can "adequate confidence and precision in the classification of the quality elements" be dealt with?*
- *Which are the circumstances for excluding quality element indicators when establishing reference conditions?*
- *How can the ecological quality class boundaries be set, and are there any alternative approaches?*

The Toolbox (Section 4)

- *Which specific tools are available for establishing reference conditions and ecological quality class boundaries?*
- *How can these tools be further developed and tested in order to be tailored for different water body types, different pressures-impacts and different quality elements?*

Good practice Examples (Section 5)

- *What examples are available of current good practice in respect of at least one aspect of the suggested approach for establishing reference conditions and ecological quality class boundaries?*

Adaptation to regional and national circumstances

The Guidance Document proposes an overall methodological approach. Because of the diversity of circumstances within the European Union, the way to deal with the logical approach and answer to questions will vary from one river basin to the next. The proposed methodology would therefore need to be tailored to specific circumstances.

What you will <u>not</u> find in this Guidance Document

The Guidance Document focuses on definitions, methods, principles and criteria to be used when establishing reference conditions and when setting the boundaries between high, good and moderate ecological status for inland surface waters. The document does not include guidance for specific quality elements and specific water body types but is restricted to general guidance that applies to most quality elements and most inland surface water body types. The Guidance does not focus on:

- *Groundwater, transitional water and coastal water (handled by CIS Working Group 2.8 (groundwater) and 2.4 (coastal and transitional water));*
- *Classification of poor and bad ecological status;*
- *Emission limit values and environmental quality standards for classification of chemical status (handled by Expert Advisory Forum on Priority Substances);*

- *Method standardisation and intercalibration (intercalibration is handled by CIS working group 2.7).*

Section 1. Introduction - Implementing the Directive

This Section introduces the overall context for the implementation of the Water Framework Directive and informs on the initiatives that led to the production of this Guidance Document.

1.1 December 2000: A Milestone for Water Policy

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force.

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the Water Framework Directive.

1.2 Purposes and timing

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

- *Prevents further deterioration and protects and enhances the status of water resources;*
- *Promotes sustainable water use based on long-term protection of water resources;*
- *Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;*
- *Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and*
- *Contributes to mitigating the effects of floods and droughts.*

Overall, the Directive aims at preventing deterioration of the status of all bodies of surface water and achieving *good water status* for all waters by 2015. For surface waters, "good status" is determined by a "good ecological status" and a "good chemical status". Ecological status is determined by biological quality elements, supported by hydromorphological and physico-chemical quality elements. The point of reference is given by "undisturbed" conditions showing no or only "very minor" human impacts.

The various articles of the directive describe what shall be done and the sometimes rather elaborate annexes are to be seen as a way to help Member States in doing the job and achieving the overall purpose of the directive. Hence, although the text at a first reading may seem difficult to comprehend, the purpose that it is intended to result in is simple and easy to understand.

The present Guidance Document (REFCOND Guidance) will, together with the other Guidance Documents published by the Commission, help Member States achieve that purpose. It does so by advising on how member states may proceed to establish reference conditions and ecological status class boundaries for lakes and watercourses.

It should be pointed out here, that the REFCOND Guidance does not provide solutions in detail that may be copied and applied as such. Rather, it offers principles, ways of reasoning and suggestions on alternative pathways of action. It is up to Member States themselves to implement these principles and suggestions under their own circumstances and to be able to verify that the solutions meet the requirements of the directive. Harmonization between Member States will be achieved through intercalibration (which is described in WFD CIS Guidance Document No. 6) and participation in the work in Pilot River Basins and International River Basin Districts.

Guidance on the establishment of reference conditions and class boundaries are needed at several stages in the implementation of the directive (Figure 1). They will first be needed for the selection of sites for the draft register of intercalibration sites which should be completed in December 2003. More specifically, criteria for selecting minimally disturbed sites (on the high/good boundary) and slightly disturbed sites (on the good/moderate boundary) representative of different water body types will be needed. The present Guidance Document will also be needed for selection of complementary sites for the final register of intercalibration sites which should be completed in December 2004. The actual intercalibration exercise should be completed 18 months after the final register of sites has been established (described in WFD CIS Guidance Document No. 6 on intercalibration). As the intercalibration exercise will be completed before the monitoring programmes are fully operational (see Figure 1) pressure criteria for selection of sites will have to be used together with existing survey data on ecological status.

The analysis of characteristics of River Basin Districts and the assessment of the risk for individual water bodies of failing the environmental objectives in accordance with Article 5 and Annex II in the Directive will also require guidance on reference conditions and classification. This analysis should be completed at the latest in December 2004. As the monitoring programmes will not be fully operational this risk assessment will have to rely very much on pressure information.

According to Article 8 of the Directive monitoring programmes shall be operational at the latest in December 2006. The REFCOND Guidance will here be needed for the specification of the monitoring requirements of reference sites (high status sites) and assessing ecological status of all monitoring sites.

Finally, the REFCOND Guidance will be needed when producing the first River Basin Management Plans which should be published at the latest in December 2009. In these plans type-specific reference conditions shall be listed together with map presentations on ecological status classifications for surface waters.

The dates given in Figure 1 outline the time schedule for Member States to deliver documentation indicating that reference conditions and class boundaries have been established. In practice this means that work has to be done well in advance and should be started immediately. The time needed to do the job will vary with circumstances, such as the variability and complexity of the water bodies in Member States as well as the available expertise.

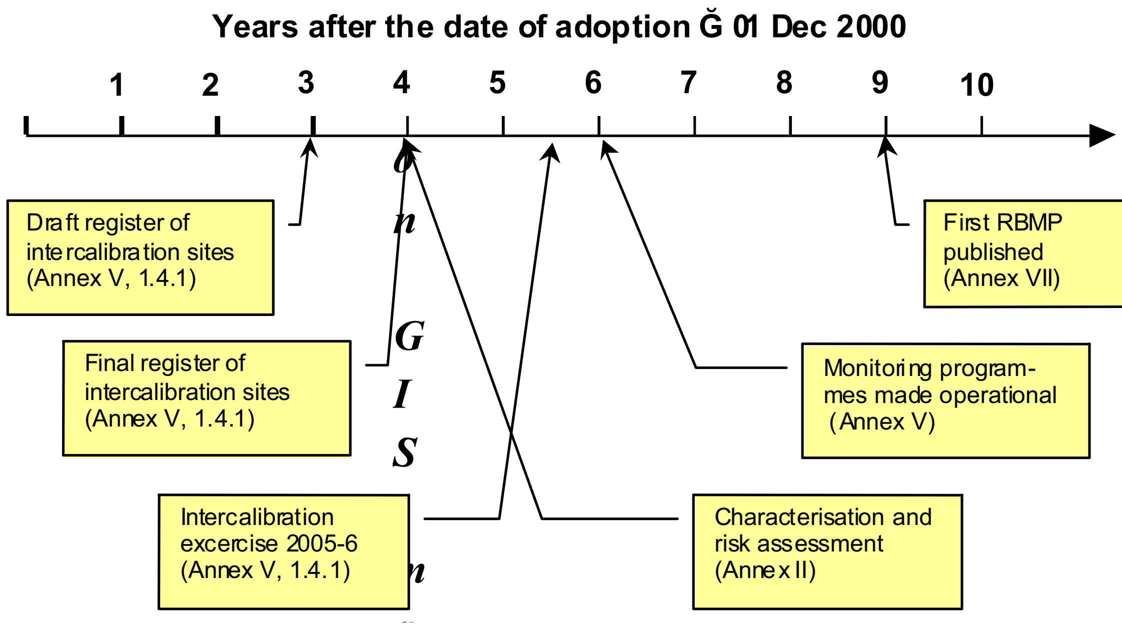

Figure 1. *Timetable for implementation of parts of the Water Framework Directive which are depending on Guidance from WG 2.3 (REFCOND).*

1.3 What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (Article 3, Article 24);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, establishing a register of protected areas lying within the river basin district and finally assessment of the risk for individual water bodies of failing the environmental objectives by 2004 (Article 5, Article 6, Annex II, Annex III);
- To make operational the monitoring networks by 2006 (Article 8);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (Article 11, Annex III);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (Article 13, Article 4.3);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (Article 9);
- To make the measures of the programme operational by 2012 (Article 11);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (Article 4)

Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water

Framework Directive offers the possibility to Member States to engage into two further six-year cycles of planning and implementation of measures.

1.4 Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular for:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

1.5 Integration: a key concept underlying the WFD

The central concept to the Water Framework Directive is the concept of *integration* that is seen as key to the management of water protection within the river basin district:

- ➢ **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- ➢ **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- ➢ **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- ➢ **Integration of disciplines, analyses and expertise,** combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- ➢ **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- ➢ **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- ➢ **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;

- **Integration of stakeholders and the civil society in decision making,** by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status,** be local, regional or national, for an effective management of all waters;
- **Integration of water management from different Member States, for river basins** shared by several countries, existing and/or future Member States of the European Union.1.6 What is being done to support implementation?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support for the implementation of the Water Framework Directive by developing coherent and common understanding and Guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community (see Annex I for the overall structure of the Common Implementation Strategy).

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance Documents (see Table 1). A strategic co-ordination group (SCG) oversees these working groups and reports directly to the water directors of the European Union and the Commission that play the role of overall decision body for the Common Implementation Strategy.

Table 1. Working Groups in the "Common Implementation Strategy" with description of lead countries/organisations (see also Annex A).

Working group	**Lead**
2.1 Analysis of pressures and impacts (IMPRESS)	UK & Germany
2.2 Heavily modified water bodies (HMWB)	UK & Germany
2.3 Reference conditions and ecological status class boundaries for inland surface waters (REFCOND)	Sweden
2.4 Typology, classification of transitional & coastal waters	UK, Germany, France, Sweden & EEA
2.5 Intercalibration	Joint Research Centre
2.6 Economic analysis (WATECO)	France & Comm.
2.7 Monitoring	Italy & EEA (ETCw)
2.8 Tools on assessment & classification of groundwater	Austria

Working group	Lead
2.9 Best practices in river basin planning	Spain
3.1 Geographical Information Systems, GIS	Joint Research Centre
4.1 Integrated testing in Pilot River Basins	Comm., SCG

1.6 Working group 2.3 – REFCOND

A working group has been created to deal specifically with issues relating to the establishment of reference conditions and ecological status class boundaries for inland surface waters. The short-term objective of this working group, with the acronym REFCOND, was the development of a non-legally binding and practical guidance to support the implementation of the relevant parts of the Water Framework Directive, specifically the Annexes II and V.

The members of the REFCOND group are ecologists and technical experts from governmental and non-governmental organisations from each European Union Member States and from Norway. A number of candidate countries and stakeholders have also been involved in the working group. A list of REFCOND partners and other contacts is given in Annex B.

To ensure an adequate input and feedback during the Guidance development phase from a wider audience, the REFCOND group has organised three workshops. The first workshop, with focus on the review of techniques and principles used in Member States for identification of reference conditions and boundaries between quality classes, was held in Uppsala, Sweden, 14-15 May 2001. The second workshop, with focus on evaluation of techniques used for establishing reference conditions and quality class boundaries, was held in Ispra, Italy 5-6 December 2001. The third workshop, with focus on review and validation of the first draft Guidance Document, was held in Stockholm, Sweden, 5-6 September 2002. Full documentation of presentations, group discussions etc are currently available at the Circa System and at the REFCOND web site (http://www-nrciws.slu.se/REFCOND/).

A questionnaire has been used to collect information for the review of techniques and principles used in Member States for identification of reference conditions and boundaries between quality classes using the quality elements included in the WFD. The questionnaire and a summary of the questionnaire returns are available at the Circa System and the REFCOND web site (see above).

Based on the questionnaire returns and other available information four discussion papers have been produced by the REFCOND group to be used for the evaluation of techniques used in Member States (De Wilde & Knoben 2001, Johnson 2001, Owen et al. 2001 and Van de Bund 2001). These documents are concerned specifically with the processes involved in the definition and setting of reference conditions, the setting of class boundaries and typology. All papers are available at the Circa System and the REFCOND web site (see above).

The present Guidance Document is based on information from REFCOND workshops, questionnaire returns, discussion papers for evaluation of techniques and other available information, e.g. from on-going EU and national research projects, CEN (European Committee for Standardization), national strategy papers and from literature reviews.

Developing the Guidance Document: an interactive process

Within a very short time period, a large number of experts have been involved at varying degrees in the development of this Guidance Document. The process has included the following activities:

- Regular meetings with the REFCOND lead group;
- Regular meetings with the Strategic Co-ordination Group and meetings with the other work group leaders in Brussels;
- Organisation of three workshops to follow up the work programme and preliminary output of REFCOND;
- Regular interactions with experts from other working groups of the Common Implementation Strategy, mainly those dealing with typology and classification of transitional and coastal waters (WG 2.4) and intercalibration (WG 2.5);
- Regular interactions with experts from past and on-going EU-funded research projects, mainly AQEM, STAR, FAME and EUROLAKES;
- Participation in several meetings and workshops organised by Member States, European organisations or EU on the subject of reference conditions and ecological status classifications.

In Annex E of this document past and on-going EU-funded research projects relevant for REFCOND are listed with full names, acronyms and web sites if available.

Section 2. Common understanding of concepts and terms

2.1 Reference conditions and high ecological status

Excerpts from the Directive pertaining to reference conditions and high ecological status:

Annex II: 1.3 (i-vi) Establishment of type-specific reference conditions for surface water body types:

> *For each surface water body type….type-specific hydromorphological and physico-chemical conditions shall be established representing the values of the hydro-morphological and physico-chemical quality elements specified….for that surface water body type at high ecological status….Type-specific biological reference conditions shall be established, representing the values of the biological quality elements…for that surface water body type at high ecological status….*
>
> *…. Type-specific biological reference conditions may be either spatially based or based on modelling, or may be derived using a combination of these methods. Where it is not possible to use these methods, Member States may use expert judgement to establish such conditions.*
>
> *Type-specific biological reference conditions based on modelling may be derived using either predictive models or hindcasting methods. The methods shall use historical, palaeological and other available data ….*

Annex V: 1.2 Normative definitions of ecological status classifications. Table 1.2. General definition of high ecological status:

> *There are no, or only very minor, anthropogenic alterations to the values of the physico-chemical and hydromorphological quality elements for the surface water body type from those normally associated with that type under undisturbed conditions.*
>
> *The values of the biological quality elements for the surface water body reflect those normally associated with that type under undisturbed conditions and show no or only very minor, evidence of distortion.*

Annex V: 1.2.1-1.2.2 Definitions for high, good and moderate ecological status. Values of quality elements at high status:

Tables 1.2.1 (rivers) and 1.2.2 (lakes) provide normative definitions of high ecological status in rivers and lakes for each biological, physico-chemical and hydromorphological quality element. In every case, the definition includes the following clause in the status description of the biological quality elements:

> *The [specific quality element value] "corresponds totally, or nearly totally, to undisturbed conditions".*

In addition, more specific criteria are provided for specific pollutants:

> **Specific synthetic pollutants:** *"concentrations close to zero and at least below the limits of detection of the most advanced analytical techniques in general use".*
>
> **Specific non-synthetic pollutants:** *"concentrations remain within the range normally associated with undisturbed conditions (background levels)".*

Conclusions and recommendations

- Reference conditions (RC) do not equate necessarily to totally undisturbed, pristine conditions. They include very minor disturbance which means that human pressure is allowed as long as there are no or only very minor ecological effects;
- RC equal high ecological status, i.e. no or only very minor evidence of disturbance for each of the general physico-chemical, hydromorphological and biological quality elements;
- RC shall be represented by values of the relevant biological quality elements in classification of ecological status;
- RC can be a state in the present or in the past;
- RC shall be established for each water body type;
- RC require that specific synthetic pollutants have concentrations close to zero or at least below the limits of detection of the most advanced analytical techniques in general use[1];
- RC require that specific non-synthetic pollutants have concentrations remaining within the range normally associated with undisturbed conditions (background values)[2];

The last two bullet points above have been subject to a long debate (cf. OSPAR) and it is clear that no scientific specification can be given for terms like "close to zero". These issues are being examined by a sub group of the Expert Advisory Forum on Priority Substances dealing with Analysis and Monitoring (AMPS). It is recommended that the approach adopted by the EAF PS, AMPS group, be adopted for substances for which national detection limits and background concentrations are to be set.

2.2 Good and moderate ecological status

Excerpts from the Directive pertaining to good and moderate ecological status:

Annex V: 1.2 Normative definitions of ecological status classifications.. Table 1.2 General Definitions

> **Good ecological status:** *The values of the biological quality elements for the surface water body type show low levels of distortion resulting from human activity, but deviate only slightly from those normally associated with the surface water body type under undisturbed conditions.*
>
> **Moderate ecological status:** *The values of the biological quality elements for the surface water body type deviate moderately from those normally associated with the surface water body type under undisturbed conditions. The values show moderate signs of distortion resulting from human activity and are significantly more disturbed than under conditions of good status.*

[1] Examples on how to select the specific pollutants that are relevant to a particular water body are described in the Guidance Document from Working Group 2.1 (WFD CIS Guidance Document No. 3 - IMPRESS).
[2] See footnote 1.

Annex V: 1.2.1-1.2.2 Definitions for high, good and moderate ecological status. Values of quality elements at good and moderate status:

Table 1.2.1 (rivers) and 1.2.2 (lakes) provides normative definitions of good and moderate ecological status in rivers and lakes for each biological quality element. In every case, the definition includes the following clause in the status description:

> **Good ecological status:** *There are slight changes in the [specific biological quality element] compared to the type-specific communities.*
>
> **Moderate ecological status:** *The [specific biological quality element] differs moderately from the type specific communities. The values are significantly more disturbed than under conditions of good status.*

For general physico-chemical quality elements it is stated that the conditions for good ecological status should *"not reach levels outside the range established so as to ensure the functioning of the type specific ecosystem and the achievement of the values specified above for the biological quality elements"* (Annex V: 1.2).

In addition, more specific criteria are provided for good ecological status for synthetic pollutants:

> **Specific synthetic and non-synthetic pollutants***: "concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 (environmental quality standards - EQS)*[3]*".*

Conclusions and recommendations

For any surface water body type in **good ecological status** the following criteria should be met:

- The values of the biological quality elements show slight deviation from reference conditions (low levels of distortion resulting from human activity);
- The levels of the general physico-chemical quality elements do not exceed the range ensuring ecosystem functioning and the achievement of the values associated to biological quality elements at good status;
- Concentrations of specific synthetic and non-synthetic pollutants are not in excess of environmental quality standards (EQS) established in accordance with Annex V 1.2.6. or under relevant Community legislation.

For any surface water body type in **moderate ecological status** the following criteria should be met:

- The values of the biological quality elements show moderate deviation from reference conditions (moderate signs of distortion resulting from human activity);
- Conditions consistent with the achievement of values for the biological quality elements and significantly more disturbed than under conditions of good status.

[3] Detailed procedures for the establishment of EQS is under elaboration in the Expert Advisory Forum on Priority Sub-stances.

2.3 Surface water bodies

Excerpt from the Directive pertaining to surface water bodies:

Article 2, point 10:

> *"Body of surface water" means a discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water".*

The recommendations given below are mainly based on the WFD CIS Guidance Document No. 2 on the application of the term "water body" in the context of the WFD.

Most of the elements of the Directive's definition of surface water body are relatively clear and do not require further elaboration. The WFD CIS Guidance Document No. 2 provides guidance to two other points that do need to be elaborated, however, namely size and whether parts of lakes or watercourses may be regarded as water bodies.

Concerning the second point, the WFD CIS Guidance Document No. 2 explicitly says that significant changes in status (i.e. level of impact) should be used to delineate water bodies so that water bodies provide for an accurate description of water status. This means that rivers and lakes may be sub-divided into those parts that are impacted by human activities and those parts that are not or not much affected, e.g. a lake may be split into more than one "water body". Sub-divisions of surface waters into smaller and smaller water bodies that does not support a clear, consistent and effective application of its objectives should, however, be avoided.

The purpose of the Directive is to establish a framework for the protection of all waters including inland surface waters, transitional waters, coastal waters and groundwater[4]. Member States must ensure that the implementation of the Directive's provisions achieves this purpose. However, surface waters include a large number of very small waters for which the administrative burden for the management of these waters may be enormous.

The Directive does not include a threshold for very small "water bodies". However, the Directive sets out two systems for differentiating water bodies into types[5]. System A and System B. Only the System A typology specifies values for size descriptors for rivers and lakes. The smallest size range for a System A river type is 10 – 100 km^2 catchment area[6]. The smallest size range for a System A lake type is 0.5 – 1 km^2 surface area[7]. No sizes for small transitional and coastal waters are given. The application of system B must achieve, at least, the same level of differentiation as system A. It is therefore recommended to use the size of small rivers and lakes according to system A. However, it is recognised that in some regions where there are many small water bodies, this general approach will need to be adapted. Having said that, it may be appropriate to aggregate water bodies into groups for certain purposes as outlined in the WFD CIS Guidance Document No. 2 on water bodies in order to avoid unnecessary administrative burden.

[4] Article 1
[5] Annex II 1.2
[6] Annex II 1.2.1
[7] Annex II 1.2.2

However, there are still large numbers of discrete rivers and lakes that are smaller than these thresholds. A possible approach for the protection of these waters is outlined in the WFD CIS Guidance Document No. 2.

Conclusions and recommendations

- "Surface water bodies" must not overlap with each other;
- A surface water body must not cross the boundaries between surface water body types;
- Physical features (geographical or hydromorphological) that are likely to be significant in relation to the objectives of the Directive should be used to identify discrete elements of surface water;
- A lake or reservoir will normally be identified as one water body. However, where different reference conditions apply within a lake due to morphological complexity (e.g. sub-basins), the lake must be sub-divided into separate water bodies (see example in Figure 2). Furthermore, where there are significant differences in status in different parts of a lake, the lake must be sub-divided into separate water bodies to achieve the desired environmental outcome in the most cost effective way;
- A whole river, stream or canal can be a "water body". However, where different reference conditions apply within a river stream or canal, it must be sub-divided into separate water bodies. Furthermore, where there are significant differences in status in different parts of a river, stream or canal, it must be sub-divided into separate water bodies to achieve the desired environmental outcome in the most cost effective way;
- The lower size limit of surface water bodies may be set lower than the ones prescribed in typology system A (described in Annex II of the Directive) in certain cases, i.e. if Member States decide that certain smaller water bodies are significant and require separate identification. This is of specific ecological relevance for lakes.

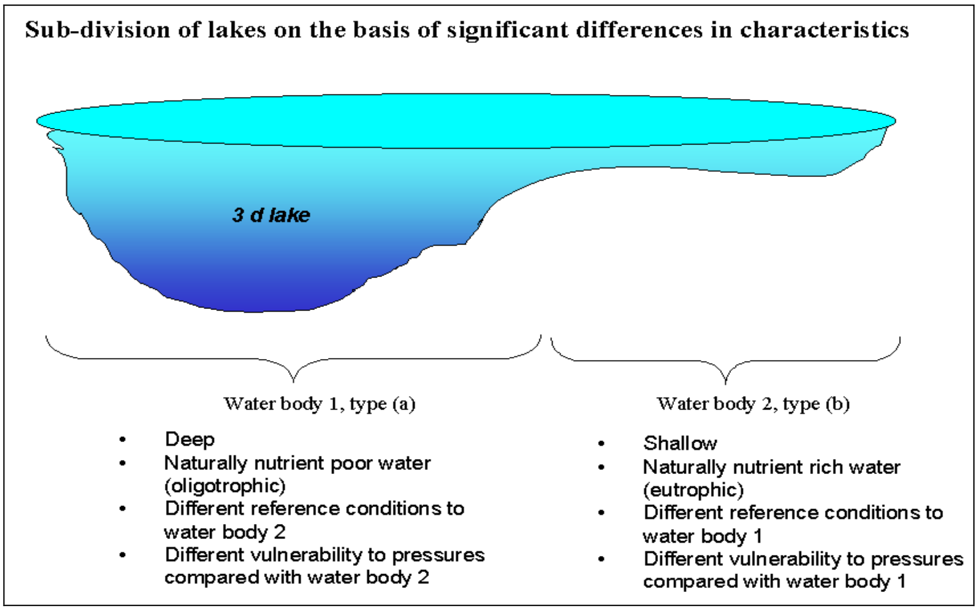

Figure 2. Sub-division of lakes on the basis of significant differences in characteristics (from the WFD CIS Guidance Document No. 2 on water bodies).

2.4 Wetlands

Excerpts from the Directive pertaining to wetlands:

Article 1

> *The purpose of this Directive is to establish a framework for the protection of inland surface waters, transitional waters, coastal waters and groundwater, which: prevents further deterioration and protects and enhances the status of aquatic ecosystems and, with regard to their water needs, terrestrial ecosystems and wetlands directly depending on the aquatic ecosystems.*

Wetland ecosystems are ecologically and functionally parts of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in WFD CIS Guidance Document No. 2 on water bodies and further considered in Guidance on wetlands.

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate Guidance paper on wetlands (currently in preparation).

2.5 Water body types

Excerpts from the Directive pertaining to water body types:

Annex II: 1.1 (ii)

> *For each surface water category, the relevant surface water bodies within the river basin district shall be differentiated according to type. These types are those defined using either "system A" or "system B" identified in Section 1.2.*

Annex II: 1.1 (iv)

> *If System B is used, Member States must achieve at least the same degree of differentiation as would be achieved using System A. Accordingly, the surface water bodies within the river basin district shall be differentiated into types using the values for the obligatory descriptors and such optional descriptors, or combinations of descriptors, as are required to ensure that type specific biological reference conditions can be reliably derived.*

The Directive requires that Member States differentiate the relevant surface water bodies with respect to type and that Member States establish reference conditions for these types. The main purpose of typology is consequently to enable type specific reference conditions to be defined which in turn is used as the anchor of the classification system. The following guidance may be given relative to specific issues concerning types.

”System A” versus ”System B”
The two systems are about the same in that the same obligatory factors are to be used in both: geographic position, altitude, size, geology and, for lakes, depth. The difference is that System A prescribes how water bodies shall be characterised spatially (ecoregions) and with respect to specific altitude, size and depth intervals, and that System B, besides lacking this prescription, permits the use of additional factors. It is up to Member States to decide on what system to use, and most Member States have indicated that they prefer to use System B.

Degree of differentiation
The Directive requires that System B, if used, must achieve at least the same degree of differentiation as would System A. This is interpreted to mean that if System B is used, it should result in no greater degree of variability in type specific reference conditions than if System A had been used. Hence, if it can be demonstrated that the same or a lower degree of variability in reference condition values may be achieved with a lower number of types than would be derived using System A, this would be acceptable, since the purpose of typing is to establish reference conditions as precisely as possible. This comparison of “degree of differentiation” does not imply an obligation to compare one system with the other in great detail, but rather at a more general level based on existing data and expert judgement. What is important is that the established typology system assists in achieving an adequate confidence in reference conditions and the subsequent classifications.

Reducing variability
Member States must establish type-specific biological reference conditions for each quality element used for classification. Where the natural variability of a quality element in a type as a whole is much larger than the natural variability expected for it in any particular water body, Member States should be able to utilise a suitable reference value for the water body when interpreting monitoring results and calculating environmental quality ratios. The relevant reference value will be from within the range of values established for the type as a whole. The reference value arrived at in this way will be water body specific. The possibility to revise the typology system or to exclude a quality element indicator showing large natural variability in reference conditions should also be considered (Annex II: 1.3 (vi)).[8]

Use of optional factors
Concerning optional factors, the interpretation of the Directive is that these are factors that may be included according to the choice of the user, who may very well also decide to use others than those suggested in the Directive.

Catchment geology
An interpretation is also needed with respect to the Directive’s alternative descriptors of geology. The Directive is interpreted here to mean a relevant catchment area of the water body and to mean, in System A, the geology with the predominating influence of the water body. This is up to Member States to decide, depending on the circumstances.

[8] It should be stressed that the Directive only requires type specific reference conditions to be established and that water body specific reference conditions only should be regarded as a complementary approach.

Conclusions and recommendations

- Water body types may be differentiated using "System A" or "System B";
- The two systems are similar in that they contain the same obligatory factors: Geographic position, altitude, geology, size and (for lakes) depth;
- Optional factors of System B can be used as desired by Member States and can be complemented with factors other than those mentioned in the Directive;
- The Directive´s descriptors of geology (in System A) refer to the dominating character (calcareous, silicious, etc.), expected to have the strongest influence on ecological quality of the water body;
- The Directive´s requirement that Member State must achieve the same degree of differentiation with System B as with System A is interpreted to mean that if System B is used, it should result in no greater degree of variability in type specific reference conditions than if System A had been used. Hence, if a lower number of types, using System B, results in equally low or lower variability of reference conditions values as would be given by System A, this would be acceptable;
- Water body specific reference conditions, within a range of values for the type as a whole, may be used in order to cope with natural variability within types.[9]

2.6 Classification of ecological status

Excerpts from the Directive pertaining to ecological status:

Article 2(17):

> *"Surface water status" is the general expression of the status of a body of surface water, determined by the poorer of the ecological status and the chemical status.*

Article 2(21):

> *"Ecological status" is an expression of the quality of the structure and functioning of aquatic ecosystems associated with surface waters, classified in accordance with Annex V.*

The Directive requires surface water classification through the assessment of ecological status. Annex V, Table 1.1, explicitly defines the quality elements that must be used for the assessment of ecological status (see Table 2 below). Biological as well as supporting hydromorphological and physico-chemical quality elements are to be used by Member States in the assessment of ecological status.

Annex V, Table 1.2, in the Directive provides a general definition of ecological quality in each of the five status classes. For each relevant quality element and a set of indicators, more specific definitions for ecological status at high, good and moderate status in rivers (Table 1.2.1) and lakes (Table 1.2.2) are given. These general and specific definitions are referred to as "normative definitions" (Table 1.2, 1.2.1 and 1.2.3 in the Directive and are listed in Annex C).

The specific hydromorphological quality elements are required for determination of high status. For other status classes the hydromorphological elements are required to have

[9] See footnote 4.

"conditions consistent with the achievement of the values specified [in Tables 1.2.1 and 1.2.2] for the biological quality elements."

The specific physico-chemical quality elements are required for determination of high and good status. For other status classes the physico-chemical elements are required to have "conditions consistent with the achievement of the values specified [in Tables 1.2.1 and 1.2.2] for the biological quality elements."

These relative roles of biological, hydromorphological and physico-chemical quality elements in status classification are presented in Figure 3.

Annex V, section 1.4.2. (i) Presentation of monitoring results and classification of ecological status and ecological potential

> *For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below.*

To classify ecological status, the Directive stipulates that the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements should be used (Annex V, 1.4.2. (i)). This implies, de facto, that Member States will need to establish methods/tools for assessing ecological status for both the biological and physico-chemical quality elements. Figure 3 illustrates that there are separate criteria in WFD Annex V, 1.2, for establishing appropriate ranges for physico-chemical elements at high and good status. It can also be concluded that classification of ecological status should be on the quality element level, i.e. not on parameter level (the quality elements are listed in Table 2).

There is a clear distinction between the role of general physico-chemical quality elements and specific pollutants in classification of ecological status. In good ecological status, general physico-chemical quality elements should not reach levels outside the range established to ensure ecosystem functioning and the achievement of the values specified for the biological quality elements ((a) in the middle box in Figure 3) and specific pollutants should meet the Environmental Quality Standards (EQS) set in accordance with Section 1.2.6 in the Directive ((b) in the middle box in Figure 3).

Once European EQS have been established, priority substances are not included in the ecological status, but are relevant for assessment of chemical status (Article 2, Annex X and Article 16(7) dealing with priority substances). For the purpose of assessing ecological status the quality elements for specific pollutants listed in Annex V, 1.1 and 1.2 ("specific synthetic pollutants" and "specific non-synthetic pollutants") must be considered and their national quality standards must be met[10]. Shifting of priority substances for which EU-wide quality standards have been set from ecological to chemical state assessment does not compromise the good status of a water body because for good status, both ecological and chemical status must be good.

The Expert Advisory Forum on Priority Substances will continue the discussion on these points in order to ensure a smooth transition from the current requirements to the upcoming proposals under Article 16 of the Water Framework Directive.

[10] Examples on how to select the specific pollutants that are relevant to a particular water body are described in the WFD CIS Guidance Document No. 3 from Working Group 2.1 (IMPRESS).

Annex V: 1.4.1 (ii). Comparability of biological monitoring results

> *In order to ensure comparability of such monitoring systems, the results of the systems operated by each Member State shall be expressed as ecological quality ratios for the purposes of classification of ecological status. These ratios shall represent the relationship between the values of the biological parameters observed for a given body of surface water and the values for these parameters in the reference conditions applicable to that body. The ratio shall be expressed as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero.*

Classification of ecological status is to be based on ecological quality ratios, which are derived from biological quality values as illustrated in Figure 4. No EQR scheme or intercalibration exercise is envisaged in the Directive for classification of ecological status for the supporting physico-chemical quality elements. Member States need to develop their own methods/tools for assessing ecological status for these supporting elements (see above, and Figure 3).

The issue of how to use physico-chemical quality elements for classification of ecological status will be further developed within the work programme of the Common Implementation Strategy during 2003.

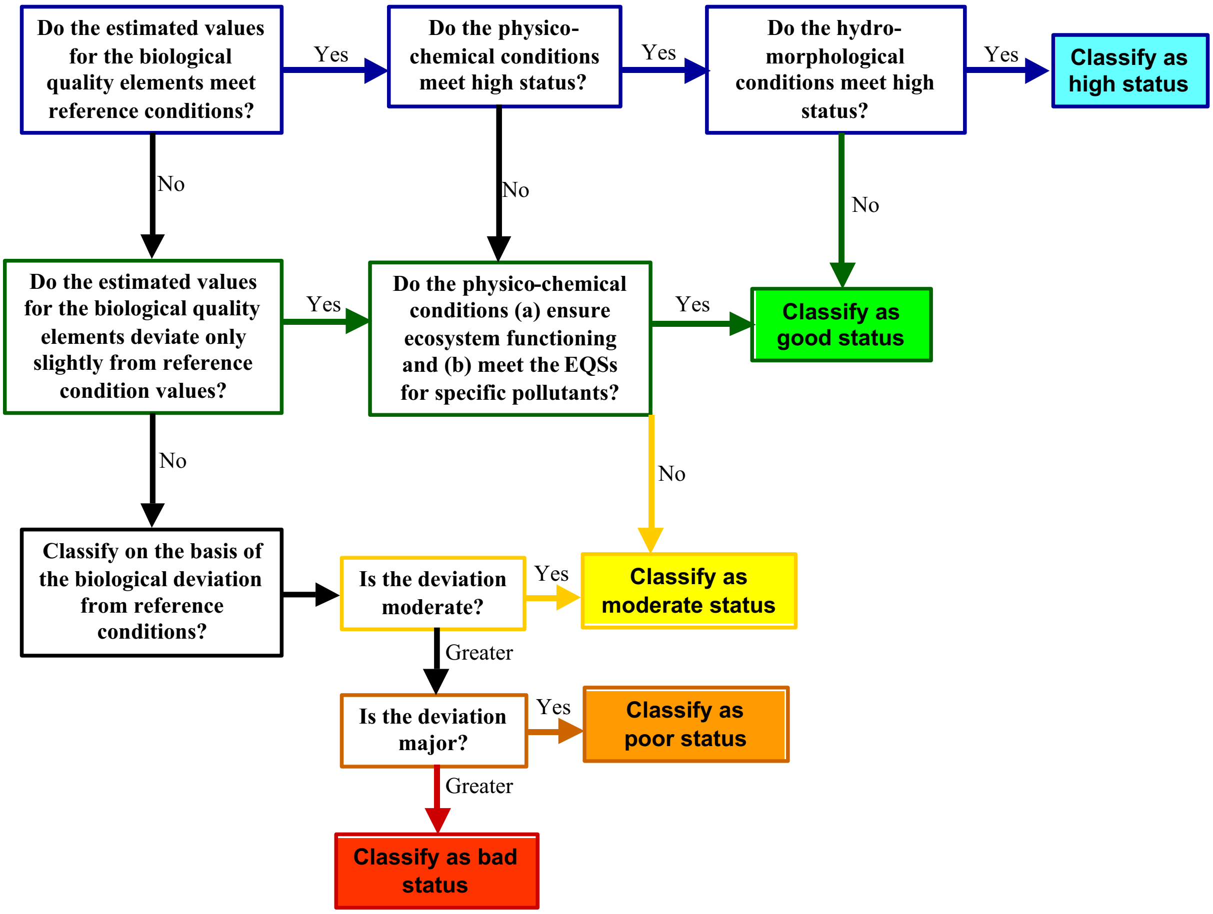

Figure 3. Indication of the relative roles of biological, hydromorphological and physico-chemical quality elements in ecological status classification according the normative definitions in Annex V:1.2. A more detailed understanding of the role of physico-chemical parameters in the classification of ecological status will be developed in specific guidance on this issue during 2003.

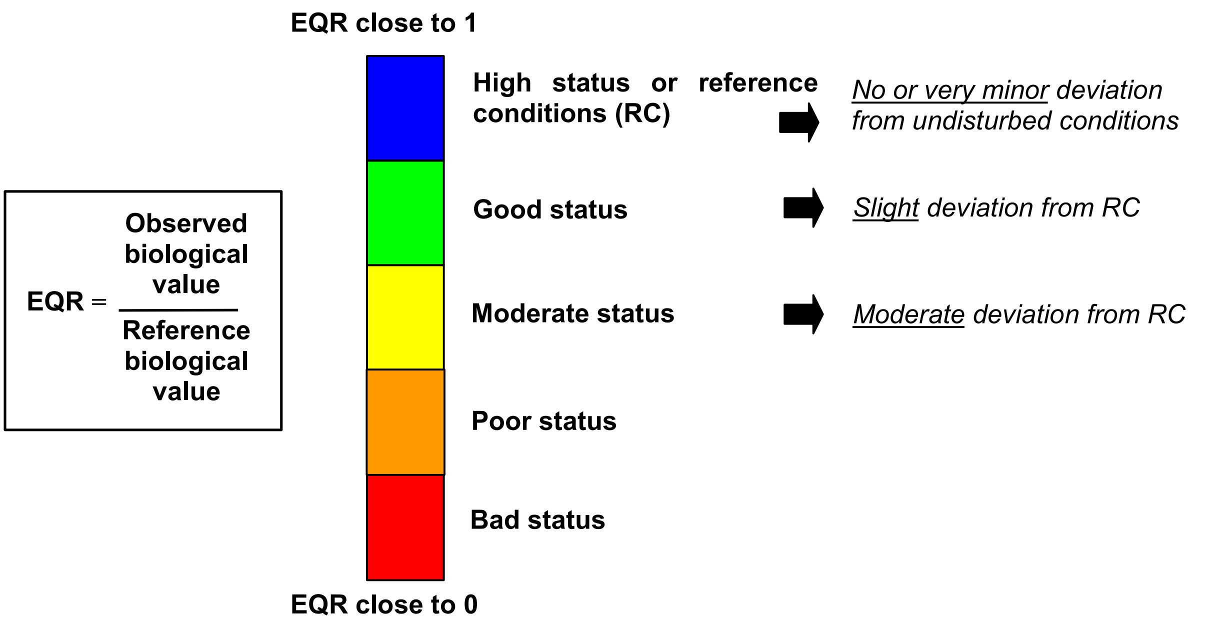

Figure 4. Basic principles for classification of ecological status based on Ecological Quality Ratios.

Table 2. Quality elements to be used for the assessment of ecological status based on the list in Annex V, 1.1, of the Directive.

Annex V 1.1.1. RIVERS	**Annex V 1.1.2. LAKES**
Biological elements	
• *Composition and abundance of aquatic flora*[11] • *Composition and abundance of benthic invertebrate fauna* • *Composition, abundance and age structure of fish fauna*	• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora* • *Composition and abundance of benthic invertebrate fauna* • *Composition, abundance and age structure of fish fauna*

Hydromorphological elements supporting the biological elements	
• *Quantity and dynamics of water flow* • *Connection to ground water bodies* • *River continuity* • *River depth and width variation* • *Structure and substrate of the river bed* • *Structure of the riparian zone*	• *Quantity and dynamics of water flow* • *Residence time* • *Connection to the ground water body* • *Lake depth variation* • *Quantity, structure and substrate of the lake bed* • *Structure of the lake shore*

Chemical and physicochemical elements supporting the biological elements	

• *Thermal conditions*
• *Oxygenation conditions*
• *Salinity*
• *Acidification status*
• *Nutrient conditions*
• *Specific pollutants*
    • *pollution by priority substances identified as being discharged into the body of water.*
    • *pollution by other substances identified as being discharged in significant quantities into the body of water.*
	• *Transparency*
	• *Thermal conditions*
	• *Oxygenation conditions*
	• *Salinity*
	• *Acidification status*
	• *Nutrient conditions*
	• *Specific pollutants*
	    • *pollution by priority substances identified as being discharged into the body of water.*
	    • *pollution by other substances identified as being discharged in significant quantities into the body of water.*

[11] Phytoplankton is not listed as a quality element in rivers in Annex V, 1.1.1., but is included as a quality element in Annex V, 1.2.1. It should therefore be possible to use phytoplankton as a separate quality element, if needed and appropriate especially in low land large rivers where phytoplankton may be important.

Conclusions and recommendations

- The normative definitions of the Directive (Annex V, Table 1.2) provide the basis for classifying surface waters according to their ecological status and each Member State must develop classification systems that conform to these status definitions;
- Biological as well as supporting hydromorphological and physico-chemical quality elements are to be used by Member States in the assessment of ecological status (relative roles illustrated in Figure 3);
- Ecological status classifications should be made on the basis of the relevant biological and physico-chemical results, and classification should be made using quality elements and not parameters;
- The ecological status is represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements. The practical implementation is to be developed within the work programme of the Common Implementation Strategy during 2003;
- Classification of ecological status is to be based on ecological quality ratios, which are derived from biological quality values as illustrated in Figure 4, and on the Member States assessments of ecological quality for physico-chemical quality elements;
- No EQR scheme is envisaged in the Directive for classification of ecological status based on physico-chemical monitoring results. Member States will apply their own methods/tools for assessing ecological quality for these quality elements (see above);
- No definitions are given in the Directive for physico-chemical or hydromorphological quality elements in poor and bad status;
- All Issues relating to how to use physico-chemical quality elements for classification of ecological status will be further developed within the work programme of the Common Implementation Strategy during 2003.

Section 3. General guidance on principles and methods for establishing reference conditions and ecological status class boundaries

3.1 Overview – a stepwise approach

The establishment of reference conditions and the establishment of ecological quality class boundaries are closely interconnected. To establish the boundary between high and good ecological status it is necessary to identify conditions representing very minor anthropogenic disturbances. To establish the boundary between good and moderate ecological status it is necessary to identify conditions corresponding to slight anthropogenic disturbances. Both the establishment of reference conditions and the setting of class boundaries are dealt with in this chapter.

Figure 5 schematically shows a number of steps that may be taken to establish reference conditions and ecological class boundaries. Reference conditions and ecological class boundaries must be established by Member States for all surface water body types and all relevant quality elements. Member State's classification systems will also be compared in the intercalibration exercise (Annex V: 1.4.1), and the outcome of this intercalibration will be used to set the class-boundaries. This means that the process of intercalibration is closely interrelated with the process of establishing reference conditions and quality class boundaries. The process of intercalibration is described in a separate Guidance Document.

The different steps in the approach outlined in Figure 5 are described in the following sub-sections of Section 3.

The suggested approach for establishment of reference conditions and ecological quality class boundaries involves several technical considerations that might not be transparent to the public, water users and stakeholders. These considerations are, however, crucial for the judgement of the risk that individual water bodies will fail to reach the overall objective good water status by 2015. It is therefore important to involve the public, water users and stakeholders at an early stage in order to reach acceptance for the quality class boundaries finally set. It is also in line with Article 14 in the Directive to involve all interested parties in the implementation of the Directive.

The Guidance Document on "Public Participation", produced by a sub-group within Working Group 2.9 (Best practices in river basin management) will tell more about these forms of participation (WFD CIS Guidance Document No. 8). In short the Directive mentions the following:

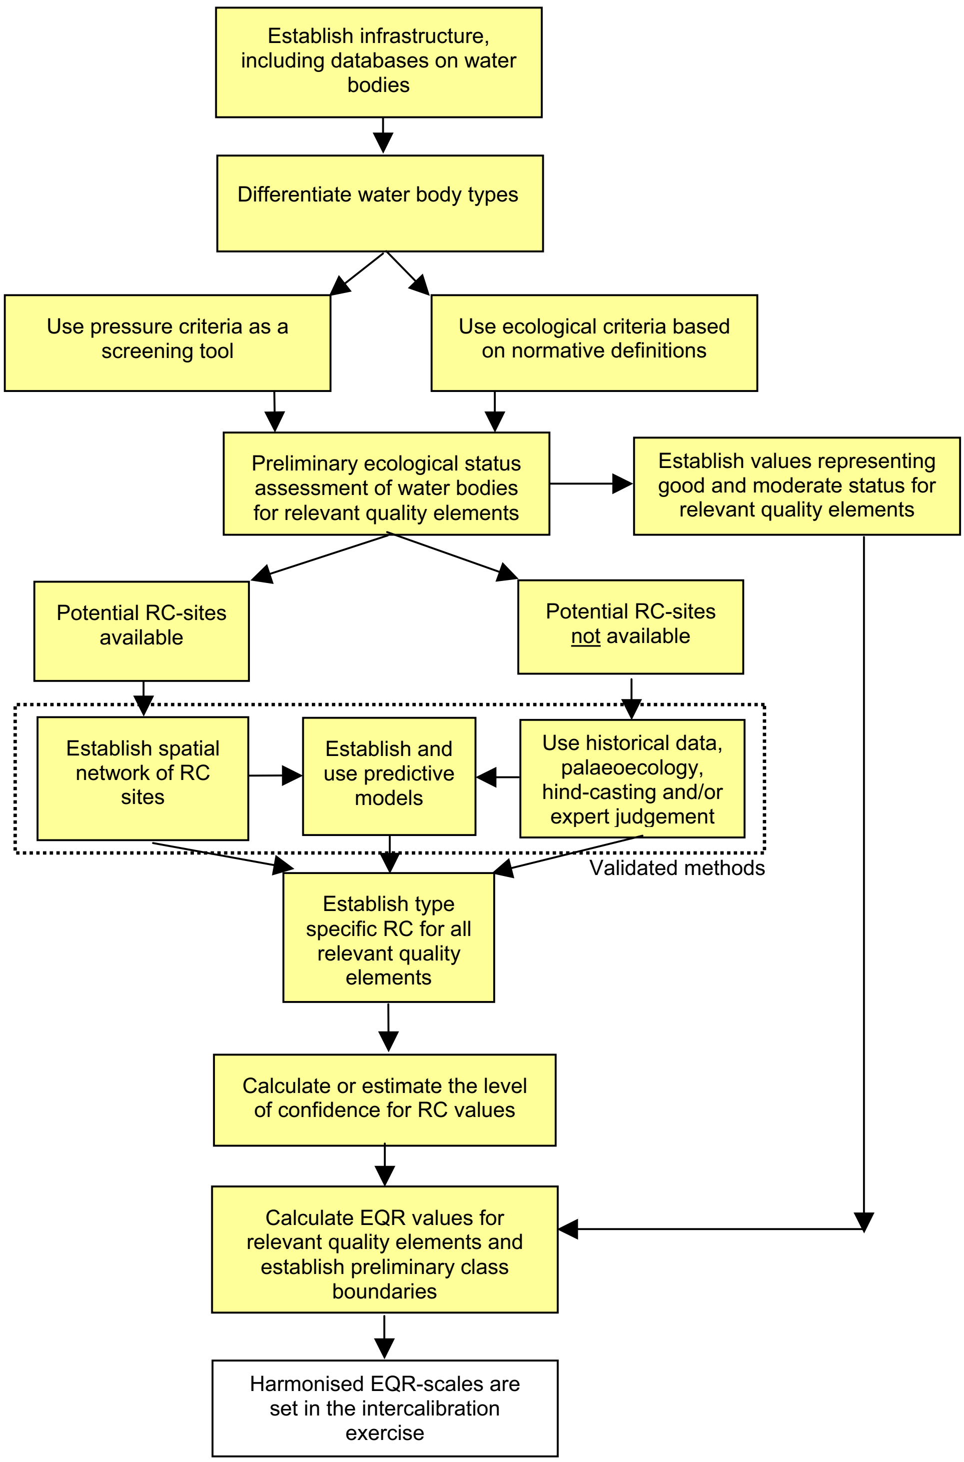

Figure 5. *Flow-chart of the suggested step-by-step approach for establishing reference conditions and boundaries between high, good and moderate ecological status classes (RC=reference conditions, EQR=Ecological Quality Ratio).*

Article 14 promotes the active participation of all interested parties in the development of River Basin Management Plans, and requires Member States to inform and consult the public. Stakeholder participation is important as it can fulfil many functions:

- Developing a process agreed by all will increase the legitimacy of its outcome;
- Stakeholders can be a useful source of information and have expertise of direct use for the reference condition analysis (see Table 1 in Annex G);
- Surveys of the public can be useful to understand how people value improvements in the environment and quality of our waters, and how far they are ready to pay for environmental improvements;
- Public involvement and the network of partners developed through participation can be useful to develop a sense of ownership over the River Basin Management Plans and may increase the effectiveness of measures taken to meet the Directive's objectives.

The Directive only specifies key dates for consultation, but rightly does not specify dates for the participation process, as this will depend on local institutions and socio-reference condition set-up. However, it will be important to start the participation process early (e.g. as part of the characterisation of the river basin before 2004) to improve its effectiveness.

See also Annex G at the back of this document showing who needs to get involved in carrying out and using the REFCOND Guidance.

3.2 Need for infrastructure

Paramount to the implementation of the directive is an infrastructure at the national as well as the water district level consisting of:

- Expertise;
- Databases;
- Assessment methods, models and other tools;
- Organisational structure.

If a robust infrastructure is not available, it would initially be important to set up a group of experts including, for matters relating to reference conditions and classification, ecological, chemical, hydrological, and statistical expertise as well as expertise on modelling, GIS and databases.

Databases are needed for the identification of relevant water bodies and characterisation of relevant pressures and ecological status, and subsequently for unconstrained implementation of the Directive. State variables would be those required in the Directive for characterisation and classification of water bodies (Annex II and V) plus optional variables suggested in the directive or other variables preferred by Member States (see Section 3.3). Pressure variables would include measures of land-use, point source discharges, hydromorphological alterations, etc (see Section 3.4).

Assessment methods, models and other tools should include (i) models for determining point-source and diffuse loadings of nutrients, metals and other substances, (ii) methods for determining biological state variables, and (iii) GIS applications.

The *organisational structure*, finally, will vary depending on the circumstances in Member States, and in many cases it will require a great effort of co-ordination among responsible authorities and stakeholders.

3.3 Differentiation of water body types

The Directive requires that Member States differentiate the relevant surface water bodies with respect to type (using either ”System A” or ”System B”.) and then establish reference conditions for these types. In the following Section guidance is given on the use of System A and B. Interpretations and clarifications regarding concepts and terms are given in Section 2.5.

Of the two systems prescribed in the Directive, System A is the most straightforward and simplest to implement. One clear disadvantage of System A is that the classes established may not adequately partition the variability of the quality elements used, resulting in poor detection of ecological change. Given the inflexibility of System A, most Member States are likely to use System B as a basis for characterising water body types.

System B provides, as indicated above, greater flexibility in defining water body typologies. Implementation of System B should contain both the obligatory factors given in Annex II:1.2 of the Directive and other relevant factors deemed useful by the Member State for minimising quality element variability.

Based on the data-availability, types may be delimited using various grouping procedures; these may be based on commonly used clustering techniques or more intuitive (expert opinion) methods. Statistical methods are also available for determining if “groups” differ from one another (e.g. using randomisation techniques) and if among-group variance can be adequately explained (e.g. using discriminant analysis). The objective of establishing typologies is to partition among-group variance to better detect ecological change.

Unlike the Guidance Document on transitional and coastal waters (WFD CIS Guidance Document No. 5) no common European typology system is proposed for inland surface waters. One reason for this difference is the apparent need for a common typology of coastal waters shared between countries. In contrast to coastal and transitional waters, a number of Member States presently use typology systems for inland surface waters.

Member States sharing the same (eco)region may, however, initiate activities to harmonise typology for inland surface waters on the most appropriate (eco)regional scale as soon as possible or latest in early 2003. This harmonisation should at least cover the types selected to be included in intercalibration and will help in the selection of sites to be included in the draft register for intercalibration network during 2003.

The suggested procedure and timetable for the development of (eco)region specific surface water body typologies to be used for selection of types and sites to be included in the intercalibration exercise is further outlined in Annex F.

Conclusions and recommendations

(Partly repeated, for the sake of clarity, from Section 2.5)

- Water body types may be differentiated using "System A" or "System B";
- The two systems are similar in that they contain the same obligatory factors: geographic position, altitude, size, depth (for lakes) and geology;
- Optional factors of System B can be used as desired by Member States and can be complemented with other factors;
- A data base including, at the least, values of the obligatory factors for relevant water bodies is a prerequisite for differentiation of water body types;
- System A is simple and easy to adopt but has the potential disadvantage of giving a lower level of precision of reference values;
- Using System B, types may be differentiated using various mathematical-statistical clustering methods, regional classifications or more intuitive methods, including expert opinion.

3.4 Use of pressure criteria and ecological criteria

It follows from the Directive that ecological criteria are the definitive test of high ecological status (Annex V:1.2). However, the use of both ecological and pressure criteria may be the most efficient way for screening of potential reference sites or values or needed to aid in at least a preliminary assessment of status of waters. Indeed, to establish reference conditions it could be most cost-effective to start with pressure criteria, because the reference community is defined as the biological community expected to occur where there is no or only very minor anthropogenic disturbance. In other words, to avoid circularity (see Section 3.6.1), pressure criteria may be used conveniently to screen for sites or values representing potential reference conditions. Once identified, biological elements should be used to corroborate this ecological high status.

Figure 6 shows how ecological and pressure criteria may be used (i) for determining potential reference sites or values and setting class boundaries between high and good ecological status, (ii) for determining potential sites for the intercalibration network, and (iii) for identifying bodies at risk of failing to achieve the Directive's objectives. Focus here is on how ecological and pressure criteria may be used for delineating potential reference sites or values and setting class boundaries. However, the approach outlined in Figure 6 may also be used to establish the class boundaries between good and moderate ecological status. Good status is defined in ecological terms as slight deviation from the expected biological reference condition. The setting of class boundaries should however explicitly incorporate the normative definitions for the ecological criteria as stipulated in the Directive (Annex V 2.1). In other words, while pressure criteria might be a proxy measure for assessing risk or screening for sites or values, their role in defining good status is secondary. Ultimately, as mentioned above, it is the biological data assessed against the normative definitions in Annex V 2.1, which will definitively assign water bodies to status classes.

For pressures and quality elements where critical loading models are established (i.e. phosphorus and phytoplankton, or acid rain and fish), pressure criteria can be used to estimate values for the related biological quality element. If the response of the biological quality element is in accordance with the normative definitions for good and moderate status, the values for the biological quality element corresponding to the critical load value can be used to set the border between good and moderate status for that element.

3.4.1 Setting a benchmark for very minor alterations

With regard to the definitions of high and good ecological status given in the Directive, it is necessary to come to a view on the spatial or temporal benchmark to set in respect of anthropogenic pressures so that appropriate comparison against the current condition of water bodies can be made across all Member States.

This allows a determination of whether current conditions in any water body equates to reference state or if a prediction of reference state will be required. The following benchmark for high ecological status or reference conditions is suggested:

- High status or reference conditions is a state in the present or in the past corresponding to very low pressure, without the effects of major industrialisation, urbanisation and intensification of agriculture, and with only very minor modification of physico-chemistry, hydromorpology and biology.

This implies that there should be no fixed temporal and spatial benchmark but raises the problem of not knowing what we are accepting as the degree of change in an anthropogenic pressure that is incorporated into the concept of reference condition.

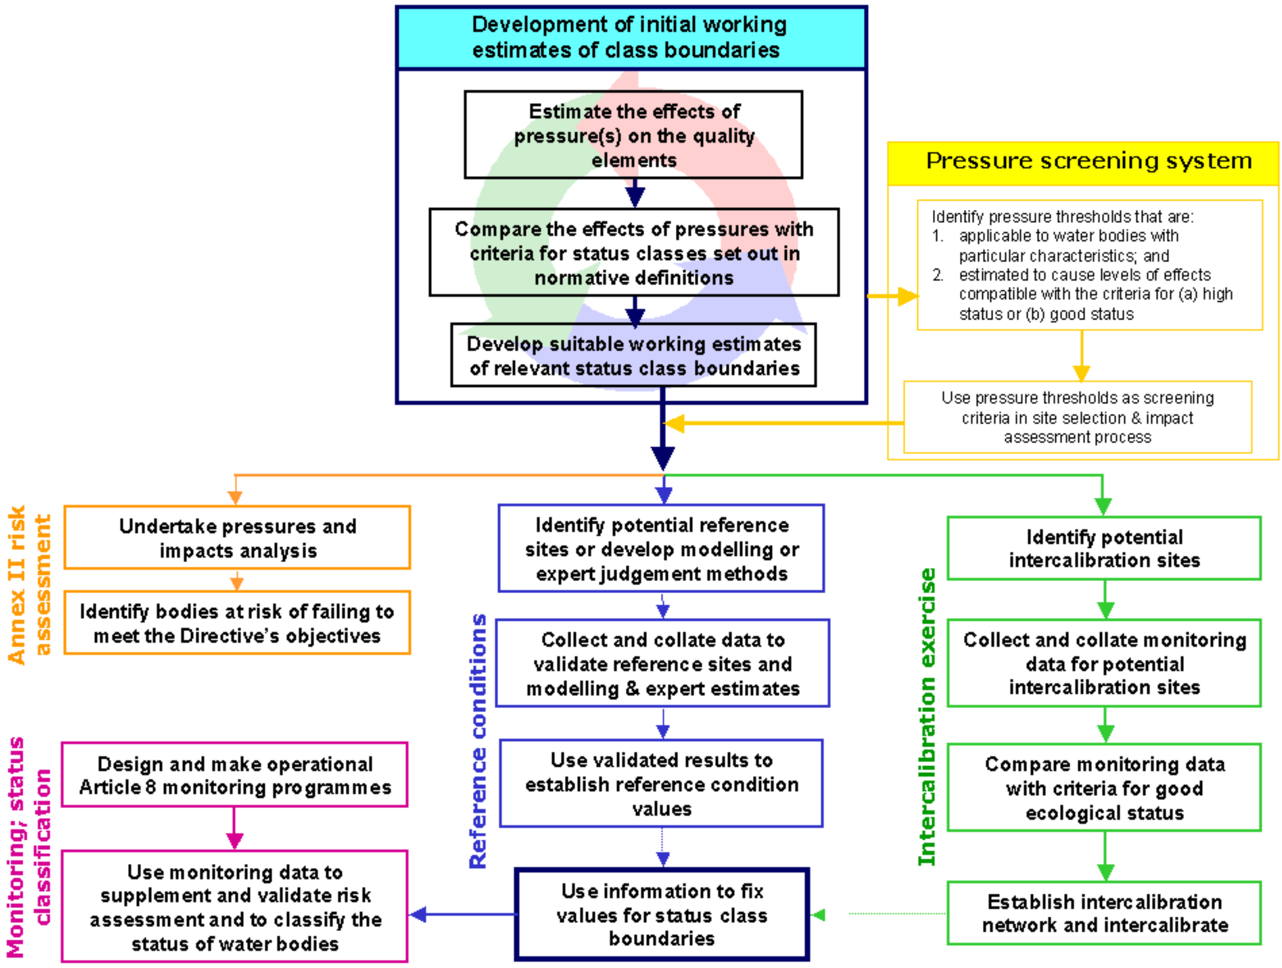

Figure 6. The respective roles of pressure criteria and ecological criteria in identifying status classes.

Bearing in mind the Directive's requirement that reference condition should represent totally, or nearly totally, undisturbed condition but also assuming that an absolutely pristine, post-glacial state is not realistic, then it is proposed that a flexible temporal benchmark as suggested above best fits the legislative intention. However, the temporal benchmark need not be coincidental for each pressure - merely chosen such that reference conditions can be adequately described.

If a water body was physically modified in the past the following recommendations are given:

- If the water body has changed category (e.g. a river impounded by a dam to form a lake) and can therefore be considered for designation as a heavily modified water body, it cannot be used as part of a network of sites for deriving spatially based type-specific reference conditions (e.g. as a reference site for lakes) under Annex II (1.3) of the Directive (see Guidance on heavily modified and artificial water bodies);

- If a water body has changed neither category nor type and the biology shows no or only minor changes, the water body can be considered as a reference site (e.g. kettle hole lakes in Northern Europe which have been artificially increased in size);

For current uses, for example water abstraction, guidance is provided on the degree of acceptable change (i.e. with negligible effect on ecological structure and functioning) within the reference condition. This should be qualified in each case by the over-riding requirement to demonstrate no or only very minor ecological change (see tool 1 in the Toolbox Section).

3.4.2 Pressure criteria as a screening tool

To facilitate the assessments of status classes, the basic process outlined in Figure 6 can be used to identify generic pressure thresholds (or criteria), which, for any water bodies with a specified set of characteristics, would be expected to result in effects that are compatible with a particular status class. These thresholds can then be used to help screen water bodies in order to identify potential reference sites or values, intercalibration sites or bodies that can be confidently identified as not at risk or at risk of failing to achieve their objectives. Critical loads for acid deposition are an example of such thresholds, although the ecological effects they reflect need to be validated with the criteria relevant to the boundary between good and moderate ecological status.

Tool no 1 in the Toolbox Section suggests a set of criteria which elaborate on the degree of acceptable change in an anthropogenic pressure, that would provide the limits of reference condition sites or values and, hence, be used as a screening tool. However, if no or only very few reference sites are available, it would be advisable to consider use of reference state sites in unaltered parts of water bodies elsewhere slightly altered, or use of sites that are altered only regarding certain biological elements. The existence of only minor alteration for all biological elements (relevant for the type) is, however, a prerequisite for the definition of reference sites. Such sites can, accordingly, not be treated as "true" reference sites even if data for a specific quality element is used for establishing reference conditions.

Different water body types will respond differently to one and the same pressure. The proposed pressure screening criteria should therefore be regarded as illustrating concepts and principles to be used for developing water body type specific pressure screening criteria. A prerequisite for the use of pressure screening criteria is that the relationship between pressure-state-impact is established and that the state corresponds to the normative definitions in the Directive (Annex V: 1.2).

3.4.3. Use of ecological criteria

Although the ecological status definitions must be used as the firm basis for establishment of classification systems by Member States (Annex V: 1.2), it might be considered useful to provide some further practical guidance on how such definitions can be developed into more quality element specific descriptions of expected ecological conditions at high, good and moderate status.

The development of robust ecological criteria requires further work beyond this Guidance Document and it is recommended that this should be given high priority. An indicative approach has been provided for the biological quality elements as interim guidance (Tool 2 in the Toolbox Section) but it should be noted that this approach may not be suitable for all types and all pressures. Certain pressures may induce specific needs for ecological status assessment and the choice of parameters may need adjustment according to type and also to prevailing monitoring systems.

With the exception of fish[12] no specific guidance is given in the directive as to the level of taxonomic resolution that is required for the purpose of the characterisation of the biological communities at reference condition and for the derivation of the interpretations of the status of these communities at the various quality classes. Depending on type of water body and pressure, different levels of taxonomic resolution might be necessary to achieve a sufficient level of confidence in classification. Even if it is not required by the Directive, a consensus on the level of taxonomic resolution will be beneficial between Member States sharing similar water body types in the intercalibration exercise, at least concerning data provided for intercalibration.

3.5 Methods for establishing reference conditions

According to the Directive reference conditions need to be established for water body types and quality elements which in turn are represented by parameters indicative of the status of the quality elements. Quality elements may however be excluded from the assessment procedure, and hence establishment of reference conditions is not necessary, if they display high degrees of natural variability (see Section 3.7). In addition, it may be difficult to establish type-specific reference communities for all quality elements with acceptable precision. However, certain biological quality element indicators, such as taxa richness or the presence of sensitive taxa, may be less variable than others (e.g. community composition) and hence more reliably inferred (e.g. if few reference sites are available). Furthermore, it should be emphasised that the reference conditions should be established for the same quality element indicators that will be used for the classification of ecological status.

The basis for the identification of reference conditions is given in Annex II, 1.3 in the Directive. Without any specific ranking of the methods the main options for establishing reference conditions are:

- Spatially based reference conditions using data from monitoring sites;

[12] For fish quality elements the Directive (Annex V 1.2.1 – 1.2.2) specifically referes to species.

- Reference conditions based on predictive modelling;
- Temporally based reference conditions using either historical data or paleoreconstruction or a combination of both;
- A combination of the above approaches.

And where it is not possible to use these methods, reference conditions can be established with expert judgement.

A short description of a number of methods commonly used to ascertain reference conditions is given below. It should be noted that establishing reference conditions for many quality elements may involve using more than one of the methods described below.

3.5.1 Spatially based reference conditions

If undisturbed or minimally disturbed sites are available and numbers are adequate for determining a reliable measure of mean, median or mode and distribution of values (percentiles, confidence limits), then the use of survey data is one of the most straightforward methods available for establishing reference conditions. This is done a priori by collection of data from reference sites only, by using inclusion/exclusion criteria for delineating a reference population. One of the reasons that spatially based or survey approaches are commonly used is that they can be designed to include natural (both spatial and temporal) variability. For example, in establishing reference communities using field surveys, water body and site stratification (e.g. by size, altitude, substratum, etc) should insure adequate representation and precision of distinctive ecosystem types. In addition, the importance of temporal variability can be dealt with directly if among-year variability is measured. A disadvantage of this approach is that spatially extensive data sets are needed to cover the inherent variability within all water body types.

3.5.2 Reference conditions based on predictive modelling

When adequate numbers of representative reference sites are not available in a region/type, predictive modelling, using the data available within a region/type or “borrowing” data from other similar regions/types, can be used in model construction and calibration.

One of the advantages of using predictive approaches is that the number of sites needed for reliable estimates of mean or median and error are usually lower than those needed if spatial approaches are used. This usually results in fewer sites that need to be sampled, and lower implementation costs. A second advantage of using predictive approaches is that the models can often be “inverted” to examine the likely effects of mitigation measures. It must be stressed that predictive models only are valid for the ecoregion and water body type they are created for.

3.5.3 Temporally based reference conditions

Temporally based reference conditions may be based on either historical data or paleoreconstruction, or a combination of both approaches. Both of these approaches are commonly used in areas where human-induced stress is widespread and unperturbed references are few or lacking entirely. For example, paleoreconstruction of past conditions may be determined either (i) directly, based on species presence/absence from fossil remains or (ii) indirectly, using relationships between fossil remains and inference to determine other values such as the reference pH situation. One of the strengths of a paleo-approach is that it can often be used to validate the efficacy of other approaches if the conditions are stable.

Another advantage is that recent step-changes in ecological status are more easily determined. A third strength of palaeoreconstruction is that if strong relationships exist between land use and ecosystem composition and function, a predictive approach (hindcasting or extrapolating dose-response relationships) may be used to predict quality elements prior to major alterations in land use (e.g. pre-intensive agriculture).

Both of these approaches share, however, some of the same weakness. They are usually site- and organism-specific, and hence may be of limited value for establishing type-specific values. Regarding palaeoreconstruction, caution should also be exercised in unequivocal reliance on this method as providing the definitive value, as choice of the calibration dataset used to infer ecological status may result in different values. Regarding the widespread use of historical data, it may be limited by its availability and unknown quality.

3.5.4 Establishing reference conditions using expert judgement

Expert judgement usually consists of a narrative statement of expected reference condition. Although an expert´s opinion may be expressed semi-quantitatively, qualitative articulation is probably most common. Use of expert judgement may by warranted in areas where reference sites are lacking or few. However, one of the strengths of this approach is that it may also be used in combination with other methods. For example, expert judgement may be used to extrapolate findings from one quality element to another (i.e. paleoreconstruction using fossil diatom remains may be used to infer invertebrate community composition) or to extrapolate dose-response relationships to those expected in unperturbed sites. Another strength of this approach is that both empirical data and opinion can be amalgamated with present-day concepts of ecosystem structure and function.

However, as a number of weaknesses are inherently associated with this approach, caution should be exercised when using this approach as the sole means of establishing reference condition. For example, subjectivity (e.g. the common perception that it was always better in the past) and bias (e.g. even sites with low diversity can be representative) may limit its usefulness. Other drawbacks include the lack of clarity or low degree of transparency in assumptions used to establish reference and the lack of quantitative measures (e.g. mean or median values) for validation. A further weakness of this (and many other approaches) is that the measure obtained is often static, and hence does not include the dynamic, inherent variability often associated with natural ecosystems.

3.5.5 Concluding remarks

Many of the above approaches may be used either singly or in concert for establishing and/or cross-validating reference condition. Knowledge of the inherent strengths and weaknesses of the various approaches or the potential problems associated with using different methods is, unfortunately, weak and fragmentary. A summary of the strengths and weaknesses with different methods is presented in Table 3. Regardless of the approach(es) used to establish reference condition, the variability (or errors) associated with the method(s) should be estimated.

In areas where human-generated disturbances are low or not widespread (e.g. in the Nordic countries), spatial approaches may be used either singly or in concert with predictive modelling to establish potential reference conditions for the quality elements. In contrast, in areas that are/have been strongly affected by single or multiple pressures, identification of potential reference conditions may require a suit of methods and substantial validation.

Table 3. Strengths and weaknesses of a few approaches commonly used to determine reference condition.

Approach	Strengths	Weaknesses
Spatially based using survey data	Region specific	Expensive to initiate
Predictive modelling	Site-specific	Requires data, calibration and validation
Historical data	Often inexpensive to obtain	Variable data, few parameters and data quality may be poor or unknown, static measure
Palaeoreconstruction	Incorporates both physico-chemical and biological data	Basically limited to lakes, high initial costs
-Direct	Site-specific	Few parameters
-Indirect	Calibration models currently available for modelling a number of stressor variables; pH, total phosphorus and temperature reconstructions	
Expert opinion or best judgement	May incorporate both historical data/opinion and present day concepts	Bias may be present

3.6 Validation of reference conditions and ecological class boundaries

Knowledge of the variability or uncertainty associated with establishing reference conditions and setting ecological class boundaries is a crucial step in the process of determining the ecological status of water bodies. Clearly, estimating the errors associated with ecological banding schemes and validation of reference conditions are important steps. An intercalibration exercise will be facilitated by the Commission in accordance with Annex V, Section 1.4.1, in the Directive. This exercise will calibrate the class boundaries established by the Member States. As there is a Guidance Document available on intercalibration (WFD CIS Guidance Document No. 6) this Section will focus more on validation of reference conditions.

3.6.1 Minimise risk of circularity

To minimise risk of circularity in establishing reference conditions, ideally mainly physico-chemical, hydromorphological and pressure criteria (i.e. community driving forces) should be used in a first step. Inclusion of biological quality elements in this first step of screening for potential reference sites or values may introduce bias (e.g. different persons/experts may have different perceptions of what reference conditions represents) and circularity (i.e. use of the same variable to delineate and validate reference condition). There will also be a risk that naturally occurring rare water body types (e.g. naturally nutrient poor, low diversity water bodies) will not be detected. In practice, however, it is likely that Member States may have to resort to using all data currently available (including biological data), to initially identify potential reference sites or values. If biological quality elements are used in this initial stage, it is important that additional biological data (e.g. for other quality elements) is collected to verify the final identification of a site as a reference.

If a water body fulfils the requirements for reference conditions in this first step, biological reference conditions can then be established in the next step. The suggested procedure can be described as follows:

- Find sites at which on the basis of all the identified pressures, the physico-chemical, hydromorphological and biological quality elements are believed to be subject to no more than minor disturbance. Use Tool 1-2 in the Toolbox Section for this initial risk assessment;

- Sample the biological quality elements to see if they appear to be only affected, if at all, by minor alterations to the physico-chemical and hydromorphological quality elements. If sampling shows that a biological value is more disturbed than predicted by the risk assessment, further investigation of possible pressures and their effects should be undertaken (i.e. refinement of the risk assessment);

- If sites deviate from what is expected to occur under reference conditions, but no known human-generated pressures are evident, removal of these sites should be considered. Care should, however, be exercised as these sites may indicate the true, natural, variability expected to occur.

3.6.2 Secure documentation

As part of the decision-making process, it is important to document how the values representing reference conditions and ecological quality class boundaries have been established. Likewise, the steps taken to validate reference and class boundaries need to be documented in detail.

3.6.3 Validation of methods

Since different methods used to establish reference conditions most likely have different inherent errors, some form of validation procedure needs to be performed. Clearly the main issue is to determine whether the reference values obtained can be used to achieve robust classifications of ecological status (see Section 3.7). When several methods have been used for establishing reference conditions, they should be compared, if possible, using the same quality element(s). If the outcome of this comparison is that there is a significant difference between the different methods there has to be an expert judgement on how to set the value.

3.7 Assessing variability in reference conditions

The Directive requires a "sufficient level of confidence about the values for the reference conditions" regardless of which method is used for establishing reference conditions (Annex II, 1.3). Adequate confidence and precision in the classification of the quality elements is another statistical requirement mentioned in the Directive (Annex V, 1.3).

Neither "sufficient level of confidence about the values for the reference conditions" nor "adequate confidence and precision in the classification" is specified in statistical terms in the Directive. It is, consequently, up to the Member States to decide about this definition, taking into account the natural spatial and temporal variability for different quality elements together with errors associated with sampling and analysis.

The Directive´s requirements about confidence levels require relevant databases including data of several years for a good temporal variations appraisal. Such databases will, however, not be necessarily available for the first River Basin Management Plan publication in 2009. So, the databases have to be improved during the first RBMP implementation and at the latest 3 years after the first RBMP publication to be able to consider in 2015 if the WFD targets have been failed or fulfilled on sufficient statistical basis.

Methods for establishing reference condition and setting class boundaries must include an estimate of error. This information is needed to determine the confidence and precision in status classification. For example, estimates of a biological reference condition will incorporate the natural (i.e. real) variability of the quality element in time and space and the errors in the method of estimation.

3.7.1 Sources of errors

A multitude of factors can affect measurement uncertainty and confound interpretations using biological parameters. The most common errors are related to measurement and include errors associated with sampling effort and sample processing. The importance of natural variability can also vary among organism groups. For example, small organisms such as those making up the phytobenthos community may change markedly over a period of weeks, whereas macrophyte and fish communities may have much longer response scales (e.g. years). An understanding of how uncertainty is related to different methods is needed to better interpret human-induced deviations from those naturally expected to occur.

Regardless of the method used to establish reference condition, it is important to estimate the errors that are inherently associated with the method used and how levels of uncertainty relate to specific quality elements. Errors can be intrinsically related to different quality elements, and different methods used to establish reference conditions can vary in accuracy and precision. For example, paleoreconstruction is probably more precise than spatially based approaches in reconstructing reference conditions of specific sites. This approach may, however, be less accurate than methods that provide estimates of mean or median values. For example, if the site measured is not representative of the type-specific population, and if an adequate number of sites are not measured to obtain reliable measures of mean or median (e.g. for regional patterns), this method can be less accurate than other methods.

The sources of uncertainty in the observed biological quality fall roughly into the following categories:

- **Sampling errors (natural spatial variation).** Within each site/water body there will be spatial heterogeneity in the microhabitats. This means e.g. that taxonomic richness and composition will vary between samples taken during the same period;
- **Sample process errors.** When e.g. sorting the material in a new macroinvertebrate sample and identifying the taxa, some taxa may be missed or misidentified. This may lead to underestimation of the EQR-value for number of taxa at the site;
- **Analytical errors.** For chemical quality elements the errors associated with different analytical techniques may vary for the same substance;
- **Natural temporal variation**. The taxa present at a site will vary naturally over time.

3.7.2 Choice of quality element indicators

The indicators used in establishing reference conditions and the subsequent classification must enable significant impacts to be reliably detected and recorded through the assignment of an ecological status class. Indicators that do not do this will be unsuitable.

The selection of indicators will be an iterative process, requiring consideration of the factors described below.

- **Relevance**. An indicator should indicate the condition of the quality element. It should be capable of indicating the effects of pressures, and thus represent the response of the quality element to pressures;
- **Responsiveness**. Different indicators may be sensitive to different pressures. The use of different indicators for the same quality element may be appropriate depending on which pressures are affecting a water body;
- **Range of sensitivity**. Indicators may detect effects over a range of pressures but reach their maximum response at a low level of pressure (e.g. a sensitive species may disappear). It may be necessary to use one set of indicators for the lower classes and another for higher classes;
- **Ability of Member States to estimate reference values**. Values for some indicators may be more easily estimated than others. For example, where there are no sites at reference condition, other options may be to borrow sites from neighbour regions or states, use historical data, modelling or expert judgement to estimate reference conditions for some indicators;
- **Variability**. Indicators whose natural variability is high and poorly understood are likely to be unsuitable. Indicators measured by methods that produce large sampling and analysis errors, or for which the size of the sampling and analysis errors has not been quantified, are also likely to be inappropriate;
- **Confidence**. Indicators should be selected so that there is good and demonstrable confidence and precision in classification of ecological status. If confidence is low, the range of uncertainty in the value of the quality element may span the boundaries of several or all the classes. This will result in random allocations of status class and false indications that class has changed.

If the risk of misclassification is too large, more than one indicator may be used to estimate the value of the quality element. In such cases, the number of indicators, and the means by which the data for these are combined, should be such as to achieve the required degree of confidence in the estimate for the quality element.

3.7.3 Exclusion of indicators and quality elements

The reference value for each indicator should be identified, including an estimate of the variance associated with it. The variance should be estimated so that a decision can be taken as to whether the indicator can be used to achieve reliable classification. If the variance is too high, reliable classification will not be possible and the indicator should not be used. One reason for excluding a specific quality element from assessment of ecological status is that the natural variability is too large. This would mean that the natural variability is too high for all relevant quality element indicators. This exclusion principle is described in the Directive in the following way:

<u>Annex II 1.3 (vi) Establishment of type-specific reference conditions for surface water body types:</u>

> *Where it is not possible to establish reliable type-specific reference conditions for a quality element in a surface water body type due to high degrees of natural variability in*

that element, not just as a result of seasonal variations, then that element may be excluded from the assessment of ecological status for that surface water type. In such circumstances Member States shall state the reasons for this exclusion in the River Basin Management Plan.

3.8 Setting EQR-based class boundaries

Excerpts from the Directive pertaining to setting quality class boundaries is given in the following Sections of the Directive:

Annex V: 1.4.1 (ii). Comparability of biological monitoring results

In order to ensure comparability of such monitoring systems, the results of the systems operated by each Member State shall be expressed as ecological quality ratios for the purposes of classification of ecological status. These ratios shall represent the relationship between the values of the biological parameters observed for a given body of surface water and the values for these parameters in the reference conditions applicable to that body. The ratio shall be expressed as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero.

Annex V: 1.4.1 (iii)

Each Member State shall divide the ecological quality ratio scale for their monitoring system for each surface water category into five classes ranging from high to bad ecological status, as defined in Section 1.2, by assigning a numerical value to each of the boundaries between the classes. The value for the boundary between the classes of high and good status, and the value for the boundary between good and moderate status shall be established through the intercalibration exercise described below.

Annex V: 1.4.1 (iv)

The Commission shall facilitate this intercalibration exercise in order to ensure that these class boundaries are established consistent with the normative definitions in Section 1.2 and are comparable between Member States.

Annex V: 1.4.1 (vi)

Each Member State monitoring system shall be applied to those sites in the intercalibration network which are both in the ecoregion and of a surface water body type to which the system will be applied pursuant to the requirements of this Directive. The results of this application shall be used to set the numerical values for the relevant class boundaries in each Member State monitoring system.

3.8.1. Options for setting class boundaries

Based on theoretical considerations and the experience from EQR-based classification systems currently used in Member States, the following guidance may be given on alternative options for setting class boundaries. These alternatives are further elaborated in tool 3 in the Toolbox Section. It should be noted, that whereas Member States may set their own class boundaries, harmonisation within a European scale will be achieved through the intercalibration procedure.

The suggested options for setting class boundaries need to be further developed and tested in Pilot River Basins and future work of the Common Implementation Strategy during 2003-4.

Within each of the alternative options A, B and C below, several alternative methods may apply (e.g. different statistical measures). It is recommended to use the method considered most relevant for the available data set.

A. With access to sufficient data from sites or historical records, derived as described in Sections 3.4-3.7, class boundaries may be set as follows for an individual quality element indicator[13]:

1. Establish a suitable summary statistic (e.g. median value or arithmetic mean) of the values pertaining to reference conditions or high status – the reference value[14].

2. Divide the values pertaining to reference conditions (or high status) by the reference value, thus creating a set of normalised values pertaining to reference conditions (or high status). These values are ratios between observed values and the reference value, and as such potential EQR values for the borderline between high and good status.

3. Invert the normalised values if the nominal values increase toward the "bad end" of the scale. This is necessary in order to achieve a final scale that descends from 1 to 0, as required by the Directive.

4. Select a suitable statistic among the normalised values to represent the class boundary between high and good status, e.g. the 10^{th} percentile.

5. Repeat step 2 (and if necessary 3) for values pertaining to good status, i.e. divide by the reference value and (if necessary) invert.

6. Select a suitable statistic among the normalised values arrived at in the preceding step to represent the class boundary between good and moderate. If the 10^{th} percentile were selected in step 4, the same statistic (of the values representing good status) would be selected here.

The same procedure as described above may be used to set the remaining class boundaries if nominal values representing these quality classes are available.

B. With scarce access to data from sites or historical records corresponding to ecological quality criteria, class boundaries may be set as follows for an individual quality element indicator[15]:

1. Establish a tentative scale of ecological quality ratios based on expert judgement of what may be considered to represent appropriate intervals from high to bad quality.

---

[13] Note: Class boundaries will have to be developed for each quality element indicator

[14] The mean or median value from the distrubution of reference site values are considered the most rubust values to be used as the reference value in classification of ecological status (relatively few data/sites needed for sufficient confidence in RC). One disadvantage with using the mean or median value as the reference value is that many reference sites will fall outside the range 0-1 (>1). However, if sufficient amount of data from the reference population exist a high percentile (eg. the 75th, 90th or 95th percentile) may be used as the reference value. This would reduce the problem of many reference sites lying outside the range 0-1. On the other hand, reference values established this way will be very much influenced by extreme values. The conclusion is that the mean or median values from the reference site/data population is considered the best staring point when establishing the classification schemes for ecological status.

[15] Note: Class boundaries will have to be developed for each quality element indicator

2. Apply the scale on a number of real or virtual data sets and compare, by expert judgement, the resulting classification with the ecological quality criteria given by the normative definitions and, if available, further developments of these such as those described in Tool 2 in the Toolbox Section.

3. If necessary adjust the scale and repeat the procedure described in Step 3 above until a scale of class boundaries has been established that results in a classification corresponding to the ecological quality criteria.

C. A statistical distribution approach may be used as an alternative to the above one based on expert judgement if the ecological quality criteria represented by the normative definitions and the developments thereof are deemed too weak to support any judgement of where the borderlines between quality classes should be:

1. Establish a suitable summary statistic (e.g. mean value or percentile) of the reference values.

2. Calculate EQR ratios by normalising all values of the reference dataset (i.e. divide all values by the selected reference value).

3. Determine the "upper anchor" and in doing so the width of the high or reference band by selecting an appropriate statistic (e.g. the 10^{th} percentile) using the distribution of the reference values. The width of this class is determined by the natural variation associated with undisturbed or least impaired reference sites. The upper anchor is also the class boundary between high and good ecological status.

4. Determine the width of the four remaining classes by dividing the interval between the upper and lower anchors equally. The lower anchor used in setting classification band widths can be a zero value. However, some thought should be given to using the minimum value measured or expected to occur in nature. Setting the lower anchor to a value > 0 might be more ecologically relevant and should result in lower probabilities of committing type 2 errors.

3.8.2 Errors associated with classification schemes

Once a classification scheme has been established, the error associated with the individual classes (i.e. misbanding errors) needs to be determined. Determination of the error or uncertainty associated with a classification scheme can be done using a number of randomisation tests. In brief, uncertainties in classification need to explicitly address the question of "what is the probability that a site is assigned to the wrong class?" If a site is incorrectly placed in a class denoting poorer ecological status than the actual condition this is considered as a type 1 or false positive error. If a site is incorrectly placed in a class denoting higher ecological status than the actual condition this would be classified as a type 2 or false negative error. False negative errors (i.e. wrongly assigned to a higher class) mean that ecological degradation may proceed undetected, while false positive errors may cause hugely wasted effort and investment in monitoring and measures. Consequently, both kinds of errors have serious associated problems.

Furthermore, attempts at lowering false negative error frequencies are in line with the European Councils precautionary principle. Article 7 of this resolution states that the Council "considers that use should be made of the precautionary principle where the possibility of harmful effects on health or the environment has been identified and preliminary scientific evaluation, based on the available data, proves inconclusive for assessing the level of risk" (European Council Resolution on the Use of the Precautionary Principle, 14328/00, 5 December 2000).

The errors associated with classification schemes can be alarmingly high. Therefore, an understanding of the errors associated with misclassification is needed so as to design and implement cost-effective monitoring and assessment programmes.

Section 4. The Toolbox

The toolbox includes the following elements and instruments which can be seen as examples illustrating possible ways of implementing the different steps in the REFCOND Guidance. All tools need to be further developed and tested by Member States for specific water body types and pressures The Pilot River Basin testing during 2003-4 will also contribute in the development of the REFCOND tools and tools from other Guidance Documents.

List on tools included in the toolbox:

1. Pressure screening criteria for high status sites or values;
2. Ecological criteria or interpretations of normative definitions for the biological quality elements;
3. Examples on setting class boundaries according to alternative A, B and C in Section 3.8.

Tool 1. Proposed pressure screening criteria for selecting potential reference condition sites or values.

In the table below a set of criteria is suggested which elaborate the degree of acceptable change in an anthropogenic pressure that would provide the limits of high status sites or values. The table may be used as a screening tool alongside with ecological criteria for selection of potential reference sites or values. A prerequisite for the use of pressure screening criteria is that the relationship between pressure and ecological impact is well established and that the impact corresponds to the normative definitions in the Directive (Annex V: 1.2). The screening criteria is suggested to be further developed into water body type specific criteria and tested in Pilot River Basins and future work of the Common Implementation Strategy during 2003-42004.

	High ecological status
General statement	• High status or reference conditions is a state in the present or in the past corresponding to very low pressure, without the effects of major industrialisation, urbanisation and intensification of agriculture, and with only very minor modification of physico-chemistry, hydromorpology and biology.
Diffuse source pollution	
Land-use intensification: Agriculture, forestry	• Pre-intensive agriculture or impacts compatible with pressures pre-dating any recent land-use intensification.
	• Pressures pre-dating any recent intensification in airborne inputs that could lead to water acidification.
Point source pollution	
Specific synthetic pollutants	• Pressures resulting in concentrations close to zero or at least below the limits of detection of the most advanced analytical techniques in general use (A Selection process for relevant pollutants in a river basin is presented as an example of best practice in Section 6 of the WFD CIS Guidance Document No. 3 from Working Group 2.1, IMPRESS).
Spec. non-synthetic pollutants	• Natural background level/load (see reference above)
Other effluents/discharges	• No or very local discharges with only very minor ecological effects.
Morphological alterations	
River morphology	• Level of direct morphological alteration, e.g. artificial instream and bank structures, river profiles, and lateral connectivity compatible with ecosystem adaptation and recovery to a level of biodiversity and ecological functioning equivalent to unmodified, natural water bodies
Lake morphology	• Level of direct morphological alteration, e.g. structural modifications that hinder fluctuations of the water surface, compatible with ecosystem adaptation and recovery to a level of biodiversity and ecological functioning equivalent to unmodified, natural water bodies
Water abstraction	
River and lake water abstraction	• Levels of abstraction resulting in only very minor reductions in flow levels or lake level changes having no more than very minor effects on the quality elements.

Flow regulation	
River flow regulation	• Levels of regulation resulting in only very minor reductions in flow levels or lake level changes having no more than very minor effects on the quality elements.
Riparian zone vegetation	
	• Having adjacent natural vegetation appropriate to the type and geographical location of the river.
Biological pressures	
Introductions of alien species	• Introductions compatible with very minor impairment of the indigenous biota by introduction of fish, crustacea, mussels or any other kind of plants and animals. • No impairment by invasive plant or animal species.
Fisheries and aquaculture	• Fishing operations should allow for the maintenance of the structure, productivity, function and diversity of the ecosystem (including habitat and associated dependent and ecologically related species) on which the fishery depends • Stocking of non indigenous fish should not significantly affect the structure and functioning of the ecosystem. • No impact from fish farming.
Biomanipulation	• No biomanipulation.
Other pressures	
Recreation uses	• No intensive use of reference sites for recreation purposes (no intensive camping, swimming, boating, etc.)

Tool 2. Interpretations of normative definitions for the biological quality elements

The table may not be suitable for all types and all pressures. Choice of indicators may need adjustment according to prevailing monitoring. The table suggested is to be further developed and tested in Pilot River Basins and future work of the ECOSTAT cluster. Interpretations of the normative definitions will also be needed for physico-chemical and hydromorphological quality elements.

Rivers	High Status	Good Status	Moderate Status
Phytoplankton	**Taxonomic composition** – the phytoplankton community will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will reflect the type specific phytoplankton community. Any taxa present that are not from the type specific reference phytoplankton community list are likely either to be at very low abundance or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance. Size structure of the phytoplankton community is indistinguishable from the type specific reference conditions. **Abundance** – Nearly all the taxa present will be within their expected abundance values at reference conditions. **Biomass** – The biomass of the phytoplankton community will be within the range of values expected at reference conditions. **Transparency**- The average transparency will not be significantly changed from that expected at type specific reference conditions as a result of phytoplankton. **Planktonic blooms** – The frequency and intensity of planktonic blooms will be within the range found at reference conditions. **Note:-** *taxonomic composition and abundance are relevant to all pressures; biomass, transparency and planktonic blooms are relevant primarily to eutrophication.*	**Taxonomic composition** – the phytoplankton community may be slightly changed from the type specific reference conditions. The community may contain a minority of taxa which indicate changes from the type specific reference community. Taxa which reflect the type specific reference phytoplankton community are likely still to be dominant. Size structure of the phytoplankton community is near or just outside the type specific reference conditions. **Abundance** – The majority of the taxa present will be within their expected abundance values at reference conditions, but some may deviate significantly from expected. **Biomass** – The biomass of the phytoplankton community will be higher than the range of values at reference conditions. The overall increase in abundance of algae will not be sufficient to significantly alter the light climate or alter the physico-chemical quality of the water or the sediment and thus change the composition of other biota from their expected condition. **Planktonic blooms** – blooms may occur more frequently than expected, but will not be sufficiently frequent or intense so as to cause any significant damage to other quality elements.	**Taxonomic composition** – the phytoplankton community may be significantly changed from the type specific reference conditions. The community may contain taxa which indicate a significant change from the type specific reference community. Size structure of the phytoplankton community is significantly outside the type specific reference conditions. **Abundance** – Many taxa will be outside their expected abundance at reference conditions. **Biomass** – The biomass of the phytoplankton community will be significantly higher than the range of values at reference conditions. Other quality elements, such as macrophytes and benthic invertebrates, may be altered by the increased algal abundance. (e.g. depth of colonisation of macrophytes may be demonstrably affected and significant areas of channel vegetation may have been lost. The benthic invertebrate fauna may be significantly altered as a result of the increased biomass) **Planktonic blooms** – persistent blooms will occur regularly. Even in types where plankton blooms are common at reference condition, these will be considerably more intense than expected at reference conditions and will frequently consist of taxa that do not usually dominate at reference conditions.
Macrophytes and phytobenthos	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will be contained in the type specific taxa list. The number of taxa present will usually be within the range of	**Taxonomic composition** – this will differ slightly from the type specific reference conditions. The majority of taxa present will be in the type specific taxa list, but taxa that are not commonly found at reference condition may constitute a significant part of the flora.	**Taxonomic composition**-– this will differ significantly from the type specific reference conditions. As few as half of the taxa present may be regularly found in the type specific taxa list. Taxa from outside the type specific list (particularly pollution tolerant taxa) may dominate the flora.

[16] Applies only to organic matter pollution.
[17] Applies only to organic matter pollution.

	values expected at reference conditions. Any taxa present that are not from the type specific list, will be naturally uncommon or rare taxa or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance. **Abundance** – Nearly all the taxa present will be within their expected abundance values at reference conditions. The total vegetated area will be within the range expected at reference conditions. **Bacterial tufts and coats**[16] - No bacterial films due to human activity present. (Bacterial tufts and coats should also be considered to include other decomposers such as fungi and microscopic animals)	The number of taxa present will be near or just outside the distribution of values at reference conditions. Dominant taxa at reference condition are likely still to be dominant **Abundance** – The majority of the taxa present will be within their expected abundance values at reference conditions, but some may deviate significantly from expected. **Bacterial tufts and coats**[17] **-** Bacterial films due to human activity may be present underneath stones etc., but not above.	The number of taxa present will be significantly outside the range expected at reference conditions. **Abundance** – Many taxa will be outside their expected abundance at reference conditions and taxa from outside the type specific list may dominate the flora. **Bacterial tufts and coats**[18] - Bacterial tufts and coats visible to the naked eye may be present on the upper surfaces of stones and other substrate, but are likely to cover less than a moderate proportion (for example, 25%) of the available substrate.
Benthic Invertebrate Fauna	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will be contained in the type specific taxa list and the number of taxa present will usually be within the range of values expected at reference conditions. Any taxa present that are not from the type specific list will be naturally uncommon or rare taxa or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance. **Abundance** – Nearly all the taxa present will be within their expected abundance values at reference conditions. **Disturbance sensitive taxa** –Taxa known to be sensitive to the pressures to which the waterbody is subject will be present at levels within the expected values at reference conditions. **Diversity** – The balance of the number of taxa present and their individual abundances is within the range expected at reference conditions. Major Taxonomic Groups –Taxonomic groups which are usually found at reference conditions are present in their expected proportion.	**Taxonomic composition** - the number of taxa present will be near or just outside the distribution of values at reference conditions. The majority of taxa present will be in the type specific taxa list, but taxa that are not commonly found at reference condition are likely to be present. Dominant taxa at reference condition are likely still to be dominant **Abundance** – Some of the taxa present will be outside their expected abundance values at reference conditions. **Disturbance sensitive taxa** –Some taxa known to be sensitive to the pressures to which the waterbody is subject may be absent. **Diversity** – The balance of the number of taxa present and their individual abundances may be outside the range expected at reference conditions. Major Taxonomic Groups – Most taxonomic groups that are usually found at reference conditions are present but numbers of individuals of some of these may be low and occasionally major groups are absent.	**Taxonomic composition** – the number of taxa present will be significantly outside the range expected at reference conditions. As few as half of the taxa present may be regularly found in the type specific taxa list. Taxa from outside the type specific list may dominate the fauna. **Abundance** – Many or even the majority of taxa will be outside their expected abundance at reference conditions. **Disturbance sensitive taxa** –Many of the taxa known to be sensitive to the pressures to which the waterbody is subject will probably be absent. **Diversity** – The balance of the number of taxa present and their individual abundances will usually be outside range expected at reference conditions. This may be due, for example, to large increases in the relative abundance of a few insensitive taxa, combined with the loss of sensitive taxa. Major Taxonomic Groups – Some of the taxonomic groups that are usually found at reference conditions are present but numbers of individuals of some of these may be low and some of the major groups are absent.

[18] Applies only to organic matter pollution.

Fish Fauna	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. Any species present that are not from the type specific list will be naturally uncommon or rare species or their presence will be attributable to the chance occurrence of species outside their normal distribution range. In either case, their presence will not be indicative of disturbance. The number of species present will usually be within the range of values expected at reference conditions. **Abundance** - Nearly all the species present will be within their expected abundance values at reference conditions. The overall fish abundance will be within the range expected at reference conditions. **Disturbance sensitive taxa** –Species known to be sensitive to the pressures to which the waterbody is subject will be present at levels within the expected values at reference conditions. **Age classes** - All expected age classes of the type specific species must be present.	**Taxonomic composition** - the number of species present will usually be just within or just outside the distribution of values expected at reference conditions. The majority of species present will be in the type specific species list, but species that are not commonly found at reference condition may be present. Dominant species at reference condition will still be dominant **Abundance** - Some of the species present may be outside their expected abundance values at reference conditions. The overall fish abundance will usually be near or just outside the range of values expected at reference conditions. **Disturbance sensitive taxa** –Species known to be sensitive to the pressures to which the waterbody is subject will be present at levels near or just outside the lower end of the range of values expected at reference conditions. **Age classes** - All expected age classes of the type specific dominant species must be present. Age classes of minor species may be absent.	**Taxonomic composition** – the number of species present will be significantly outside the range expected at reference conditions. As few as half of the species present may be regularly found in the type specific species list. Species from outside the type specific list may dominate the fauna. **Abundance** – Many or even the majority of species will be outside their expected abundance at reference conditions. **Disturbance sensitive taxa** –Many of the species known to be sensitive to the pressures to which the waterbody is subject will probably be absent. **Age classes** - The type specific dominant species is still present, although expected age classes may be missing. Minor species may be completely absent or represented only at abundances significantly outside the expected range of values for reference condition sites.

Lakes	High Status	Good Status	Moderate Status
Phytoplankton	**Taxonomic composition** – the phytoplankton community will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will reflect the type specific phytoplankton community. Any taxa present that are not from the type specific reference phytoplankton community list are likely either to be at very low abundance or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance. Size structure of the phytoplankton community is indistinguishable from the type specific reference conditions. **Abundance** – Nearly all the taxa present will be within their expected abundance values at reference conditions. **Biomass** – The biomass of the phytoplankton community will be within the range of values expected at reference conditions. **Transparency**- The average transparency will not be significantly changed from that expected at type specific reference conditions as a result of phytoplankton. **Planktonic blooms** – The frequency and intensity of planktonic blooms will be within the range found at reference conditions. **Note:-** *taxonomic composition and abundance are relevant to all pressures; biomass, transparency and planktonic blooms are relevant primarily to eutrophication.*	**Taxonomic composition** – the phytoplankton community may be slightly changed from the type specific reference conditions. The community may contain a minority of taxa which indicate changes from the type specific reference community. Taxa which reflect the type specific reference phytoplankton community are likely still to be dominant. Size structure of the phytoplankton community is near or just outside the type specific reference conditions. **Abundance** – The majority of the taxa present will be within their expected abundance values at reference conditions, but some may deviate significantly from expected. **Biomass** – The biomass of the phytoplankton community will be higher than the range of values at reference conditions. The overall increase in abundance of algae will not be sufficient to significantly alter the light climate or alter the physico-chemical quality of the water or the sediment and thus change the composition of other biota from their expected condition. **Planktonic blooms** – blooms may occur more frequently than expected, but will not be sufficiently frequent or intense so as to cause any significant damage to other quality elements.	**Taxonomic composition** – the phytoplankton community may be significantly changed from the type specific reference conditions. The community may contain taxa which indicate a significant change from the type specific reference community. Size structure of the phytoplankton community is significantly outside the type specific reference conditions. **Abundance** – Many taxa will be outside their expected abundance at reference conditions. **Biomass** – The biomass of the phytoplankton community will be significantly higher than the range of values at reference conditions. Other quality elements, such as macrophytes and benthic invertebrates, may be altered by the increased algal abundance. (e.g. depth of colonisation of macrophytes may be demonstrably affected and significant areas of vegetation may have been lost. The benthic invertebrate fauna may be significantly altered as a result of the increased biomass) **Planktonic blooms** – persistent blooms will occur regularly. Even in types where plankton blooms are common at reference condition, these will be considerably more intense than expected and will frequently consist of taxa that do not usually dominate at reference condition.
Macrophytes and phytobenthos	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will be contained in the type specific taxa list. The number of taxa present will usually be within the range of values expected at reference conditions. Any taxa present that are not from the type specific list will be naturally uncommon or rare taxa or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance.	**Taxonomic composition** – this will differ slightly from the type specific reference condition. The majority of taxa present will be in the type specific taxa list, but taxa that are not commonly found at reference condition may constitute a significant part of the flora. The number of taxa present will be near or just outside the distribution of values at reference conditions. Dominant taxa at reference conditions are likely still to be dominant	**Taxonomic composition**-– this will differ significantly from the type specific reference conditions. As few as half of the taxa present may be regularly found in the type specific taxa list. Taxa from outside the type specific list (particularly pollution tolerant taxa) may dominate the flora. The number of taxa present will be significantly outside the range expected at reference conditions.

	Abundance – Nearly all the taxa present will be within their expected abundance values at reference conditions. The total vegetated area will be within the range expected at reference conditions. **Bacterial tufts and coats** - No bacterial films due to human activity present. (Bacterial tufts and coats should also be considered to include other decomposers such as fungi and microscopic animals)	**Abundance** – The majority of the taxa present will be within their expected abundance values at reference conditions, but some may deviate significantly from expected. **Bacterial tufts and coats** - Bacterial films due to human activity may be present underneath stones etc., but not above.	**Abundance** – Many taxa will be outside their expected abundance at reference conditions. **Bacterial tufts and coats** - Bacterial tufts and coats visible to the naked eye may be present on the upper surfaces of stones and other substrate, but are likely to cover less than a moderate proportion (for example, 25%) of the available substrate..
Benthic Invertebrate Fauna	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. All or nearly all of the taxa present will be contained in the type specific taxa list and the number of taxa present will usually be within the range of values expected at reference conditions. Any taxa present that are not from the type specific list will be naturally uncommon or rare taxa or their presence will be attributable to the chance occurrence of taxa outside their normal distribution range. In either case, their presence will not be indicative of disturbance. **Abundance** – Nearly all the taxa present will be within their expected abundance values at reference conditions. **Disturbance sensitive taxa** –Taxa known to be sensitive to the pressures to which the waterbody is subject will be present at levels within the expected values at reference conditions. **Diversity** – The balance of the number of taxa present and their individual abundances is within the range expected at reference conditions. **Major Taxonomic Groups** –Taxonomic groups which are usually found at reference conditions are present in their expected proportion.	**Taxonomic composition** - the number of taxa present will be near or just outside the distribution of values at reference conditions. The majority of taxa present will be in the type specific taxa list, but taxa that are not commonly found at reference condition are likely to be present. Dominant taxa at reference condition are likely still to be dominant **Abundance** – Some of the taxa present will be outside their expected abundance values at reference conditions. **Disturbance sensitive taxa** –Some taxa known to be sensitive to the pressures to which the waterbody is subject may be absent. **Diversity** – The balance of the number of taxa present and their individual abundances may be outside the range expected at reference conditions. **Major Taxonomic Groups** – Most taxonomic groups that are usually found at reference conditions are present but numbers of individuals of some of these may be low and occasionally major groups are absent.	**Taxonomic composition** – the number of taxa present will be significantly outside the range expected at reference conditions. As few as half of the taxa present may be regularly found in the type specific taxa list. Taxa from outside the type specific list may dominate the fauna. **Abundance** – Many or even the majority of taxa will be outside their expected abundance at reference conditions. **Disturbance sensitive taxa** –Many of the taxa known to be sensitive to the pressures to which the waterbody is subject will probably be absent. **Diversity** – The balance of the number of taxa present and their individual abundances will usually be outside range expected at reference conditions. This may be due, for example, to large increases in the relative abundance of a few insensitive taxa, combined with the loss of sensitive taxa. **Major Taxonomic Groups –** Some of the taxonomic groups that are usually found at reference conditions are present but numbers of individuals of some of these may be low and some of the major groups are absent.
Fish Fauna	**Taxonomic composition** – this will be indistinguishable from the type specific reference conditions. Any species present that are not from the type specific list will be naturally uncommon or rare species or their presence will be attributable to the chance occurrence of species outside their normal distribution range. In either case, their presence will not be indicative of disturbance.	**Taxonomic composition** - the number of species present will usually be just within or just outside the distribution of values expected at reference conditions. The majority of species present will be in the type specific species list, but species, that are not commonly found at reference condition, may be present. Dominant species at reference condition will still be dominant	**Taxonomic composition** – the number of species present will be significantly outside the range expected at reference conditions. As few as half of the species present may be regularly found in the type specific species list. Species from outside the type specific list may dominate the fauna.

	The number of species present will usually be within the range of values expected at reference conditions. **Abundance** - Nearly all the species present will be within their expected abundance values at reference conditions. The overall fish abundance will be within the range expected at reference conditions. **Disturbance sensitive taxa** –Species known to be sensitive to the pressures to which the waterbody is subject will be present at levels within the expected values at reference conditions. **Age classes** - All expected age classes of the type specific species must be present.	**Abundance** - Some of the species present may be outside their expected abundance values at reference conditions. The overall fish abundance will usually be near or just outside the range of values expected at reference conditions. **Disturbance sensitive taxa** –Species known to be sensitive to the pressures to which the waterbody is subject will be present at levels near or just outside the lower end of the range of values expected at reference conditions. **Age classes** - All expected age classes of the type specific dominant species must be present. Age classes of minor species may be absent.	**Abundance** – Many or even the majority of species will be outside their expected abundance at reference conditions. **Disturbance sensitive taxa** –Many of the species known to be sensitive to the pressures to which the waterbody is subject will probably be absent. **Age classes** - The type specific dominant species is still present, although expected age classes may be missing. Minor species may be completely absent or represented only at abundances significantly outside the expected range of values for reference condition sites.

Tool 3. Numerical examples on setting class boundaries according to alternative A, B and C in Section 3.8.

The setting of class boundaries is illustrated below, using imaginary data on a particular quality element indicator – species richness of benthic macroinvertebrates. The description follows the steps outlined in Section 3.8.1.

A. Sufficient data from sites (or historical records) are available

1. Observations at reference condition sites representative of rivers of type XX gave the following set of data (numbers of species per unit area or per effort): 35, 28, 29, 43, 45, 31, 37, 29, 33, 34, 39, 35, 32.

The median value – 34 – was selected to represent the reference value.

2. The data set was divided by the reference value, thus creating a set of normalised values: 1.03, 0.82, 0.85, 1.26, 1.32, 0.91, 1.09, 0.85, 0.97, 1.00, 1,15, 1.03, 0.94.

3. Species richness does not increase toward the ”bad” end of the scale. Hence, there was no need to invert the values arrived at in the previous step in order to achieve a scale that descends from 1 to 0.

4. A lower percentile of the normalised data set arrived at in step 2 above, in this case the 10th percentile, was selected to represent the class boundary between high and good status: 0.83.

5. Observations at sites of river type XX considered to be representative of good ecological status gave the following data set: 30, 27, 28, 31, 27, 29, 28, 23, 27, 24.

6. Division by the reference value (34) gave the following set of normalised values: 0.88, 0.79, 0.82, 0.91, 0.79, 0.85, 0.82, 0.68, 0.79, 0.71.

7. The 10th percentile was, again, selected to represent the class boundary: 0.68.

In summary, the following class boundaries were thus established in terms of EQR values:

High status: ≥ 1.00 – 0.83
Good status: 0.83 – 0.68.

The remaining class boundaries might have been established in the same way, had nominal values representing these quality classes been available.

Finally, one would have to decide weather the scale developed for a particular type of river would be applicable to all types. If not, separate scales would have to be developed.

B. Few data from sites (or historical records) available

1. The following tentative scale of EQR values was established by a group of experts, based on their judgement of what would be appropriate intervals from high to bad in terms of species richness of benthic macroinvertebrates:

High status: ≥1.00 – 0.80
Good status: 0.80 – 0.60
Moderate status: 0.60 – 0.40
Poor status: 0.40 – 0.20
Bad status: <0.20

2. Application of the tentative scale on a number of real and virtual data sets and consideration of whether the scale is compatible with the normative definitions of ecological status in Appendix V, 1.2, of the Directive, and the interpretations of the normative definitions given in Tool 2 of the toolbox of this Guidance Document, caused the group of experts to adjust the class boundaries upwards into the following scale:

High status: ≥1.00 – 0.85
Good status: 0.85 –0.70
Moderate status: 0.70 – 0.55
Poor status: 0.55 – 0.40
Bad status: <0.40.

3. No further iterations were considered necessary. It was recommended that the scale be subject to re-evaluation as more data become available from monitoring and intercalibration procedures.

It was decided to apply the scale on all types of rivers, pending re-evaluation with more data.

C. A statistical approach (alternatives A and B deemed not applicable)

1. Same as A1 above.

2. Same as A2 above.

3. The 10th percentile was selected as the ”upper anchor” and the class boundary between high and good (same as A4 above): 0.83.

4. The width of the four remaining classes was evenly spaced over the remaining interval (the ”lower anchor” was set to 0 as there was considered to be no need to set a higher value). This resulted in the following class boundaries:

High status: ≥1.00 – 0.83
Good status: 0.83 – 0.62
Moderate status: 0.62 – 0.41
Poor status: 0.41 – 0.20
Bad status: <0.20.

The scale would presumably have been levelled off to more even figures, since there was no quantitative basis for a two decimal accuracy.

General comment to tool 3:
When establishing the class boundaries it will be obvious that some sites/data that was pre-selected for a specific quality class will fall in another class in the classification scheme (sites/data close to the boundaries). This means that the first preliminary classification have to be reassessed for these sites/data in the final status classification.

Section 5. Examples on Good Practice

Example 1. Development of a risk based prioritisation protocol for standing waters in Great Britain, based on a georeferenced inventory, as an aid to defining reference conditions.

Principle

Standing waters respond to catchment pressures (including development, land use, changes in land management, and atmospheric deposition) by displaying changes in their physicochemical environment. This in turn leads to changes in the condition of the biological elements supported, and in WFD terms, may lead to movement away from reference condition. The rationale is developed therefore that a measure of catchment pressures will give an indirect estimate of proximity to reference condition. This approach can, therefore, be regarded as a preliminary screening tool or risk assessment method to identify potential reference sites which can then be tested against the ecological criteria of the WFD for reference condition. The crux of this approach is the definition of the WFD high status class boundary based on pressure criteria for "no or only very minor" disturbance, this has not yet been achieved.

Method

Implementation of the WFD requires a procedure to identify lakes at risk of a deterioration in water quality as a result of the presence of a hazard(s) in their catchment. A protocol using a three-tiered hierarchical prioritisation system was developed to assess environmental harm using nutrients and acid deposition as example hazards. In order to carry out these prioritisations, basic information was required on the location, number and size of lakes, in association with ecological and water quality data and target (reference) conditions. Since no single comprehensive inventory of lakes and reservoirs in Great Britain existed, prior to this study, the development of a georeferenced inventory of standing waters in Great Britain and their physical, chemical and ecological properties was an integral part of the project.

In Great Britain there are some 46000 standing waters identified on the 1:50,000 OS maps, and some 14000 waters of >1ha surface area. The regulatory agencies have little data on most of these waters, including many of the larger waters which have been assumed to be in good condition. The only realistic approach to collating information on the bulk of these waters to assist in implementing the WFD was seen as using macro scale datasets covering most of the land surface of GB, together with some simple models to derive estimates of various pressures. The focus of the project to date has been the identification of waters at risk of failing to meet the requirements of the WFD, and this work is described below.

The inventory itself contains basic physical characteristics for all standing waters in Great Britain derived from the 1:50 000 ordnance survey panorama digital dataset. For those water bodies >1 hectare, catchment boundaries were generated and associated attribute data were derived, to allow implementation of the risk based prioritisation protocol. The inventory was linked to external databases using a metadata system and summary water chemistry data were collated from some of these databases for over 400 water bodies. It is hoped that further meta-data and summary data can be added in the future as and when data become available.

Project outline

The project was comprised of two phases, Phase 1, completed in 2001, was a scoping study to identify the content and structure of the inventory and to design the risk based prioritisation protocol. During Phase 2, the inventory has been populated and the risk based prioritisation protocol further developed, tested and refined. The approach used to develop the risk based prioritisation protocol largely follows the framework for environmental risk assessment and management detailed by the DETR (2000). The scheme is based on the three properties, importance, hazard and sensitivity, and appropriate measures of each were determined. A three-tiered approach was adopted whereby an initial rapid assessment is made at Risk Tier 1 for all standing waters in Great Britain (approximately 14,000 greater than 1ha), based on the minimum of information gained from already available data sources. This assessment is then used to guide the acquisition of further data for more detailed evaluation of a subset of standing waters at Risk Tier 2 (a few hundred to a few thousand) and, in even finer detail at Risk Tier 3 on a very small subset of waters (a few tens) for which remedial action is likely to be taken.

Phosphorus as an indication of nutrient enrichment

The anthropogenic phosphorus load (human sewage, run-off from land and domestic farm animal waste – the latter data were not available for Scotland) was used as a measure of the eutrophication hazard. The loads were converted into in-lake concentrations using relevant OECD equations, and lakes were given a rank on the basis of the standard Vollenweider classifications of lake trophic status. Retention time was used to identify lakes where the algae would remain in the lake long enough to utilise the phosphorus in the water. Depth data were unavailable for most lakes so that modelled depths were used in calculations.

Acidification from atmospheric deposition

The Risk Tier 1 estimation of hazard and sensitivity to acidification was much simpler since the appropriate data sets had already been compiled for other purposes. Total acid deposition load was used to identify the level of hazard. Five classes were defined and only those in class 1 (<0.5 keq/ha/y) were not passed through to the sensitivity assessment. Data were already available on the sensitivity of lakes to acidification. The data are available at 1 km square grid scale and relate to the buffering capacity of the dominant soil type and baseline geology within each square. Five sensitivity classes were defined. Only classes 1 and 2 (High and medium-high, respectively) were passed on to the final tier 1 risk assessment. The acid deposition class and freshwater sensitivity class for each lake was assessed jointly and lakes with specified combinations of deposition class and sensitivity class were passed through to the Risk Tier 2 assessment.

Identification of potential reference sites

Eutrophication and acidification have been identified as the two major causes of downgrading of water quality in standing waters across Europe (Ref: Dobris Assessment). The method described here permits National screening of all standing waters greater than 1 ha in size for exposure to the risk of damage from these two hazards. The sub-set of standing waters identified as having minimal exposure to catchment pressures in the Tier 1 assessment form the basis for a Tier 2 more detailed assessment at the site level, both to validate the assessment of the principle pressures of enrichment and acidification and to assess other pressures and impacts of relevance to reference condition such as impoundment, shoreline development etc.

Testing of the protocol outputs

Application of the protocol to 30 test lakes across Great Britain indicates that the schemes for both eutrophication and acidification produce reliable risk assessments. These 30 lakes were sites which are well studied by direct survey and sampling of both their physicochemical and ecological quality. Additionally some sites had undergone palaeolimnological investigation.

It is recommended that this method of identifying potential reference lakes is employed as a first screening step offering a method of dealing with a large number of standing waters for which no direct evidence of condition exists. It could be used in conjunction with the method outlined in Example 2 in this section of this Guidance, the use of palaeolimnology and species turnover measures to select potential reference lakes, to provide a two-way assessment of sites for further evaluation.

Example 2. The use of palaeolimnology and species turnover measures to select potential reference lakes

Principle

The Water Framework Directive requires lakes to be classified according to the assemblage of biological elements they currently support. The system specified for this classification is a state-changed system, comparing any lake's current condition with its condition at a reference state (where: There are no, or only very minor, anthropogenic alterations to the values of the physico-chemical and hydromorphological quality elements for the surface water body type from those normally associated with that type under undisturbed conditions). The identification of a suite of lakes at an undisturbed condition is difficult in Western Europe, and presupposes that all possible causes of disturbance are known and quantified. An alternative method exists for lakes – the use of palaeolimnology. This permits a direct comparison of sub-fossil elements of the biological assemblage representing conditions at some previous undisturbed state with the same biological element in its current state.

Method

In Great Britain most palaeolimnological investigations have worked with diatoms, and for this reason diatoms are the most practical choice for the identification of potential reference lakes across all lake types. Additionally, diatoms have been shown to be amongst the most sensitive of biological elements and responsive to the two most significant pressures in Western European lakes, eutrophication and acidification (Ref: Dobris Assessment). Sediment cores from the deepest part of lakes may be dated and the diatom assemblages characterised and their development traced over long periods of time. For the purposes of the WFD, undisturbed conditions may be interpreted as being those pertaining before the intensification of agriculture and before any gross disturbance by industrialisation. For Great Britain this broadly indicates a period circa 1850. Classification of diatom assemblages existing around this date allows a provisional "diatom based typology" of lakes to be made and comparison of sediment strata at this date with current diatom assemblages permits an assessment of the proximity of each lake to reference condition.

Project outline

Analysed sediment cores exist for 166 lakes across the United Kingdom (England, Scotland, Wales and Northern Ireland) and the strata for circa 1850 or earlier were examined and their diatom assemblages described. Analysis by Ward's minimum variance clustering produced an optimal number of 6 end groups of diatom assemblage. The 166 lakes in the diatom dataset appear to represent a broad range of UK lake types and cover a wide geographical distribution, their diatom assemblages from circa 1850 may be taken then, in the first instance, as representing the major reference assemblages for UK lakes.

Comparison of these bottom core strata with diatom assemblages in the most recent strata allows a direct comparison of previous and current diatom assemblages. The degree of floristic change (diatom species turnover) between the core bottom and surface sample for each of the 166 lakes was assessed using a simple chord distance dissimilarity measure. The scores range from 0 to 2 whereby 0 indicates that two samples are exactly the same and 2 indicates that they are completely different. Any score <0.39 can be judged to have insignificant species turnover at the 2.5th percentile, a score <0.48 at the 5th percentile, and a score <0.58 can be judged to have insignificant species turnover at the 10th percentile.

Within each of the six diatom end groups, the lakes are ranked according to the degree of floristic change between the base and surface core sample.

In Group 1 there are very few lakes with low species turnover, with only two having a chord distance of <0.48. This indicates that there are currently few examples of potential reference lakes for this group in the diatom dataset. Similarly for Group 2, where only 4 lakes have a chord distance <0.48. Both Groups 1 and 2 are largely lowland sites in relatively productive catchments and hence many are impacted by eutrophication. It may be difficult, therefore, to find good examples of potential reference lakes for these lake types.

In Group 3 there are many examples of lakes with low species turnover (c. 50% of lakes in this group have a chord distance of <0.48). Therefore, good examples of reference lakes are available for this lake type. Note, however, that there are very few lakes in this group in England and Wales.

In Group 4, only 7 lakes have a species turnover of < 0.48. Given that this group includes most of the large (deep) lakes, more examples of potential reference lakes in this group may need to be found.

In Group 5, 11 lakes have a species turnover of < 0.48. Many lakes in this group have acidified.

In Group 6, 15 lakes have a species turnover of < 0.48. Whilst there are a number of potential reference lakes, many lakes in this group have been impacted and the pressures appear to include both eutrophication and acidification.

Testing of the project outputs

Sites selected as potential reference sites will be cross checked using pressure criteria from Example 1 in this section of the Guidance “Development of a risk based prioritisation protocol for standing waters in Great Britain, based on a georeferenced inventory, as an aid to defining reference conditions”.

Representative sites having a chord distance of <0.4 from each of the 6 diatom based types have been selected for survey and sampling to determine their current biological assemblages. These data should prove useful for classification tool development and for intercalibration purposes.

At each stage, assessment will be made of compliance with reference state criteria as described in the WFD.

Example output from analysis: Type 4 lochs (highlighted potential reference lochs).

Example 3. The establishment and validation of reference conditions for lakes and large rivers in German parts of the Central European Lowland, ecoregion 14, using paleolimnology

Introduction

The member states of the European Community shall finish the establishment of type-specific reference conditions for surface water body types by 2004. Spatially based reference conditions cannot be derived for all types of lakes and rivers in ecoregion 14. Methods based on modelling are therefore required, especially for shallow and flushed lakes. Type-specific biological and physico-chemical reference conditions based on modelling may be derived using hindcasting methods. One valid opportunity to obtain quantitative data about the natural biota and physico-chemical conditions is to analyse fossil diatom communities in sediment cores and to reconstruct nutrient concentrations based on diatom-environment-transfer functions. These quantitative paleolimnological approaches make use of multivariate statistics and regional calibrated data sets.

Situation in the ecoregion 14

In northern Germany there are approximately 500 lakes each greater than 50 ha. Trophic status ranges from oligotrophic to hypereutrophic. The water bodies are 1 to 68 m deep and fully imbedded in the loamy sand of the Weichselian ice age moraines. Groundwater is rich in hydrogen carbonate and phosphorus, coming from Interglacial lake deposits. The lake internal phosphorus concentration strongly depends on residence time (<0.1 to >30 years) and the latter on lake volume and catchment size (1 to 20,000 km²). All the lake catchments were clear cut during the 12^{th} to 13^{th} centuries and no one lake can be classified undisturbed. After 1750 approximately 30% of the landscapes have been afforested. An assemblage of approximately 30 lakes with small catchment areas were kept from agriculture during the last 200 years and have been quasi renaturalized. These lakes form the web of ecological reference sites of the oligotrophic and slightly mesotrophic stratified lake types. The higher mesotrophic and eutrophic reference conditions for lakes with larger catchments and inflow of surface water by rivers are not available from present-day conditions. Therefore three cooperating REFCOND-relevant paleolimnological projects are in progress or starting in October 2002:

- Paleolimnological reconstruction of reference conditions for flushed lakes in the catchment area of the lowland river Havel (Brandenburg Office for the Environment, funded by Federal Ministry of Education and Research, 2002-2004);
- Biotic reference conditions for shallow lakes: Paleolimnological studies on diatoms, algal pigments, chironomids and macrophytes in the catchment area of the lowland river Spree (Brandenburg University of Technology Cottbus, funded by Ministry of Agriculture, Environment and Structural Development Brandenburg, 2001-2002);
- Reconstruction of natural biotic reference conditions in combination with hydromorphological, hydraulic and hydrochemical conditions on rivers in the northeastern German lowland (Leibniz-Institute of Freshwater Ecology and Inland

Fisheries Berlin, funded by the Senate Department of Urban Development Berlin, 2002-2004).

Type specific reference conditions for lakes using diatoms – principles and first results

The paleolimnological approach is used to reveal undisturbed diatom communities (benthic and planktonic) and to quantify the relationship between catchment size and undisturbed water chemistry with respect to the assumed strong influence of lake morphology.

Weighted-averaging regression and calibration of 304 indicator taxa with tolerance down-weighting and classical deshrinking was used to develop transfer functions between littoral diatoms and TP, TN, DIC, pH, chloride and the DOC:TP ratio in 84 German lakes and river sites (Schönfelder *et al.* 2002). Transfer functions based on littoral diatoms have been used successfully for the reconstruction of past water chemistry in flushed and shallow lakes, for example in the lake Großer Treppelsee, (see Figure 1). For deep lakes a diatom data set based on profundal samples from >100 sites is in progress. Twelve lakes have been selected to drill long sediment cores. They can be grouped into four lake types in respect of their water residence times. Diatom based inferences of TP and TN will be used to establish a model to predict in-lake TP and TN as a bivariate function of lake catchment size and lake volume for undisturbed conditions. The model will be validated using data from the most renaturalized lakes in the region. Recent studies on flushed lakes with a great catchment area such as Großer Treppelsee have shown that the anthropogenic influence on water quality has been evident since AD 1250. In other lakes with smaller catchment areas anthropogenic pressures from settling and intensifying agriculture were not indicated by fossil diatoms before the end of the 18th century.

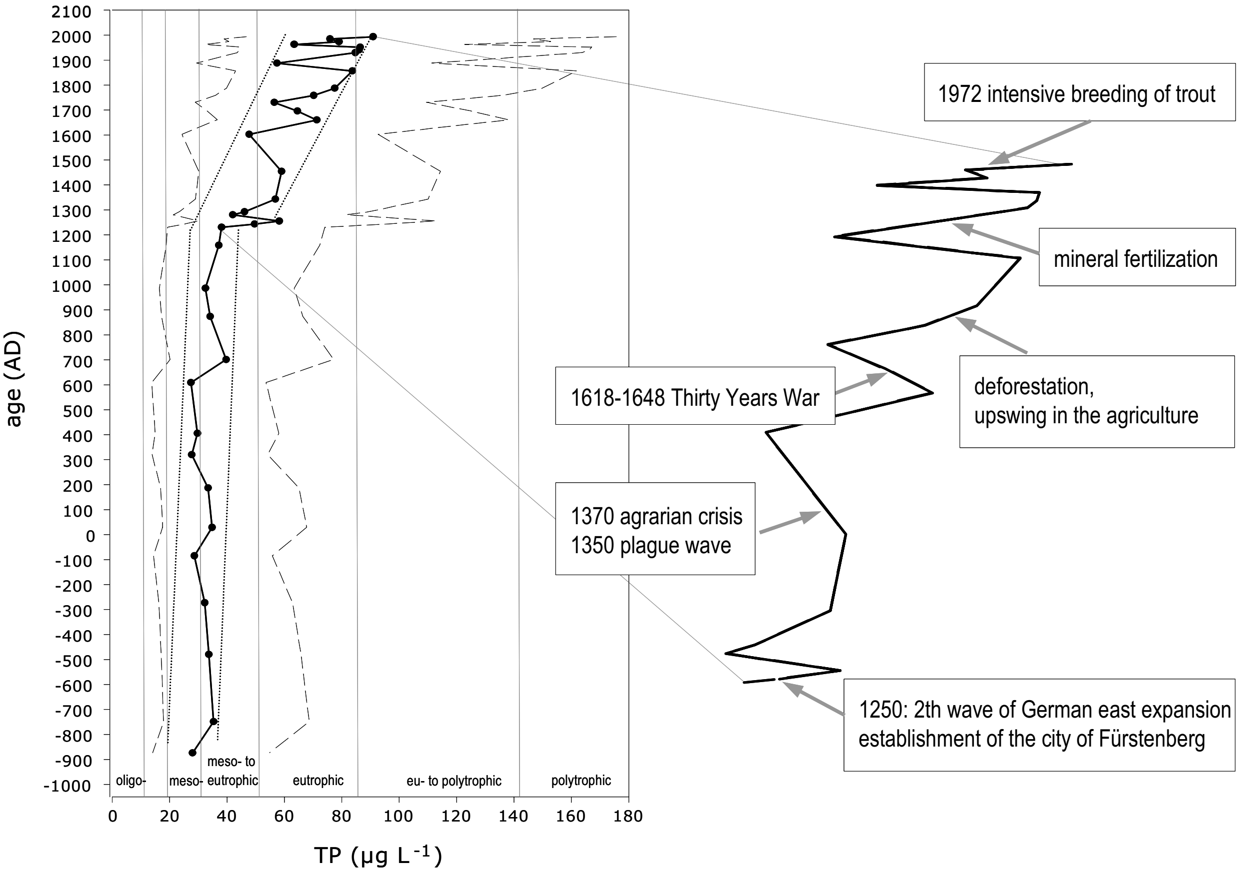

Figure 1. Long term changes of TP concentration of the lake Großer Treppelsees based on diatoms and the main historical events in the catchment which led to higher or lower TP concentrations. The strong anthropogenic impact in this flushed lake started in 1250. To reconstruct undisturbed conditions in such lake types with a large catchment area the water authorities require a quantitative look on past centuries.

Annex C. Normative definitions in WFD of ecological status classifications for rivers and lakes.

1.2 Normative definitions of ecological status classifications

Table 1.2 General definition for rivers, lakes, transitional waters and coastal waters

The following text provides a general definition of ecological quality. For the purposes of classification the values for the quality elements of ecological status for each surface water category are those given in tables 1.2.1 - 1.2.4 below.

	High status	**Good status**	**Moderate status**
General	There are no, or only very minor, anthropogenic alterations to the values of the physicochemical and hydromorphological quality elements for the surface water body type from those normally associated with that type under undisturbed conditions. The values of the biological quality elements for the surface water body reflect those normally associated with that type under undisturbed conditions, and show no, or only very minor, evidence of distortion. These are the type specific conditions and communities.	The values of the biological quality elements for the surface water body type show low levels of distortion resulting from human activity, but deviate only slightly from those normally associated with the surface water body type under undisturbed conditions.	The values of the biological quality elements for the surface water body type deviate moderately from those normally associated with the surface water body type under undisturbed conditions. The values show moderate signs of distortion resulting from human activity and are significantly more disturbed than under conditions of good status.

Waters achieving a status below moderate shall be classified as poor or bad.

Waters showing evidence of major alterations to the values of the biological quality elements for the surface water body type and in which the relevant biological communities deviate substantially from those normally associated with the surface water body type under undisturbed conditions, shall be classified as poor.

Waters showing evidence of severe alterations to the values of the biological quality elements for the surface water body type and in which large portions of the relevant biological communities normally associated with the surface water body type under undisturbed conditions are absent, shall be classified as bad.

1.2.1 Definitions for high, good and moderate ecological status in RIVERS

Biological quality elements

Element	High status	Good status	Moderate status
Phytoplankton	The taxonomic composition of phytoplankton corresponds totally or nearly totally to undisturbed conditions. The average phytoplankton abundance is wholly consistent with the type-specific physicochemical conditions and is not such as to significantly alter the type specific transparency conditions. Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physicochemical conditions.	There are slight changes in the composition and abundance of planktonic taxa compared to the type-specific communities. Such changes do not indicate any accelerated growth of algae resulting in undesirable disturbances to the balance of organisms present in the water body or to the physico-chemical quality of the water or sediment. A slight increase in the frequency and intensity of the type specific planktonic blooms may occur.	The composition of planktonic taxa differs moderately from the type specific communities. Abundance is moderately disturbed and may be such as to produce a significant undesirable disturbance in the values of other biological and physico-chemical quality elements. A moderate increase in the frequency and intensity of planktonic blooms may occur. Persistent blooms may occur during summer months.
Macrophytes and phytobenthos	The taxonomic composition corresponds totally or nearly totally to undisturbed conditions. There are no detectable changes in the average macrophytic and the average phytobenthic abundance.	There are slight changes in the composition and abundance of macrophytic and phytobenthic taxa compared to the type-specific communities. Such changes do not indicate any accelerated growth of phytobenthos or higher forms of plant life resulting in undesirable disturbances to the balance of organisms present in the water body or to the physico-chemical quality of the water or sediment. The phytobenthic community is not adversely affected by bacterial tufts and coats present due to anthropogenic activity.	The composition of macrophytic and phytobenthic taxa differs moderately from the type-specific community and is significantly more distorted than at good status. Moderate changes in the average macrophytic and the average phytobenthic abundance are evident. The phytobenthic community may be interfered with and, in some areas, displaced by bacterial tufts and coats present as a result of anthropogenic activities.
Benthic invertebrate fauna	The taxonomic composition and abundance correspond totally or nearly totally to undisturbed conditions. The ratio of disturbance sensitive taxa to insensitive taxa shows no signs of alteration from undisturbed levels The level of diversity of invertebrate taxa shows no sign of alteration from undisturbed levels.	There are slight changes in the composition and abundance of invertebrate taxa from the type-specific communities The ratio of disturbance sensitive taxa to insensitive taxa shows slight alteration from type specific levels. The level of diversity of invertebrate taxa shows slight signs of alteration from type specific levels.	The composition and abundance of invertebrate taxa differ moderately from the type-specific communities. Major taxonomic groups of the type-specific community are absent. The ratio of disturbance sensitive taxa to insensitive taxa, and the level of diversity, are substantially lower than the type specific level and significantly lower than for good status.

Element	**High status**	**Good status**	**Moderate status**
Fish fauna	Species composition and abundance correspond totally or nearly totally to undisturbed conditions. All the type specific disturbance sensitive species are present. The age structures of the fish communities show little sign of anthropogenic disturbance and are not indicative of a failure in the reproduction or development of any particular species.	There are slight changes in species composition and abundance from the type specific communities attributable to anthropogenic impacts on physicochemical and hydromorphological quality elements. The age structures of the fish communities show signs of disturbance attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements, and, in a few instances, are indicative of a failure in the reproduction or development of a particular species, to the extent that some age classes may be missing.	The composition and abundance of fish species differ moderately from the type specific communities attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements. The age structure of the fish communities shows major signs of anthropogenic disturbance, to the extent that a moderate proportion of the type specific species are absent or of very low abundance.

Hydromorphological quality elements

Element	**High status**	**Good status**	**Moderate status**
Hydrological regime	The quantity and dynamics of flow, and the resultant connection to groundwaters, reflect totally, or nearly totally, undisturbed conditions.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
River continuity	The continuity of the river is not disturbed by anthropogenic activities and allows undisturbed migration of aquatic organisms and sediment transport.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Morphological conditions	Channel patterns, width and depth variations, flow velocities, substrate conditions and both the structure and condition of the riparian zones correspond totally or nearly totally to undisturbed conditions.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.

Physico-chemical quality elements [19]

Element	High status	Good status	Moderate status
General conditions	The values of the physico-chemical elements correspond totally or nearly totally to undisturbed conditions. Nutrient concentrations remain within the range normally associated with undisturbed conditions. Levels of salinity, pH, oxygen balance, acid neutralising capacity and temperature do not show signs of anthropogenic disturbance and remain within the range normally associated with undisturbed conditions.	Temperature, oxygen balance, pH, acid neutralising capacity and salinity do not reach levels outside the range established so as to ensure the functioning of the type specific ecosystem and the achievement of the values specified above for the biological quality elements. Nutrient concentrations do not exceed the levels established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Specific synthetic pollutants	Concentrations close to zero and at least below the limits of detection of the most advanced analytical techniques in general use	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<eqs)	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Specific non synthetic pollutants	Concentrations remain within the range normally associated with undisturbed conditions (background levels = bgl).	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 [20] without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<eqs)	Conditions consistent with the achievement of the values specified above for the biological quality elements.

19 The following abbreviations are used: bgl = background level, eqs = environmental quality standard
20 Application of the standards derived under this protocol shall not require reduction of pollutant concentrations below background levels: (eqs>bgl)

1.2.2 Definitions for high, good and moderate ecological status in LAKES

Biological quality elements

Element	High status	Good status	Moderate status
Phytoplankton	The taxonomic composition and abundance of phytoplankton correspond totally or nearly totally to undisturbed conditions. The average phytoplankton biomass is consistent with the type-specific physicochemical conditions and is not such as to significantly alter the type specific transparency conditions. Planktonic blooms occur at a frequency and intensity which is consistent with the type specific physicochemical conditions.	There are slight changes in the composition and abundance of planktonic taxa compared to the type-specific communities. Such changes do not indicate any accelerated growth of algae resulting in undesirable disturbance to the balance of organisms present in the water body or to the physico-chemical quality of the water or sediment. A slight increase in the frequency and intensity of the type specific planktonic blooms may occur.	The composition and abundance of planktonic taxa differ moderately from the type specific communities. Biomass is moderately disturbed and may be such as to produce a significant undesirable disturbance in the condition of other biological quality elements and the physico-chemical quality of the water or sediment. A moderate increase in the frequency and intensity of planktonic blooms may occur. Persistent blooms may occur during summer months.
Macrophytes and phytobenthos	The taxonomic composition corresponds totally or nearly totally to undisturbed conditions. There are no detectable changes in the average macrophytic and the average phytobenthic abundance.	There are slight changes in the composition and abundance of macrophytic and phytobenthic taxa compared to the type-specific communities. Such changes do not indicate any accelerated growth of phytobenthos or higher forms of plant life resulting in undesirable disturbance to the balance of organisms present in the water body or to the physicochemical quality of the water. The phytobenthic community is not adversely affected by bacterial tufts and coats present due to anthropogenic activity.	The composition of macrophytic and phytobenthic taxa differ moderately from the type-specific communities and are significantly more distorted than those observed at good quality. Moderate changes in the average macrophytic and the average phytobenthic abundance are evident. The phytobenthic community may be interfered with, and, in some areas, displaced by bacterial tufts and coats present as a result of anthropogenic activities.
Benthic invertebrate fauna	The taxonomic composition and abundance correspond totally or nearly totally to the undisturbed conditions. The ratio of disturbance sensitive taxa to insensitive taxa shows no signs of alteration from undisturbed levels The level of diversity of invertebrate taxa shows no sign of alteration from undisturbed levels	There are slight changes in the composition and abundance of invertebrate taxa compared to the type-specific communities. The ratio of disturbance sensitive taxa to insensitive taxa shows slight signs of alteration from type specific levels. The level of diversity of invertebrate taxa shows slight signs of alteration from type specific levels.	The composition and abundance of invertebrate taxa differ moderately from the type-specific conditions Major taxonomic groups of the type-specific community are absent. The ratio of disturbance sensitive to insensitive taxa, and the level of diversity, are substantially lower than the type specific level and significantly lower than for good status

Element	High status	Good status	Moderate status
Fish fauna	Species composition and abundance correspond totally or nearly totally to undisturbed conditions. All the type specific sensitive species are present. The age structures of the fish communities show little sign of anthropogenic disturbance and are not indicative of a failure in the reproduction or development of a particular species.	There are slight changes in species composition and abundance from the type specific communities attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements. The age structures of the fish communities show signs of disturbance attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements, and, in a few instances, are indicative of a failure in the reproduction or development of a particular species, to the extent that some age classes may be missing.	The composition and abundance of fish species differ moderately from the type specific communities attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements. The age structure of the fish communities shows major signs of disturbance, attributable to anthropogenic impacts on physicochemical or hydromorphological quality elements, to the extent that a moderate proportion of the type specific species are absent or of very low abundance.

Hydromorphological quality elements

Element	High status	Good status	Moderate status
Hydrological regime	The quantity and dynamics of flow, level, residence time, and the resultant connection to groundwaters, reflect totally or nearly totally undisturbed conditions.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Morphological conditions	Lake depth variation, quantity and structure of the substrate, and both the structure and condition of the lake shore zone correspond totally or nearly totally to undisturbed conditions.	Conditions consistent with the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.

Physico-chemical quality elements [21]

Element	High status	Good status	Moderate status
General conditions	The values of physico-chemical elements correspond totally or nearly totally to undisturbed conditions. Nutrient concentrations remain within the range normally associated with undisturbed conditions. Levels of salinity, pH, oxygen balance, acid neutralising capacity, transparency and temperature do not show signs of anthropogenic disturbance and remain within the range normally associated with undisturbed conditions.	Temperature, oxygen balance, pH, acid neutralising capacity, transparency and salinity do not reach levels outside the range established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements. Nutrient concentrations do not exceed the levels established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Specific synthetic pollutants	Concentrations close to zero and at least below the limits of detection of the most advanced analytical techniques in general use.	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<eqs)	Conditions consistent with the achievement of the values specified above for the biological quality elements.
Specific non synthetic pollutants	Concentrations remain within the range normally associated with undisturbed conditions (background levels = bgl).	Concentrations not in excess of the standards set in accordance with the procedure detailed in Section 1.2.6 [22] without prejudice to Directive 91/414/EC and Directive 98/8/EC. (<eqs)	Conditions consistent with the achievement of the values specified above for the biological quality elements.

[21] The following abbreviations are used: bgl = background level, eqs = environmental quality standard

[22] Application of the standards derived under this protocol shall not require reduction of pollutant concentrations below background levels

Annex D. Glossary

Complementary to Article 2 in the Directive:

Term	Definition
Anthropogenic	Caused or produced by human influence.
Baseline scenario	Projection of the development of a chosen set of factors in the absence of policy interventions.
Benthic Invertebrate Fauna	Invertebrate animals living at least for part of their lifecycles on or in the benthic substrates of rivers, lakes, transitional waters or coastal waters.
BEQUALM	Biological Effects Quality Assurance in Monitoring Programmes.
Birds Directive	Council Directive 79/409/EEC of 2 April 1979 on the conservation of wild birds.
Catchment	Refer to definition of 'River Basin' in Article 2 of the WFD (2000/60/EC).
CEN	European Committee for Standardization.
Common Implementation Strategy	The Common Implementation Strategy for the Water Framework Directive (known as the CIS) was agreed by the European Commission, Member States and Norway in May 2001. The main aim of the CIS is to provide support in the implementation of the WFD, by developing a common understanding and guidance on key elements of this Directive. Experts from the above countries and candidate countries as well as stakeholders from the water community are all involved in the CIS to: Raise awareness an exchange information; Develop Guidance Documents on various technical issues; and, Carry out integrated testing in pilot river basins. A series of working groups and joint activities has been developed to help carry out the activities listed above. A Strategic Co-ordination Group (or SCG) oversees these working groups and reports directly to the Water Directors of the European Union, Norway, Switzerland, the Candidate Countries and Commission, the engine of the CIS. For more information refer to the following website: http://europa.eu.int/comm/environment/water/water-framework/index_en.html.
Confidence	The long-run probability (expressed as a percentage) that the true value of a statistical parameter (e.g. the population mean) does in fact lie within calculated and quoted limits placed around the answer actually obtained from the monitoring programme (e.g. the sample mean).
Critical Load	A quantitative estimate of an exposure to one or more pollutants below which significant harmful effects on specified elements of the environment do not occur, according to present knowledge (UNECE 1994).

Term	Definition
Deterioration	A reduction in quality of one or more of the quality elements.
Diffuse Source Pollution[23]	Pollution which originates from various activities, and which cannot be traced to a single source and originates from a spatially extensive land use (e.g. agriculture, settlements, transport, industry). Examples for diffuse source pollution are atmospheric deposition, run-off from agriculture, erosion, drainage and groundwater flow.
Discharge[24]	The release of polluting substances from individual or diffuse sources in the installation through effluent directly or indirectly into water bodies as defined under Article 2 (1) of Directive 2000/60/EC.
Disturbance	Interference with the normal functioning of the ecosystem.
Ecological Quality Ratio	Ratio representing the relationship between the values of the biological parameters observed for a given body of surface water and values for these parameters in the reference conditions applicable to that body. The ratio shall be represented as a numerical value between zero and one, with high ecological status represented by values close to one and bad ecological status by values close to zero (Annex V 1.4(ii)).
Eco-region	The geographical areas illustrated in Annex XI Maps A (rivers and lakes) and B (transitional waters and coastal waters).
Emissions[25]	The direct or indirect release of polluting substances from individual or diffuse sources in the installations into air, water or land including "discharges" as defined below.
Habitats Directive	Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora.
Hydromorphology	The physical characteristics of the shape, the boundaries and the content of a water body. The hydromorphological quality elements for classification of ecological status are listed in Annex V.1.1 and are further defined in Annex V.1.2 of the Water Framework Directive.
Impact	The environmental effect of a pressure (e.g. fish killed, ecosystem modified).
Intercalibration	An exercise facilitated by the Commission to ensure that the high/good and good/moderate class boundaries are consistent with the normative definitions in Annex V Section 1.2 of the Directive and are comparable between Member States (see Guidance produced by WG 2.5) (Annex V 1.4. (iv)).
Losses[26]	Any intentional or unintentional release or transfer of polluting substances, other than discharges, emissions or the result of accidents, directly or indirectly into water bodies as defined under Article 2 (1) of Directive 2000/60/EC.
Macrophyte[27]	All aquatic higher plants, mosses and characean algae, but excluding single celled phytoplankton or diatoms.

[23] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[24] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[25] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[26] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[27] Interim working definition. Discussions in the context of the WFD implementation are ongoing.

Term	Definition
Parameter	Parameters indicative of the quality elements listed in Annex V, Table 1.1 in the Directive that will be used in monitoring and classification of ecological status. Examples on parameters relevant for the biological quality element composition and abundance of benthic invertebrate fauna are.: number of species or groups of species, presence of sensitive species or groups of species and proportion of tolerant/intolerant species.
Phytobenthos[28]	Vascular plants, heterotrophic organisms and photosynthetic algae (including cyanobacteria) living on or attached to substrate or other organisms in surface waters.
Phytoplankton	Unicellular algae and cyanobacteria, both solitary and colonial, that live, at least for part of their lifecycle, in the water column of surface water bodies.
Point source pollution	Pollution arising from a discrete source , e.g. the discharge from a sewage treatment works.
Precision	A measure of the statistical uncertainty equal to the half width of the C% confidence interval. For any one monitoring exercise, the estimation error is the discrepancy between the estimated sample statistic (e.g. mean) calculated from the sampling result and the true value. The precision is then the level of estimation error that is achieved or bettered on a specified (high) proportion C% of occasions.
Pressure[29]	The direct effect of the driver (for example, an effect that causes a change in flow or a change in the water chemistry of surface and groundwater bodies.
Quality Element	Annex V, Table 1.1 in the Directive, explicitly defines the quality elements that must be used for the assessment of ecological status (eg. composition and abundance of benthic invertebrate fauna). Quality elements include biological elements and elements supporting the biological elements. These supporting elements are in two categories: 'hydromorphological' and 'chemical and physicochemical'.
Reference conditions	For any surface water body type reference conditions or high ecological status is a state in the present or in the past where there are no, or only very minor, changes to the values of the hydromorphological, physico-chemical, and biological quality elements which would be found in the absence of anthropogenic disturbance. Reference conditions should be represented by values of the biological quality elements in calculation of ecological quality ratios and the subsequent classification of ecological status.
Register of Protected Areas	A register of areas lying within the river basin district which have been designated as requiring special protection under specific Community legislation for the protection of their surface water and groundwater, or for the conservation of habitats and species directly depending on water (see Annex IV). This register must be completed by December 2004 (Art 6, 7 and Annex IV).
Risk	Chance of an undesirable event happening. It has to aspects: the chance and the event that it might happen. These are conventionally called the probability and the confidence.

[28] Interim working definition. Discussions in the context of the WFD implementation are ongoing.
[29] Interim working definition. Discussions in the context of the WFD implementation are ongoing.

Term	Definition
River Basin Management Plan	A plan that must be produced for each River Basin District within a Member State in accordance with Article 13. The plan shall include the information detailed in Annex VIII.
Specific Pollutants	Pollution by all priority substances defined as being discharged into the body of water; and pollution by other substances identified as being discharged in significant quantities into the body of water (Annex V, 1.1).
Specific Non-Synthetic Pollutants	Naturally occurring priority substances identified as being discharged into the body of water and other substances identified as being discharged in significant quantities into the body of water (Annex V 1.1).
Specific Synthetic Pollutants	Man-made priority substances identified as being discharged into the body of water and other substances identified as being discharged in significant quantities into the body of water (Annex V 1.1).
State	2.1 IMPRESS: the condition of the water body resulting from both natural and anthropogenic factors (i.e. physical, chemical and biological characteristics).
Strategic Co-ordination Group	A group led by the Commission with participants from all Member States which was established to co-ordinate the work of the different working groups of the Common Implementation Strategy.
Taxa	Taxonomic groups of any rank.
Type specific reference conditions	Reference conditions (see separate definition) representative for a specific water body type.
Wetland	Refer to Guidance on wetlands currently under preparation.
WFD, The Directive	Directive 2000/60/EC establishing a framework for Community action in the field of water policy.

Annex E. List of Relevant EU-funded research projects

EU-funded projects can provide a strong support as far as the classification of inland surface water status is concerned, but very little has been and is being done as far as the definition and identification of reference conditions is concerned. Most of the past or on-going EU-funded projects have also been directed towards streams and rivers. This means that limited support for classification of ecological status of lakes can be gained from these projects.

For the first aspect, at least five main projects, among the others in the list in Annex E, have to be cited, because they represent today the main effort carried out at European level with the objective of development and standardisation of assessment methodologies. One of these projects, the AQEM project, was recently concluded with the production of all the expected deliverables. The AQEM web site (www.aqem.de/) contains in a downloadable format all the main results of AQEM:

- assessment software
- manual how to apply the AQEM system
- taxa list (>7700 European macroinvertebrate taxa)
- several reports, tools and interesting software products

AQEM (http://www.aqem.de/)
Development and testing of an integrated assessment system for the ecological quality of streams and rivers throughout Europe using benthic macroinvertebrates.
The aim of the project is to develop and test an assessment procedure for streams and rivers which meets the demands of the EU Water Framework Directive using benthic macroinvertebrats. The assessment system will be based on a European stream typology and on near-natural reference conditions. The method will be adapted to regional conditions in order to allow comparable use in all EU member states. It will be combined with methods for stream assessment and indication currently used in the EU member states. If these methods supply additional information for certain regions they will be included in the assessment system as additional modules. Data bases on European macroinvertebrate taxa used for the assessment system will be generated. Finally, the method will be transferred into water management application via a manual and a PC program.

PAEQANN (http://www-cesac.ecolog.cnrs.fr/~paeqann/)
Predicting Aquatic Ecosystem Quality using Artificial Neural Networks: Impact of Environmental characteristics on the Structure of Aquatic Communities (Algae, Benthic and Fish Fauna).
The goal of the project is to develop general methodologies, based on advanced modelling techniques, for predicting structure and diversity of key aquatic communities (diatoms, micro-invertebrates and fish), under natural (i.e. undisturbed by human activities) and under man-made disturbance (i.e. submitted to various pollutions, discharge regulation, ...). Such an approach to the analysis of aquatic communities will make it possible to: i) set up robust and sensitive ecosystem evaluation procedures that will work across a large range of running water ecosystems throughout European countries; ii) predict biocenosis structure in disturbed

ecosystems, taking into account all relevant ecological variables; iii) test for ecosystem sensitivity to disturbance; iv) explore specific actions to be taken for restoration of ecosystem integrity. Among the available modelling techniques, artificial neural networks are particularly appropriate for establishing relationships among variables in the natural processes that shape ecosystems, as these relationships are frequently non-linear.

STAR (http://www.eu-star.at/)
Standardisation of river classifications: Framework method for calibrating different biological survey results against ecological quality classifications to be developed for the Water Framework Directive.
The ecological status of rivers will be determined in the STAR project from a range of taxonomic groups and a variety of methods. Most Member States will have their own assessment procedures, but a common European standard is still missing. Through field sampling and desk studies the project aims to: 1) cross-calibrate and integrate assessments using different methods and taxonomic groups 2) recommend which procedures to use in which situations 3) define the precision and reliability of each method and 4) assist the EU in defining the boundaries of classes of ecological status. A decision support system will be developed for applying the project findings. The research will be used to assist in the establishment of a European standard for assigning the ecological status of rivers on the basis of multiple sources of ecological data. The STAR project builds upon the results of the previously funded AQEM project and will be clustered with the complementary FAME project.

FAME (http://fame.boku.ac.at/)
Development, Evaluation and Implementation of a Standardised Fish-based Assessment Method for the Ecological Status of European Rivers: A Contribution to the Water Framework Directive.
The objective of the project is to develop, evaluate and implement a standardised Fish-based Assessment Method for the ecological status of European rivers (FAME), a method identified as priority requirement for the implementation of the Water Framework Directive. FAME will follow a pan-European approach in developing models to characterise reference and degraded conditions based on existing fish data of 17000 sites (5200 rivers) in 16 of the 25 eco-regions of Europe. An integrated system to assess the ecological status will be developed in close co-operation with end-users integrated into the project as "Applied partners". The new method will be evaluated by field tests within ongoing national monitoring programmes. A manual and PC-software will be produced and made available to the public via a project web site. FAME will be clustered with the complementary STAR project.

ECOFRAME
Ecological quality and functioning of shallow lake ecosystems with respect to the needs of the European Water Framework Directive.
Contact address: Prof. Brian Moss, School of Biological Sciences, Derby Building, University of Liverpool, Liverpool L69 3GS, UK (brmoss@liverpool.ac.uk). The ECOFRAME project was recently concluded and a draft summary final report is available. Using expert workshops and subsequent field testing a practical pan-European typology and classification system have been developed for shallow lakes, which can be expanded to all lakes. It is minimal, based on current limnological understanding and as cost-effective as possible given the provisions of the Directive.

The typology is a core typology that can be expanded easily in particular States to met local conditions. The core includes 48 ecotypes across the entire European climate gradient and incorporates climate, lake area, geology of the catchment and conductivity. The classification system is founded on a liberal interpretation of Annexes of the Directive and uses variables that are inexpensive to measure and ecologically relevant. Taxonomic expertise is minimised. The scheme has been through eight iterations, two of which were tested in the field on tranches of 66 lakes. The final version, Version 8, is offered for operational testing and further refinement by statutory authorities.

Annex F. (Eco)region specific typology

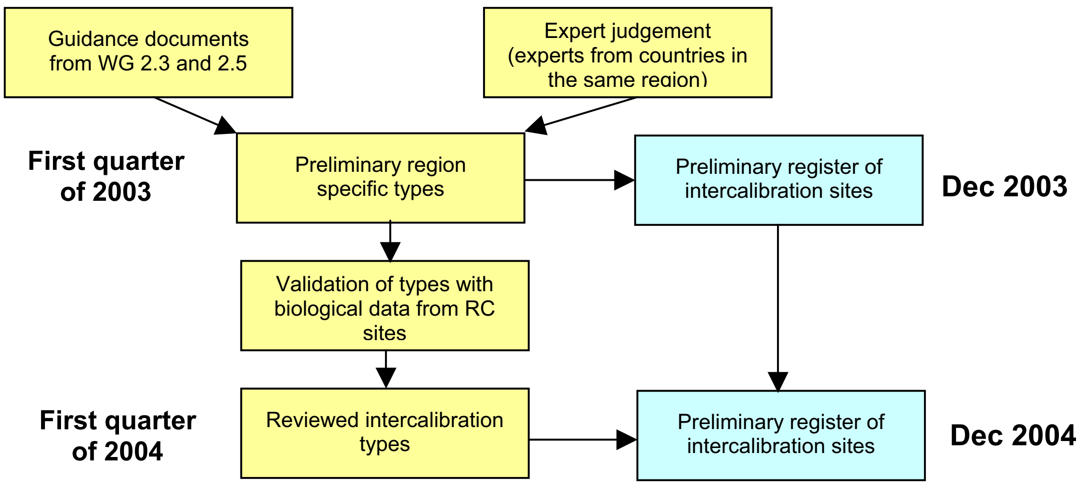
One important use of typology systems is for the selection of types and sites to be included in the intercalibration exercise (see separate WFD CIS Guidance Document No. 6 on intercalibration). Ideally, the chosen typology system should be validated using biological data from reference condition sites. Monitoring programmes will, however, not be fully operational until 2007 and the availability of biological data for validation purposes will be scarce before that. Below a stepwise approach is suggested for establishing inland surface water body types for the purpose of selecting sites for the intercalibration network.

Based on the information in the Guidance Documents from workgroup 2.3 (REFCOND) and 2.5 (Intercalibration) together with expert judgement preliminary (eco)region specific typology system is suggested to be developed in co-operation between Member States sharing the same (eco)region. Based on the preliminary (eco)region specific typology, types are selected for the preliminary selection of intercalibration sites.

Hydromorpological, physico-chemical and biological data is collected from the selected sites together with data on different human pressures. Data from potential high status sites are used for validating the preliminary types (only reference sites can be used for testing and validation to avoid impact from human pressure on the typology). The minimum requirement on the validation result is that the variability in reference conditions within types is smaller than the variability between types.

Depending of the outcome of the validation procedure the types may be revised and complementary types and sites are selected for the final register of intercalibration sites. The typology system may be revised once again when monitoring data from all water bodies at risk and other selected water bodies will be available.

The suggested procedure and timetable for the development of (eco)region specific surface water body types to be used for selection of intercalibration sites is described in the figure below.



Assessing "who needs to get involved" in the reference condition and class boundary analysis requires addressing some of the following questions:

- Who will be responsible for the analysis?
- Who will undertake the analysis?
- Who will provide input into the analysis?
- Who will control the quality of the analysis?
- Who will use the results of analysis?
- Who will pay for the analysis?

Answers to these "Who" questions are likely to include a wide range of organisations, stakeholders and individuals according to questions. For example, experts from the Ministry of Environment or other ministries (land planning, nature protection units, GIS units, agriculture, etc), experts from river basin agencies or regional authorities, managers in charge of developing river basin management plans, ministry heads of water departments, researchers and consultants, historians, the public and a wide range of stakeholders that have developed expertise in specific fields (see table 1) and are involved in water management.

Developing a stakeholder analysis with possible involvement of key stakeholders can be an appropriate step for finding answers to these questions. It also helps in identifying key steps in the analytical process when involvement or input from specific stakeholders is required (different "Who" for different steps).

Annex G. Who needs to get involved in carrying out and using the reference condition analysis?

Table G1. Key Stakeholders can be a Very Important Source of Information and expertise

Key Stakeholders	Where they can help with information and expertise
Water Service Suppliers	➢ Characterising water services and their relations to the river system condition, e.g. impact on groundwater levels ➢ Knowledge about previous water quality situation ➢ Developing trends in water services and their impact on river system conditions
Experts from Ministries (agriculture, transport, planning, finance…) -	➢ Characterising water uses and their impact of the anticipated reference condition ➢ Assessing changes in key national and regional policies and drivers for the trend analysis, e.g. drainage of wetlands ➢ Defining coherent methodologies for assessing key variables at Member State level
Environmental NGOs	➢ Identifying key environmental issues ➢ Providing information about previous stage of the river system ➢ Developing methodologies for estimating impacts on anticipated reference condition ➢ Assessing political complications related to choosing between various reference condition alternatives ➢ Providing social acceptance of agreed reference condition
Economic sectors (farmers, industrialists, etc)	➢ Assessing trends in economic sectors and their previous impact on the river system ➢ Identifying possible measures needed for achieving a certain water quality status based on an anticipated reference condition, and their costs
Researchers/Experts	➢ Assessing key policies/drivers for the trend analysis ➢ Assessing impact of such policies on pressures ➢ Assessing impact of climate change on water quality ➢ Assessing the impact of previous impacts and pressures on water status (e.g. via modelling)
Stakeholders/civil society/public	➢ Assessing changes in key policies/drivers for the trend analysis ➢ Assessing (local, regional, national) priorities *vis-à-vis* water quality improvements, ➢ Providing input into the assessment of disproportionate costs and analysis aimed at explaining derogation, when taking into account various reference condition alternatives ➢ Providing input into the assessments of socio-economic impacts and costs ➢ Providing historic knowledge about the river system in previous decades / centuries

European Commission

Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 11

Planning process

COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 11

Planning Processes

Produced by Working Group 2.9 – Planning Processes

Disclaimer:

This technical document has been developed through a collaborative programme involving the European Commission, all the Member States, the Accession Countries, Norway and other stakeholders and Non-Governmental Organisations. The document should be regarded as presenting an informal consensus position on best practice agreed by all partners. However, the document does not necessarily represent the official, formal position of any of the partners. Hence, the views expressed in the document do not necessarily represent the views of the European Commission.

Foreword

The EU Member States, Norway and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of this strategy, an informal working group dedicated to best practices in river basin planning issues of the Directive has been set up. The main objective of this working group, launched in July 2001, is the development of a non-legally binding and practical Guidance Documents on four elements of the Water Framework Directive: Identification of river basin districts, planning process, public participation and integrated river basin management planning. Spain and the Commission have the responsibility of the secretariat and animation of the working group that is composed of technical experts from governmental and non-governmental organisations (NGOs).

The present document is the final version of the Guidance on planning process. It presents a general overview of the whole planning cycle and provides some recommendations for its successful implementation. It builds on the input and feedback from a wide range of experts and stakeholders from both EU Member States and candidate countries.

We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union have examined and endorsed this Guidance by means of a written procedure in March 2003. We would like to thank the participants of the Working Group and, in particular, the leaders for preparing this high quality document

We strongly believe this and other Guidance Documents developed under the common implementation strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a *living document* that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond, We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the Guidance is applicable in practice.

We also commit ourselves to assess and decide upon the necessity for reviewing this document following the pilot testing exercises and the first experiences gained in the initial stages of the implementation.

Table of contents

Section 1. Introduction - A Guidance Document: What For?

This document aims at guiding the competent authorities entrusted with the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy (the Water Framework Directive – "WFD"). The document focuses on the interactions and scheduling activities and tasks to accomplish WFD requirements. This Guidance claim to be a management tool to WFD implementation at national level.

To whom is this Guidance Document addressed?

It addresses in particular the competent authorities responsible for implementing the Directive at the level of River Basin Districts although it also includes information at other planning scales: sub-basin, national and international.

The document may also help governments in taking decisions concerning the allocation of responsibilities and resources to the implementing authorities. It can further be interesting for stakeholders and non-governmental organisations (NGOs) with a view to a better understanding of the planning process.

What are the objectives of this Guidance Document?

The objective of this Guidance Document is to inform practitioners on the issues and activities to be organised and co-ordinated during the planning process and to provide procedural guidance on the production and development of River Basin Management Plans. This will ensure consistency in approach and efficiency in their preparation. These guidelines are not intended to be overly prescriptive and detailed, but to provide for a conceptional framework which can and has to be tailored to the character and needs of individual river basins.

The Guidance Document is trying:

- To create a common understanding with regard to planning process in the Directive;
- To provide guidelines by explaining the requirements of the Directive with regard to the implementation steps and stages of river basin management planning and by analysing the possibilities the Directive offers;
- To provide recommendations and experiences of how to make the planning process operational;
- To explain how to organise the planning process, providing information on what, who and when.

The Guidance Document is not about:

- Providing Guidance on the specific technical elements of the planning process. Other Working Groups have produced this (See Annex 3 of this Guidance).

What can you find in this Guidance Document?

This Guidance is mainly divided into four sections:

- Section 3 that introduces the ***concept*** of Water Planning;
- Section 4 that proposes ***good practices*** in Water Planning;
- Section 5 that describes the ***requirements of the Directive*** on the Planning Process; and
- Section 6 that provides flowcharts that summarise the ***main tasks to be done*** in the process.

Therefore, the Guidance is answering the following questions:

The concept of planning process

- *What does planning mean?*
- *Which are the main types of planning processes?*
- *Relation to other planning concepts and links to other planning processes*
- *What is the spatial scope of the planning process?*

Good practices on water planning

- *What are the key elements for a sound planning process?*
- *How do these elements fit with the Directive's overall river basin planning process?*
- *Recommendations for a successful planning.*

Requirements of the Directive and main tasks to be done

- *Which are the main activities and when do they have to be developed in the planning process?*
- *Where in the Directive are these activities made explicit or referred to?*
- *Which are the links between main activities?*
- *Which are the main preparatory constraints and bottlenecks?*
- *Which are the objectives and functions of the river basin management plan?*
- *From planning to plan; What has to be taken into consideration during the planning process to meet the requirements set by the Directive for the River Basin Plan?*
- *How should the different results of the planning process be reported through the Plan?*

... and Where are the main contents of the Guidance?

The concept of planning process

***Section 3**: Principles relevant for the water planning and needs for the decision making process – 3.1 Introduction – 3.2 General scope, functions and types of planning processes – 3.3 Planning of water management and links with other planning processes*

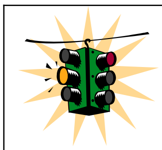
Good practices in water planning

***Section 4: Some considerations for a sound planning process - 4**.1 Long-term vision for the RBD –4.2 Knowledge and information management. The need of building capacity – 4.3 Integration at the operational level. Links with other planning policies – 4.4 The right timing– 4.5 The appropriate toolbox*

Requirements of the Directive and main tasks to be done

***Section 5**: Specific requirements in the WFD with regards to the planning process – 5.1 General considerations - 5.2 to 5.9 Main components in the planning process*

***Section 6**: General overview and overall flowchart of the planning process – 6.1 Introduction: Why and how to use flowcharts in the planning process? – 6.2 The legally binding timetable of the WFD– 6.3 The planning levels and the planning cycle – 6.4 Overall flowchart for the planning process – 6.5 Main bottlenecks in the planning process – 6.6 Recommendations for the preparation and use of flowcharts.*



Look out! The methodology from this Guidance Document needs to be adapted to regional and national circumstances within the frame of the Directive.

The Guidance Document proposes an overall methodological approach. It describes principles and the processes in the management cycle. Because of the diversity of circumstances within the European Union, the logical approach and answers to questions will vary from one river basin to the other. This proposed methodology will therefore need to be tailored to specific circumstances.

What you will not find in this Guidance Document?

The Guidance does not focus on:

- Specific methodologies for the planning process: hydrologic modelling, decision support systems, etc.;
- The establishment of the programmes of measures. There will be a specific Guidance Document.

Section 2. Implementing the Directive: Setting the Scene

This Section introduces you to the overall context for the implementation of the Water Framework Directive and informs you of the initiatives that led to the production of this Guidance Document.

December 2000: A Milestone for Water Policy

A long negotiation process

December 22, 2000, will remain a milestone in the history of water policies in Europe: on that date, the Water Framework Directive (or the Directive 2000/60/EC of the European Parliament and of the Council of 23 October 2000 establishing a framework for Community action in the field of water policy) was published in the Official Journal of the European Communities and thereby entered into force!

This Directive is the result of a process of more than five years of discussions and negotiations between a wide range of experts, stakeholders and policy makers. This process has stressed the widespread agreement on key principles of modern water management that form today the foundation of the Water Framework Directive.

The Water Framework Directive: new challenges in EU water policy

What is the purpose of the Directive?

The Directive establishes a framework for the protection of all waters (including inland surface waters, transitional waters, coastal waters and groundwater) which:

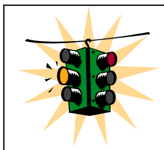
- Prevents further deterioration of, protect and enhance the status of water resources;
- Promotes sustainable water use based on long-term protection of water resources;
- Aims at enhancing protection and improvement of the aquatic environment through specific measures for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances;
- Ensures the progressive reduction of pollution of groundwater and prevents its further pollution; and
- Contributes to mitigating the effects of floods and droughts.

…and what is the key objective?

Overall, the Directive aims at achieving good water status for all waters by 2015.

What are the key actions that Member States need to take?

- To identify the individual river basins lying within their national territory and assign them to individual River Basin Districts (RBDs) and identify competent authorities by 2003 (Article 3, Article 24);
- To characterise river basin districts in terms of pressures, impacts and economics of water uses, including a register of protected areas lying within the river basin district, by 2004 (Article 5, Article 6, Annex II, Annex III);
- To carry out, jointly and together with the European Commission, the intercalibration of the ecological status classification systems by 2006 (Article 2 (22), Annex V);
- To make operational the monitoring networks by 2006 (Article 8);
- Based on sound monitoring and the analysis of the characteristics of the river basin, to identify by 2009 a programme of measures for achieving the environmental objectives of the Water Framework Directive cost-effectively (Article 11, Annex III);
- To produce and publish River Basin Management Plans (RBMPs) for each RBD including the designation of heavily modified water bodies, by 2009 (Article 13, Article 4.3);
- To implement water pricing policies that enhance the sustainability of water resources by 2010 (Article 9);
- To make the measures of the programme operational by 2012 (Article 11);
- To implement the programmes of measures and achieve the environmental objectives by 2015 (Article 4).



Look out!
Member States may not always reach good water status for all water bodies of a river basin district by 2015, for reasons of technical feasibility, disproportionate costs or natural conditions. Under such conditions that will be specifically explained in the RBMPs, the Water Framework Directive offers the possibility to Member States to engage into two further six- year cycles of planning and implementation of measures.

Changing the management process – information, consultation and participation

Article 14 of the Directive specifies that Member States shall encourage the active involvement of all interested parties in the implementation of the Directive and development of river basin management plans. Also, Member States will inform and consult the public, including users, in particular about:

- The timetable and work programme for the production of river basin management plans and the role of consultation at the latest by 2006;
- The overview of the significant water management issues in the river basin at the latest by 2007;
- The draft river basin management plan, at the latest by 2008.

Integration: a key concept underlying the Water Framework Directive

The central concept to the Water Framework Directive is the concept of integration that is seen as key to the management of water protection within the river basin district:

- **Integration of environmental objectives**, combining quality, ecological and quantity objectives for protecting highly valuable aquatic ecosystems and ensuring a general good status of other waters;
- **Integration of all water resources**, combining fresh surface water and groundwater bodies, wetlands, coastal water resources **at the river basin scale**;
- **Integration of all water uses, functions and values** into a common policy framework, i.e. investigating water for the environment, water for health and human consumption, water for economic sectors, transport, leisure, water as a social good;
- **Integration of disciplines, analyses and expertise**, combining hydrology, hydraulics, ecology, chemistry, soil sciences, technology engineering and economics to assess current pressures and impacts on water resources and identify measures for achieving the environmental objectives of the Directive in the most cost-effective manner;
- **Integration of water legislation into a common and coherent framework.** The requirements of some old water legislation (e.g. the Fishwater Directive) have been reformulated in the Water Framework Directive to meet modern ecological thinking. After a transitional period, these old Directives will be repealed. Other pieces of legislation (e.g. the Nitrates Directive and the Urban Wastewater Treatment Directive) must be co-ordinated in river basin management plans where they form the basis of the programmes of measures;
- **Integration of all significant management and ecological aspects** relevant to sustainable river basin planning including those which are beyond the scope of the Water Framework Directive such as flood protection and prevention;
- **Integration of a wide range of measures, including pricing and economic and financial instruments, in a common management approach** for achieving the environmental objectives of the Directive. Programmes of measures are defined in **River Basin Management Plans** developed for each river basin district;
- **Integration of stakeholders and the civil society in decision making**, by promoting transparency and information to the public, and by offering an unique opportunity for involving stakeholders in the development of river basin management plans;
- **Integration of different decision-making levels that influence water resources and water status**, be local, regional or national, for an effective management of all waters;
- **Integration of water management from different Member States**, for river basins shared by several countries, existing and/or future Member States of the European Union.

WHAT IS BEING DONE TO SUPPORT IMPLEMENTATION?

Activities to support the implementation of the Water Framework Directive are under way in both Member States and in countries candidate for accession to the European Union. Examples of activities include consultation of the public, development of national Guidance, pilot activities for testing specific elements of the Directive or the overall planning process, discussions on the institutional framework or launching of research programmes dedicated to the Water Framework Directive.

May 2001 – Sweden: Member States, Norway and the European Commission agreed a Common Implementation Strategy

The main objective of this strategy is to provide support to the implementation of the Water Framework Directive by developing coherent and common understanding and guidance on key elements of this Directive. Key principles in this common strategy include sharing information and experiences, developing common methodologies and approaches, involving experts from candidate countries and involving stakeholders from the water community.

In the context of this common implementation strategy, a series of working groups and joint activities have been launched for the development and testing of non-legally binding Guidance. A strategic co-ordination group oversees these working groups and reports directly to the water directors of the European Union and Commission that play the role of overall decision body for the Common Implementation Strategy.

The Working Group on Best Practices in River Basin Planning

A working group has been created under the common strategy for the implementation of the Water Framework Directive for dealing specifically with river basin planning issues. The main short-term objective of this working group is the development of a legally non-binding and practical guidance for supporting the implementation of the planning process as it is foreseen in the Water Framework Directive. The members of the group are experts and stakeholders from European Union Member States and from a limited number of candidate countries to the European Union (see Annex 4).

The main work packages involved in the group are as follows:

Work Package 1. Guidance on the identification of river basin districts;
Work Package 2. Guidance on the planning process;
Work Package 3. Guidance on public participation;
Work Package 4. Manual on how to produce an integrated river basin management plan and a program of measures.

This document is the final version of the Work Package 2, "Guidance on the planning process".

The Working Group and Drafting Group meetings held and the timetable followed for the completion of Work Package 2, "Guidance on planning process" were as follows:

Date	***Activity***
16 April 2002	*First meeting of the drafting group of the so-called Work Package 2 (WP 2), "Guidance on planning process" in Madrid.*
25 June 2002	*Terms of reference and draft of document on preliminary steps available.*
4-5 July 2002	*Working Group Meeting. Discussion of terms of reference and draft on preliminary steps. Re-elaboration of the table of contents and timetable of WP 2.*
14-15 October 2002	*Drafting group and working group meeting in Brussels.*
25 October	*Version of the Guidance in CIRCA, considering conclusions from working group meeting and new comments.*
7-8 November 2002	*Presentation of first version of "Guidance on planning process" and new work programme to Strategic Co-ordination Group.*
21-22 November 2002	*Presentation of first version of "Guidance on planning process" and new work programme to Water Directors' meeting in Copenhagen.*
2 December 2002	*Drafting groups meeting (text).*
9 December 2002	*Drafting groups meeting (flowcharts).*
20 December 2002	*Revised version in CIRCA.*
20-21 January 2003	*Workshop with other Working Groups and water planners in Madrid.*
21 February 2003	*Final version of the Guidance on planning process to be presented to Strategic and Co-ordination Group.*
March 2003	*Final version of the Guidance to be endorsed by Water Directors by means of a written procedure.*

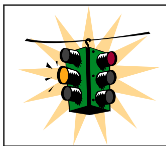
At the Meeting of Water Directors held in Copenhagen (21-22 November 2002) four themes in the follow-up of the Common Implementation Strategy were identified. Among them, the so called in the conclusions of the meeting WG 2B "Integrated River Basin Management" will continue the work already carried out by the former WG 2.9. A detailed mandate for the new WG is in preparation but it is expected to include as key working areas the development of the pilot river basin exercise and the elaboration of new Guidance Documents as "Preparation of river basin management plans and programmes of measures including the integration of different river basin management plans".

Section 3. Principles relevant for the water planning and needs for the decision making process.

3.1 Introduction

This Section discusses some backgrounds of planning processes. It does not deal with the details of the Directive (this is done in the following Sections), but gives insights into the theories of planning itself. The system of planning introduced with the Directive is not the only possible one, yet the deadlines and objectives from the Directive are compulsory. In planning, decisions are made on who is doing what and when. There is no a single best approach to make this decision. This has led to the development of different types of planning process. A flexible use of different planning styles can be useful for competent authorities in order to achieve the requirements from the Directive. This Section provides the information to make that flexibility possible. It presents general principles of planning processes, and the different aspects that must be taken into account when making a choice for a certain type of planning during the implementation of the Directive in a Member or Accession State.

The primary purpose of planning is to provide a Plan as an instrument for making decisions in order to influence the future. Planning is a systematic, integrative and iterative process that is comprised of a number of steps executed over a specified time schedule.



Look out! Water planning is a means to improve and support a sound management of water resources. In this sense, water planning has to be regarded as a process and not as an objective of the Directive in itself.

Planning culminates when all the relevant information has been considered and a course of action has been selected. The plan is then produced and implemented in order to achieve the goals and objectives.

The Directive introduces environmental objectives for water bodies in the river basins. The planning process adopted in the Directive is best characterised by the term 'end result planning'; from the start of the process it is clear what the final outcome will be, in this case 'good water status' (or ´good potential´).

There are certain factors that have to be taken into account in the planning process, so they do not prevent the achievement of the objectives of the Directive:

- In the river basins concerned, not only is the planning process of the Directive is ongoing, but also other initiatives exist, e.g. the development of regional industrial zones, the building of houses, extension of infrastructure, restructuring the agriculture, construction of recreational areas, etc., from which conflicts with the objectives of the WFD can arise. The planning process has to be flexible, dynamic, cyclic and prospective, so it can anticipate and take into account events such as flooding or droughts;

- The different Member States have their own planning traditions, which means they all have their own long-established manners of adjusting developments in society, with corresponding division of roles and allocation of tasks between public and private sectors. In order to implement the Directive in a socially acceptable manner, every Member State should be able to inform, capacitate and promote the active involvement of stakeholders and the public which may mean that the current planning can be improved and revised.

The Directive provides a framework; the actual operational implementation must take place at Member State level. Within this framework there are opportunities to act in different scales: per Member State, per (sub-)basin or per water theme, as long as the prospect of 'good status' stays the leading principle, and the different prescribed steps of the Directive are followed.

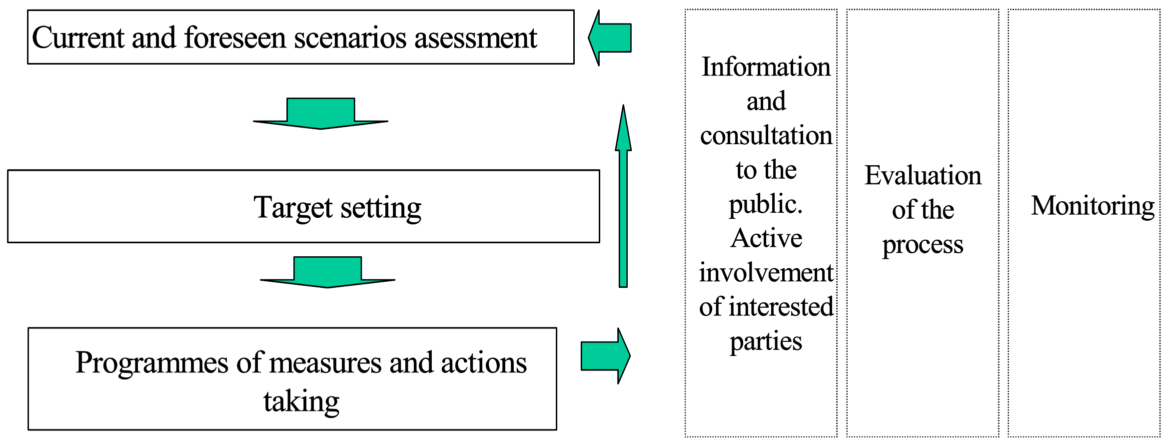
Look out! Needs for the decision making process.

Examples of questions relevant for decision making (and therefore for planning process):

- *When to make the particular decision?*
- *Who will be in response of it?*
- *How "independently" is it possible to make the particular decision in the member states? What kind of co-ordination is needed in a Community level?*
- *Is it a decision, which will be specified later? (iterative process)*
- *What kind of consequences does the decision have?*
- *In which way will the decision limit range of choices in the further steps of implementation of the WFD?*

3.2 General scope, functions and types of planning processes

The classical approach for planning usually includes three main stages: current and foreseen scenarios assessment, target setting and development of alternative programmes of measures including action taking. These stages are part of a cyclical and iterative process in which it is possible to define three additional elements (public participation, monitoring and evaluation of the process) that will be developed in a continuous way in parallel, serving as a link between the others. The process is shown in the figure below.



As it will be described in Sections 5.1 and 6.3, the planning process to be followed in accordance with the WFD comprises ten main components that can be identified with the stages shown in the above figure as follows:

Main Stage	***Components according to WFD***
Current and foreseen scenarios assessment	▪ Setting the scene ▪ Assessment of the current status and analysis of preliminary gaps
Target setting	▪ Gap analysis ▪ Setting up of the environmental objectives
Alternative programmes of measures and actions taking	▪ Setting up of the programme of measures ▪ Development of river basin management plans ▪ Implementation of the programme of measures and preparation of the interim report.
Linking stages	▪ Establishment of monitoring programmes ▪ Evaluation of the first and second period ▪ Information and consultation of the public, active involvement of interested parties

Effective water planning will provide a way of anticipating a water issue, analysing the alternatives management options and proposing policies and specific measures while making the optimum use of resources.

However, water planning provides not only a strategic approach. Although the role of the water planning in the Directive is aimed at the implementation of programmes of measures to improve and to maintain the current water status, other additional functions can be identified[1]:

To provide a framework for developing institutional arrangements and co-ordination with other planning schemes (See next Section).

[1] Note that some of these functions are Directive requirements indeed.

To increase the legitimacy and transparency for water management

Planning has the capacity to increase the legitimacy of decisions to be taken by enabling open and wide dialogue between the public, interest groups and authorities. It's crucial for the legitimacy of a planning process to start dialogue as early as the phases of problem defining and setting the agenda. Better understanding of the interests of those involved arising during the planning process and so the chance to influence planning will increase their willingness to co-operate in problem solving.

To facilitate the interaction and discussion among managers and stakeholders providing tools for conflicts resolution

Some issues can create conflicts in water resources planning that are not necessarily the result of wrong or illicit approaches. As different people have different goals, perspectives, and values, water resources planning should take into account multiple users, multiple purposes, and multiple objectives. Planning for maximum net economic benefits is not sufficient. Issues of equity, risk, redistribution of national wealth, environmental quality, and social welfare can be as important as economic efficiency. It is clearly impossible to develop a single objective that satisfies all interests and all political and social viewpoints.

In consequence, the water planning process should develop a number of reasonable alternatives to consider; evaluating from each one its economic, environmental, political, and social impacts.

However, achieving environmental, social and economic goals simultaneously can be impossible. Therefore, it will be necessary to develop a balance between environmental functioning and users with conflicting aims. Planning can help practitioners to approach complex problems, to organise thinking, and to form the understanding necessary to strike that appropriate balance. Only in that way, crucial issues can be identified and sometimes difficult choices made on the basis of adequate information and a full review of the options.

To report on water management policy

The Directive explicitly requires Member and Accession States to produce a management plan for each RBD. The River Basin Management Plan (RBMP) is intended to record the current status of water bodies within the RBD, set out, in summary, what measures are planned to meet the objectives, and act as the main reporting mechanism to the Commission and the public.

There are a number of outputs of this process, in the form of reports, that Member and Accession States are required to submit to the Commission by prescribed deadlines in order to confirm progress. The river basin planning process is followed by the implementation of the management plan.

The actual planning process may vary significantly because of different traditions in policy making and implementing of policy. Distinguishing factors that characterise the different planning types are:

- the way (public and private) stakeholders are involved;
- the way the objectives are set; and
- the types of operational plans that form the outcome of the process.

The variation in these factors reflects the vision on planning of the initiating authority. Among the different types of planning, the table below describes four visions on planning that are internationally distinguished.

Vision on planning	**Policy making means:**	**Participants**	**Type of plans**
1a. plain rational-instrumental	achieving targets with certain means within a certain time.	the problem is defined by the initiating authority; public actors are responsible for the preparation of the plans, private actors can participate during implementation.	spatial-technical imagination of the desired state; implementation following target-means-rationality.
1b. rational-instrumental with an open eye for the complexity of the political, administrative and social context	identifying of sets of related targets and measures, on the basis of an analysis of the actions possible.	the problem is defined by the initiating authority; the analysis of the situation and the preparation of the plans is done in co-operation with several public actors; private actors can participate during implementation.	framework of agreements (who will do what when, what has when to be geared to each other, in which cases must the plan be adjusted); the plan may be incremental (= periodically review of targets and measures, in the light of the target).
2a. plain interactive	policies are the outcome of a process (of learning and negotiating) between interdependent public actors (among themselves) and private actors, each using their own resources.	the definition of the problem is stable if the network of participants is stable; public and private actors both contribute to preparation and implementation of the plans.	picture of the agreed desired target status, in which public as well as private targets are achieved; programme with in any case everybody's tasks and financial inputs.
2b. interactive with an open eye for the power of fundamental debate	on the basis of a powerful discourse, regrouping of actors and means with the aim of achieving certain targets (e.g. 'water service').	the problem is defined by a coalition of public and private actors; a broader audience (public and private) is invited to preparation and implementation of the plans.	review of the activities of public and private actors, in the setting of the discourse; plan with sub-plans for the adjustment of everybody's activities, tasks, responsibilities and financial consequences.

1a In the *rational-instrumental* type of planning (top-down), the initiating authority defines the problem, the solution to the problem, and the means and time schedule for achieving that solution. Other stakeholders are not involved during this process, although they might be informed once the solution is set. Private actors may be involved in the implementation of the plans.

E.g. the planning of the (re)construction of dikes, after the authorities decided that the problem of flooding has to be solved by enlarging the hydraulic capacity of the river. The actual work on the dikes can be carried out by private actors.

1b In the *rational-instrumental planning 'with an open eye'*, the authority recognises the complexity of the social structure in which policy making takes place. Yet the problem is defined by the initiating authority. In the phase of problem analysis and preparation of solutions, other public stakeholders (= other authorities) can co-operate. As in the first type, private actors may be involved in the implementation of the plans.

E.g. the drafting of a programme, initiated by a water authority, of several upstream measures in municipalities a region, in order to reduce risks of flooding downstream by decreasing the peak flow in a certain river.

2a In the *interactive* planning form, the initiating authority starts a process of learning and negotiation between interdependent public actors and private actors, each with their own resources. The definition of the problem is an outcome of that process, and stays stable as long as the network of participants is stable. Public and private actors both contribute to the preparation and implementation of the plans. In short, the initiating authority sets the objectives, while other stakeholders have a say in the means employed.

E.g. an overall plan against flooding in a certain district, with measures agreed on by all different actors involved, concerning the hydraulic capacity of the river, the rainwater sewer system in municipalities, reduction of rainwater runoff from roofs, fields and car parks of private persons, and the retention of water in agriculture and nature grounds.

2b In the *interactive planning 'with an open eye'*, the initiative may come from the authority, but also from other actors. Nevertheless, the authority facilitates the process of problem definition. The discussion in this type of planning is structured by new viewpoints on a problem that are recognised by several actors. On the basis of these viewpoints, strong coalitions can be formed, pursued by the adjustment of ongoing activities.

E.g. the understanding that the available space for water cannot be tightened endlessly without consequences, and that in spatial planning the water flow must be taken into consideration. This brings a reversal in the thinking on planning, from water management rendering services to spatial planning, to water management being prescriptive on the possibilities for spatial planning.

In the order of the four visions on planning, the uncertainties present in planning processes are judged of an increasing importance. Although an historical development is recognisable in the planning types, all forms are applicable at present. More than that, the different planning types can occur at the same time in a certain region!

For example, in several countries as in the Netherlands and in policies on certain forms of non-point sources of water pollution, the interactive planning style is predominant. At the same time, after large flooding, in some cases, the tackling of high water levels became so urgent, that for that particular issue, the rational-instrumental planning style was used. At present, since the memories of the impressive water masses have fainted, the call for more participation is growing louder, which results in a shift in planning style to a more interactive one.

This example shows that the predominant planning style can vary, not only in a geographical scale, but also in a time scale.

As has been substantiated in other Guidance Documents (e.g. WFD CIS Guidance Documents No. 1 – WATECO and No. 8 - Public Participation), for the competent authority it is a matter of the utmost importance to know the social context of an issue, starting with a stakeholder analysis. By knowing the positions of stakeholders – by this is meant public and private stakeholders – a competent authority can choose which type of planning best suits the given situation. It brings the opportunity to flexible shift between the different planning styles, resulting in the best results.

3.3 Planning of water management and links with other planning processes

One of the most significant characteristics of planning is that it is a dynamic process and therefore can be characterised in terms of a set of activities that take place over time and that interact through the transmission and feedback of information. It is the function of these activities to convert that information into forms from which a set of decisions (i.e., plans) can be produced. At all stages of this process, co-ordination with other relevant planning processes should be ensured. In fact, water resources must be planned and managed in an integrated and holistic way. This is likely to involve the co-ordination of river basin planning with the planning processes of other relevant sectors in order to ensure that the objectives of the Directive are met.

For example, many land use activities depend on water. Therefore, a sound water management is crucial to avoid undesirable side effects. Vice versa, land use also affects determinants of water flow and can alter its characteristics, for example, by introducing pollutants along water pathways. Land use regulations can be needed for water protection purposes.

Although WFD contains no explicit provisions in relation to land-use planning, the arrangements for implementation will need to ensure that bodies responsible for land use planning take account of the objectives which it creates. Therefore, it will be advisable to ensure that the land use and water planning processes support one each other as far as possible. Regarding this issue, the requirements of the Directive on Strategic Environmental Assessment (2001/42/EC) will also need to be taken into account.

Although, as it has been stressed above, there are a lot of links with other planning processes, water management planning has some characteristics that cause significantly differences from other planning fields (as for example spatial or economic planning).

In the first place water – on the one hand – is something we use, so that in water management those functions are planned and facilitated (e.g. shipping, water for industry and drinking, etc.). Yet at the same time – on the other hand – policies are carried out to preserve water from deterioration, in order to guarantee the preconditions for those functions. The Directive especially deals with the care for the functioning of water systems, and only in a derived manner with the interests associated with it (e.g. via the concept of water services).

Another characteristic that makes water a special good to manage, are the two types of functions existing at the same time: first the territorial functions; water being the imperative basis for other activities that highly depend on the water system (e.g. agriculture, shipping, spatial planning), and second the utility functions; water being materially used in processes (e.g. drinking water, industrial water).

These characteristics make water planning pre-conditional for other types of planning. Yet it is not an easy precondition to deal with, since the natural dynamics of water systems bring permanent uncertainty. If, for example, the spatial planning is neglected for a certain period, the landscape won't suddenly change by itself. If the same is done with the planning of water systems, dangerous situations can occur with respect to risks of flooding, droughts and health.

Planning is not 100% accurate
Uncertainty can be defined as the occurrence of events that are beyond our control. Uncertainty is always an element in the planning process. It arises because the complexity of the many factors involved. In fact, meteorological, demographic, social, technical, and political conditions which will determine the planning process have behaviour patterns not always known with sufficient accuracy. Uncertainty arises mainly due to the stochastic nature of some key elements affecting these processes.

The programme of measures can be a tool to deal with this uncertainty since it can be revised according to the circumstances (article 11(5) and Annex VII.B)

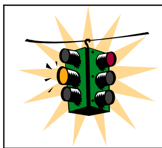
Finally water is not stationary, but a flowing substance, not constrained by administrative or political boundaries, but following physical and hydromorphological limits. This spatial context is commonly known as the catchment.

The Directive – in reflection of the natural water cycle – prescribes the management activities to take place within geographical areas called River Basin Districts (RBDs). These are based largely on surface water catchments, together with the boundaries of associated groundwater and coastal water bodies. In the case of small river basins, adjacent to larger ones, or of several neighbouring small basins, the Directive allows the competent authority to combine or join them in order to make water management in the River Basin District more efficient.

For coastal waters the planning process should consider the influence of other plans that may affect the coastal water beyond the Water Framework Directive controlled one nautical mile coastal strip. Water exchange with more offshore waters may influence the coastal, or even transitional waters, and to not account for this could lead to incorrect assumptions about quality downgrades and the programme of measures required to improve the situation

By creating a spatial unit for water management, based on river basins, it is likely that spatial conflicts will occur with other policy sectors that have a significant impact on water, but are structured along administrative and political boundaries.

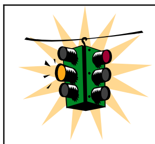
This point also brings the scale-issue into the picture. The complexity of the planning process of water management depends for a great deal on the characteristics of the catchment of the water system considered; in a small scale water system, the planning is more easily carried out than in very large scale systems, such as the Danube or the Rhine, with many countries involved. The Directive requires co-ordination across administrative and political borders.



Look out!
Directive requires that spatial context for integrated and co-ordinated water management has to be the river basin district level.

Section 4. Some considerations for a sound planning process

Planning is a tool or working methodology for preparing decision making with the objective of improving the use of resources available to achieve certain goals. It requires knowledge of the reality on which it operates and capacity to evaluate both the expected outcome and the process through which it can be attained.



Look out! Think globally, act locally.
As a matter of "good practice", river basin planners and managers need to build some cross-cutting principles into all components of their work, to ensure that co-ordination and coherence required for effective results is actually achieved.

The following preconditions for a sound planning process according to the relevant aspects of the WFD can be underlined:

- Long-term vision for the RBD;
- Knowledge and information management. The need of building capacity;
- Integration on the operational level. Links with other planning policies;
- The right timing;
- Appropriate toolbox.

4.1 Long-term vision for the RBD

Having a vision of what the RBD will be in the future can help to determine what measures have to be taken in the perspective of a sustainable development and thus to leave water resources in sufficient quantity and quality for the future generations. Article 1 of the Directive stresses on the necessity to promote sustainable water use based on a long-term protection of available water resources.

Working on a long-term vision for the RBD is an essential tool :

- to reach an agreement between authorities and stakeholders on objectives;
- and then, to plan the necessary actions to reach progressively these objectives.

A stable long-term planning is also important to have a reference during the whole implementation process. At the end of the period covered, the progress made can be compared with the initial vision so to revise the measures if necessary.

Long-term vision for the river basin district is mentioned several times in the Water Framework Directive:

- Baseline scenario.
  Annex III asks the Member States to take account of long term forecasts of supply and demand for water in the River Basin District. The WFD CIS Guidance Document No. 1 on water economics (WATECO) explains why and how the establishment of a baseline scenario for the district is necessary;

- Surveillance monitoring.
  According to Annex V, surveillance monitoring programmes must provide information for the assessment of long term changes in natural conditions and the assessment of long term changes resulting from widespread anthropogenic activity;

- Taking into account the natural time-lag for the pollution transfers and renewal of resources.
  Such time-lag should be taken into account in timetables when establishing measures for the achievement of good status of groundwater and reversing any significant and sustained upward trend in the concentration of any pollutant in groundwater.

4.2 Knowledge and information management. The need of building capacity

The foundation for effective management is good scientific information. In particular, an understanding of freshwater ecosystems and key hydrological and ecological processes is essential and should be used to decide on all aspects of integrated river basin management."Good practice" means that for any river basin management process, the ecological components should be based on a freshwater ecoregional assessment to establish a scientifically based, shared vision on how to conserve the freshwater plants and animals in each river basin.

Similarly, socio-economic analyses are key to understanding the drivers behind water uses. Information databases must be regularly updated through effective programmes. This does not mean measuring everything all the time, but rather carrying out a strategic, targeted and integrated programme, the results of which can be used to inform and adjust management decisions. In many cases, socio economic data is mainly collected at other than river basin spatial scale by central statistical offices. In that case, the implementation of co-ordination mechanisms between them and RBDs may be needed.

Sound information management and analysis needs capacity. Capacity is generally defined as the availability of instruments to take actions. Given the complex and challenging nature of the WFD, it is vitally important that capacity for actual implementation is maximised among all relevant actors. General elements of a capacity-building programme might include raising public awareness (e.g. to help secure broad support for the river basin management objectives), informal transfer of "know how" (e.g. through the exchange of experience between river basin managers), and formal training (e.g. in specialised monitoring techniques), both internal and external. However, the exact needs will vary from country to country and from river basin to river basin, *inter alia* according to different socio-economic conditions, or the concrete water management issues identified. The relevant aspects are:

- The need to build capacity (starting with awareness raising) among economic sectors and NGOs, as well as among officials, planners and administrators;
- The need to enhance sharing of information and experience between countries and regions sharing river basins, with the internet providing valuable new opportunities;
- The need to allocate adequate human and financial resources for capacity building activities in each RBD as part of overall WFD implementation.

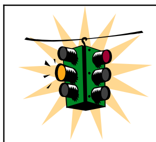
4.3 Integration at the operational level. Links with other planning policies

The WFD sets out a coherent framework for the sustainable management of the water environment (article 1, recitals 3, 5 and 16). This sustainable view is more integrative and places water within the fabric of a larger environmental system.
For example, the management of the water environment is directly and indirectly influenced by many different activities. These activities can be attributed to sectors other than water e.g. transport, agriculture and land-use planning etc.

Clearly, for effective water management, it is essential for activities that impact the water environment, but that fall within the competence of other sectors, to be co-ordinated with the objectives of water management and protection. Failure to take such a holistic approach to water management is recognised as one of the main deficiencies of the existing aquatic legislative framework and has contributed to its inadequate implementation across Europe.

The approach taken by the WFD recognises the need for co-ordination across sectors and proposes a system of planning and management to accommodate it. The river basin planning process will be the central tool for the co-ordination of policies for the purpose of water management.

This does not necessarily mean that the policy objectives of other sectors will be constrained by those of water management. However, it will mean achieving economic and social goals in ways that safeguard, and wherever enhance, the status of the water environment.



Look out! The WFD can only contribute to environmental sustainability if it co-ordinates policy in other relevant sectors for the purposes of water management.

MS will need to establish a planning framework with a clear and explicit purpose and clear national policies, including a set of objectives for protecting and improving the environment in relation to other sectors.
Better overall co-ordination at the river basin level is a pre-requisite for implementing the WFD effectively. This, in turn, needs more integration at the operational level, especially:

- Among bodies involved directly with water management (e.g. those responsible for water storage and supply, flood management and treatment of waste water);
- Between water managers and other sectors, such as land-use planning, agriculture, forestry, flood management, industry and tourism/recreation;
- Integration of surface- and ground-water management (at present often dealt with separately);
- Integration of "inland" and coastal waters, for example by applying the approach and principles of Integrated Coastal Zone Management (ICZM);
- In the case of international river basins, establishing co-operation (where not already in place) between countries and seeking consistency between WFD implementation and any existing bilateral or multilateral agreements that affect water management.

The scale is a very relevant aspect for a good integration. In this sense, sometimes integration needs to happen at the river basin scale, e.g. between flood management, water supply and environmental protection measures; sometimes at the national scale, e.g. between water resource legislation and environmental protection legislation; and some other times at the European scale, e.g. between WFD, Common Agricultural Policy (CAP) and Structural Funds. In this sense, it is important to recognise that the great variation in the size of river basins within and between countries means that approaches suitable for one location are not automatically transferable elsewhere. Good integration on the planning scale implies also the need to co-ordinate "top–down" and "bottom–up" approaches (i.e. to ensure that many physically separate actions at local scale are sufficiently co-ordinated to reach, in combination, the objective of "good status" at the river basin scale). As a matter of "good practice", river basin planners and managers need to build some cross-cutting principles into all components of their work, to ensure that the co-ordination and coherence required for effective results is actually achieved.

Therefore, the planning process in general and the drafting of a RBMP in particular, will depend on contributions from various administrations and institutions. In larger basins and in particular in international basins, the input for the draft RBMP will most probably have to pass different levels of co-ordination and decision-making.

In order to make the drafting of the RBMP easier and to ensure coherence and compatibility of the contributions, it is necessary to define as early as possible the overall structure of the RBMP. Furthermore, the requirements in terms of scale, level of detail, etc. should be clarified at an early stage to set the framework for all involved in the production of the RBMP. It might be a good idea to test the basic structure with the preparation of the report on the analysis required by article 5 of the WFD.

4.4 The right timing

The deadlines for achieving the objectives of the WFD are extremely challenging. It is therefore better to begin implementation "early and imperfectly" than to wait for "perfect conditions" (e.g. when all possible data have been collected and analysed). Consequently, the deadlines in the WFD text must not be seen as a step-by-step timetable for implementation. Result-oriented "good practice" will require many elements to be run simultaneously. Furthermore:

- Timing of preparatory work by Member States should recognise that achievement of WFD deadlines and "good practice" approaches will require immediate action. Primary or secondary legislative changes may be necessary though the appropriate organisational arrangements may not be in place and the required skills and resources may not be available or adequately developed;
- Time can be saved by using existing structures, processes and tools wherever possible. However, this should be subject to the outcomes of a review, checking the suitability and capacity of these structures for delivering WFD requirements. In many cases, a certain degree of adaptation will be needed;
- Monitoring and planning are tools to facilitate management actions in the WFD context. However, management action should not be delayed until all possible planning and monitoring has been completed. For example, if

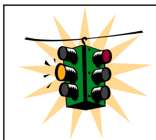
monitoring is not operational until the final deadline of 2006, there will be a severe "bottleneck" in preparing an effective programme of measures by the corresponding final deadline of 2009;

- It is especially important that strategies for public participation and stakeholder involvement are developed and implemented from the beginning, though recognising that different groups will need to be engaged at different stages of the process (see also Work Package 3 of Working Group 2.9, Guidance on public participation);
- Timing of initiatives in related policy areas (e.g. land-use planning policy, capital investment in infrastructure) may impact significantly on the timetable for achieving WFD objectives if the links are not considered at an early stage.

4.5 The appropriate toolbox

Knowledge and information management, capacity building and integration on the operational level needs appropriate tools. Tools are needed for e.g.

- collecting appropriate data (data bases, GIS);
- picking up relevant data and information on data bases;
- analysing and describing the content and planning process of the WFD (flowcharts and GIS-based maps directed to the authorities and the public);
- facilitating administrative requirements;
- public participation (actor analysis, workshops, logical framework etc.)**;**
- decision support tools able to make right priorities concerning the program of measures.



Look out! Under the Common Implementation Strategy a specific Guidance Document (WFD CIS Guidance Document No. 9) has been developed on the GIS elements of the WFD (WG 3.1)

However, those who are involved in the development of water resources systems methodology know that the use of the appropriate tools cannot guarantee by itself the development of optimal plans for water resources and management. In fact, given the competing and changing objectives and priorities of different interest groups, it is unclear how useful the concept of an "optimal plan" really is. What system methodology can do, however, is to help define and evaluate, in a rather detailed manner, numerous alternatives that represent various possible compromises among conflicting groups, values, and management objectives. In particular, a rigorous and objective analyses should help to identify the possible trade-offs between quantifiable objectives so that further debate and analysis can be more informed. The art of systems analysis is to identify those issues and concerns which are important and significant and to structure the analysis to shed light on these issues.

Although the systems approach to water resources planning is not restricted to mathematical modelling, models do exemplify the approach. They can represent in a fairly structured and ordered manner the important interdependencies and interactions among the various control structures and users of a water resources system. Models permit an evaluation of the economic and physical consequences of alternative engineering structures, of various operating and allocating policies, and of different assumptions regarding future flows, technology, costs, and social and legal requirements. Although this systems methodology cannot define the best objectives or assumptions, it can identify good decisions, given those objectives and assumptions.

To engage in a successful water resource systems study, the systems analyst must possess not only the requisite mathematical and systems methodology skills, but also an understanding of the environmental engineering, economic, political, cultural, and social aspects of water resources planning problems.

Thus, the role models may be viewed as that of tools from which to derive answers to well-posed questions about the performance or behaviour of the system that is being planned. However, because of the dynamics of the planning process, it may happen that the answers derived from the models will suggest that the original questions were not well conceived and need to be reformulated. Hence, the role of models is iterative. They are used to produce information that may be fed forward to aid in decision-making (i.e., plan formulation). With equal value, they may produce information that is fed back to aid in redefining the problem.

Section 5. Specific requirements in the Water Framework Directive with regards to the planning process

5.1 General considerations

The publishing of the Water Framework Directive forms a legal obligation for the competent authorities to organise the management of water within River Basin Districts. Understanding the planning and management requirements of the Directive is the basis on which these guidelines on the planning process are considered and established. The planning process is aimed to improve the establishment of river basin management plans and the programmes of measures and hence contribute to the establishment of the overall environmental goals of the Directive: that of achieving "good water status"(recital 25), prevent "further deterioration", "promote sustainable water use" and enhance protection and improvement of the aquatic environment through measures "for the progressive reduction of discharges, emissions and losses of priority substances and the cessation or phasing-out of discharges, emissions and losses of the priority hazardous substances"(Article 1).

Common understanding

There are a number of different planning concepts related to the WFD that are often used interchangeably and require some clarification – these relate to river basin planning, river basin management, river basin management plan, programme of measures and the appraisal process.

The River Basin Management Plan

The WFD requires MS to produce a management plan for each river basin district. This requirement is described in Article 13 and 15. The RBMP will act as the central focal point for the outcome of river basin planning. It will record the current status of water bodies within the River Basin District, set out, in summary, what measures are planned to meet the objectives, and act as the main reporting mechanism to the Commission and the public. The full contents of the plan are specified in Annex VII.

River basin planning and river basin management

River basin planning is the process of collecting and analysing river basin data and evaluating management measures in order to achieve the objectives of the WFD within prescribed timescales.

The river basin planning process is followed by implementation of the programme of measures. The planning process together with the implementation of the programme of measures is often referred to as river basin management.

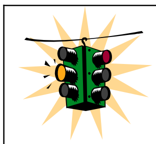
As the name implies, the WFD establishes an outline framework for the planning and management of the water environment. The framework includes a series of key tasks to be completed by prescribed deadlines. In order to confirm progress against these tasks, MS are required to submit a number of outputs from this process, in the form of reports, to the Commission.

Although the key tasks represent milestones in a planning process, the WFD does not specify the procedural detail necessary to support the development of the river basin management plans. The specific nature of river basin planning process is at the discretion of MS.

In the Directive there is no specific article on the planning process. The preambles of the Directive deal with the planning process in an explicit way only to stress the needs of considering different solutions for different conditions and to note that water planning is a long term process (Preambles 13 and 28, see Annex 2).

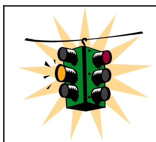
However, several articles deal with tasks that are linked with the planning process as has been summarised in Section 3 and it is shown in more detail in Section 6 of this Guidance. In fact, according the Directive, the general approach for water planning can be seen as based in the following main components:

- Setting the scene;
- Assessment of the current status and analyse preliminary gaps;
- Setting up of the environmental objectives;
- Establishment of monitoring programmes;
- Gap analysis;
- Setting up of the programme of measures;
- Development river basin management plans;
- Implementation of the programmes of measures and prepare the interim report on the implementation;
- Evaluation the first and the second period;
- Information and consultation of the public, active involvement of interested parties.



Look out!
The Directive includes specific requirements for non deterioration and the implementation of extra measures to comply with previously existing water related community legislation. The Commission is leading the production of a horizontal paper that will shed light on the requirement to "prevent deterioration".

There is a tendency to view the planning process based in the above mentioned components as a clearly defined linear sequence. In reality these components are unlikely to be followed in rigid succession, but involve non-linear iterative processes.



Look out! River basin planning process will not run in a linear sequence
The planning includes a number of components that depend on each other, and ideally should be developed as soon as possible. The planning flowchart in Section 6 gives a clear image of work plans that overlap on the time scale.

Each component in the process will consist of numerous activities. Detail on these activities is given later in this Section and in Section 6. Additional technical detail is provided in the other Guidance Documents.

Look out! This Guidance on planning is focused specifically in the general approach of the process.
The technical aspects and tools to be used in planning will be dealt with in a comprehensive Manual on integrated river basin management planning to be prepared at a later stage. On the other hand, specific and detailed information of every step of the planning process mentioned in this Guidance can be found in the Guidance Documents developed by the working groups involved in the Common Implementation Strategy.

5.2 First component: Assessment of current status and preliminary gap analysis

The initial stage in the process of implementing the Water Framework Directive can be called as "Setting the scene" and includes the identification of the River Basin Districts, establishment of the appropriate administrative arrangements for co-ordination of activities, and designation of competent authorities.

Following this, the **first component of the planning process** is to describe the characteristics of each River Basin District. This requirement is outlined in Article 5 (see Annex 2).

Hence, the assessment on current water status is based in the four following tasks:
- General description of the river basin district that should include the establishment of reference conditions for surface waters;
- Register of protected areas;
- Identification of significant pressures and assessment of their impacts;
- Economic analysis of water uses.

These tasks should be completed by 22 December 2004, and reported to the Commission by the 22 March 2005.

Look out! *The general description of the RBDs is important because it will serve as the foundation of the subsequent process*

The general description of the RBD includes assigning coastal water bodies to districts. Article 2(7) of WFD defines coastal waters as extending for a nautical mile from the territorial baseline.

Shared groundwaters must only be assigned to one RBD. This is an outstanding difference with respect to coastal waters, where the Directive allows them to be assigned to more than one RBD.

Look out! Under the Common Implementation Strategy the following specific documents have been developed on:

- ***Guidance document on the Definition of water bodies (WFD CIS Guidance Document No. 2);***
- ***Information document on the Identification of River Basin Districts (WG 2.9);***
- ***Establishing reference conditions and ecological status class boundaries for inland surface waters (WFD CIS Guidance Document No. 10 from WG 2.3);***
- ***Typology, reference conditions and classification systems for transitional and coastal waters (WFD CIS Guidance Document No. 5 from WG 2.4).***

Moreover a specific Guidance Document in Wetlands is in preparation and expected to be finished in 2003.

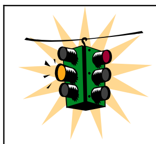
For all water bodies, good status must be achieved unless a derogation is applied. Each water body has to be characterised according to ecoregion types (System A) or to the differentiation of water bodies into types using the different obligatory and optional factors (System B). This work will provide the foundation for further activities to establish what "good status" will mean for each "type".

According to the Directive, it is necessary to identify what the relevant aspects of a waterbody's characteristics would be like if there were "no or only very minor alterations" to the body resulting from human activities. In the Directive these nearly undisturbed conditions are called as reference conditions.

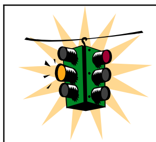
Reference conditions also have to be included in the general description of the RBD and they should be selected according to chemical and hydro-morphological characteristics and evaluated more specifically in quantitative terms on the basis of biological parameters. Reference conditions must be defined for each quality element and each water body type in order to allow an ecological quality ratio to be calculated and a class determined for each surface water body. They also have to be included in the general description of the RBD and they should be selected according to chemical and hydro-morphological characteristics and evaluated more specifically in quantitative terms on the basis of biological parameters. The characterisation of surface waters requires that Member States develop a reference network for each surface water body type. If no reference waters are available, reference conditions could be based on modelling or on expert judgement.

Sometimes it will not be possible to achieve a "nearly undisturbed condition" of a water body because of substantial physical alterations made to it to permit activities as irrigation, drinking water supply, power generation, navigation and so on. The Directive recognises that in some cases the benefits of such uses need to be retained and if a series of criteria are fulfilled, allows their designation as artificial or heavily modified water bodies.

The reference conditions for artificial or heavily modified water bodies of surface water is the "maximum ecological potential", that has to be derived from the water body type that is most similar to the uninfluenced body of surface water.



Look out! First characterisation of water bodies may also include a provisional identification of artificial and heavily modified water bodies.
The designation of artificial or heavily modified water bodies can be also considered as an exemption from the "good ecological status objective" but this task is required in the river basin management plan in which the final designation shall be made before December 2009. In any case, a provisional identification of artificial and heavily modified water bodies may be undertaken by 2004 and the formal designation by 2009.



Look out! Under the Common Implementation Strategy a specific Guidance Document has been developed on the identification and designation of heavily modified and artificial water bodies (WFD CIS Guidance Document No.4 from WG 2.2)

The Directive provides protection to higher standards through the *designation and registration of protected areas*. Protected areas are those that have been designated as requiring special protection under EU legislation, either to protect their surface water or groundwater or to conserve habitats and species that directly depend on those waters. A register of protected areas within the district shall also be published by the end of 2004 (article 6 and Annex IV).

Under Article 4 of the Directive, for individual protected areas, any standards and objectives that have been set for them must be complied with within 15 years of the Directive entering into force unless otherwise specified in the Community legislation under which they have been designated.

The register of protected areas required under article 6 must include the following types of protected areas:

- areas designated for the abstraction of water intended for human consumption;
- areas designated for the protection of economically significant aquatic species;
- bodies of water designated as recreational waters;
- nutrient sensitive areas; and,
- areas indicated for the protection of habitats or species where the maintenance or improvement or the status of water is an important factor in their protection.

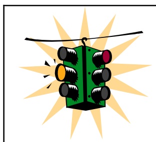
The following table shows the Community legislation more relevant for each type.

Protected areas	***Community legislation***
Abstraction of water intended for human consumption.	Surface Water Abstraction Directive (75/440/EEC)
Protection of economically significant aquatic species	Shellfish waters designated under the Shellfish Waters Directive (79/923/EEC)
Recreational waters	Bathing waters designated under the Bathing Waters Directive (76/160/ECC)
Nutrient sensitive areas	NVZs designated under the Nitrates Directive (91/676/EEC) and sensitive areas designated under the Urban Waste Water Treatment Directive (91/272/EEC)
Protection of habitats or species	Natura 2000 sites designated under the Habitats D

Generally, protected areas derive their status from the specific Community legislation under which those areas are identified or defined. Consequently, it is considered that no specific power to "designate" new categories of protected areas will be needed, although a power is needed to specify the protected areas to which the article 6 (and then article 4) obligations will apply.

An exception to this general rule concerns article 7 (water used for the abstraction of drinking water), which provides a new obligation to identify all bodies of water used for the abstraction of drinking water and those bodies intended for such future use.

The identification of significant anthropogenic current and foreseen pressures and the assessment of their impacts are based on Annex II (1.4) of the WFD. Once the main pressures have been identified, an assessment shall be made to predict how they can impact on the water bodies, i.e. how they influence the achievement of the environmental quality objectives. The susceptibility of the surface water bodies status to the pressures can be obtained using both monitoring data and modelling techniques.

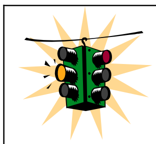


Look out! Under the Common Implementation Strategy a specific Guidance Document has been developed on the analysis of pressures and impacts in accordance with the WFD (WFD CIS Guidance Document No. 3 from WG 2.1)

For both surface and groundwaters, although the requirements are phrased slightly differently, the approach is essentially the same. That is, to gather available information about pressures on water bodies, and to assess the impact of those pressures on water bodies and the risk of them failing to meet the environmental status objectives set for the water bodies.

In fact, what the Directive requires from the identification is an assessment of which water bodies are at risk of failing to meet the environmental objectives. This information will be used to define the programmes of measures and the design of monitoring programmes.

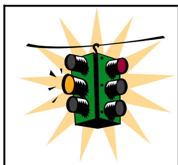
The risk assessment for groundwater considers that groundwater can take a long time to recover once it is polluted. If achieving good status by 2015 is technically unfeasible or disproportionately expensive, lower objectives can be established. Groundwater bodies which will have these lower objectives have to be identified and require an evaluation of the feasibility of natural or artificially assisted restoration. The use of derogations is subject to a number of tests that must be reported to the Commission in the RBMPs.



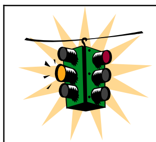
Look out! Under the Common Implementation Strategy a specific Guidance Document has been developed on the Statistical aspects of the identification of groundwater pollution trends, and aggregation of monitoring results (WG 2.8). A so-called daughter directive on Groundwater is expected to be finished during 2003.

For 2004, a provisional identification of HMWB is needed on the basis of significant hydromorphological alterations. The risk assessment for surface water bodies will determine whether the effects of hydromorphological alterations to a surface body are likely to prevent the achievement of good ecological status.

If the achievement of good ecological status is considered as uncertain, a further assessment will be required after 2004 to determine what improvements to the hydromorphological conditions would be needed to achieve good ecological status and whether such improvements would have significant adverse effects on the activity related to the alteration (derogation on the basis of disproportionate costs). The result of this assessment of the risk to fail to meet the objectives is the identification of HMWB. At this stage, a third assessment will be required to determine the risk of the HMWB to fail to achieve the good ecological potential.



Look out! For 2004, only a first assessment of risk of failing to meet the objectives is required.
Results of monitoring will precise this risk in 2005-2006 (confirmation of the risk or not). Monitoring is a task that is greatly related to the risk assessment. Specific requirements for monitoring can be found in Article 8 (see Annex 2 of this document). Results of monitoring are necessary in order to decide if it is necessary to make further assessment.



Look out! Risk assessment is one of the main tool of the river basin planning process.
If every pressure could be reliably identified and its effects accurately predicted, monitoring would be redundant. However, risk assessments can never be perfect. They always need to be tested. The risk assessments completed by the end of 2004 will provide an estimate of which water bodies could be at risk of failing to achieve environmental objectives. The monitoring programmes must provide the information needed to supplement and validate these assessments and to establish the status of the bodies confirmed at risk.

Wetland ecosystems are ecologically and functionally significant parts elements of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in WFD CIS Guidance Document No. 2

on water bodies and further considered in Guidance on wetlands (currently under preparation).

Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.

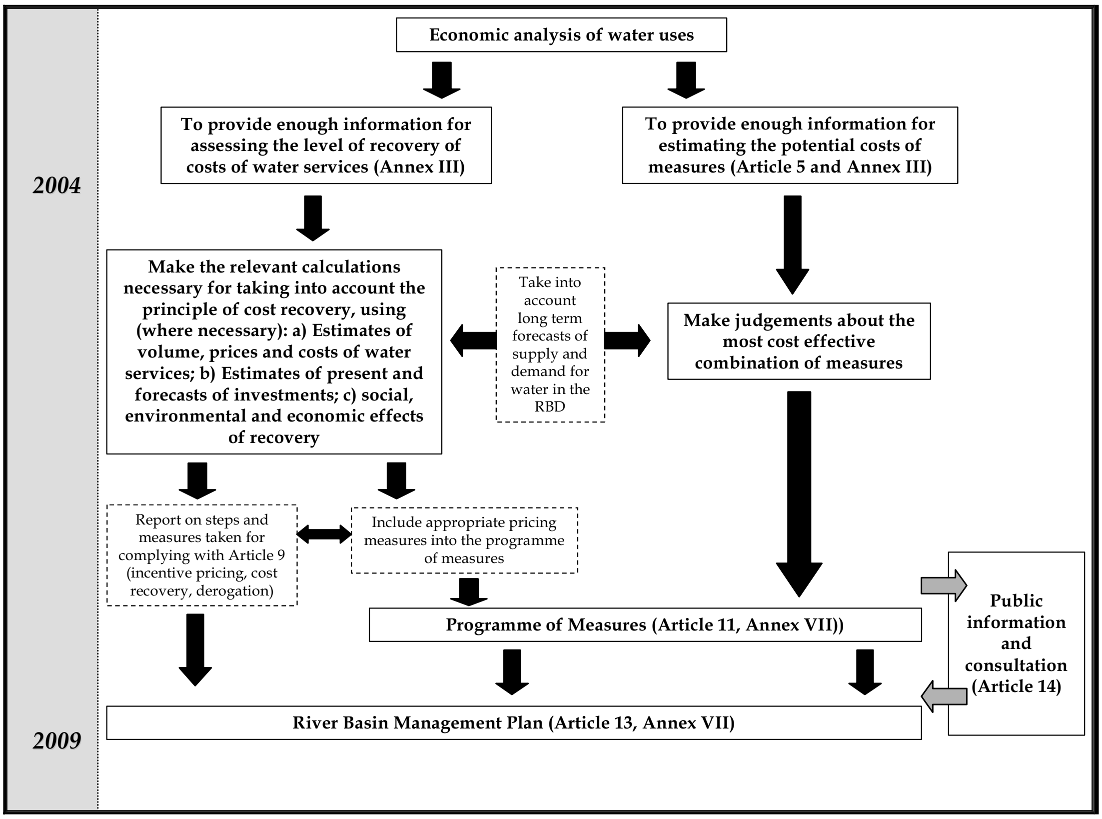
Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater recharge. The relevance of wetlands within programmes of measures is examined further in a separate horizontal Guidance paper on wetlands (currently in preparation).

The economic analysis of water uses is mainly described in the Article 9 and Annex III of the WFD (see Annex 2).

	***Look out! Under the Common Implementation Strategy a specific Guidance Document (WFD CIS Guidance Document No. 1) has been developed on "Economics and the environment - The implementation challenges of the WFD" (WG 2.6).***

The comparison between the economic elements of the Directive reviewed and the content of Annex III of the WFD shows that not all components of the economic analysis required to support the implementation of the economic elements of the Directive are specifically spelt out in Annex III.

A difference is made between the explicit and implicit functions of the economic analysis, the term explicit referring to the economic components that are specifically outlined in Article 5 and Annex III (see Figure 5.1), and the term 'implicit' referring to references made to economic issues in other parts of the text of the Directive that will also require some economic analysis which has not been mentioned in Article 5 and Annex III (see following figures).



Source: WFD CIS Guidance Document No. 1 - WATECO.

Figure 5.1 **The *explicit* economic functions of the economic analysis.**

Look out! The economic analysis undertaken by 2004.

2004 is the first major deadline aimed at characterising river basin districts as referred to primarily in Article 5 and relevant annexes of the Directive. Therefore, 2004 is also the first milestone for the economic analysis that requires for each river basin district to:

- *Undertake **the economic analysis of water uses** – the main objective is to assess how important water is for the economy and socio-economic development of the river basin district. The analysis needs to pave the way for the identification of significant water issues to be reported to the public by 2007;*
- *Investigate the dynamics of the river basin and providing economic input into the **development of a baseline scenario** – The economic analysis will assess forecasts in key economic drivers likely to influence pressures and thus water status;*
- *Assess **current levels of recovery of the costs of water services**, in accordance to Article 9 of the Water Framework Directive – The main elements to be investigated include the status of water services, the extent of the recovery of the costs (financial, environmental and resource costs) of these services, the institutional set-up for cost-recovery and the contribution of key water uses to the costs of water services;*
- *Prepare for the **cost-effectiveness analysis** – It is suggested that data are collated on costs for the key measures that will be considered, after 2004, in the development of the river basin management plans.*

	➢ *Propose activities* ***for enhancing the information and knowledge base*** *- Practical steps and measures will be identified for filling key economic-related information and knowledge gaps, both identified during the characterisation of the river basin and likely to arise when undertaking the cost-effectiveness analysis.*

5.1 Second component: Setting up of the environmental objectives

The second component in the implementation of the planning process includes the setting up of the **environmental objectives** mainly based in Article 4 of the WFD (see Annex 2).

The Directive specifies the following principal environmental objectives for surface water bodies:

- ➢ to prevent deterioration in their status ;
- ➢ to restore to good surface water status (or good ecological potential for heavily modified and artificial water bodies) by 2015; and
- ➢ to implement the necessary measures with the aim on progressively reducing pollution from priority substances and ceasing or phasing out emissions, discharges and losses of priority hazardous substances.

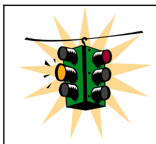
For groundwater:

- to implement the measures necessary to prevent or limit the input of pollutants into groundwater and to prevent the deterioration of the status of all bodies of groundwater;
- to protect, enhance and restore all bodies of groundwater, ensure a balance between abstraction and recharge of groundwater, with the aim of achieving good groundwater status on December 2015 at the latest; and
- to implement the measures necessary to reserve any significant and sustained upward trend in the concentration of any pollutant resulting from the impact of human activity in order to reduce pollution of groundwater progressively.

For protected areas:

- to achieve compliance, by December 2015 at the latest, with specific standards and objectives specified in the Community legislation under which the individual protected areas have been established;

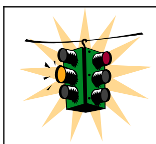
- to achieve compliance with good status objectives by December 2015, unless delay or less stringent objective if all the necessary improvements in the water status cannot reasonably be achieved within 2015.



Look out! Classification schemes.
Ultimate aim of the WFD is the achievement of "good water status".
*The status of **surface water bodies** will be determined by the poorer of its chemical or ecological status.*
Chemical status describes whether or not the concentration of any pollutant exceeds standards that have been set at the European level
Ecological status is principally a measure of the effects of human activities to water.
*The status of **groundwater bodies** will be determined by the poorer of its chemical and quantitative status.*
Quantitative status is an expression of the degree to which a body of groundwater is affected by direct and indirect abstractions.

The main aim of the definition of environmental objectives is to set goals and targets which then serve as the foundation of the decision on programmes of measures. Goals and targets should fix into a long-term vision for the RBD, and be seen as steps to achieve the vision via a concrete planning process.

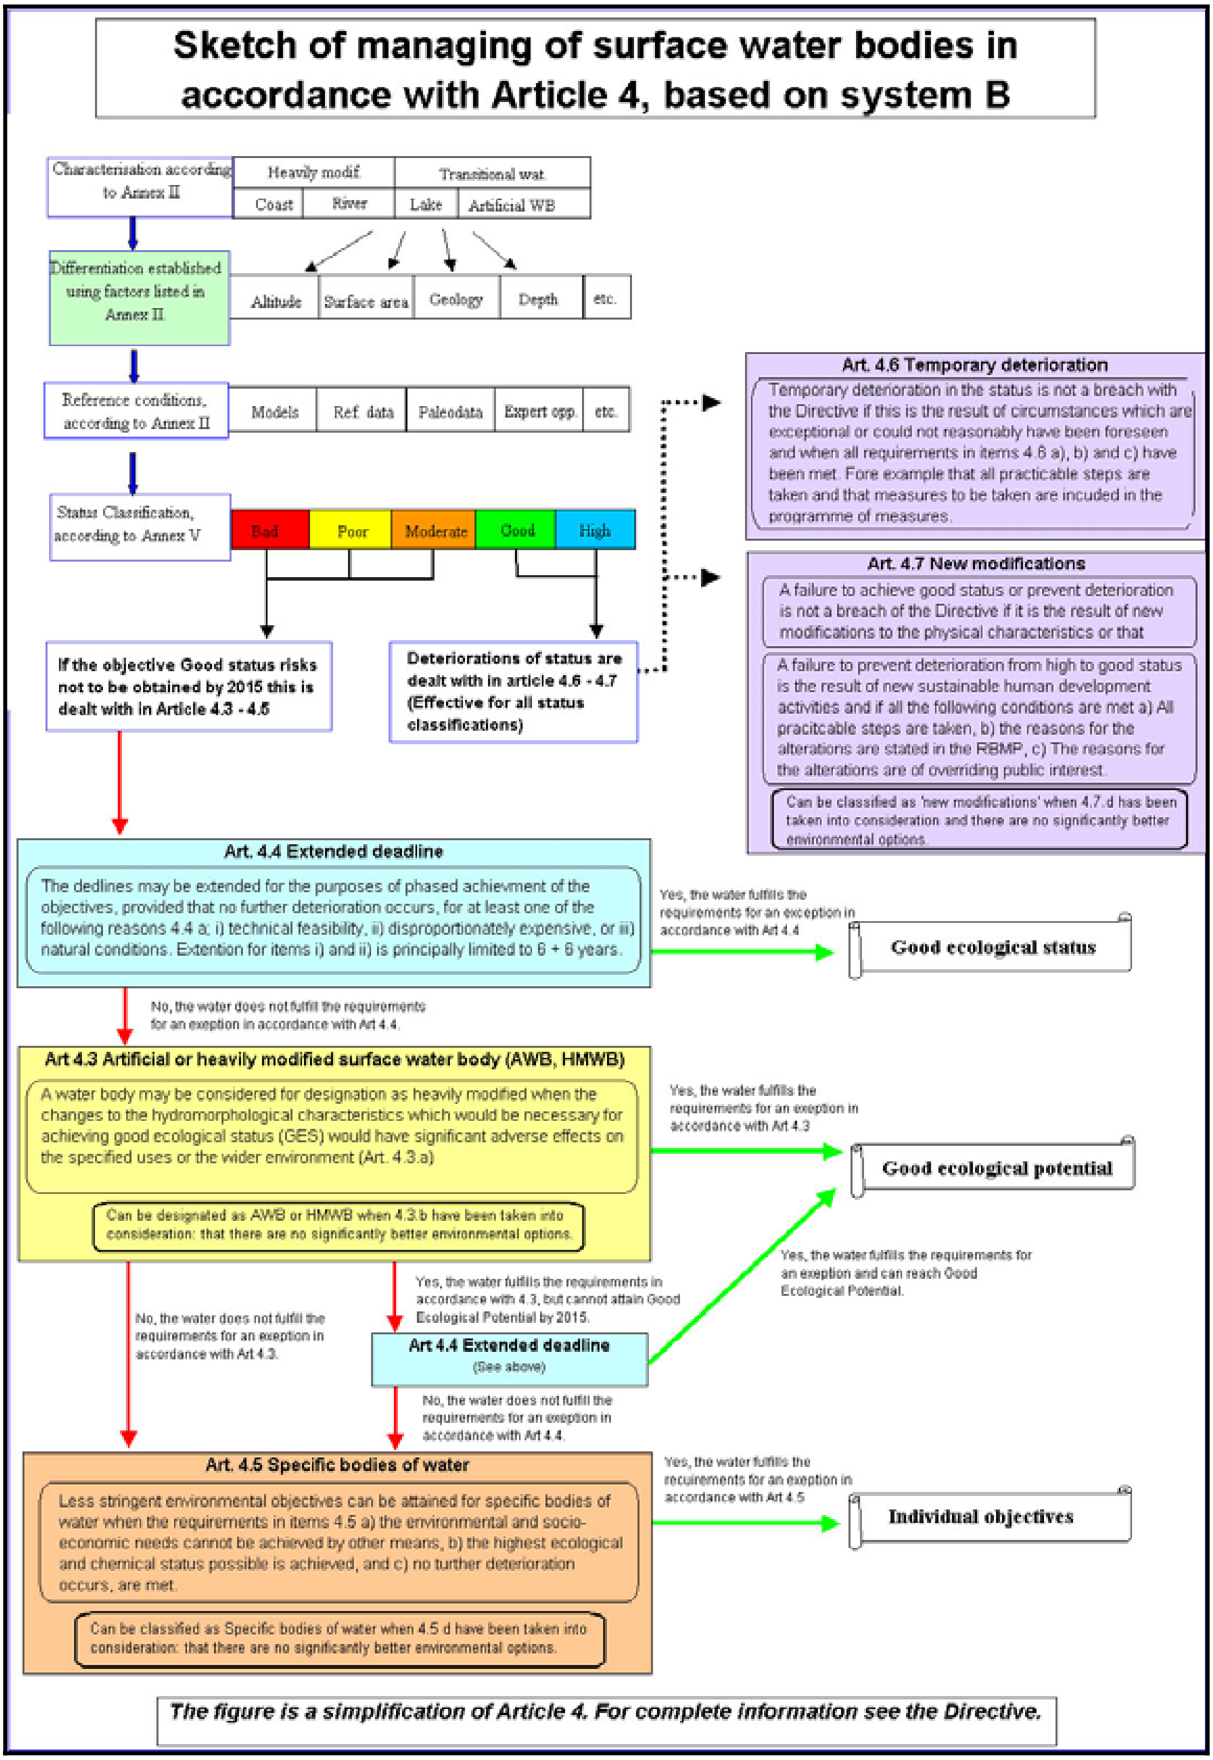
In certain circumstances, different objectives may be specified through the river basin planning process, e.g. for water bodies for which the restoration of good status would be technically unfeasible or disproportionately expensive. For surface waters designated as heavily modified or artificial, the status objectives that must be achieved by 2015 are good ecological potential and good surface water chemical status.



Look out! Boundaries have to be defined for every ecological region.
The intercalibration process developed by the European Commission will be the key element to define high ecological status and boundaries between high and good, as well as good and moderate. There is a specific Guidance Document on this basis to create the intercalibration network developed by WG 2.5 (WFD CIS Guidance Document No. 6).

Look out! Classification for heavily modified and artificial surface water bodies.
Despite being designated as heavily modified, water bodies still have to achieve good chemical status and good ecological potential.
Maximum Ecological potential defines the reference conditions considering all mitigation measures which do not have a significant adverse effect on specified uses or the wider environment.
Good ecological potential is defined as a "slight" shortfall from the maximum ecological potential these bodies can achieve.

The setting of the environmental objectives can be considered as one of the core components of the implementation of the WFD and also of its planning process. As explained before, setting the objectives in the context of the WFD means taking decisions on using the different options of Article 4. The definition of environmental objectives is not only a question of what exactly the status of a certain water body (and not that of an entire basin) should be but also a question of when this status should be achieved. Thus, the expression of setting of objectives is used in order to make a distinction between what is defined as objectives in the WFD itself and what is at the discretion of the river basin authorities. As the process required by Article 4 is very complex, it was felt useful to provide in this Guidance a more detailed explanation of the implementation tasks to be carried out and the steps to be taken in the form of a sketch included below.



Sketch of managing of surface water bodies in accordance with Article 4, based on system B

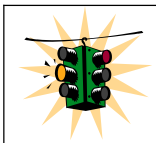
Status Classification, according to Annex V
Bad
Poor
Moderate
Good
High
If the objective Good status risks not to be obtained by 2015 this is dealt with in Article 4.3 - 4.5
Deteriorations of status are dealt with in article 4.6 - 4.7 (Effective for all status classifications)
Art. 4.6 Temporary deterioration
Temporary deterioration in the status is not a breach with the Directive if this is the result of circumstances which are exceptional or could not reasonably have been foreseen and when all requirements in items 4.6 a), b) and c) have been met. Fore example that all practicable steps are taken and that measures to be taken are incuded in the programme of measures.
Art. 4.7 New modifications
A failure to achieve good status or prevent deterioration is not a breach of the Directive if it is the result of new modifications to the physical characteristics or that
A failure to prevent deterioration from high to good status is the result of new sustainable human development activities and if all the following conditions are met a) All pracitcable steps are taken, b) the reasons for the alterations are stated in the RBMP, c) The reasons for the alterations are of overriding public interest.
Can be classified as 'new modifications' when 4.7.d has been taken into consideration and there are no significantly better environmental options.
Art. 4.4 Extended deadline
The dedlines may be extended for the purposes of phased achievment of the objectives, provided that no further deterioration occurs, for at least one of the following reasons 4.4 a; i) technical feasibility, ii) disproportionately expensive, or iii) natural conditions. Extention for items i) and ii) is principally limited to 6 + 6 years.
Yes, the water fulfils the requirements for an exception in accordance with Art 4.4
Good ecological status
No, the water does not fulfil the requirements for an exeption in accordance with Art 4.4.
Art 4.3 Artificial or heavily modified surface water body (AWB, HMWB)
A water body may be considered for designation as heavily modified when the changes to the hydromorphological characteristics which would be necessary for achieving good ecological status (GES) would have significant adverse effects on the specified uses or the wider environment (Art. 4.3.a)
Can be designated as AWB or HMWB when 4.3.b have been taken into consideration: that there are no significantly better environmental options.
Yes, the water fulfils the requirements for an exception in accordance with Art 4.3
Good ecological potential
Yes, the water fulfils the requirements for an exeption and can reach Good Ecological Potential.
Yes, the water fulfils the requirements in accordance with 4.3, but cannot attain Good Ecological Potential by 2015.
No, the water does not fulfil the requirements for an exeption in accordance with Art 4.3.
Art 4.4 Extended deadline
(See above)
No, the water does not fulfil the requirements for an exeption in accordance with Art 4.4.
Art. 4.5 Specific bodies of water
Less stringent environmental objectives can be attained for specific bodies of water when the requirements in items 4.5 a) the environmental and socio-economic needs cannot be achieved by other means, b) the highest ecological and chemical status possible is achieved, and c) no further deterioration occurs, are met.
Can be classified as Specific bodies of water when 4.5 d have been taken into consideration: that there are no significantly better environmental options.
Yes, the water fulfils the requirements for an exception in accordance with Art 4.5
Individual objectives
The figure is a simplification of Article 4. For complete information see the Directive.

5.3 Third component: Establishment of monitoring programmes

Monitoring is a task that is greatly related to the risk assessment and to the evaluation of the effectiveness of the measures taken to achieve the environmental objectives in the planning process. Specific requirements for monitoring can be found in Article 8 (see Annex 2).

The Directive, in its Annex V, describes three types of monitoring programmes with different information purposes:

- ***Surveillance monitoring*** that is mainly devoted to improve the assessment of which bodies are at risk of failing to meet the Directive's objectives and which are not. It includes monitoring of surface water bodies and the chemical status and pollutant trends of groundwater bodies;
- ***Operational monitoring*** that is exclusively focused on those water bodies that, on the basis of the risk assessments and the surveillance monitoring programmes, are at risk of failing to meet the Directive's environmental objectives. Operational monitoring has to be based on indicators that are sensitive to the identified pressures. This program should also include monitoring of groundwater levels to assess groundwater at risk according to their quantitative status;
- ***Investigative monitoring*** is to be used to ascertain the response why a water body is at risk and it should help to design the appropriate management measures.

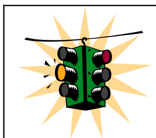


Look out! Under the Common Implementation Strategy a specific Guidance Document (WFD CIS Guidance Document No. 7) has been developed on monitoring for the WFD (WG 2.7)

By the end of 2006, the Directive requires the implementation of the monitoring programme (article 8) for surface and groundwater. The monitoring of the water status is to be operational in 2006. It particularly includes the definition of reference sites and water status evaluation grids and the performance of comparative analyses on the European level (intercalibration). The monitoring systems shall be made to comply with the requirements of the Directive and the monitoring programme shall be operational by 2006.

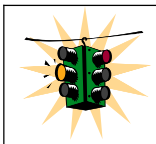
5.4 Fourth component: Gap analysis

Gap analysis has to take account of the results carried out in the assessment of the current status (first step) comparing them with the environmental objectives (defined in the second step).



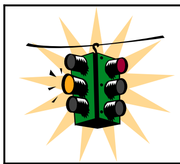
Look out! Gap analysis must be developed having in mind that the Directive is broader and more ambitious than the former European water legislation.
Previous European water legislation set objectives to protect particular uses of the water environment from the effects of pollution and to protect water environment from specially dangerous substances. The Directive introduces broader ecological objectives, designed to protect and where necessary, restore the aquatic ecosystems.

Effective gap analysis requires sound data, information and knowledge. To increase the effectiveness of the activity this information usually has to be aggregated for example in the form of indicators and systems for benchmarking. In fact, existing information is often sufficient to get started, but difficult to assemble and integrate. One key element is to assess what is available versus what information is really needed.



Look out! RBD characterisation is mainly to support gap analysis
Gap analysis tools should be considered at early stage to design the current status assessment Tools as GIS, expert systems, mathematical models, etc are useless for gap analysis if accurate data is not available.

Different analytical tools can support the analysis but it must not be forgotten that gap analysis can not rely on quantitative information only. Moreover, these methods should be transparent and flexible, promoting public participation and facilitating negotiation processes.



Look out! The results from gap analysis will give elements to elaborate the overview of main significant issues for water management in the district (required by Article 14(1)).

5.5 Fifth component: Setting up of the programme of measures

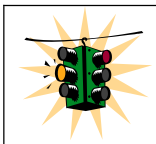
The fifth component in the implementation of the planning process is the establishment and implementation of the programmes of measures. The Directive requirements are in Article 11 (See Annex 2 of this Guidance Document).

WFD requires river basin plans to integrate the management of water quality and water resources and surface and groundwater management in order to meet the environmental objectives.

The programme of measures to be established by the end of 2009 will consist of defining, for each district, the regulatory provisions or *basic measures* to be implemented in order to achieve the objectives defined for 2015 by the management plan in accordance with Community and/or national laws (e.g. extension of sensitive or vulnerable areas, reporting and authorisation system, definition of resource protection areas, discharge control etc.). These measures also include pricing measures taken to provide users with incentives to manage water more efficiently. Measures may be decided on the national level.

If the aforementioned provisions do not suffice to achieve the set objectives, *supplementary measures* shall be taken. The Directive provides a non-exclusive list of such measures, which are aimed at either reinforcing the previous provisions or setting up new provisions such as good practices codes, voluntary agreements, economic and tax instruments etc. *Additional measures* have also been defined. They particularly relate to the implementation of international agreements.

In international RBDs the implementation of the programmes of measures should be co-ordinated for the whole of the river basin district for the significant water management issues identified. For river basins extending beyond the boundaries of the Community, Member States should endeavour to ensure the appropriate co-ordination with the relevant non-member states.



Look out! Co-ordination must be ensured from the very beginning of the planning process.
It is not possible to co-ordinate programmes of measures of river basin management plans without a co-ordinated analysis and review of the status, co-ordinated monitoring programmes, co-ordinated assessment and co-ordinated approaches for the involvement of the public. Therefore, co-ordination must be ensured from the very beginning of the planning process. One possible approach that competent authorities could take is to develop a co-ordination network, work plan and a timetable indicating the various co-ordination steps within the planning process.

Basic measures include the so-called combined approach (Article 10). This means that water policy should be based on using control of pollution at source through the setting of emission limit values and of environmental quality standards. For example, for point source discharges liable to cause pollution, basic measures can be a requirement for prior regulation (i.e. a prohibition on the entry of pollutants) or a requirement of authorisation or registration laying down emission controls for the pollutants concerned. For diffuse sources liable to cause pollution, basic measures are to prevent or control the input of pollutants or prior regulation, authorisation or registration in a similar way to point source discharges. Prohibition of direct discharges of pollutants into groundwater is a basic measure subject to some provisions – use for geothermal purposes, injection for mining activities, construction, civil engineering and so on – that are listed in Article 11 (j).

Article 10(1) (combined approach for point and diffuse sources) refer to a range of directives such as Integrated Pollution Prevention and Control (IPPC) (96/61/EC), Cadmium Discharges (85/513/EEC), Mercury Discharges (82/176/EEC) and nitrates, and any future relevant directives. Controls required by these directives must be established by 2012 at the latest (the same date that programmes of measures must be operational), unless otherwise specified in the legislation concerned. These parts of article 10 therefore have no additional effect to what is required by the directives to which they refer.

Article 10(3) specifies that where different quality objectives or quality standards have been established according to the different directives referred to in article 10, and they require stricter conditions than those which result from the application or article 10, the emission controls must be tightened. Therefore, if the application of the environmental quality standard approach required tighter controls on emissions than would otherwise be the case, those controls would need to be tightened.

The use of economic instruments is part of the basic measures. As it is mentioned in preamble 38, the principle of recovery of the costs of water services, including environmental and resource costs associated with damage or negative impact on the aquatic environment should be taken into account in accordance with, in particular, the polluter-pays principle. An economic analysis of water services based on long-term forecast of supply and demand for water in the river basin district will be necessary for this purpose.

The Directive aims to ensure that pricing policies improve the sustainability of water resources. Within this broad framework, water charging policy already meets the water charging provisions in WFD, which require water pricing policies to perform the following functions by Dec 2010:

- take account of the principle of the recovery of costs or water services, including environmental and resource costs;
- embody the "polluter pays" principle;
- provide adequate incentives to use water resources efficiently;
- ensure that water use groups (separated into at least industry, households and agriculture) make an adequate contribution to the recovery of the cost of water services.

WFD requires the "principle of recovery of the costs of water services" to be taken into account. It also requires that an adequate contribution of the different water uses be made to the recovery of the costs of water services.

Very often, water users, as customers of the companies who supply water and sewerage services, already in aggregate meet the financial costs of their services. The industry not subsidised, and all costs placed on the water and sewerage companies have to be recovered from the customers.

As well as meeting in full the aggregate costs of water services, the breakdown of the aggregate costs among water customers broadly reflects both a division between sectors of water users and the polluter pays principle.

Basic measures must ensure good water quality in the supply for the population including the identification of waters used for the abstraction of drinking water.
Drinking water quality must be safeguarded in order to reduce the level of purification treatment.

The obligation in the Directive requires the adoption of a programme of measures to meet the requirements of article 7 and additionally to safeguard water quality in order to reduce the level of water treatment required for the production of drinking water.

The general requirement of article 7 is the identification, within the river basin districts proposed, of water bodies that are used or are intended to be used for human consumption. The requirement applies to both surface waters and groundwaters where the rate of abstraction exceeds 10 m^3/d and will therefore apply to public water sources and some private water sources. Article 7 also requires monitoring of water sources where the rate of abstraction exceeds 100 m^3/d.

Article 7 also requires that all waters intended for human consumption meet the objectives of article 4 for surface waters and groundwaters. In addition surface waters must meet additional quality standards prescribed in article 16. Member States are required to ensure that under the treatment regimes applied, drinking water produced meets the requirements of the Directive on the Quality of Water Intended for Human Consumption (80/778/EEC) as amended (98/83/EC).

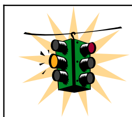
The final provision of article 7 is the requirement to ensure that the necessary protection for the water bodies identified is provided, with the aim of avoiding deterioration in their water quality, in order to reduce the level of water treatment required. Article 11 requires that the measures to be taken for the protection of each river basin district are specified within a programme.

Basic measures must deal also with controls over relevant abstractions of fresh surface water or groundwater and impoundment of fresh surface water and artificial recharge or augmentation of groundwater bodies. For water quantity, overall principles should be laid down for control on abstraction and impoundment in order to ensure the environmental sustainability of the affected water systems.

The obligation in WFD in respect of the abstraction of fresh surface water and groundwater has four parts to it:

- there must be controls over abstraction of fresh surface water and groundwater;
- a register of abstractions (but not impoundments) must be maintained;
- abstraction must have prior authorisation;
- controls must be periodically reviewed and, where necessary, updated.

The philosophy of the approach in WFD to regulating abstraction is "risk-based".
Consequently, in the case of abstraction, the Directive does not provide for generic exemptions from controls on the basis of purpose, location, source or size of the abstraction. Rather, following the "risk-based" principle and according Article 11(3)(e), abstractions that have no significant impact of water status can be exempted from control.



Look out! The programme of measures can be phased in order to spread the costs of implementation.

The Directive includes a number of provisions that allow for derogation from the environmental objectives for legitimate economic and technical reasons. This will help Member States to strike a balance between environmental, economic and social goals. Justification for the use the derogation must, in all cases, be included with the RBMP.

5.6 Sixth component: Development of the River Basin Management Plans

A management plan must be produced for each river basin district. The milestone of the river basin planning process (analysis, monitoring, objective setting, consideration of measures to maintain or improve water status) is the RBMP which will summarise the relevant planning information for its river basin district.

Indeed the outcome of the planning process is not the RBMP: the planning process continues after the elaboration of the RBMP. After the publication of the RBMP the planning process enters in a concrete phase in which the RBMP is followed and the programme of measures is applied. In this phase, the role of the planning process is to guide the implementation of measures in an appropriate way so to reach the objectives. Besides the first RBMP will be followed by updated RBMP in the next management cycles.

One way of thinking about the first generation RBMPs is to regard them as representing the transition between initial analysis and implementation, i.e. they are to be adopted after having worked out what the current situation is (both terms of the state of the environment and the pressures on it), and having determined where the Member States is aiming to get to (what the objectives should be for specific water bodies) and having decided how the Member State is going to get to there (a summary of the programme of measures).

The plans are not the principal mechanism for implementing measures to achieve the environmental obligations imposed by the Directive. Those measures are to be set out in the programme of measures required by article 11 that is to be adopted for each river basin district. Programmes of measures will then be summarised in the relevant RBMP. The role of RBMPs is rather broader than this. For example, they are to be the primary vehicle for consulting the public and stakeholders on plans for managing the water environment within the river basin district.

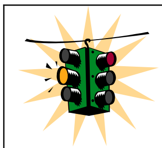
The plans will also be, ultimately, the main reporting mechanism to the Commission and to the public. The plan will be a summary of how the objectives set for the river basin (ecological status, quantitative status, chemical status and protected area objectives) are to be reached within the timescale required.

The plan will include a summary of the results of the analyses; the characteristics of the river basin; a review of the impact of human activity on the status of waters in the basin; estimation of the effect of existing measures and the remaining “gap” to meeting those objectives; and, what more is required.

The plans must include the information detailed in annex VII of WFD. This is split into 12 parts, which are summarised in the box below.

Contents of the RBMP

- General description of the characteristics of the river basin district, including a map showing the location and boundaries of surface water bodies and groundwater bodies and a map showing the different surface water body types within the river basin.
- Summary of significant pressures and impact of human activity on the status of surface water and groundwater, including estimations of point source pollution, diffuse source pollution (including a summary of land-use) and pressures on the quantitative status of water including abstractions, and an analysis of other impacts of human activity on the status of water.
- Map identifying protected areas.
- Map or the monitoring network.
- Presentation in map of the results of the monitoring programmes showing the ecological and chemical status of surface water, the chemical and quantitative status of groundwater and the status of protected areas.
- List of the environmental objectives established for surface waters, groundwaters and protected areas, including where use has been made of the derogations.
- Summary of the economic analysis of water use.
- Summary of the programme or programmes of measures.
- Register of any more detailed programmes and management plans and a summary of their contents.
- Summary or the public information and consultation measures taken, their results and the changes to the plan as a consequence.
- List of competent authorities.
- Contact points and procedures for obtaining background documentation and information, including actual monitoring data.



Look out! The River Basin Management Plan summarises the results of the planning process.

A RBMP is a strategic planning document and an operational guide to implement programmes of measures that will form the basis for integrated, technically, environmentally and economically sound and sustainable water management within a River Basin District for a period of six years. It will be developed in consultation with the public.

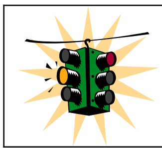
In conclusion, the plan has a number of functions, but primarily it is intended to record the current status of water bodies within the river basin district and to set out, in broad terms, what measures are planned to meet environmental objectives.

The functions of the plan are to:

- serve as a fundamental inventory and documentation mechanism for information gathered according to the directive including, e.g.:
  - environmental objectives for surface waters and ground waters;
  - information on quality and quantity of waters;
  - information on main impact of human activity on the status of surface water and ground water bodies.
- co-ordinate programmes of measures and other relevant programs concerning the area of river basin district;
- serve as main reporting mechanism of river basin district authorities to EC.

The plan, to be published by 22 December 2009, shall finalise the quality and quantity objectives to be achieved by 2015. The objective of good water status being the rule, the management plan must justify any derogation from that objective, particularly on the basis of an economic analysis. Derogations shall first be studied from the viewpoint of postponing the deadline, followed by a change in the objective if necessary. The plan shall define the provisions and action priorities (or measures in the terminology of the Directive) to be implemented in order to achieve the set objectives.

With regards to the preparation of the management plan, the Directive provides for consultation with the public at three stages – the first time before the end of 2006, as regards the planned work programme, the second time before the end of 2007, as regards the significant issues and the third before the end of 2008, as regards the draft management plan.



***Look out!** The Directive only requires a summary of programmes of measures to be included in RBMPs.*

Article 13 paragraphs 1 to 3 of the WFD require one RBMP for each river basin district. Annex VII lists the information to be included in the RBMP. According to Article 13 paragraph 5, the RBMP can be supplemented by producing more detailed programmes or management plans for sub-basins, sectors, issues, or water types.

Planning levels

Member States need to set out how river basin planning can be effectively co-ordinated at all levels (sub basin, basin, District and international District) to ensure that the plans are

- coherent and consistent at each level; and
- compatible between levels.

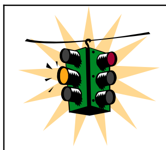
Although river basin planning should be organised (and reported) at a River Basin District level, the detail required for management decisions will mean that planning will need to be carried out at a lower spatial scale. For example, it may be necessary to collate and review data at a basin/sub-basin level in order to make planning decisions. The data, information and decision making should be capable of aggregation and disaggregation. This will facilitate the straightforward production of the Characterisation Report and River Basin Plan at District level. It will also help to ensure transparency. For example, users of the River Basin Plan – government, industry, public etc - may want to examine and compare plans at the same level and between levels.

The Directive contains a definition for "sub-basin" (article 2(14)). These are distinct parts of a basin (sometimes referred to as "sub-catchments"). WFD does not require sub-basins to be identified and plans to be produced for them, but where they are identified and plans are produced for the purposes of the Directive, then their existence has to be recorded on a register (as required in annex VII, paragraph 8), together with a summary of their contents.

In consequence, plans can be made for individual basins where a river basin district comprise more than one river basin. Article 13(5) or WFD is not absolutely clear on this point, but it would be impossible to prepare a district plan where more than one basin is involved, without building up the district plan based on basins.

But what does it mean to produce one RBMP? In fact, there are various options and the choice among these options will to a large extent be influenced by the size and characteristics of the basin, the number of political entities (states, provinces, regions etc) involved, the way co-ordination and the involvement of the public is organised in the River Basin District. For large River Basin Districts, but probably also for medium sized River Basin Districts with a decentralised administrative and political structure, sub-dividing the River Basin District into manageable sub-units could be necessary.

Regarding other planning instruments it is too soon to say what additional plans would be necessary, but they could have a valuable role in overall plan preparation, including consultative processes. On the other hand, they could come to represent an unwelcome administrative burden.

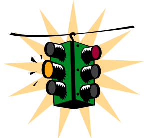


Look out! The target is a single River Basin Management Plan for international RBDs.
The directive requires the Member States to ensure co-ordination with the aim of producing a single international river basin management plan, with support from existing structures stemming from international agreements.

The Directive does not explicitly require or specify the process of developing the management plans. The nature of the river basin planning process is something that is at the discretion of Member and Accession States. This brings the opportunity to the Member and Accession States, to apply the appropriate planning type for the physical and social circumstances in River Basin District concerned, as long as the outcome of the process stays in line with the objective of the Directive (to achieve good water status).

5.7 Seventh and eighth components: Implementation of the programmes of measures and evaluation

The implementation of the programmes of measures has to be linked with a continuous process of evaluation. This evaluation has quite often been seen as a last - more or less additional - box in a planning process. However, evaluation has usually been done after the planning process to get feedback about what has actually been planned or even carried through already. This means that evaluation has not been used as a tool of continuous development and making choices or in other words as an ordinary part of a planning process.



Look out!
After implementing the programme of measures, the evaluation of the first planning period (to be made from 2012 to 2015) is the key element for the preparation of the second period.

The planning process according to WFD is iterative by nature and offers various steps and decisions which need to be evaluated: e.g. identification of water bodies, discrimination into types, analysis of the impact on the status of waters, setting environmental objectives etc.

5.8 Ninth component: Information and consultation of the public, active involvement of interested parties

Public Participation is not only another step in the process. Best practices in the implementation of the WFD can be only reached if public participation is taken in mind in every component. A more detailed Guidance on public participation (WFD CIS Guidance Document No. 8) has been produced as the so called "Work package 3" under the same working group that has developed this Guidance on planning process.

That Guidance Document on Public Participation (WFD CIS Guidance Document No. 8):

- explains why stakeholders should engage in river basin management planning and what can be expected by them and the general public: to voice opinions and concerns about future decisions and to ensure that relevant locally-held knowledge finds its way to the right decision platform;
- outlines practical opportunities and approaches for engaging at different levels and at different stages of planning;
- clarifies, that this is a new process and a new form of partnership which requires patience and mutual trust.

Public consultation and involvement are crucial for successful planning, and must therefore be highlighted in this Section. The potential benefits of greater stakeholder can be summarised as follows:

- RBMPs are likely to be more successful through achievement of "buy-in" to their objectives and delivery by promoting "ownership", acceptability and the co-operation of relevant stakeholders;

- Decision making is likely to be more efficient through earlier identification and, where possible, resolution of conflicts;
- Solutions are likely to be more sustainable and equitable through the input of a wider range of knowledge and perspectives;
- In the longer term, relationships between competent authorities and stakeholders are likely to be strengthened.

In order to achieve best practice in the planning process, high priority must be given to establishing effective mechanisms for public participation (consultation and active involvement) in planning and decision-making, right from the start of the IRBM process.

Provision of genuine opportunities for participation means far more than simply distributing information or setting up a consultation exercise, and needs to be carefully adapted to the appropriate scale, target group(s) and issue(s). Participation initiatives must be managed carefully to ensure that they are transparent and accessible, that all opinions are respected and that expectations from all sides are clear at the beginning.

Co-ordination and public participation

It is necessary to distinguish between administrative co-ordination and public participation. Administrative co-ordination should be treated as a managerial process, and public participation as an integral part of the planning process.

Effective river basin planning will require the Competent Authority to establish the appropriate management structures with other relevant authorities and organisations. These relationships will help to provide the Competent Authority with information for characterisation, input to planning and delivery of the Programme of Measures with organisations responsible for other sectors that have an impact on water status e.g. agriculture and land-use development. Administrative co-ordination should be organised between the Competent Authority and relevant bodies at the appropriate scale (sub-basin, basin, district and international district).

Section 6. General overview and overall flowchart on the planning process

6.1 Introduction: Why and how to use flowcharts in the planning process?

The role of flowcharts in the definition of a planning process for the WFD implementation

Defining a precise planning process with flowcharts for the implementation of the WFD is necessary on account of:

- the complexity of the WFD and its implementation;
- the necessity to anticipate the obligatory deadlines and determine the deadlines which are necessary in practice to meet the obligatory deadlines;
- numerous interdependent tasks;
- urgency regarding the first deadlines (2004);
- involvement of numerous working groups, numerous institutions, numerous stakeholders;
- integration of several levels : European , national and districts working groups;
- the necessity to have a common reference among stakeholders, among institutions;
- the necessity to check during the process if we are late or not according to the deadlines which were defined.

Objectives of the flowcharts

The purpose of the definition of flowcharts describing the planning process is to:

- identify the different tasks, their duration and links between them;
- identify the different key products and key steps;
- identify the actions or sub-tasks required to meet the requirements for the obligatory deadlines;
- assess the organisational level at which they should be carried out;
- build up a sequencing plan of these tasks and stages, compatible with both the technical preparatory constraints & the requirements of the directive;
- identify the critical path for project scheduling and resources allocation.

Recommendations for the preparation and use of flowcharts

The overall flowchart presented in Section 6.4 below can be used as a starting point for developing a more detailed management project for the implementation of the Water Framework Directive in the River Basin Districts or part of them. It is ***strongly recommended*** to set up such a management project and to establish a controlling of its implementation. Such a management project can help to check the coherence between River Basin Districts at national level and re-adjust the process if there is a gap between the forecast timing and the practical state of play.

At River Basin District level a more detailed breakdown of the level III task will be necessary taking into account the recommendations of the respective WFD CIS

Guidance Documents. Each single task has to be assigned to a responsible organisational entity or more than one organisational entity with a strong co-ordination between them. Deadlines have to be set for delivering the expected results taking into account the time needed for aggregation and co-ordination.

Example: The district review (Art. 5 and 6) has to be completed for December 2004 according to the deadline defined by the Water Framework Directive. In practice the draft district review has to be finished several months before to take into account the time needed for potential consultation and validation procedures.

Be aware that according to the reporting deadlines as defined by the Water Framework Directive information on the results of accomplishing certain tasks is required rather late in the process, mainly as part of the River Basin Management Plan. However, in most cases the task itself has to be implemented earlier in the process because the results are necessary for further steps.

Example: A first report on the results of the monitoring programmes has to be delivered as part of the River Basin Management Plan only in 2009. However, at River Basin level monitoring results will *inter alia* be necessary for the identification of the water bodies at risk of failing to meet the objectives which has to be done before defining the programme of measures by the end of 2004.

Be aware that implementing certain tasks will at a starting point require decisions on the approach to be followed by all organisations involved. To prepare such decisions will take time and resources. Furthermore these decisions usually will be taken at another organisational level than the operational one. This is a particular problem for international River Basin Districts where a co-ordination or even harmonisation of national approaches will have to be achieved.

Be aware that, although theoretically some activities cannot begin until others are finished, it will be necessary to begin these activities as early as possible and in parallel to meet the obligatory deadlines. As a consequence, an **iterative process** has to be put in place between such interlinked activities.

In other terms, in some cases, a "parallel" scheduling of tasks will have to be implemented rather than a sequential one.

Examples : Evaluation of the risk of failure to meet the environmental objectives (defined in terms of good status) and definition of what good status is: the first evaluation of the risk of failing to meet the objectives (line 33 of the flowchart) has to be made by using provisional classifications before the reference conditions and the class boundaries of the classification schemes are established; then the results of the first evaluation of water bodies can have an influence on refining the classification scheme.

Iterative elaboration of management plans and programmes of measures: the management plan should set the guidelines and priorities for the programme of measures; the measures will be detailed in the programmes of measures themselves which have to be developed in parallel with the preparation of the management plan.

The flowcharts can also be used as a starting point for developing national or River Basin District specific guidelines for implementing the tasks. For each of the listed tasks such guidelines could contain:

- a reference to the respective provisions in the Water Framework Directive and the national legislation;
- a description of the approach taken at national/district level to address the task, including recommendations concerning methods and tools to be used and reference to the WFD CIS Guidance Documents;
- a list and description of materials and data already available and accessible (for example GIS-data sets, maps, monitoring data) and information on how to get access to the material and data;
- a description of the specific activities to be carried out by the respective responsible organisational entity;
- requirements concerning the documentation and presentation of results (text, spread sheets, maps, data format).

Such guidelines should provide all actors involved with the information necessary to understand the overall organisational setting (who is responsible for what?) and their specific role in the process.

The advantage of developing such guidelines are *inter alia*:

- It requires stock taking of what is already available;
- It helps to make the available information accessible to all actors involved;
- It helps to ensure coherence;
- It helps to assign responsibilities and to avoid double or parallel work.

Ensure a general coherence between tasks and between scales and levels

It is essential to ensure a general coherence of the general process, beyond the own objective of the specific tasks. The right succession of the tasks must be found in order to succeed in the elaboration of the final products. It is also necessary to ensure consistency of timetables between district, national and international levels.

Set up an iterative process

In theory, some activities cannot begin until others are finished. However, to meet the obligatory deadlines, it will be necessary to begin these activities as early as possible. As a consequence, an iterative process has to be put in place between both activities. In other terms, in some cases, a "parallel" scheduling of subtasks will be implemented rather than a sequential basis.

Examples:

- Evaluation of the risk of failure to meet the environmental objectives (defined in terms of good status) and definition of what good status is;
- The evaluation of the risk to fail to the objectives has to be made with draft evaluation grids of the good water status ; then these grids can be precised according to the results of the first evaluation of water bodies at risk;
- Iterative elaboration of management plans and programmes of measures;
- The management plan should set the guidelines and priorities of the programme of measures. The measures will be detailed in the programmes of measures itself.

Ensure follow up and co-ordination

The flowcharts need to be followed and updated all along the process and a co-ordination must be ensured:

- between the national districts;
- between the national and international districts;
- between the national parts of international districts.

In the particular case of international districts, a specific co-ordination between the national parts of international districts must be ensured concerning timetables and succession of tasks, taking into account the time needed for the exchange of information and the consultation between the competent authorities of the national parts of international districts.

6.2 The legally binding timetable of the Water Framework Directive

As explained above, one of the main interests for defining a precise planning process with flowcharts for the implementation of the WFD is the necessity to anticipate the obligatory deadlines and determine the deadlines which are necessary in practice to meet the obligatory deadlines. In principle, deviation from this timetable is not allowed and deadlines cannot be postponed, except for the derogations mentioned in Article 4.

As the WFD and its implementation are very complex, it was felt necessary to include in this Guidance a readily understandable and exhaustive enumeration of all deadlines and dates mentioned in the WFD.

This is done in a schematic and graphical form as follows:

- In the first place, an exhaustive chart for Member States, which contains all deadlines and dates mentioned in the WFD regarding obligations for Member States. The flow-chart contains a reference to the specific WFD article in which the date is mentioned. Reporting dates are also explicitly indicated;
- Secondly, an exhaustive chart for the European Commission, which contains all deadlines and dates mentioned in the WFD regarding obligations for the European Commission.

Legally binding deadlines for Member States

Action/ Member States	Article	2002	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27
The laws, regulations and administrative provisions necessary into force	24.1																										
Identification of competent authority by MS	3.7																										
MS provide EC with a list of competent authorities and of competent authorities of all international bodies in which they participate *(updates of this list should be reported to EC within 3 months)*	3.8, 24.1				* 22.06.2004																						
Analyses and reviews mentioned in Art 5.1: - Establishment of characteristics of the River Basin District, - Review of the environmental impact of human activity, - Economic Analysis of water use	5.1																										
Establishment of register of Protected Areas	6.1																										
Submission of summary reports of analyses according to Art.5 (RBD characteristics, human activity, economics) undertaken for the purposes of the *first* RBMP	15.2					* 22.03.2005																					
In absence of EC agreement MS shall establish appropriate criteria for strategies to prevent and control groundwater pollution	17.4																										
The EC and MS shall complete the intercalibration exercise.	Annex V 1.4.1 (viii)																										
Programmes for monitoring of surface water status, groundwater status and protected areas shall be operational. *Unless otherwise specified in the legislation concerned.*	8.2																										
For Public information and consultation about the RBMP, MS make available for comments a timetable and work programme for the production of the RBMP *(three years before the beginning of the period to which the plan refers. MS shall allow at least six months to comment on those documents)*	14.1a																										
Review of the designation of HMWB	4.3																										
In absence of EC agreement: *MS* establish environmental quality standards for priority substances and controls on the principal sources.	16.8																										
Submission of summary reports of monitoring programmes according to Art.8 (surface water status, groundwater status and protected areas) undertaken for the purposes of the *first* RBMP	15.2							* 22.03.2007																			
For Public information and consultation about the RBMP, MS make available for comments an overview of significant water management issues *(two years before the beginning of the period to which the plan refers. MS shall allow at least six months to comment on those documents)*	14.1b																										
For Public information and consultation about the RBMP, MS make available for comments a draft copy of RBMP *(one year before the beginning of the period to which the plan refers. MS shall allow at least six months to comment on those documents)*	14.1c																										
Establishment of programme of measures for River Basin District	11.7																										
Publication of River Basin Management Plans (detailed information in annex VII of the WFD)	13.6																										
In absence of EC agreement: For substances subsequently included on the PS-list, MS take such action (establishment of environmental quality standards for priority substances and controls on the principal sources)	16.8																										
Sending of copies of RBMP to EC and other MS concerned	15.1										* 22.03.2010																
MS shall ensure that: - water pricing policies provide adequate incentives for users to use water resources efficiently - adequate contribution of the different water uses to the recovery of the costs of water services	9.1

Deadline in the WFD

Reporting to the EC and date * 22.06.2006

Legally binding deadlines for Member States (2)

Action/ Member States	Article	2002	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27
Establishment and/or implementation of emission controls (BAT, BEP) and limit values for the combined approach for point and diffuse sources	10.2																										
Programme of measures for RBD shall be made operational	11.7																										
Submission of interim report describing progress in implementation of the planned programme of measures under Art.13	15.3											* 22.12.2012															
Review and update of analyses and reviews mentioned in Art 5.1: - Establishment of characteristics of the River Basin District - Review of the environmental impact of human activity - Economic Analysis of water use	5.2												* 22.12.2013														
Environmental objectives to be achieved; good surface water status good ecological potential and good surface water chemical status for heavily modified waters (HMWB and AWB) good groundwater status compliance with any standards and objectives for Protected Areas (Less stringent environmental objectives under certain conditions)	4.1																										
Review and update of programme of measures for RBD	11.8																										
Review and update of the RBMP	13.7														* 22.12.2015												
Revised measures established under an updated programme of measures shall be made operational.	11.8																										
Submission of interim report describing progress in implementation of the planned programme of measures under Art.13	15.3																	* 22.12.2018									
Review and update of analyses and reviews mentioned in Art 5.1: - Establishment of characteristics of the River Basin District - Review of the environmental impact of human activity - Economic Analysis of water use	5.2																		* 22.12.2019								
Cessation or phasing out of priority hazardous substances	16.6																							See footnote			
Environmental objectives to be achieved; (first extended deadline) good surface water status good ecological potential and good surface water chemical status for heavily modified waters (HMWB/AWB) good groundwater status compliance with any standards and objectives for Protected Areas	4.1																										
Review and update of programme of measures for RBD.	11.8																										
Review and update of the RBMP	13.7																				* 22.12.2021						
Revised measures established under an updated programme of measures shall be made operational.	11.8																										
Review and update of analyses and reviews mentioned in Art 5.1: - Establishment of characteristics of the River Basin District - Review of the environmental impact of human activity - Economic Analysis of water use	16.6																								22.12.2025 *		
Environmental objectives to be achieved; (second extended deadline) good surface water status good ecological potential and good surface water chemical status for heavily modified waters (HMWB/AWB) good groundwater status compliance with any standards and objectives for Protected Areas	4.1																										22.12.2027 *

Note: For priority substances and according to Article 16.6, the Comission shall submit proposals of controls for the cessation or phasing out of discharges, emissions and losses. Tentatively, the Commission is going to do that at the end of 2003, so, the European Parliament and the Council could adopt them in 2004 or 2005 that will be the starting date for operational purposes. The Directive establishes that from that date, the timetable shall not exceed the duration of 20 years.

Legally binding deadlines for the European Commission

Action/ European Comission	Article	2002	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27
For issues which can not be dealt with at MS-level, the MS may report and make recommendations to the EC. The EC shall respond within 6 months.	12.2																										
Presentation of a proposal for strategies to prevent and control groundwater pollution.	17.1																										
Submission of proposals by the EC for emission controls for point sources and environmental quality standards.	16.8																										
Presentation to the Committee (Art. 21) of an indicative plan of measures having an impact on water legislation which it intends to propose in the near future. *(once a year after 2002)*	19.1																										
Preparation of a draft register of sites to form the intercalibration network which may be adapted in accordance with the procedures laid down in article 21.	Annex V 1.4.1 (vii)																										
Review of adopted list of priority substances	16.4																										
The final register of sites (for intercalibration) shall be established and published by the EC.	Annex V 1.4.1 (vii)																										
Completing the intercalibration exercise together with the MS.	Annex V 1.4.1 (viii)				*			22.06.2006																			
Publication of the results of the intercalibration exercise and the values established for the MS monitoring system classifications.	Annex V 1.4.1 (ix)																										
Submission of proposals by the EC for emission controls for point sources and environmental quality standards.	16.8																										
Publication of a report on progress in implementation of analyses according to Art.5 based on summary reports of MS under Art. 15.2:	18.3																										
Repeal of certain existing directives	22.1																										
Review of adopted list of priority substances	16.4																										
Publication of a report on progress in implementation of monitoring programmes according to Art.8 based on summary reports of MS under Art. 15.2	18.3																										
Submission of proposals by the EC for emission controls for point sources and environmental quality standards. (if necessary)	16.8																										
Submission of an interim report describing progress in the implementation of the planned programme of measures.	15.3																										
Review of adopted list of priority substances	16.4																										
Publication of a report on the implementation of the WFD	18.1																										
Repeal of certain existing directives	22.2																										
Submission of proposals by the EC for emission controls for point sources and environmental quality standards. (if necessary)	16.8																										
Publication of an interim report describing progress in implementation on basis of the interim reports of MS mentioned in Art. 15.3	18.4																										
Review of adopted list of priority substances	16.4																										
Publication of a report on the implementation of the WFD	18.1																										
Review of Water Framework Directive, proposal of amendments	19.2																										
Review of adopted list of priority substances	16.4

Deadline in the WFD

Reporting and date * 22.06.2006

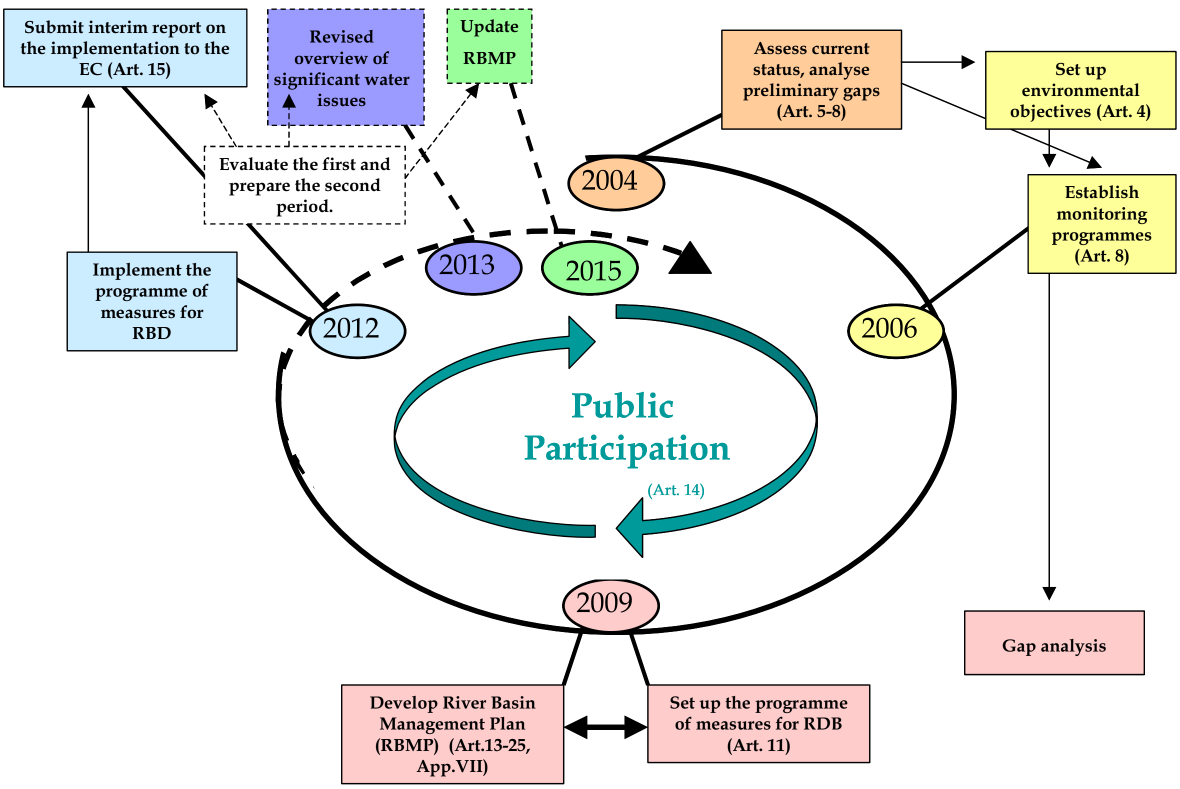
6.3 The planning cycle

The overall flowchart of the planning process presented in the following Section 6.4 includes the first so-called planning cycle required in the WFD to be finalised in 2015. Accordingly, the flowcharts apply to the first period (2002-2015) and the preparation of the second one (2015-2027), this second period being managed as the first one (same tasks and time schedule). It should be also noted that the second planning cycle until 2027 needs to be developed on the basis of the experience of the first cycle outlined below.

In order to develop the flowchart the following ten components of the planning process were considered:

1. Setting the scene;
2. Assessment of the current status and analyse preliminary gaps;
3. Setting up of the environmental objectives;
4. Establishment of monitoring programmes;
5. Gap analysis;
6. Setting up of the programme of measures;
7. Development river basin management plans;
8. Implementation of the programmes of measures and prepare the interim report on the implementation;
9. Evaluation the first and the second period;
10. Information and consultation of the public, active involvement of interested parties.

The following figure shows the sequence of and the relations between these activities as well as the main deadlines and milestones of the first planning cycle.



The previous chart is the most aggregated level information on the planning process: it indicates the 10 main components which are distinguished and developed in the following flowcharts (sub-Section 6.4).

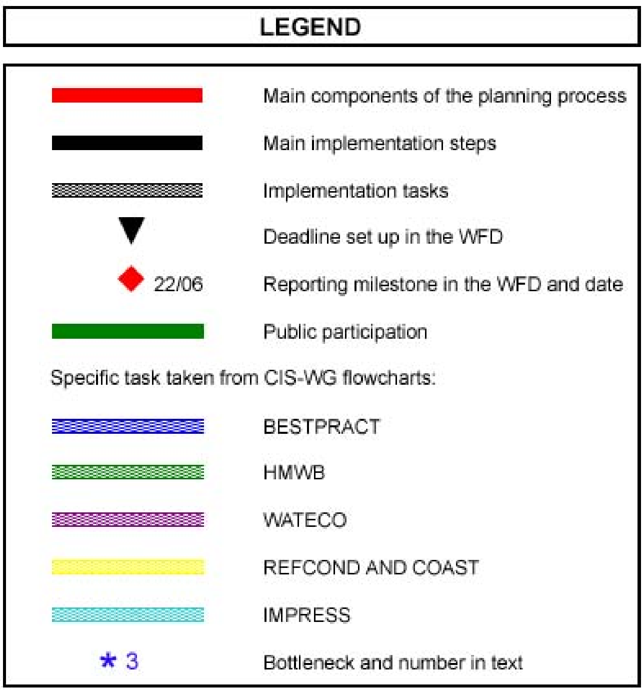
For every component, the main "steps" for the implementation of the WFD were identified and within each step, different implementation tasks could be again identified. Starting from the most aggregated level of information, three levels of details can finally be identified through components, steps and tasks.

At the scale at which these flowcharts were established, it was not possible to go into more details. However, river basin districts should develop their own flowcharts with a level of detail more adapted to the scale at which they work.

6.4 Overall flowchart for the planning process

The following overall flowchart for the WFD planning process lists the major steps to implement the Water Framework Directive, indicates linkages between the tasks, shows milestones and deadlines and includes recommendations on the overall timing for accomplishing the tasks. The chart is structured into three different levels. The first level mirrors the overall planning cycle and its main components as described in the previous Section, the second level represents the main implementation steps whereas the third level indicates the specific tasks to be performed within the respective steps. The third level tasks are taken from the specific WFD CIS Guidance Documents but not as detailed as the information provided by them. These specific tasks related to Guidance Documents are distinguished by different colours as shown in the legend below.

The following legend is used throughout the flowchart:

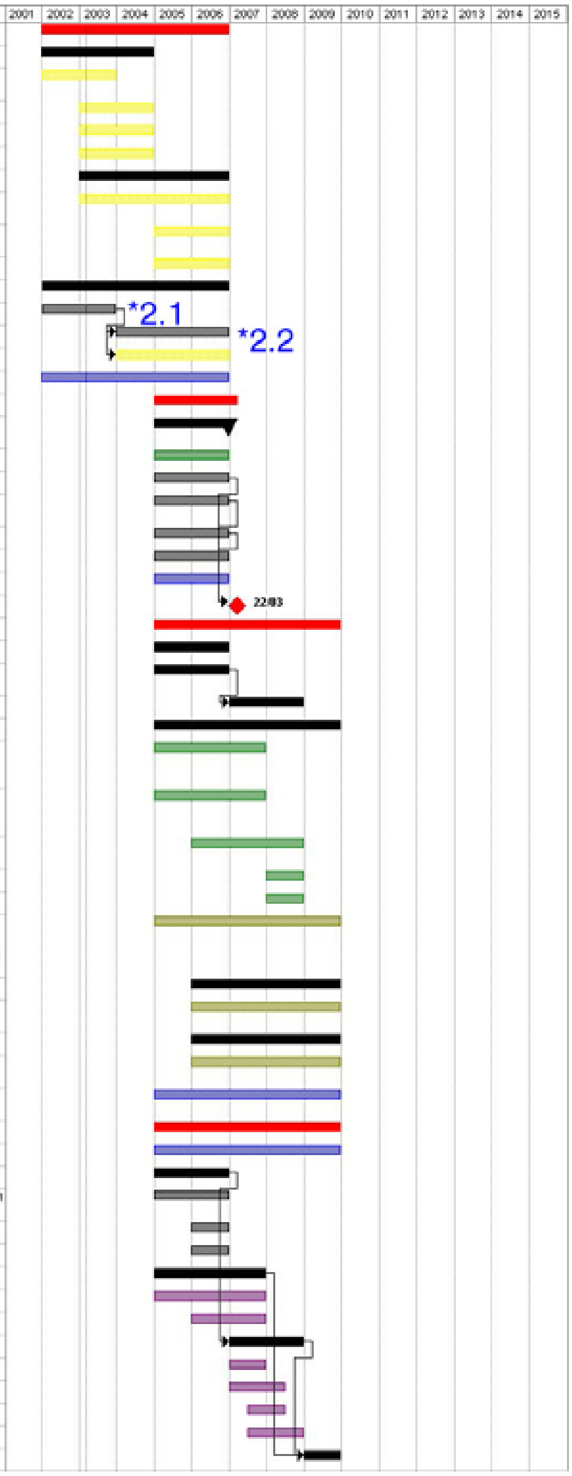


Flowchart for the first cycle of the planning process

No.	Key activities for the first planning cycle	WFD articles	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
1	**Set the scene**																
2	**Identify river basin districts and assign coastal water and groundwater**	**3.1**															
3	Identify and delimitate river basins																
4	Identify and delimitate coastal and transitional waters																
5	Identify and delimitate groundwaters																
6	Designate river basin districts																
7	Assign coastal and transitional waters to nearest or most appropriate river basin districts																
8	Assign groundwaters to nearest or most appropriate river basin district																
9	**Identify stakeholders and design public participation procedures**																
10	Provide information on the WFD and the planning process via existing structures																
11	Develop strategy for stakeholder identification																
12	Design public participation procedures																
13	**Establish necessary GIS infrastructure and take necessary steps for harmonisation**	**3.8, Annex I (ii)**															
14	Produce map/GIS-layers on RBD boundaries, main rivers, subbasins, etc.	Annex I (ii)															
15	**Bring into force laws, regulations and adminitrative provisions necessary to comply with the WFD**	**24.1**															
16	Bring into force laws, regulations and administrative provisions necessary to comply with the WFD																
17	**Inform the EC of the legislative provisions adopted**	24.2			22/12												
18	**Identify competent RBD authority**	**3.7**															
20	Produce map/GIS-layers on competent RBD authorities	Annex I															
21	**Provide the EC with a list of competent authorities including the relevant information of Annex 1**	3.8, Annex I				22/06											
22	**Assess the current status and analyse preliminary gaps**																
23	**Analyse the characteristics of RBDs**	**5.1**															
24	Establish typology	Annex II															
25	Identify the boundaries of water bodies	Annex II															
26	Produce map on surface water body types	Annex II, Annex VII A.1.1															
27	Active involvement of stakeholders (e.g. information supply)																
28	**Review the pressures and impacts of human activity on the status of waters**	**5.1**															
29	Collect available information and data on human activities and pressures	Annex II															
30	Evaluate existing monitoring data and assess gap with respect to objectives																
31	Set up databases of information on human activities and existing monitoring data for the whole river basin district and at the level of water bodies when available																
32	Identify pressures caused by human activities, in particular those listed in Annex II	Annex II															
33	Assess the impacts of these pressures	Annex II															
34	Active involvement of stakeholders (e.g. inventory of knowledge and perceptions)																
35	**Provisional identification of AWB and HMWB**	**4.3**															
36	Screening for hydromorfological changes in water bodies	Annex II 1.4															
37	Describe significant changes in hydromorphology in water bodies that have not been "screened out"	5.1, Annex II.1.4-5															
38	Identify water bodies likely to fail good ecological potential due to changes in hydromorphology	Annex II.1.5															
39	Select water bodies substantially changed in character due to physical alterations by human activity and identify them provisionally as HMWB	5.1, Annex II.1.1															
40	Active involvement of stakeholders (e.g. transparent designation via formal consultative mechanisms)																
41	**Evaluate the gap between current status and objectives**	**Annex V.1.4.2**					*1										
42	Define and apply the baseline scenario and evaluate the gap between trend status and objectives																
43	Define the provisional identification of water bodies at risk of failing to reach the WFD objectives in 2015	Annex II															
44	Active involvement of stakeholders (e.g. information flow)																
45	**Provide an economic analysis of water use**	**5.1, Annex III**															
46	Identify water uses and services by economic sector																
47	Conduct an economic analysis of water use																
48	Assess current pricing policies																
49	Project trends in key indicators and drivers up to 2015 by constructing a business as usual (BAU) scenario for pressures (refine beyond 2004)																
50	Active involvement of stakeholders (e.g. information flow, evaluate current levels of costs)																
51	**Register protected areas**	**6.1, Annex IV.2, Annex VII.3**															
52	Register protected areas																
53	Active involvement of stakeholders (e.g. information flow)																
54	**Inform the public on the results of the analysis**																
56	**Submit summary reports to EC on the analyses of the current status**	15.2					22/03										

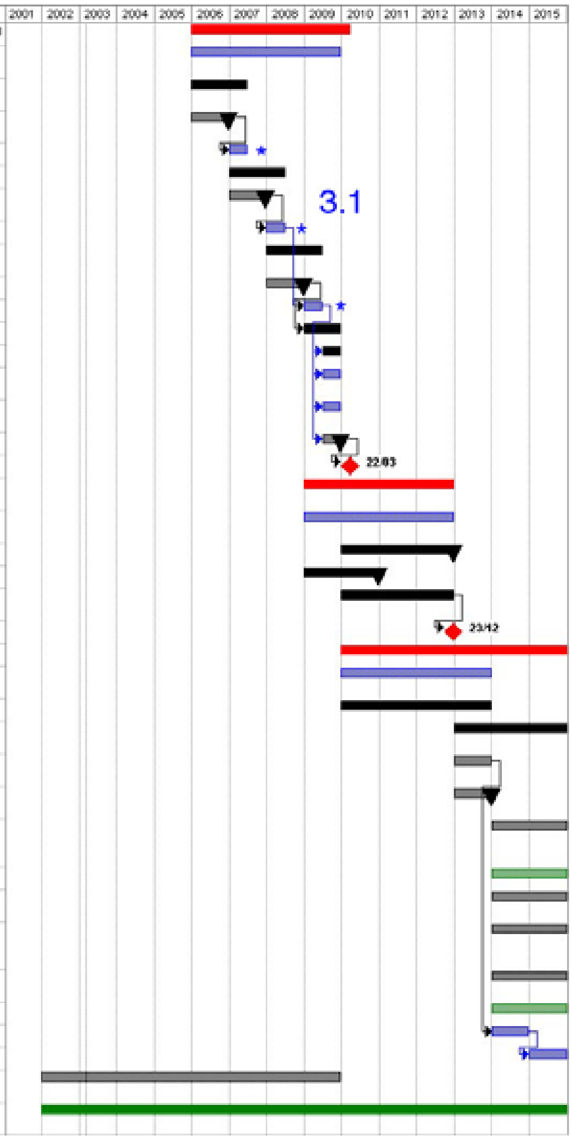
Flowchart for the first cycle of the planning process (2)

No.	Key activities for the first planning cycle	WFD articles
57	**Set up environmental objectives**	Annex II/V
58	**Establish provisional reference conditions**	
59	Establish necessary infrastructure (authorities, expert groups, databases, models, etc.) at national and water district level	5.1
60	Assign body types for assisting in establishing reference conditions	Annex II.1.3
61	Establish criteria for high and good status	
62	Select potential high and good status sites	
63	**Establish reference conditions and ecological quality class boundaries**	
64	Choose quality elements and methods for establishing reference conditions (RC) and ecological quality class boundaries	5.1
65	Establish type specific RC and calculate ecological quality ratio (EQR) values for all relevant quality elements	Annex V.1.4
66	Propose ecological quality class boundaries	
67	**Carry out intercalibration**	
68	Select intercalibration sites	
69	Conduct the intercalibration exercise	
70	Establish ecological class boundaries	
71	Active involvement of stakeholders (e.g. information flow)	
72	**Establish monitoring programmes**	8, Annex V
73	**Establish the monitoring programmes taking into account the identification of water bodies at risk of failing the objectives**	
74	Select the most sensitive indicators for operational monitoring of HMWB and AWB	
75	Design surveillance monitoring networks	
76	Design operational monitoring networks for water bodies at risk and transboundary groundwater bodies	
77	Design investigative monitoring if necessary	
78	Design additional monitoring for protected areas	
79	Active involvement of stakeholders (e.g. information flow)	
80	**Submit summary reports of the monitoring programmes according to Art. 8**	
81	**Gap analysis**	
82	**Verify and refine the preliminary gap analysis**	
84	**Evaluate whether cost for closing the gap are disproportionate and justify potential derogations**	**4.4, 4.5**
86	**Decide on deadline extensions and application of less stringent objectives**	**4.3-4.7**
88	**Designate HMWB and AWB**	**4.3**
89	Designation test (a): Identify restoration measures necessary to achieve GES and check whether these measures have significant adverse effects on the wider environment or the "specified uses"	4.3.a
90	Designation test (b): Check whether the beneficial objectives served by the AWB or the modifications of the HMWB can be achieved by other means which are a significantly better environmental option, technically feasible and not disproportionately costly	4.3.b
91	Designate the water bodies not meeting the designation test (b) as HMWB or AWB	
92	Establish environmental objectives: Maximum Ecological Potential (MEP)	
93	Establish environmental objectives: Good Ecological Potential (GEP)	
94	Mapping/GIS-layer of monitoring networks (operational,surveillance, investigative and reference monitoring sites and sites for monitoring of drinking water abstraction points)	Annex V.1.3.1-1.3.3, 1.3.5, 2.2, 2.4, Annex II.1.3
95	**Apply ecological status/potential classification to surface water bodies**	
96	Produce maps/GIS-layers on classification (ecological status, ecological potential, bad status/potential caused by (non-)synthetic pollutants, chemical status	Annex V.1.4.2.
97	**Apply status classification to groundwater bodies**	
98	Produce maps/GIS-layers on quantitative and chemical status of groundwater bodies or groups of groundwater bodies	
99	Active involvement of stakeholders (e.g. building-in of knowledge and perceptions, reality-test)	
100	**Set up the programme of measures**	
101	Active involvement of stakeholders (e.g. information flow)	
102	**Define potential measures**	
103	Assess the status of implementation of basic measures according to Art. 11.3 and Annex VI	11.3, Annex VI
104	Select additional basic measures if necessary	
105	Select potential supplementary measures (Annex VI, Part B)	Annex VI/B
106	**Analyse the cost-effectiveness of potential measures**	
107	Develop database on costs and effectiveness on measures	
108	Estimate costs and effectiveness of measures in river basin	
109	**Set up a cost-effective programme of measures**	
110	Assess and rank cost effectiveness	
111	Construct programme of measures and estimate total costs	
112	Assess whether total costs are disproportionate	
113	Assess the financial implementation of the programmes of measures	
114	**Finalise the detailed programme of measures**	**11.7**



Flowchart for the first cycle of the planning process (3)

No.	Key activities for the first planning cycle	WFD articles
116	**Develop river basin management plans**	**13, Annex VII**
117	Active involvement of stakeholders (e.g. workshops, inventory of key issues, expert sessions and field observations)	
118	**Prepare and consult the timetable and work programme for the production of the RBMP**	
119	Publish and make available to the public a timetable and a work programme for the production of the RBMP	14.1.a
120	Allow a period of at least six months for comments by the public	
121	**Provide an interim overview of significant water management issues**	**14.1.b**
122	Publish and make available for comments to the public an interim overview of the significant water management issues identified in the RBs	
123	Allow a period of at least six months for comments by the public	
124	**Complete the draft river basin management plans and make it available for comments to the public**	**14.1.c**
125	Complete the draft river basin plans	
126	Allow a period of at least six months for comments by the public	
127	**Produce a summary of the programme of measures**	
129	**Finalise and publish river basin management plans**	**13.6**
130	Summary of public information and consultation measures taken, results and changes to the plan made as a consequence	
131	Active involvement of stakeholders to ensure a continuation of PP after the normal consultation period	
132	Finalise and publish river basin management plans	
133	**Send copies of the river basin management plans to the EC**	**15**
134	**Implement the programmes of measures and prepare the interim report on the implementation**	
135	Active involvement of stakeholders (e.g. workshops, inventory of key issues, expert sessions and field observations)	
136	**Make the measures of the programme of measures operational**	**11.7**
138	**Establish incentive water pricing policies**	**9**
140	**Prepare an interim report describing progress in the implementation of the planned programme of measures**	**15.3**
142	**Submit the interim report to the EC**	
143	**Evaluate the first and prepare the second period**	
144	Active involvement of stakeholders (e.g. collecting information and knowledge and assessment)	
145	**Update the RBD status**	**5**
147	**Review the programme of measures and the RBMP**	**13.7, 11.8, Annex VII**
148	Prepare a new timetable, work programme and make it available for public consultation	
149	Review and update of analyses and reviews of significant water management issues mentioned in Art. 5.1	5.2
150	Prepare a summary of changes or updates since the publication of the previous version of the RBMP including a summary of the reviews to be carried out under Art. 4, 5, 6 and 7	
151	Review of MEP and GEP values for AWB and HMWB	
152	Prepare a summary of and explanation for any measures foreseen in the earlier version of the RBMP which have not been undertaken	
153	Assess the progress made towards the achievement of the environmental objectives including a presentation of the monitoring results for the period of the previous plan in map form and an explanation of the unachieved environmental objectives	
154	Prepare a summary of any additional interim measures adopted under Art. 10 since the publication of the previous version of the RBMP	
155	Review of MEP and GEP values for AWB and HMWB	
156	New draft river basin management plan and public consultation	
157	Publish the updated river basin management plan	
158	**Interim measures to prevent further deterioration of the status of aquatic ecosystems**	**1, 4.3-4.9**
159	**Information and consultation of the public, active involvement of interested parties in accordance with the Public Participation Guidance document**	**14**



Notes:

- The reporting deadline for tasks no. 22, 67, 86 and 88 is 22 March 2010, as part of the River Basin Management Plan.

- Tasks no. 59 and 60 are co-ordinated by the Working Group on Ecological Status and Intercalibration.

- Task no. 158 is related to the array of measures necessary to meet one of the main objectives of the WFD, which is to prevent further deterioration of the status of aquatic ecosystems (Article 1). Articles 4.3 to 4.7 have to be taken into account for the application of this principle and to define the deadlines. For the moment, an ongoing task is proposed throughout the whole first assessment and planning period until December 2009 although, in any case, details of the time schedule of this issue will be dealt with in a specific document.

- Task nº 159. A specific Guidance Document has been produced on Public Participation as one of the outputs of Working Group 2.9, (WFD CIS Guidance Document No. 8) explaining in detail activities and deadlines.

6.5 Bottlenecks in the planning process

The analysis of the flowchart has allowed the identification of the so-called "bottlenecks" of the implementation of the Directive, i.e. the incongruities in planning that occur when comparing the official deadline requirements of the Directive with a pragmatic approach regarding the implementation. As a result of the scrutiny of the Directive by the Working Groups for preparing the Guidances under the Common Implementation Strategy, several incongruities have been made explicit. This Guidance on planning has intended to bring together the activities and bottlenecks that have been identified by the different Working Groups of the Common Implementation Strategy.

All Working Groups have been confronted with the ambitious and legally binding timetable of the Directive. In principle deviation from this timetable is not allowed and deadlines cannot be postponed, except for the derogations as mentioned in Article 4. Several Working Groups experienced on the one hand that the timetable is tight and leaves little time to go through the matter in to great depth and on the other hand that the chronological order of the deadlines is not always logical when dealing with the practical implementation. This combination often results in bottlenecks. The scope of this document is on the bottlenecks that primarily identify *timing-related* implementation problems. These are common for all Member States dealing with the implementation. Bottlenecks that occur due to lacking financial or technical means or institutional arrangements are often specific for a Member State or river basin due to priority-setting, habits and traditions and not covered explicitly by this document. However it is recognised that these "local" bottlenecks can be of interest to a wider public and can be added to this document at a later stage. During the preparation of the Guidances so called "open issues" were identified by the Working Groups. Not all of these issues are related to planning and therefore not always mentioned here.

Some of the bottlenecks are indicated in the flowchart and are identified for the period until the first River Basin Management Plan in 2009. For each bottleneck identified an information sheet has been prepared which clarifies the bottleneck. For the moment the list is not exhaustive or finalised and will be completed later on in the Manual for Integrated River Basin Management to be developed by the "cluster group" as well as during the testing of Pilot River Basins which will be a part of the manual.

As a result of the above-mentioned preliminary analyses, the following bottlenecks have been identified:

- The lack of data for the first district review: need for existing information and data on pressures and impacts, need for a definition for the significant pressures, need for a translation between pressures and impacts, need for the baseline scenario before estimating the forecasted impacts, need to know the 2015 objectives to assess the risk to fail;
- Data on RC prerequisite for assigning ecologically relevant typology;
- Need to start monitoring potential RC sites before monitoring programmes are operational;
- Need for monitoring data from intercalibration sites for calculating EQRs;
- Evaluation of the testing and review of Guidances is too late for the reporting on the status in 2005;

- Typology, reference conditions and class boundaries not available. Draft register based on expert judgement and (little available data);
- Finishing intercalibration exercise before monitoring programmes are operational;
- Pressed time schedule for assessing comments and reviewing document concerning the draft management plan;
- Simultaneously elaboration of the programme of measures and the management plan, with a summary of the programme within the plan;
- The 2004 review of the districts should be done with data and tools currently available, but these have to be used in a pragmatic manner in order to meet the requirements of the directive. Making the 2004 review is an opportunity to assess the lacking data and shortcomings to be resolved.

It can be observed that most bottlenecks can be reduced to a few basic issues or deadlines within the Directive:

1. Objectives to be achieved in 2015 are unclear. The Directive refers to the achievement of "good water status" in 2015 which can be defined by the help of Annex II and V. Still this information is general and needs to be elaborated and made operational for the several water types and/or water bodies which takes time and is planned to finish by 2004. This has as a consequence that it is hard to tell if a water body is at risk of failing the environmental quality objectives before 2004 (gap analysis) and which measures need to be taken.

2. Data availability: the monitoring programme does not have to be in place until 2006. This means that recent and complete information (measured values) on parameters that are of importance to the pressure and impact analysis, reference conditions, ecological class boundaries, intercalibration sites, and indirectly to the designation of heavily modified water bodies, will be available earliest in 2007. In combination with a low monitoring frequency the availability of this data is not optimal. As a consequence assumptions will be made about missing data which increases the uncertainties in the analyses and affects the validity of the assessments.

3. The publication of the *draft* River Basin Management Plan (RBMP) in 2008 in order to allow for comments of the public. This means that the RBMP (which officially has to be published in 2009) should be ready in quite an advanced state by the end of 2008 in order to give a realistic and truthful impression of the RBMP as it will be in 2009. Consequently it implies that activities for producing the contents of the plan should be wrapped up by 2008 which shortens the available time.

Some solutions for the bottlenecks are recommended in this document and can be divided into 3 principal types of solutions:

a. Anticipated deadlines

It is recommended to adopt a pragmatic approach for the setting up of intermediary and informal or anticipated deadlines for certain tasks if necessary so as to be able to meet in practice the obligatory deadlines required in the WFD. The advancing of activities might help to meet the deadlines but also confronts the actors with an even tighter planning scheme. Member States might have different priorities and can shift or delete the informal deadlines accordingly. However for the international level good co-ordination on informal deadlines is recommended.

b. Use of existing information.
As existing information can be considered a range is available from expert judgement to existing monitoring data resulting from existing legislation. Also when using existing data, the collection and collation of data will require good co-ordination and a good deal of time. The information is usually neither readily available in one place nor in the right format.
In this context, a consultation to stakeholders and the scientific community can improve the existing data and/or help advance where gaps have been identified.

c. Preliminary exercises
It is recommended to perform preliminary exercises that are checked, refined and finalised later when more information will be available.
The combination of unclear objectives, missing data and the first major deadline in 2004 (Article 5) makes it nearly impossible to give a very exact assessment of the current water status and the risk of failing to meet the objectives. Therefore several Working Groups already considered the process being iterative and to do *preliminary* analyses and assessments, based on available data (if necessary assumptions) by 2004 and to check these assessments at a later stage when monitoring data become available. It is important to estimate the uncertainty of these preliminary exercises.

Note that this is a preliminary identification of the possible bottlenecks in the planning process. Testing in Pilot River Basins (PRB) will deal more deeply and at a more local scale with bottlenecks, since one of the main objectives is to check for inconsistencies between Guidance Documents. The results of testing will probably help to identify other bottlenecks and provide more information on the possible solutions. This new information could be integrated in further updated version of this Guidance on Planning Process, as it is considered as a "living" document.

From the bottlenecks listed above, the following have been developed into information sheets:

Number	**Title**
1	Gap analysis*
2	Intercalibration*
3	Public participation*
4	River basin management plan and programme of measures**

* Sheets provided in this Guidance.
** Topic to be dealt with in more detail in the Manual for Integrated River Basin Management to be developed by the future "cluster group".

Bottleneck 1: Gap analysis: assessment of the likelihood that water bodies will fail to meet the environmental objectives

Related to	Data availability, objectives of the Directive
Scale	General
Sources	• WFD Annex II 1.4-2.5, (Annex V) • Guidance for the analysis of Pressures and Impacts in accordance with the WFD (WFD CIS Guidance Document No. 3)
Pilot River Basin testing	Yes
Flow chart	
Explanatory text	The role of the gap analysis (making use of the pressure and impact analysis and the baseline scenario) is to assess the likelihood that water bodies will fail to meet the environmental objectives of the Directive. It tells if there is a gap (and how big) between the current status of the water body and the good status that is to be achieved by 2015 This analysis is a central issue in the implementation of the Directive but not mentioned very explicitly in the main text (only Annex II 1.5). The bottleneck lies in the fact that the first pressures and impacts analysis must be complete by the end of 2004 while the environmental objectives of the Directive are not established yet. The objectives depend on issues such as the definition of ecological class boundaries and reference conditions (scheduled 2004) which in their turn need to be verified by the monitoring programme that won't be in place until 2006.
Recommen-dations	Carry out a preliminary gap analysis by 2004, which gives a first insight in the water bodies at risk. A start can be made with the development of the Programme of Measures. Along the line, when more and more precise information becomes available this gap analysis shall be refined and measures adapted accordingly. While performing the preliminary gap analysis, one should be aware and take account of the uncertainties in the environmental conditions required to meet the Directive's objectives and the uncertainties in the estimated impact.

Bottleneck 2: Intercalibration

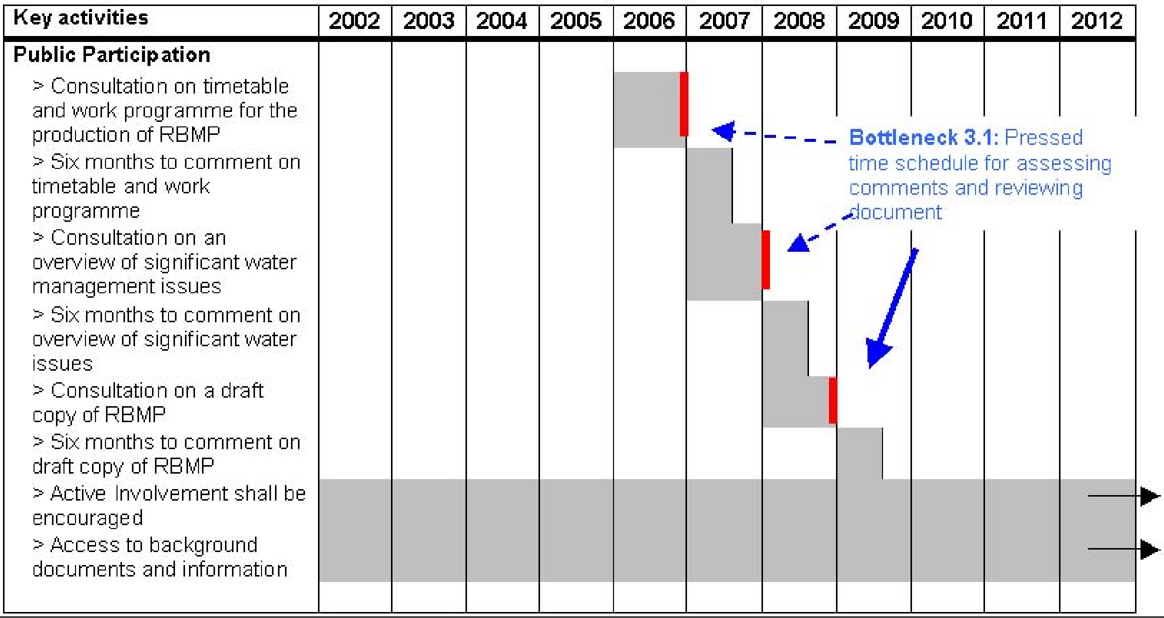
Related to	Data availability, objectives of the Directive
Scale	General
Sources	• WFD Annex V 1.4.1 • Guidance on establishment of the intercalibration network and on the process of the intercalibration exercise (WFD CIS Guidance Document No. 6)
Pilot River Basin testing	No
Flow chart	
Explanatory text	The aim of the intercalibration exercise is to compare between Member States types of water bodies which represent the ecological quality boundaries for high-good and good-moderate status. The result shall be expressed in ecological quality ratios (EQR). The intercalibration timetable does not match the implementation timetable of the Directive in the Member States. Crucial information for the intercalibration will be available during the progress in implementation. The major bottlenecks are: 2.1) Water body types selected for intercalibration networks (2003) may not be compliant with water body types differentiated by Member States, because sites for the draft register are selected before the typology in Member States needs to be ready (2004); moreover the choice for parameters used for establishing the sites depends on choices made for reference conditions and ecological quality elements (ready earliest 2004); 2.2) At present (2002) there is not sufficient data available to carry out a scientifically sound site selection, since not all parameters necessary for site selection have been monitored by Member States until now. The monitoring programme for the Directive will start in 2006, after the finalisation of the intercalibration exercise. The objectives of the intercalibration exercise - agreement on class boundaries and harmonised classification systems - can be only partially met in the single intercalibration exercise that is required by the Directive. The intercalibration network established will not reflect the impacts of all pressures and all biological quality elements.
Recommen-dations	• Site selection targeted to water body types where most data is available; • Establish a review mechanism at a time when more data with better quality and compatible with the requirements of the Directive will be available (after 2006); • Clarify the legal possibilities and practical implications for such a revision.

Bottleneck 3.1: Public Participation

<table>
<tr><td>Related to</td><td>Publication of draft River Basin Management Plan (RBMP)</td></tr>
<tr><td>Scale</td><td>General</td></tr>
<tr><td>Sources</td><td>

- WFD Article 14, Annex VII.9
- Guidance on Public Participation in relation to the WFD: active involvement, consultation and public access to information (para 2.6, 4.7) (WFD CIS Guidance Document No. 8)

</td></tr>
<tr><td>Pilot River Basin testing</td><td>No</td></tr>
<tr><td>Flow chart</td><td>



</td></tr>
<tr><td>Explanatory text</td><td>

At the end of 2008 a draft copy of the RBMP shall be published and made available to the public. The public shall be given half a year (June 2009) to comment on this draft. Then the comments of the public shall be considered, when relevant incorporated in the plan, and the plan itself shall be finalised and published by 22 December 2009. In the plan it shall be indicated what consultation measures have been taken and what their results and changes to the plan as a consequence of the consultation have been made.

3.1) Since there is scarcely time between June and December 2009 to change the RBMP (and strategy) based on the comments of the public, there is a risk that these comments will not be taken into account due to lack of time which is against the spirit and requirements of the Directive. This comment is to a lesser degree also valid for the consultation on the timetable and work programme and the overview of significant water management issues.

</td></tr>
<tr><td>Recommen-dations</td><td>

- Consult and inform (if even possible: to involve) the public more intensively at an earlier stage, this will help to overcome surprises and can prevent a too large adaptation of the RBMP at a later stage;
- Publication of the draft RBMP at an earlier stage, this however will often be difficult since it shortens the duration of other activities;
- Another possibility would be to organise the two first public consultations before the obligatory deadlines (respectively 2006 and 2007 at the latest). This would allow more time to prepare and organise the third public consultation on the draft RBMP and then, to take account of the comments, which will be probably more numerous than for the two previous consultations.

</td></tr>
<tr><td></td><td></td></tr>
</table>

Bottleneck 3.2: Public Participation

Related to	Institutional aspects
Scale	International River Basin Districts (RBD), Member States
Sources	• WFD Article 14, Annex VII.9, Article 13.2 • Guidance on Public Participation in relation to the WFD: active involvement, consultation and public access to information (Section 4) (WFD CIS Guidance Document No. 8)
Pilot River Basin testing	Yes (?)
Flow chart	-
Explanatory text	Several documents shall be presented to the public for information and consultation. Also background information shall be available on request at the contact points listed in the RBMP. Member States need to plan in advance how to reach the public, where to collect the comments, how to process the comments and at what level these activities will take place. Especially international River Basin Districts, which are often dealing with several languages and with local public which are confronted with international/transboundary matters, should think twice about how to organise this.
Recommen-dations	The solution is different for every Member State or RBD. The following questions might help to orientate: • Should the public be confronted with (detailed) information of the whole area to which the RBMP refers? Or should tailor-made information be prepared, targeted to that part of the area where the public is affected and most likely interested in? Recognise that measures taken in one area can have an effect somewhere else; • Will there be one central contact point to obtain background information for the whole area where the plan refers to, or several local ones? How are these points communicated to the public? • Shall the comments of the different consultation rounds be collected and processed locally or at a central point? How will feedback to the public be organised? • Will Member States in an international RBD report one single plan for this RBD to the Commission (Article 13.2) or separately for each Member State?

Bottleneck 4: River basin management plan and programme of measures

Related to	Timing problems between the river basin management plan and the programme of measures
Scale	International River Basin Districts (RBD), Member States
Sources	• WFD Articles 11 and 13, Annex VII • Flowcharts for the planning process
Pilot River Basin testing	Yes
Flow chart	-
Explanatory text	Necessity to have the programme of measures finished before the RBMP so to include the summary into the RBMP as required by Annex VII. This topic will be examined within the future activities of the Working Group Integrated River Basin Management.
Recommen-dations	-

Annex 1 – List of Abbreviations

The following abbreviations are used throughout the text of this Guidance:

AWB	Artificial Water Body
BAU	Business As Usual
BESTPRACT	Working group on BEST PRACTices in river basin planning
CAP	Common Agricultural Policy
COAST	Working group on typology, classification of transitional and COASTal waters
DPSIR	Driving forces, Pressures, States, Impacts, Responses
EAF	Expert Advisory Forum

WATECO	Working group on (WATer) ECOnomic analysis
WG	Working Group

Annex 2 – Preambles and articles of the Water Framework Directive relevant to this Guidance

The planning process in the preambles

Preamble 13
There are diverse conditions and needs in the Community which require different specific solutions. This diversity should be taken into account in the planning and execution of measures to ensure protection and sustainable use of water in the framework of the river basin. Decisions should be taken as close as possible to the locations where water is affected or used. Priority should be given to action within the responsibility of Member States through the drawing up of programmes of measures adjusted to regional and local conditions.

Preamble 28
Surface waters and groundwaters are in principle renewable natural resources; in particular, the task of ensuring good status of groundwater requires early action and stable long-term planning of protective measures, owing to the natural time lag in its formation and renewal. Such time lag for improvement should be taken into account in timetables when establishing measures for the achievement of good status of groundwater and reversing any significant and sustained upward trend in the concentration of any pollutant in groundwater.

Assessment on current water status

Article 5

Each Member state shall ensure that for each river basin district or for the portion of an international river basin district falling within its territory: an analysis of its characteristics, a review of the impact of human activity on the status of surface waters and on groundwater and an economic analysis of water use, is undertaken according to the technical specifications set out in Annexes II and III and that it is completed at the latest four years after the date of entry into force of this Directive.

Monitoring

Article 8

1. Member States shall ensure the establishment of programmes for the monitoring of water status in order to establish a coherent and comprehensive overview of water status within each river basin district:
- for surface waters such programmes shall cover:
(i) the volume and level or rate of flow to the extent relevant for ecological and chemical status and ecological potential; and
(ii) the ecological and chemical status and ecological potential;
- for groundwaters such programmes shall cover monitoring of the chemical and quantitative status,
- for protected areas the above programmes shall be supplemented by those specifications contained in Community legislation under which the individual protected areas have been established.

Economic analysis and recovery of the costs of water services

Article 9

1. Member States shall take account of the principle of recovery of the costs of water services, including environmental and resource costs, having regard to the economic analysis conducted according to Annex III, and in accordance in particular with the polluter pays principle.
Member States shall ensure by 2010:
- that water-pricing policies provide adequate incentives for users to use water resources efficiently, and thereby contribute to the environmental objectives of this Directive,
- an adequate contribution of the different water uses, disaggregated into at least industry, households and agriculture, to the recovery of the costs of water services, based on the economic analysis conducted according to Annex III and taking account of the polluter pays principle.
Member States may in so doing have regard to the social, environmental and economic effects of the recovery as well as the geographic and climatic conditions of the region or regions affected.
2. Member States shall report in the river basin management plans on the planned steps towards implementing paragraph 1 which will contribute to achieving the environmental objectives of this Directive and on the contribution made by the various water uses to the recovery of the costs of water services.
3. Nothing in this Article shall prevent the funding of particular preventive or remedial measures in order to achieve the objectives of this Directive.
4. Member States shall not be in breach of this Directive if they decide in accordance with established practices not to apply the provisions of paragraph 1, second sentence, and for that purpose the relevant provisions of paragraph 2, for a given water-use activity, where this does not compromise the purposes and the achievement of the objectives of this Directive. Member States shall report the reasons for not fully applying paragraph 1, second sentence, in the river basin management plans.

Definition of environmental objectives and gap analysis

Article 4

1. In making operational the programmes of measures specified in the river basin management plans:

(a) for surface waters

(i) Member States shall implement the necessary measures to prevent deterioration of the status of all bodies of surface water, subject to the application of paragraphs 6 and 7 and without prejudice to paragraph 8;
(ii) Member States shall protect, enhance and restore all bodies of surface water, subject to the application of subparagraph (iii) for artificial and heavily modified bodies of water, with the aim of achieving good surface water status at the latest 15 years after the date of entry into force of this Directive, in accordance with the provisions laid down in Annex V, subject to the application of extensions determined in accordance with paragraph 4 and to the application of paragraphs 5, 6 and 7 without prejudice to paragraph 8;
(iii) Member States shall protect and enhance all artificial and heavily modified bodies of water, with the aim of achieving good ecological potential and good surface water chemical status at the latest 15 years from the date of entry into force of this Directive, in accordance

with the provisions laid down in Annex V, subject to the application of extensions determined in accordance with paragraph 4 and to the application of paragraphs 5, 6 and 7 without prejudice to paragraph 8;
(iv) Member States shall implement the necessary measures in accordance with Article 16(1) and (8), with the aim of progressively reducing pollution from priority substances and ceasing or phasing out emissions, discharges and losses of priority hazardous substances without prejudice to the relevant international agreements referred to in Article 1 for the parties concerned;

(b) for groundwater

(i) Member States shall implement the measures necessary to prevent or limit the input of pollutants into groundwater and to prevent the deterioration of the status of all bodies of groundwater, subject to the application of paragraphs 6 and 7 and without prejudice to paragraph 8 of this Article and subject to the application of Article 11(3)(j);
(ii) Member States shall protect, enhance and restore all bodies of groundwater, ensure a balance between abstraction and recharge of groundwater, with the aim of achieving good groundwater status at the latest 15 years after the date of entry into force of this Directive, in accordance with the provisions laid down in Annex V, subject to the application of extensions determined in accordance with paragraph 4 and to the application of paragraphs 5, 6 and 7 without prejudice to paragraph 8 of this Article and subject to the application of Article 11(3)(j);
(iii) Member States shall implement the measures necessary to reverse any significant and sustained upward trend in the concentration of any pollutant resulting from the impact of human activity in order progressively to reduce pollution of groundwater.
Measures to achieve trend reversal shall be implemented in accordance with paragraphs 2, 4 and 5 of Article 17, taking into account the applicable standards set out in relevant Community legislation, subject to the application of paragraphs 6 and 7 and without prejudice to paragraph 8;

(c) for protected areas

Member States shall achieve compliance with any standards and objectives at the latest 15 years after the date of entry into force of this Directive, unless otherwise specified in the Community legislation under which the individual protected areas have been established.

2. Where more than one of the objectives under paragraph 1 relates to a given body of water, the most stringent shall apply.

Programmes of measures

Article 11

1. Each Member State shall ensure the establishment for each river basin district, or for the part of an international river basin district within its territory, of a programme of measures, taking account of the results of the analyses required under Article 5, in order to achieve the objectives established under Article 4. Such programmes of measures may make reference to measures following from legislation adopted at national level and covering the whole of the territory of a Member State. Where appropriate, a Member State may adopt measures applicable to all river basin districts and/or the portions of international river basin districts falling within its territory.

2. Each programme of measures shall include the "basic" measures specified in paragraph 3 and, where necessary, "supplementary" measures.
3. "Basic measures" are the minimum requirements to be complied with and shall consist of:
(a) those measures required to implement Community legislation for the protection of water, including measures required under the legislation specified in Article 10 and in part A of Annex VI;
(b) measures deemed appropriate for the purposes of Article 9;
(c) measures to promote an efficient and sustainable water use in order to avoid compromising the achievement of the objectives specified in Article 4;
(d) measures to meet the requirements of Article 7, including measures to safeguard water quality in order to reduce the level of purification treatment required for the production of drinking water;
(e) controls over the abstraction of fresh surface water and groundwater, and impoundment of fresh surface water, including a register or registers of water abstractions and a requirement of prior authorisation for abstraction and impoundment. These controls shall be periodically reviewed and, where necessary, updated. Member States can exempt from these controls, abstractions or impoundments which have no significant impact on water status;
(f) controls, including a requirement for prior authorisation of artificial recharge or augmentation of groundwater bodies. The water used may be derived from any surface water or groundwater, provided that the use of the source does not compromise the achievement of the environmental objectives established for the source or the recharged or augmented body of groundwater. These controls shall be periodically reviewed and, where necessary, updated;
(g) for point source discharges liable to cause pollution, a requirement for prior regulation, such as a prohibition on the entry of pollutants into water, or for prior authorisation, or registration based on general binding rules, laying down emission controls for the pollutants concerned, including controls in accordance with Articles 10 and 16. These controls shall be periodically reviewed and, where necessary, updated;
(h) for diffuse sources liable to cause pollution, measures to prevent or control the input of pollutants. Controls may take the form of a requirement for prior regulation, such as a prohibition on the entry of pollutants into water, prior authorisation or registration based on general binding rules where such a requirement is not otherwise provided for under Community legislation. These controls shall be periodically reviewed and, where necessary, updated;
(i) for any other significant adverse impacts on the status of water identified under Article 5 and Annex II, in particular measures to ensure that the hydro-morphological conditions of the bodies of water are consistent with the achievement of the required ecological status or good ecological potential for bodies of water designated as artificial or heavily modified. Controls for this purpose may take the form of a requirement for prior authorisation or registration based on general binding rules where such a requirement is not otherwise provided for under Community legislation. Such controls shall be periodically reviewed and, where necessary, updated;
(j) a prohibition of direct discharges of pollutants into groundwater subject to different provisions(.../...)
(k) in accordance with action taken pursuant to Article 16, measures to eliminate pollution of surface waters by those substances specified in the list of priority substances agreed pursuant to Article 16(2) and to progressively reduce pollution by other substances which would otherwise prevent Member States from achieving the objectives for the bodies of surface waters as set out in Article 4;
(l) any measures required to prevent significant losses of pollutants from technical installations, and to prevent and/or to reduce the impact of accidental pollution incidents for example as a result of floods, including through systems to detect or give warning of such

events including, in the case of accidents which could not reasonably have been foreseen, all appropriate measures to reduce the risk to aquatic ecosystems.
4. "Supplementary" measures are those measures designed and implemented in addition to the basic measures, with the aim of achieving the objectives established pursuant to Article 4. Part B of Annex VI contains a non-exclusive list of such measures.
Member States may also adopt further supplementary measures in order to provide for additional protection or improvement of the waters covered by this Directive, including in implementation of the relevant international agreements referred to in Article 1.
5. Where monitoring or other data indicate that the objectives set under Article 4 for the body of water are unlikely to be achieved, the Member State shall ensure that:
- the causes of the possible failure are investigated,
- relevant permits and authorisations are examined and reviewed as appropriate,
- the monitoring programmes are reviewed and adjusted as appropriate, and
- additional measures as may be necessary in order to achieve those objectives are established, including, as appropriate, the establishment of stricter environmental quality standards following the procedures laid down in Annex V.
Where those causes are the result of circumstances of natural cause or force majeure which are exceptional and could not reasonably have been foreseen, in particular extreme floods and prolonged droughts, the Member State may determine that additional measures are not practicable, subject to Article 4(6).
6. In implementing measures pursuant to paragraph 3, Member States shall take all appropriate steps not to increase pollution of marine waters. Without prejudice to existing legislation, the application of measures taken pursuant to paragraph 3 may on no account lead, either directly or indirectly to increased pollution of surface waters. This requirement shall not apply where it would result in increased pollution of the environment as a whole.
7. The programmes of measures shall be established at the latest nine years after the date of entry into force of this Directive and all the measures shall be made operational at the latest 12 years after that date.
8. The programmes of measures shall be reviewed, and if necessary updated at the latest 15 years after the date of entry into force of this Directive and every six years thereafter. Any new or revised measures established under an updated programme shall be made operational within three years of their establishment.

River Basin Management Plans and their reporting

Article 13

1. Member States shall ensure that a river basin management plan is produced for each river basin district lying entirely within their territory.
2. In the case of an international river basin district falling entirely within the Community, Member States shall ensure co-ordination with the aim of producing a single international river basin management plan. Where such an international river basin management plan is not produced, Member States shall produce river basin management plans covering at least those parts of the international river basin district falling within their territory to achieve the objectives of this Directive.
3. In the case of an international river basin district extending beyond the boundaries of the Community, Member States shall endeavour to produce a single river basin management plan, and, where this is not possible, the plan shall at least cover the portion of the international river basin district lying within the territory of the Member State concerned.
4. The river basin management plan shall include the information detailed in Annex VII.
5. River basin management plans may be supplemented by the production of more detailed programmes and management plans for sub-basin, sector, issue, or water type, to deal with

particular aspects of water management. Implementation of these measures shall not exempt Member States from any of their obligations under the rest of this Directive.
6. River basin management plans shall be published at the latest nine years after the date of entry into force of this Directive.
7. River basin management plans shall be reviewed and updated at the latest 15 years after the date of entry into force of this Directive and every six years thereafter.

Article 15

1. Member States shall send copies of the river basin management plans and all subsequent updates to the Commission and to any other Member State concerned within three months of their publication:
(a) for river basin districts falling entirely within the territory of a Member State, all river management plans covering that national territory and published pursuant to Article 13;
(b) for international river basin districts, at least the part of the river basin management plans covering the territory of the Member State.
2. Member States shall submit summary reports of:
- the analyses required under Article 5, and
- the monitoring programmes designed under Article 8
undertaken for the purposes of the first river basin management plan within three months of their completion.
3. Member States shall, within three years of the publication of each river basin management plan or update under Article 13, submit an interim report describing progress in the implementation of the plan.

Annex 3 – Members of the Drafting Group of this Guidance and list of the experts of Working Group 2.9

The Drafting Group responsible for preparing this Guidance on the planning process was composed of the following members:

Leaders:

Manuel Menéndez (Spain)
José María Piñero (Spain)

Co-ordinators of the flowchart section:

Coralie Noël (France)
Zsigmond Kovács (Spain)
Jetske Verkerk (The Netherlands)

Other drafting group members:

Heikki Mäkinen (Finland)
Marta Moren Abat (European Commission)
Marc de Rooy (The Netherlands)
Guido Schmidt (WWF)
Thomas Stratenwerth (Germany)
Anne Thorén (Sweden)
Aram Wood (United Kingdom).

The list and contact information of the experts of Working Group 2.9 are attached in the table below.

ISSN 1725-1087

Foreword

The EU Member States[1], Candidate Countries[2], EFTA countries[3] and the European Commission have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC establishing a framework for Community action in the field of water policy, hereafter referred to as Common Implementation Strategy (CIS) for the Water Framework Directive (WFD). The main aim of this strategy is to allow a coherent and harmonious implementation of this Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the WFD.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to experts and stakeholders involved in the implementation of the WFD in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, the European Commission (Directorate General for the Environment, Unit B.1) was invited to set up an informal process for drafting a Horizontal Guidance on the Role of Wetlands in the Water Framework Directive.

A drafting group was established in January 2003 and a first draft was discussed at the wetlands kick-off meeting on the 21st January, 2003. This was followed by discussions at two Strategic Co-ordination Group (SCG) meetings (5th May 2003; 27th & 28th October, 2003) and a further two drafting group meetings. The document combines the opinions and conclusions of experts from Member States, New Member States and candidate countries, stakeholders and expert groups, as well as experts from the Expert Advisory Forum (EAF) on Groundwater. Due to intensive discussions between these groups, it was possible to present a final draft to the Water Directors meeting in Rome, Italy, on the 24th and 25th November, 2003, where the Water Directors reached the following conclusions:

"We, the Water Directors have examined and endorsed this Guidance during our informal meeting under the Italian Presidency in Rome (24/25 November 2003). We would like to thank the participants of the Drafting Group and, in particular, the leaders, Italy, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

Moreover, we welcome that several volunteers have committed themselves to test and validate this and other documents in the so-called pilot river basins across Europe during 2003 and 2004 in order to ensure that the guidance is applicable in practice.

[1] Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden, United Kingdom, Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovak Republic, Slovenia,

[2] Bulgaria, Romania

[3] Iceland, Liechtenstein, Norway, Switzerland

We also commit ourselves to assess and decide upon the necessity for reviewing this document in 2004 following the pilot testing exercises and the first experiences gained in the initial stages of the implementation."

Why this document?

The 1995 Commission Communication to the Council and the European Parliament on the *Wise Use and Conservation of Wetlands* recognises the very critical situation of Europe's wetlands and the very urgent need for action. It underlines the widespread loss and degradation of wetlands that has resulted in a significant reduction of the beneficial functions they perform in renewing natural resources. By promoting the wise use and conservation initiative the Commission stresses the EU's involvement in wetland protection and enhancement and its commitment in setting up strategic policies for sector integration.

The Water Framework Directive (2000/60/EC) clearly identifies the protection, restoration and enhancement of the water needs of wetlands as part of its purpose at Article 1(a):

> *The purpose of this Directive is to establish a framework for the protection of inland surface waters, transitional waters, coastal waters and groundwater which:*
>
> *(a) prevents further deterioration and protects and enhances the status of aquatic ecosystems and, with regard to their water needs, terrestrial ecosystems and wetlands directly depending on the aquatic ecosystems.*

However, it does not provide any specific definition of what a wetland is, nor does it clearly state the extent to which wetlands should be used for the achievement of environmental objectives. Member States and stakeholders felt that it would be helpful to explore and clarify the role of wetlands in implementing the Water Framework Directive.

The Water Directors Meeting in November 2002 provided common text (cited in 1.1) to be inserted in Common Implementation Strategy Guidance Documents, in which the Directors acknowledge pressures on wetlands, highlight their potential important role in river basin management (RBM) and in helping to achieve WFD environmental objectives, and recommend the preparation of a Horizontal Guidance on Wetlands to implement these principles.

Support for the present document can be found in the WFD CIS Guidance Document No. 2 *Horizontal Guidance on the Identification of Water Bodies* (Water Bodies), compiled in order to provide additional guidance on the definition and protection of "water bodies" as intended by the Directive), in the *WFD CIS Guidance Document No.5 on Typology, Reference Conditions and Classification Systems for Transitional and Coastal Waters* (COAST), in the *WFD CIS Guidance Document No. 4 on Identification and Designation of Heavily Modified and Artificial Water Bodies (HMWB)* and in the *WFD CIS Guidance Document No. 3 for the Analysis of Pressures and Impacts in accordance with the WFD* (IMPRESS). These documents have undergone a negotiated participatory drafting process, therefore the present Guidance Document will build upon definitions and recommendations proposed in them. In addition, this document will provide a description of how wetlands are relevant to WFD implementation, and will describe and provide guidance on the role of wetlands in the achievement of the environmental objectives of the WFD.

TABLE OF CONTENTS

1 INTRODUCTION

1.1 Background to the document

Scope for the initiative has been acquired through the endorsement of the *Common text on wetlands* agreed upon at the Water Directors Meeting in Copenhagen, November 2002.

> *Common text to be inserted in the Guidance Documents:*
>
> *Wetland ecosystems are ecologically and functionally significant elements of the water environment, with potentially an important role to play in helping to achieve sustainable river basin management. The Water Framework Directive does not set environmental objectives for wetlands. However, wetlands that are dependent on groundwater bodies, form part of a surface water body, or are Protected Areas, will benefit from WFD obligations to protect and restore the status of water. Relevant definitions are developed in CIS Horizontal Guidance Documents on Water Bodies (WFD CIS Guidance Document No. 2) and are further considered in a Guidance on Wetlands.*
>
> *Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive.*
>
> *Wetland creation and enhancement can in appropriate circumstances offer sustainable, cost-effective and socially acceptable mechanisms for helping to achieve the environmental objectives of the Directive. In particular, wetlands can help to: abate pollution impacts, contribute to mitigating the effects of droughts and floods, help to achieve sustainable coastal management and to promote groundwater re-charge. The relevance of wetlands within programmes of measures is examined in the horizontal Guidance paper on wetlands*.

Following an initiative from some NGOs involved in the Common Implementation Strategy for the Water Framework Directive (WFD), a drafting group composed of the delegates of several Member States (see foreword) developed this Horizontal Guidance on Wetlands to fulfil the mandate set by the Water Directors.

1.2 Purpose of Guidance

The purpose of the WFD in relation to wetlands as stated in Article 1 is unambiguous. Article 1(a) states that the Directive will:

> '*establish a framework for the protection of inland surface waters, transitional waters, coastal waters and groundwater, which:*
>
> '*prevent further deterioration and protects and enhances the status of aquatic ecosystems and, with regard to their water needs, terrestrial ecosystems and* ***wetlands*** *directly depending on the aquatic ecosystems.'*

The protection and enhancement of surface water and groundwater will be achieved through the application of the WFD's environmental objectives, and where appropriate through the use of wetland protection and restoration to help fulfil these objectives in a cost effective and sustainable manner. These aspects of implementation are outlined in the main body of the paper.

As wetlands are a crosscutting issue, the purpose of this Guidance is to elaborate a common understanding of the WFD requirements regarding wetlands and identify their role in its implementation.

In some cases, where additional effort could lead to considerably enhanced results, the Guidance goes one step further and illustrates best practices beyond the legal requirements of the WFD.

The text of the Guidance Document is aimed at making as clear as possible a distinction between legal obligations and best practice recommendations; best practice recommendations are given in the blue boxes presented within the Guidance, as well as within the text itself. It is recognised that Member States have the flexibility to establish stricter environmental protection according to their particular national concerns.

1.3 Structure of Guidance

The following Section on the status of wetlands within the WFD brings forward a functional description of wetlands coherent with WFD purposes (Section 2.1) and in agreement with the consideration of wetlands in other Horizontal Guidance Documents, with particular reference to the Water Bodies Guidance (WFD CIS Guidance Document No. 2). Furthermore, an illustration of the main wetland attributes recognised under the WFD (Section 2.2) introduces the analysis of relationships between wetlands and surface water bodies (Section 2.3), terrestrial ecosystems (Section 2.4) and other elements of surface water having an influence on water bodies and catchment management (Sections 2.5 and2.6).

The specific role of wetlands in achieving WFD environmental objectives is illustrated in Chapter 3, specifying minimum WFD requirements (Section 3.1), the relationship between wetlands and WFD objectives for surface water (Section 3.2), the relevance of wetlands for the achievement of environmental objectives for groundwater (Section 3.3) and for transitional and coastal waters (Section 3.4).

Chapter 4 illustrates the relationship between wetland systems and Heavily Modified and Artificial Water Bodies. Chapter 5 addresses Protected Areas. Chapter 6 clarifies impacts and pressures relative to wetlands, following the general issues highlighted by the IMPRESS WFD CIS Guidance Document No. 3. Chapter 7 illustrates the role of wetlands in the Programme of Measures (PoM) and discusses wetlands in relation to basic and supplementary measures (Section 7.1). Particular attention is given to the consideration of wetland restoration and recreation as measures to be assessed, among other technical means, to prevent catchment degradation and the loss of environmental quality, also taking into account the concept of cost effectiveness (Section 7.2). Chapter 8 illustrates issues concerning wetland monitoring. Chapter 9 lists some conclusions and outlines issues that may be developed further.

2 IDENTIFYING WETLANDS UNDER THE WATER FRAMEWORK DIRECTIVE

2.1 What is a wetland?

Wetlands are diverse, hydrologically complex ecosystems, which tend to develop within a hydrological gradient going from terrestrial to mainly aquatic habitats.

There is a wide range of definitions and interpretations of the term ‘wetland’. These definitions tend to reflect different national traditions as well as differences in the characteristics of the environment across Europe. From an ecological perspective, wetlands are heterogeneous but distinctive ecosystems which develop naturally, or are the product of human activities. Their biogeochemical functions depend notably on a constant or periodic shallow inundation by fresh, brackish or saline water, or saturation at, or near, the surface of the substrate. They are characterised by standing or slowly moving waters. Common features include hydric soils, micro-organisms, hydrophilous and hygrophilous vegetation and fauna which has adapted to chemical and biological processes reflective of periodic or permanent flooding and/or water-logging.

Wetlands perform regularly, and to a high capacity, a range of processes that in combination result in the delivery of significant benefits for human welfare, wildlife and for the maintenance of environmental quality. Some wetlands have been recognised for their international conservation values.

The particular temporal and spatial patterns of the hydrological regime as well as other special wetland characteristics, such as distinctive plant and animal communities, ecosystems actively accumulating biomass and the provision of seasonal spawning sites for fish, combine to explain the unique features which characterise wetlands. These features bear the potential to generate benefits such as water quality improvement, hydrological regulation, food web support and preservation of important environmental and cultural values.

Wetlands are part of the hydrological continuum. They comprise parts of other surface water bodies and may significantly influence their status. When not immediately contiguous to surface waters, wetlands are often linked to these through hydrological pathways. Their common occurrence at the interface between surface waters and agro-ecosystems underlines the potential relevance of wetlands for the protection of surface waters.

Situations in which there has been artificial separation between water bodies and their adjacent wetlands, or the disruption of the wetland’s ecological health and/or hydrological regime, result in the degeneration of wetland functions.

Rather than attempting to establish a new international definition of wetlands for the purposes of the WFD, this Guidance explains their relevance to the achievement of the Directive’s environmental objectives.

2.2 Wetlands within the operational structure of the Water Framework Directive

One of the greatest contributions of the Directive in setting up a new framework for river basin management (RBM) is in the attention given to key relationships among significant elements of the hydrological network. The role of wetlands in this respect could be useful.

The recognition of these interdependencies is a major strength of the WFD as a management tool, in contrast to previous water pollution control or nature conservation Directives (see WFD CIS Guidance Document No. 5). This recognition supports the real purpose of the WFD as stated in Article 1.

Although the WFD refers to wetlands (Recitals 8 and 23, Article $1_{(a)}$ and Annex $VI_{(vii)}$) it does not define them or provide a size range to indicate their dimension. Nor does the Directive set obligations or recommendations for wetlands or other terrestrial ecosystems *per se*. However, the environmental objectives of the WFD are to be applied to, and monitored through, 'water bodies', therefore it is important for Member States to have a clear understanding of the relationship between water bodies (ground and surface) and wetlands, in order to understand how these systems might be encompassed within the cycle of river basin planning.

The WFD's environmental objectives of: (i) preventing deterioration in status; (ii) achieving good surface water status or, for artificial or heavily modified surface water bodies, good ecological potential and good surface water chemical status; (iii) good groundwater status; or (iv) any less stringent objective applicable under Article 4.5, apply exclusively to water bodies. WFD CIS Guidance Document No. 2 provides guidance on the identification of surface water and groundwater bodies and forms the starting point for the discussion and diagrams which follow.
The WFD's focus on water bodies and their relationships helps to highlight the functional role of wetland systems within the hydrological cycle and the river basin. This is reflected in the Directive by means of a complex set of provisions which are illustrated in the Figure 1 and the text in this Chapter.

Figure 1 (bubble chart) represents the different ecosystems that may be present in a river basin district and which may be relevant, in different ways, to the achievement of the Directive's objectives. The relative sizes and overlaps of the bubbles depend on the sorts of ecosystems present within each river basin district. The central bubble represents the 'universe' of wetlands. The following sections of the Guidance describe the role of these different ecosystems in the river basin management planning process.

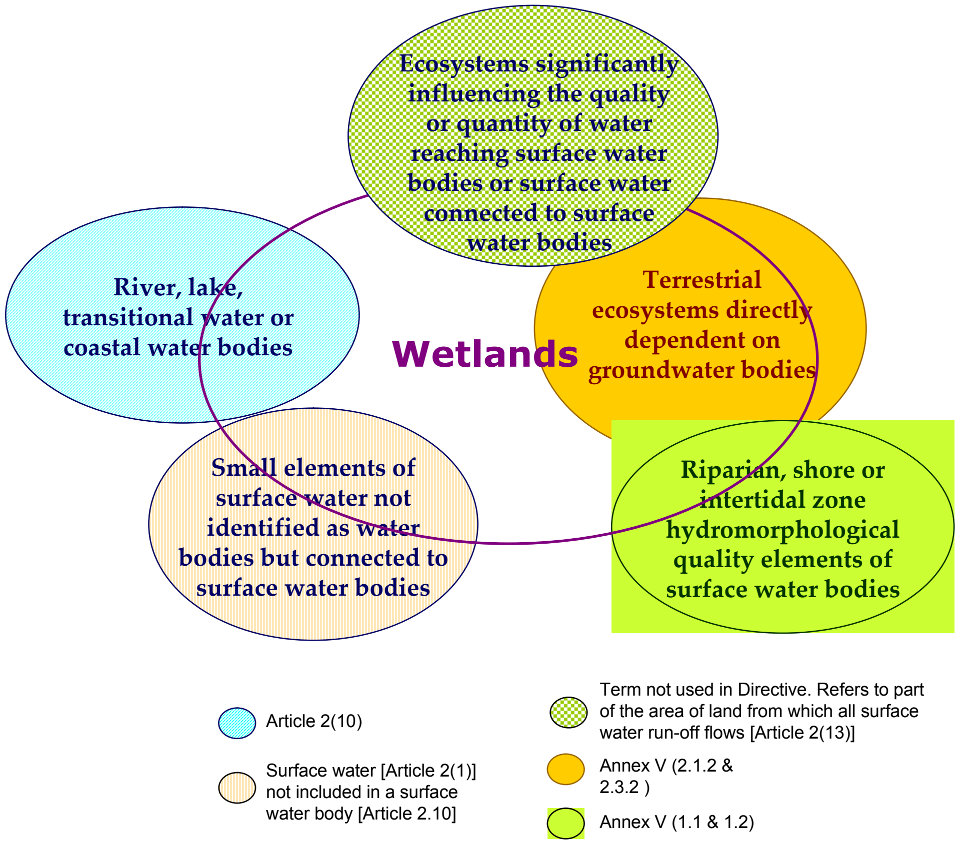

Figure 1: Ecosystems relevant to the achievement of the Directive's objectives (bubble chart)

Case Study 1. Biebrza: a floodplain at reference condition

In Europe, many formerly dynamic rivers have become highly managed, single thread channels, isolated from their floodplains. However, in an undisturbed condition, channels in lowland floodplain systems may be part of an interconnecting series of biotopes that constitute the riverine ecosystem. The river in its natural state tends to migrate across the floodplain, producing a range of lotic and lentic aquatic environments such as side channels, dead arms connected at one end, abandoned braids, ox bow lakes and ponds. This can result in a mosaic of habitat patches, ecotones and successional stages, characterised by different communities and enhanced by natural forms of disturbance.

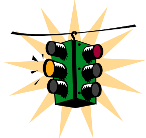
The physical modification of rivers generally prevents the formation of such complex floodplain ecosystems. For example, on the Isar floodplain in Germany, relatively unmodified areas have an abundance of short-lived ponds close to the stream system, whilst in sections more strongly influenced by water engineering, the abundance and diversity of ponds has declined due to embankments restricting the river to a single channel. New ponds cannot be created and existing ponds are isolated from the river (Homes *et al.,* 1999).

A lowland floodplain river water body in a totally undisturbed condition should be unchannelised, intact and connected, and include the full complement of seral stages. Parts of the Biebrza River in Poland illustrate these concepts. The river meanders 164 km through a large floodplain of peat fens and marshes. Although its major tributaries have been channelised for agriculture, the River Biebrza itself remains unregulated. Large meanders are divided by mineral islands and the floodplain contains a complex network of waters including oxbow lakes, backwaters and abandoned channels. In Spring, natural flooding swells the river to form a vast shallow lake up to 1 km wide. This heterogeneous wetland complex allows great species diversity – 186 species of breeding bird have been recorded including 21 threatened species and there are over 60 plant communities present including nearly all the water, marsh and peatland plant communities found in Poland. The delineation of the river water body and the understanding of the extent of the riparian zone hydromorphological quality element should reflect the dynamic nature of the river and the ecological diversity this generates.

River Biebrza, Poland (Photograph: Zbigniew Mroczkowski)

The following paragraphs describe the nature of the role of each single category of wetland typology identified in Figure 1; obligations related to each wetland type are indicated using the symbol  .

2.3 Surface water bodies (river, lake, transitional and coastal waters)



Look out! For protected areas which may be included under these water bodies, please refer to Chapter 5.

a) Wetland ecosystems identified as water bodies

Many wetland ecosystems are composed of mosaics of surface water, permanently and temporarily inundated or waterlogged land, such as lowland mire systems, or floodplain wetlands. WFD provisions in relation to surface waters will *in themselves,* help to protect and enhance wetland ecosystems, by defining parts of them as water bodies, and setting objectives for them, where they fall within the WFD categories of rivers, lakes, transitional or coastal waters.

In paragraph 3.5 and Figure 8 of the Water Bodies Guidance (WFD CIS Guidance Document No. 2), a step-wise approach is suggested to guide in the identification of small elements of surface water and their potential designation as significant and discrete water bodies. The Guidance discusses in detail the issue of 'size limits' following Annex II.1.2, introducing systems A and B for defining surface water typology. It proposes that the identification of water bodies should reflect the ecological significance of surface waters within a river basin district. It states (paragraph 3.3):

> *Member States may identify "surface water bodies" using additional criteria designated to take account of local circumstances and therefore assist in the river basin management planning process.*

Case Study 2. The UK Biodiversity Action Plan:
a resource to assist with implementation of the WFD

The UK has identified a range of species and habitats which are priorities for conservation action, and developed an 'Action Plan' to support them, as part of its contribution to the Convention on Biological Diversity.

This plan includes provisions for the identification, protection and enhancement of wetland habitats such as floodplain grasslands, and habitats supporting important wetland species such as the natterjack toad, water vole and charophyte beds. Information about the whereabouts and features of interest of such habitats is held by a variety of Government and Non-Government organisations, who together make up the 'biodiversity partnership'. Plans to bring this information together by means of a web-based 'National Biodiversity Network' are underway, and much data is already available through local and national site registers. This important resource could be used during WFD implementation, to assist in the selection of water bodies and to help identify features of interest in groundwater receptor sites.

Among such criteria there is consideration of geographical, hydromorphological and nature protection features (e.g. Natura 2000 sites) as well as of human use and of other elements consistent with the context of the Directive's purposes and objectives.

Member States may thus use existing information about the presence and value of wetland features of interest, including biodiversity and cultural significance, to help to select water bodies. We recommend that the multiple role of wetlands within river basin management be given due consideration in the definition of "water body" status.

☞ Obligations to achieve the objectives for surface water bodies specified under Article 4 and Annex 5.

b) Riparian, shore, and intertidal zone quality elements of surface water bodies

The hydromorphological quality elements of surface water bodies include the structure and condition of the riparian zone of rivers, the shore zone of lakes and the intertidal zones of transitional and coastal waters (See WFD Annex V Sections 1.1–1.4). The Water Bodies Guidance (WFD CIS Guidance Document No. 2) makes it clear that these zones may include ecosystems regarded as wetlands, where the structure and condition of such wetlands is relevant to the achievement of the objectives for a surface water body. Reference conditions should be set in accordance with Annex 2.

As stated in WFD CIS Guidance Document No. 2 (paragraph 3.6):

In concrete terms this means that, e.g., a river water body comprises:

(a) the hydromorphological quality elements, which include the water flow, the bed of the channel, that part of the land adjacent to the channel that's structure and condition is directly relevant to the achievement of the values for the biological quality elements (i.e. the riparian zone;, and

(b) the relevant biological elements.
In relation to wetlands, this means that those wetlands must be associated with a "water body", which are directly influencing the status of the related "water body". The boundaries of such wetlands must be identified in a pragmatic way in order to meet the requirement of a "discrete and significant" element.

☞ Obligation to ensure that the hydromorphological quality elements at reference condition are subject to no more than minor alterations; and

☞ Obligation to ensure that the hydromorphological elements are in the condition needed to achieve the objectives of Article 4.

Where rivers are found within naturally functioning floodplains, wetlands in the riparian zone may have important implications for the development of an appropriate reference condition.

Case Study 1 illustrates a river water body representing a relatively undisturbed hydromorphology.

2.4 Terrestrial ecosystems directly depending on groundwater bodies

The WFD's objectives of achieving good groundwater quantitative status (Annex V.2.1.2) and good groundwater chemical status (Annex V.2.3.2) require that, among other things, the groundwater needs of terrestrial ecosystems that depend directly on bodies of groundwater be protected, and where necessary restored to the extent needed to avoid or remedy significant damage to such ecosystems.

Terrestrial ecosystems that depend directly on a body of groundwater will include types of terrestrial ecosystems that occur in areas where the water table is at or near the surface of the ground.

> ☞ Obligation to achieve good groundwater status to manage quality and quantity of groundwater to avoid significant damage to terrestrial ecosystems directly dependent on groundwater bodies, in accordance with WFD Article 4, Annex 5.

2.5 Small elements of surface water connected to water bodies but not identified as water bodies

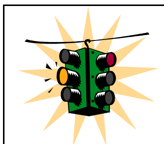
As noted in the Water Bodies Guidance (WFD CSI Guidance Document No. 2), it will not be practical to identify every element of surface water in a river basin district as a water body or part of a water body. Member States will have to decide within the river basin management planning process which elements of surface water are not sufficiently discrete and significant to be identified as water bodies. Many of the elements of surface water that are not identified will nevertheless be connected to surface water bodies. In accordance with the WFD CIS Guidance Document No. 2, such elements will need to be protected or, in some cases, enhanced and restored to the extent needed to ensure that any impacts of human activity on them do not compromise the achievement of the environmental objectives of the water bodies to which they are connected. In some cases, Member States may even choose to artificially create such surface waters where they determine that this is an appropriate or necessary means of achieving the objectives of the WFD for surface water bodies. For example, some Member States use artificially created detention ponds to help mitigate the impacts of urban run-off on river water bodies.

> ☞ Obligation to achieve objectives for connected surface water bodies.

2.6 Ecosystems significantly influencing the quality and quantity of water reaching surface water bodies, or surface waters connected to surface water bodies

Ecosystems which are adjacent to water bodies and which may influence the status of those water bodies should be encompassed within the riparian, lakeshore or intertidal zones (see Section 2.3b), in order to ensure the most effective operation of WFD environmental objectives. However, there may be other wetland ecosystems in river basins which, although they are not adjacent to water bodies and do not therefore form part of the riparian, shore or intertidal zones, may nevertheless significantly influence the quality and quantity of water reaching those bodies, or reaching small elements of surface waters connected to those bodies. Member States will need to ensure that the quality and quantity of water entering surface water bodies via these ecosystems is such as to ensure the achievement of the relevant objectives for the water bodies. In doing so, Member States may determine where appropriate, relevant actions to, protect, enhance, restore or even artificially create such ecosystems.

> ☞ Obligation to achieve objectives for surface water bodies influenced by such ecosystems.



Look out! The WFDs objectives of protecting, enhancing or restoring surface water status apply to BODIES of surface water - lakes, rivers, transitional waters, and stretches of coastal water. Its groundwater status objectives apply to BODIES of groundwater.

Figure 2 (map chart) provides a schematic summary of the different types of ecosystem within a river basin that may be relevant to the achievement of the Directive's objectives, and which may include ecosystems regarded as wetlands.

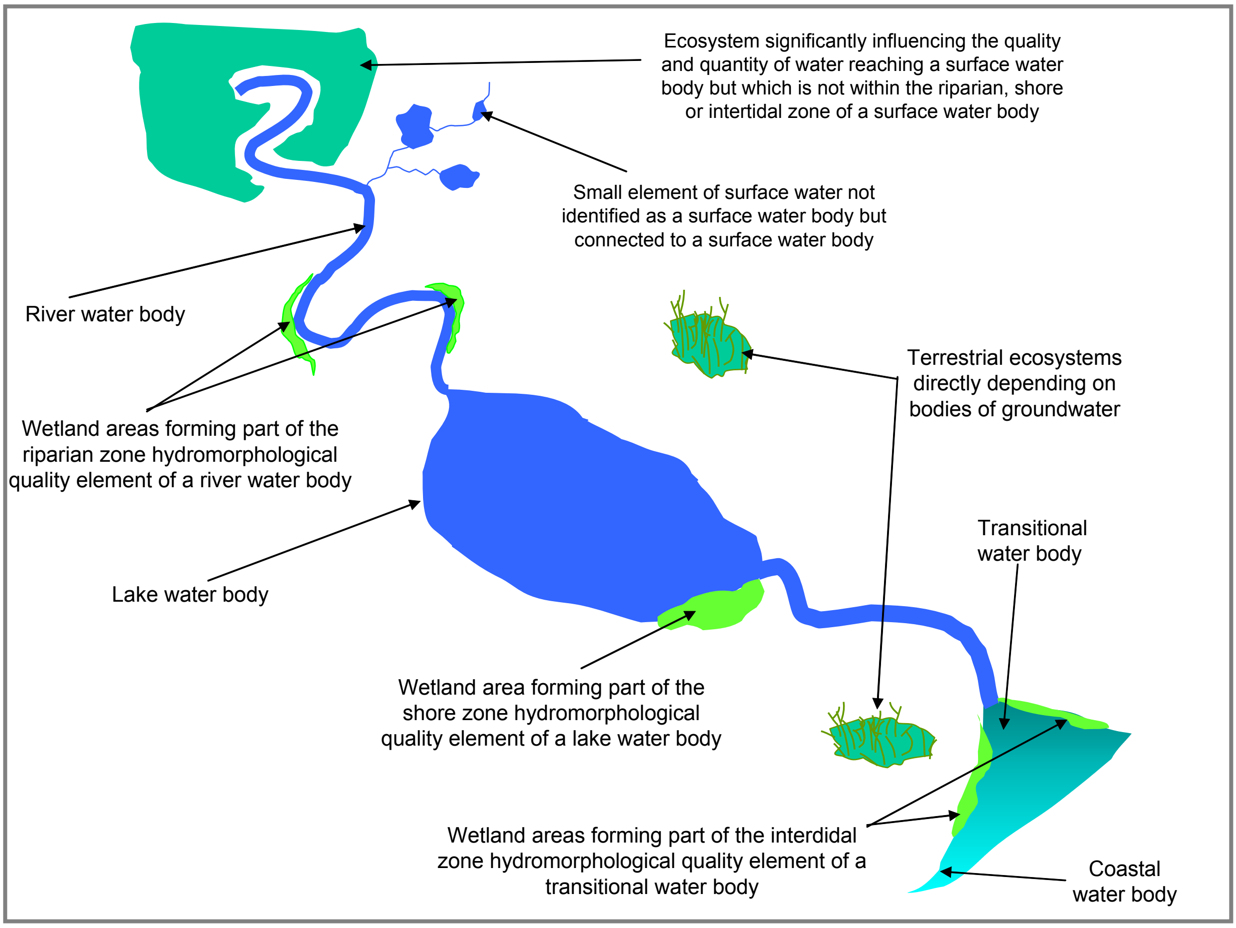


Figure 2: Ecosystems within a river basin that may be relevant to the achievement of the Directive's objectives (map chart)

3 WFD ENVIRONMENTAL OBJECTIVES AND WETLANDS

This Chapter addresses ways in which wetlands may be relevant to the achievement of surface and groundwater body objectives.

3.1 Summary of the main requirements

The WFD does not set independent ecological objectives for wetlands other than where those wetlands, or parts of them, are surface water bodies.

The WFD does however: (a) set groundwater objectives that include obligations towards these ecosystems; and (b) identify the use of wetland functions as a possible means of achieving the Directive's objectives.

The most important WFD provisions in relation to wetlands are:

- ☞ Obligations to surface waters, which will apply to those 'open water' wetlands which are identified as water bodies [Article 4.1(a)$_{(i)}$] (see Chapter 2) and belong therefore either to rivers, lakes, transitional waters or coastal waters;

- ☞ Obligations to prevent more than very minor anthropogenic disturbance to the hydro-morphological condition of surface water bodies at high ecological status (HES). The hydro-morphological quality elements of a surface water body include the structure and condition of riparian, lakeshore or inter-tidal zone, and hence the condition of any wetlands encompassed by these zones. This protection is necessary to achieve the objective of preventing deterioration from HES [Article 4.1(a)$_{(i)}$; Annex V 1.2], bearing in mind the exceptions identified at Article 4.6, 4.7 and the additional requirement in Article 4.8;

- ☞ Obligations to protect, enhance and restore wetlands identified as water bodies, where this is necessary to support the achievement of: (a) good ecological status (GES) or good ecological potential (GEP); (b) good surface water chemical status; or (c) a less stringent objective [Article 4.1(a)$_{(i\ \&\ ii)}$; Article 4.5]. If damage to any such surface water body, wherever it occurs within a river basin district, is causing a failure to achieve one of the WFDs environmental objectives, then appropriate measures will be required;

- ☞ Obligations towards wetlands that are not individual water bodies, but part of the riparian zone. Member States are required under Article 11.3(i) to establish measures to control and mitigate modifications to the structure and the condition of these zones, including that of any wetland they contain, to the extent necessary to ensure that the hydromorphological conditions of the water bodies are consistent with the required ecological status or ecological potential;

- ☞ Obligations to achieve good groundwater status [Article 4.1(b)$_{(i\ \&\ ii)}$, as defined in Annex V 2.1.2 and 2.3.2.] and to reverse any significant and sustained upward trends in the concentration of any pollutant in groundwater in order to progressively reduce pollution of groundwater [Article 4.1(b)$_{(iii)}$]. Member States must, among other things, control and remedy anthropogenic alterations to groundwater quality and water levels to the extent needed to ensure that such alterations are not causing, and will not cause: (a) significant damage to terrestrial ecosystems that directly depend on bodies of groundwater; and (b) significant diminution in the chemical or ecological quality of bodies of surface water associated with bodies of groundwater. This also includes an obligation to ensure that dependent surface waters achieve their environmental objectives under Article 4, as far as these depend on groundwater quality and quantity. Fens and marshes, that are dependent on groundwater to maintain their characteristic structure and function, may fall within the category of dependent terrestrial ecosystems; and

- ☞ Obligations, as requested specifically under the Habitats (92/43/EEC) and Wild Birds (79/409/EEC) Directives, to take protective or restorative action in the management of wetlands which are included in the register of protected areas following Annex IV(v).

Furthermore, wetlands could play a relevant role in facilitating the achievement of other WFD requirements concerning Protected Areas that do not target wetlands directly. The list below largely refers to objectives established under other Community legislation, the achievement of some of which may conceivably be assisted by the management of wetlands. These are:

- ☞ Obligations to take protective or restorative action in the management of areas designated for the abstraction of drinking water and areas relevant for the protection of economically significant aquatic species (WFD Annex $IV_{(i \& ii)}$);

- ☞ Obligations to take protective or restorative action in the management of recreational water bodies under the Bathing Water Directive (76/160/EEC) (WFD Annex $IV_{(iii)}$); and

- ☞ Obligations to take protective or restorative action in the management of sensitive areas and vulnerable zones designated under the Nitrate Directive (91/676/EEC) and the Urban Wastewater Directive (91/271/EEC) (WFD Annex $IV_{(iv)}$).

Please refer to Chapter 5 for further details concerning obligations established under the Protected Areas Register.

3.2 Surface waters objectives and wetlands

The description of wetlands adopted for the purposes of this Guidance includes areas of surface water. The WFDs status objectives [Article $4.1a_{(i)}$, $_{(ii)}$ and $_{(iii)}$] apply to surface waters identified as a "water body". In the WFD (2.1) "surface water" is defined as:

> *Inland waters, except groundwater, transitional waters and coastal waters, except in respect of chemical status for which it shall also include territorial waters;*

and "body of surface water" (Article 2.10) is :

> *A discrete and significant element of surface water such as a lake, a reservoir, a stream, river or canal, part of a stream, river or canal, a transitional water or a stretch of coastal water.*

Chapter 2 discussed in detail the ways in which some wetland systems may be encompassed within the definition of surface water bodies, either as lakes, rivers, coastal or transitional waters in themselves, or as part of the riparian, lakeshore or inter-tidal zones of such water bodies. This section of the Guidance will explore in more detail the implications of achieving the relevant environmental objectives for such water bodies.

3.2.1 Biological quality elements for surface water bodies

River Basin Districts (RBDs) typically include complex mosaics of surface waters, temporarily inundated and terrestrial habitats. The Water Bodies Guidance (WFD CIS Guidance Document No.2) provides a pragmatic approach to determine the area of surface water which constitutes the water body *per se* and parts of 'wetland' ecosystems that may be identified as, or form parts of, water bodies.

The following paragraphs provide a guideline for identifying the area of adjacent land which is included when assessing water bodies' *biological quality elements* described in Annex V, and the relationship between these and water bodies' *hydro-morphological quality elements.*

Case Study 3. The Great Ouse: effects of river regulation on fish species composition in an English lowland river

Continued and extensive regulation of lowland rivers such as the Great Ouse has caused considerable changes in fish populations. The Great Ouse is strongly regulated by weirs, dredging, flood embankments and navigation locks, and is largely disconnected from its floodplain. Since there are no lowland rivers in the UK that can be considered to be at reference condition, the Great Ouse has been compared to the unregulated River Biebrza in Eastern Poland, which had similar characteristics to the Great Ouse prior to its regulation.

On the Ouse, generalist species (roach and minnow) dominated the system and often made up more than 70% of the fish population. Gudgeon, three spine stickleback, chub, bullhead and silver bream occasionally co-dominated. When compared to the relatively unmodified River Biebrza, the Great Ouse has a poor recruitment of specialist fish - both limnophilic (slow-flowing and standing water specialists) and rheophilic (characteristic of faster flowing water). In the River Biebrza limnophilic species such as silver bream, tench and rudd were found throughout the length of the river, principally in adjacent oxbows and abandoned side channels. The Ouse has few connected floodplain waters and therefore reproduction of limnophilic species is restricted to downstream sites. The absence of the rheophile burbot was notable, as it is a common species of unregulated lowland rivers and their floodplain waters, and historical records indicate that it was common in the Great Ouse prior to modification. The general absence of salmonids also suggests that modification has lead to the severe reduction of more sensitive rheophilic fish and a dominance of generalist species.

Copp G.H. (1990) Effect of regulation on fish recruitment in the Great Ouse, a lowland river. Regulated Rivers: Research and Management ***5:****251-263.*

3.2.1.1 Rivers

Depending on river morphology, riverine systems may be characterised at reference condition (and therefore at High Status) by complex and dynamic patterns of channels, oxbow lakes and temporary surface waters. In such cases, it may not be appropriate to assess biological quality elements from single parts of the river environment without consideration of the condition of other parts (for example, by treating 'main channels' as separate from backwaters, side arms and oxbows).

Large channels vary in their course over time, and biological quality elements can depend on the presence of a range of habitats within the river and floodplain ecosystem to sustain their life-cycles and abundance. In these contexts, the river water body, and its biological reference condition, should reflect this dynamism and ecological integrity.

The following biological quality elements are required for the assessment of the ecological status of rivers (Table 1):

Table 1. Biological quality elements relevant in the assessment of the ecological status of rivers (WFD Annex V)

Biota	Characteristics				
Phytoplankton	Taxonomic composition	Abundance			
Macrophytes and phytobenthos	Taxonomic composition	Abundance			
Macro-invertebrates	Taxonomic composition		Proportion of disturbance sensitive to insensitive taxa	Level of diversity	
Fish	Species composition	Abundance	Presence of disturbance sensitive taxa		Age structure of communities

The following case studies demonstrate the interaction between relevant biological quality elements and the condition and delineation of the floodplain river water body.

Case Study 4. The importance of flood disturbance for maintenance of macrophyte communities

A natural alluvial floodplain contains areas of water created as the channel moves across the floodplain which are variously disturbed by flooding. Flood disturbance has a positive role in the maintenance of Charophyte species diversity in cut-off channels. Charophytes are usually considered pioneer species occurring in disturbed habitats supplied with groundwater. They occur abundantly in large river floodplains influenced by floods. Data collected from 63 cut off channels on the Doubs, Saône, Ain and Rhône rivers showed that *Chara vulgaris* and *Nitella conferuacea* were more frequent in and even limited to channels with high flood disturbance. In contrast, *C. major* and *C. globularis* occurred in channels with little or no flood disturbance indicating that some species can survive under low disturbance conditions. In order to maintain optimal species diversity a range of ages of cut off channels are required, containing different successional stages of vegetation. If rivers are channelised and cut off from side channels the early successional stages and therefore pioneer species will be lost as all channels gradually reach climax vegetation.

*Bornette, G. and Arens, M. (2002) Charophyte communities in cut-off river channels – the role of connectivity. Aquatic Botany **73:**149-162.*

Lowland floodplains historically suffered radical physical modification in many parts of Europe, as a result of land drainage and flood management activities, aimed at maximizing agricultural production and protecting people and property. In many cases, decisions about how practical or desirable it will be to restore the hydro-morphology (and the associated biology) of such river systems to the extent needed to achieve good ecological status, will be determined through the application of the tests for the heavily modified water body (HMWB) designation (see Chapter 4). However, the principle of the WFD in relation to the development of a type-specific reference condition for natural waters is clear. The reference condition for such systems should reflect no (or only very minor) anthropogenic impacts on the biological quality elements, whilst good status should represent an acceptable, but slight deviation from this condition. The reference condition for heavily modified or artificial water bodies is maximum ecological potential (MEP).

For some floodplain river types, the reference condition values for the biological quality elements may be strongly dependent on the range of surface water and adjacent riparian zone habitats that would be present under totally, or nearly totally, undisturbed conditions. Such dependency should be taken into account when defining the good status values for the biological quality elements and identifying the hydromorphological conditions consistent with the achievement of those values.

In the uplands, river channels are often clearly distinguishable even at reference condition; the identification of the water body, and its associated riparian zone, (the land adjacent to the channel whose condition directly influences its ecology), is less complex. However, the requirement to ensure that this riparian zone, including any relevant wetlands, are in a physical condition capable of supporting the biological elements found in the water body at good status, will remain. This is discussed in more detail in Section 3.2.3, which describes the role of hydro-morphological elements at reference condition, and as supporting elements for the biological quality elements at good status.

3.2.1.2 Lakes

Lakes with substantial, shallow littoral zones (which might in many cases be defined as 'wetlands'), including areas of seasonal inundation, derive much of their ecological character from their characteristic littoral communities. This should be reflected in the development of an appropriate biological reference condition for the relevant biological quality elements.

The following biological quality elements are required for the assessment of the ecological status of lakes (Table 2):

Table 2. Biological quality elements relevant in the assessment of the ecological status of lakes (Annex V)

Biota	Characteristics			
Phytoplankton	Taxonomic composition	Biomass		
Macrophytes and phytobenthos	Taxonomic composition	Abundance		
Benthic invertebrate fauna	Taxonomic composition	Ratio of disturbance sensitive to insensitive species	Level of diversity	
Fish	Species composition	Abundance	Presence of type-specific sensitive species	Age structures

Case Study 5 illustrates the relevance of seasonal inundation in water bodies with naturally fluctuating water levels, and demonstrates how in such contexts the biological quality elements will encompass taxa and communities associated with 'wetland' and semi-terrestrial habitats.

Case Study 5. Turloughs and Breckland Meres: Lakes with high levels of natural fluctuation in water level and associated biological diversity

Naturally fluctuating water levels in these lakes result in characteristic plant and animal communities that may appear almost or wholly terrestrial at certain times of the year. In the UK, a habitat action plan exists for these lakes which describes their typical fauna and flora.

As a result of the fluctuating water levels, aquatic vegetation is absent (or, in Northern Ireland, restricted to residual pools) at some periods in the cycle of these lakes and abundant at others. An element common to both turloughs and meres is the prevalence of aquatic and semi-aquatic mosses such as *Fontinalis antipyretica* and *Cinclidotus fontinaloides*, which are more resistant to desiccation than higher (vascular) aquatic plants. Rare plants of the inundation zone include the moss *Physcomitrium erystomum* in the meres and the rare fen violet *Viola persicifolia* in the turloughs of Northern Ireland. Although some permanent pools in the Northern Irish turloughs support white water lily *Nymphaea alba* and other water plants, in the Breckland meres, where deep flooding can occur for long periods, aquatic vegetation becomes better established and more diverse than in most turloughs. Water plants typical of the meres are shining pondweed *Potamogeton lucens* and various-leaved pondweed *Potamogeton gramineus*, sometimes accompanied by their hybrid, long-leaved pondweed *Potamogeton x zizii*, which is scarce nationally.

The aquatic fauna of these fluctuating water bodies is adapted to intermittent desiccation. Fish are generally absent, but a range of amphibians can be found, including the protected great crested newt *Triturus cristatus* in the Breckland. Invertebrates include many insect species such as dragonflies, water boatmen and diving beetles, which are highly mobile and are therefore able colonisers. Typically, there is also a rich assemblage of micro-crustaceans such as water fleas, which have resting stages that can remain viable in the soil during dry phases. Snails such as the marsh snail *Lymnaea palustris*, which breathe air and can persist during periods of drought under stones and in damp vegetation, are common in both turloughs and meres. Numerous rare invertebrates have been recorded, including the large mussel-shrimp (ostracod) *Cypris bispinosa*, the small diving beetle *Bidessus unistriatus* and the scarce emerald damselfly *Lestes dryas* from the Breckland meres. During their wet phase the meres support breeding coot *Fulica atra*, tufted duck *Aythya fuligula*, mallard *Anas platyrhynchos*, shelduck *Tadorna tadorna*, pochard *Aythya ferina* and gadwall *Anas strepera*.

UK Habitat Action Plan for Naturally Fluctuating Aquifer Fed Water Bodies, UK Biodiversity Group Tranche 2 Action Plans - Volume II: Terrestrial and freshwater habitats HMSO (December, 1998) Tranche: 2, Volume: II, 25 pages.

3.2.1.3 Coastal and Transitional Waters

As with rivers and lakes, there will be contexts in which the biological quality elements of coastal and transitional water bodies encompass taxa and communities traditionally associated with ‘wetlands’; this is well illustrated by the importance of wetland vegetation in assessing the environmental quality of the Solway and Forth estuaries (Case Study 6).

Case Study 6. The Solway and Forth estuaries: significance of vegetation in assessing the biological quality of saltmarshes

1 The transitional nature of a saltmarsh leads to a zonation of vegetation from pioneer species that require frequent inundation to those that are more terrestrial in character, growing up the shore. Saltmarsh vegetation naturally traps sediment, slows water movement and encourages sediment deposition raising the level of the marsh which allows successional change and gradual terrestrialisation of the habitat. Within the pioneer, upper and lower marsh zones, 28 communities of saltmarsh vegetation have been described throughout the UK, each of them providing a unique habitat for invertebrates and fish and bird fauna.

2
The Solway and Forth estuaries are saltmarshes of international importance, harbouring large winter bird populations (Solway 120 000 birds, Forth 20 000 birds) and include mudflats and sandflats providing nursery and feeding areas for many fish species. At the Solway estuary the land abutting the saltmarshes is lowland grazing marsh, which allows controlled winter flooding and the majority of the coastline is unembanked. The transition from saltwater to freshwater habitats is wide and complete. Vegetation is present from *Puccinellia* pioneer communities through four distinct lower and mid marsh zones to terrestrial transition zones of mature upper marsh dominated by *Phragmites*.

In contrast, the area adjacent to the Forth estuary has high human population density. Land use includes agriculture and industry and much mudflat and saltmarsh has been reclaimed. Bird numbers have been reduced due to loss of invertebrate food, net loss of mudflats and saltmarshes. Vegetation surveys showed that 52% of the vegetation belongs to the *Puccinellia* community. A further 20% of vegetation belongs to the *Festuca rubra* community which tends to occur above the *Puccinellia* community. Vegetation of the upper marsh or later successional stages is missing due to the fact that most of the marsh is a thin 5-80 m strip backed by a sea wall which prevents the natural sequence moving up the shore. The community is extremely poor in species and community richness, reflecting the high level of disturbance resulting from land claim activities.

GeoData Institute (2002). Inner Solway. Potential for managed realignment. Report by GeoData Institute to Scottish Natural Heritage.

Section 2.1.5 of the WFD CIS Guidance Document No. 5 (COAST) recognizes that:

> *The Directive gives no indication of the landward extent of either transitional or coastal waters. One of the hydromorphological quality elements for both transitional and coastal waters is the structure of the intertidal zone. Since it is likely that some of the quality elements may be monitored within the intertidal area, it is recommended that transitional and coastal water bodies include the intertidal area from the highest to the lowest astronomical tide.*

In particular, this is relevant to the monitoring of inter-tidal vegetation, whose composition and abundance are relevant to the assessment of ecological status as shown in the case study above which demonstrates how the condition and extent of intertidal mudflats (a ‘coastal wetland’) bears a direct influence on the biological quality elements measured in the WFD.

The biological quality elements illustrated in Table 3 are required for the assessment of status for coastal and transitional water bodies.

Table 3. Biological quality elements relevant in the assessment of the ecological status of coastal and transitional waters (WFD Annex V)

Biota	Characteristic				
Phytoplankton	Taxonomic composition	Abundance	Biomass		
Macro-algae	Taxonomic composition (transitional)			Cover	Disturbance sensitive taxa (coastal)
Angiosperms	Taxonomic composition (transitional)	Abundance			Disturbance sensitive taxa (coastal)
Benthic invertebrate fauna	Diversity	Abundance			Ratio: disturbance sensitive to insensitive taxa
Fish (not coastal)	Species composition	Abundance			

3.2.2 Physico-chemical quality elements for surface water bodies

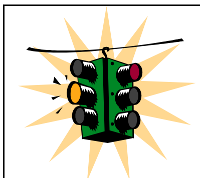
The general physico-chemical elements of ecological status for surface water bodies, such as thermal conditions, salinity, nutrient condition and acidification status (WFD Annex V 1.1.1), may be affected by the condition of wetlands within the riparian, lakeshore or inter-tidal zones, or in the wider catchment. These potential impacts will need to be considered during the impacts and pressures analysis and subsequently in the design of programmes of measures to achieve the Directive's environmental objectives.
For example, nutrient levels and cycling in a lowland river with intact riparian wetlands may be significantly different to those in a river channel adjacent to drained land under intensive agricultural production.

In order to restore nitrogen and phosphorous fluxes to levels capable of supporting the functioning of the type-specific ecosystem, one option may be to consider the role which wetland restoration or enhancement could play as part of a programme of measures (see Chapter 7).

3.2.3 Hydro-morphological quality elements for surface water bodies

The quality elements comprised in the assessment of surface water status include hydro-morphological elements *supporting biological ones* (WFD Annex V,1.1.2.). Hydro-morphological quality elements include the structure and condition of the riparian zone of rivers, the shore zone of lakes and the inter-tidal zones of coastal and transitional waters; many of these include wetlands.

The definitions proposed here are compatible with, and form an elaboration of, similar definitions proposed in the Water Bodies Guidance (WFD CIS Guidance Document No.2). The Water Bodies Guidance Document makes it clear that the water body itself '*comprises the quality elements described in the Directive for the classification of ecological status*', which includes the structure and condition of the riparian, lakeshore or inter-tidal zone.



Look out! For some water bodies, the structure and condition of wetlands in the riparian, shore or intertidal zones will be important for supporting the achievement of the good status values for the biological quality elements.

The WFDs inclusion of hydro-morphological elements is designed to encompass the interactions between physical conditions in the catchment, hydrological processes and the biological condition of surface waters. In developing definitions of the riparian, lake-shore and inter-tidal zones, therefore, it is appropriate to consider first and foremost how adjacent land and ecosystems (including wetlands) help to determine the physical, chemical and biological characteristics of water bodies, rather than to rely on definitions based on size thresholds or return flood events. The definitions given here are designed to ensure that the land defined as riparian, shore or inter-tidal zone directly influences other quality elements within the WFD.

There is no requirement to map the boundaries of riparian and shore zones (nor the location of any other quality elements), however the significance of their influence on the status of water bodies should be given due consideration by Member States when assessing risks to the achievement of the WFDs environmental objectives for surface water bodies, and designing programmes of measures.

The level of effort required in determining the extent of the riparian and the shore zones should be proportional to the potential risks to the WFDs objectives caused by pressures, which may alter the structure and condition of those zones.

Riparian zone: Land immediately adjacent to a river, the structure and condition of which significantly influences the river's other hydro-morphological quality elements, biological quality elements and physico-chemical quality elements, and which may in turn be influenced by the river. The zone will include relevant parts of islands and floodplains. It may include a variety of wetland habitats that rely on over-bank flows for their maintenance, but which in turn influence the conditions in the river. The extent of the riparian zone will be variable depending on the significance of its influence on the biological quality elements relevant to the classification of ecological status. Rivers flowing through gorges may depend on only a very narrow riparian zone, whereas rivers in delta areas may be directly dependent on the structure and condition of a more extensive area of land.

Shore zone: That part of the land immediately adjacent to a lake, the structure and condition of which significantly influences the values attained by other hydro-morphological quality elements, the biological quality elements or the physico-chemical quality elements, and which may in turn be influenced by lake flooding or wave action.

The level of effort required to determine the extent of the riparian and the shore zones should be proportional to the potential risks to the WFDs objectives from pressures which may alter the structure and condition of those zones.

Intertidal zone: The zone between mean high water spring tides and mean low water spring tides. The zone typically includes a variety of terrestrial and aquatic ecosystems such as salt, brackish and freshwater tidal marshes, mud flats, rock pools, beaches etc. (see Section 3.4). Table 4 illustrates the Hydro-morphological quality elements of surface waters (Annex V.1.2).

Table 4. Hydro-morphological quality elements of surface waters

Rivers	Lakes	Transitional Waters	Coastal Waters
Hydrological regime (flow and connection to groundwater)	Hydrological regime (flow, level, residence time, connection to groundwater)	Tidal regime (freshwater flow)	Tidal regime (freshwater flow, dominant currents)
River continuity			
Morphological Conditions (Channel patterns, width and depth variations, flow velocities, substrate conditions, structure and condition of riparian zone)	Morphological Conditions (depth variation, substrate, structure and condition of lake shore zone)	Morphological Conditions (depth variation, substrate conditions, structure and condition of inter-tidal zone)	Morphological Conditions (depth variation, substrate conditions, structure and condition of inter-tidal zone)

3.2.4 Categories of environmental quality

a) Objectives for water bodies at HES or MEP

The provisions of the WFD for water bodies at HES and MEP differ from those for other water bodies. HES water bodies must demonstrate, for their hydro-morphology, the conditions reported in Table 5.

For the purposes of classification, the definitions of ecological status set out in Annex V (1.2.1-1.2.4) describe the values for the quality elements of ecological status for each surface water category. Where a water body is at HES, the relevant values specified for the biological, hydromorphological, and physico-chemical quality elements in these tables must be maintained to achieve the WFDs objective of preventing deterioration in status.

To prevent a water body deteriorating from HES, Member States must prevent any more than minor alterations to the water body's hydromorphological conditions, since the values of the biological quality elements on the boundary of the high good status class are defined in WFD Annex V as those that are compatible with only very minor alterations to the hydromorphological quality elements. The hydromorphological conditions include the structure and condition of the riparian, shore or inter-tidal zones. These provisions have important implications for wetlands. For a river, lake, transitional or coastal water to be at HES, adjacent land, which significantly influences its ecology (the riparian, lake or inter-tidal zone) must show no or only very minor disturbance. This may in turn, provide the conditions necessary for the development and maintenance of wetland ecosystems. In practice, this means that the WFD will help provide protection for our remaining 'natural' wetland ecosystems, where these are riparian zones, lake shores or intertidal zones of high status water bodies.

Table 5. Definitions of hydro-morphological quality elements at HES (Annex V.1.2)

Rivers	Hydrological Regime	River Continuity	Morphological Conditions
	The quantity and dynamics of flow, and the resultant connection to groundwater, reflect totally, or nearly totally, undisturbed conditions.	The continuity of the river is not disturbed by anthropogenic activities and allows undisturbed migration of aquatic organisms and sediment transport	Channel patterns, width and depth variations, flow velocities, substrate conditions and both the structure and condition of the riparian zones correspond totally or nearly totally to undisturbed conditions
Lakes	Hydrological Regime		Morphological Conditions
	The quantity and dynamics of flow, level, residence time, and the resultant connection to groundwater, reflect totally or nearly totally undisturbed conditions.		Lake depth variation, quantity and structure of the lake shore zone correspond totally or nearly totally to undisturbed conditions.
Transitional	Tidal Regime		Morphological Conditions
	The freshwater flow regime corresponds totally or nearly totally to undisturbed conditions		Depth variations, substrate conditions, and both the structure and condition of the inter-tidal zones correspond totally or nearly totally to undisturbed conditions.
Coastal	Tidal Regime		Morphological Conditions
	The freshwater flow regime and the direction and speed of dominant currents correspond totally or nearly totally to undisturbed conditions		The depth variation, structure and substrate of the coastal bed, and both the structure and condition of the inter-tidal zones correspond totally or nearly totally to the undisturbed conditions.

Concerning HMWBs at MEP, the condition of the hydro-morphological quality elements must be consistent with the only impacts on the surface water body being those which result from the artificial or heavily modified characteristics of the water body, once all the mitigation measures have been taken to ensure the best approximation to ecological continuum.

b) Objectives for water bodies at good status and below

At GES, (or for any less stringent objective) the hydro-morphological elements of a water body must be in a condition to support the values established for relevant biological quality elements (see also Art.11.3$_{(i)}$).

In reality, GES is unlikely to be achieved where there are substantial changes to the flow and velocity of a river, the depth and residence time of a lake, or the tidal patterns of an estuary; changes of the kind which frequently result from damage to wetlands within the riparian, lake or inter-tidal zones. The mutual dependence of water bodies and associated wetlands should be included within the impact/pressure analysis when relevant as recognised by the WFD CIS Guidance Document No. 3 (IMPRESS) Guidance (Section 2.3.7):

> *"Pressures on wetlands (for example physical modification or pollution) can result in impacts on the ecological status of water bodies. Measures to manage such pressures may therefore need to be considered as part of river basin management plans, where they are necessary to meet the environmental objectives of the Directive."*

Where pressures on the floodplain have resulted in an impact on the status of a river, for example, the restoration of the floodplain to a more natural condition may be an effective remedy. In some cases, such restoration may form part of a combination of measures to achieve the WFDs objectives unless economic tests demonstrate that it is not a practical or appropriate option (WFD Art. $4.5_{(a)}$ and Annex III).

In all cases wetland management can be proposed as a supplementary measure at the discretion of Member States to assist in achieving RBM objectives (see Chapter 7).

3.3 Wetlands and groundwater

Although not all groundwater is within an aquifer, the WFDs environmental objectives for good groundwater status apply *only* to groundwater bodies identified within aquifers.

Specifically, WFD Article 2.2 defines 'groundwater' as:

> *all water, which is below the surface of the ground in the saturated zone and in direct contact with the ground or subsoil*;

and 'body of groundwater' is given (Article 2.12) as:

> *a distinct volume of groundwater within an aquifer or aquifers.*

The first step in identifying groundwater bodies is to determine which geological strata qualify as aquifers. Following the definitions cited above and the requirements set by WFD Article 7 and Article 1(a), Section 4.2 of the Water Bodies Guidance (WFD CIS Guidance Document No. 2) recommends (see Figure 3 below) that an aquifer is a subsurface layer or layers of rocks or other geological strata that:

- *Is capable of supporting abstraction of 10 cubic meters per day on average or sufficient to serve 50 or more people;*

or:

- *Provides a flow of groundwater the reduction of which may result in a significant diminution of the ecological quality of an associated surface water body, or significant damage to a directly dependent terrestrial ecosystem.*

The identification of aquifers is therefore partly dependent on determining whether groundwater supports directly dependent terrestrial ecosystems. Where such ecosystems are supported by groundwater, the groundwater upon which they depend will qualify as an aquifer.

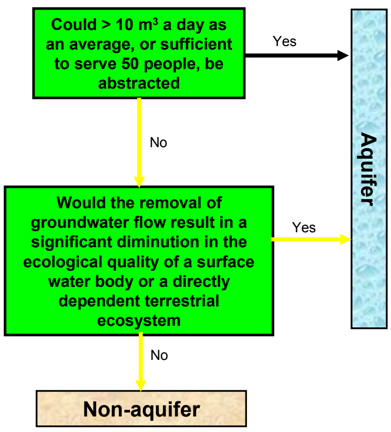


Figure 3: Illustration of the process for determining whether a geological stratum qualifies as an aquifer reproduced from the WFD CIS Horizontal Guidance No. 2 (Water Bodies)

Figure 4 outlines a suggested approach to determining which terrestrial ecosystems to consider in deciding if a geological strata provides significant flow to directly dependent terrestrial ecosystems, and should therefore qualify as an aquifer.

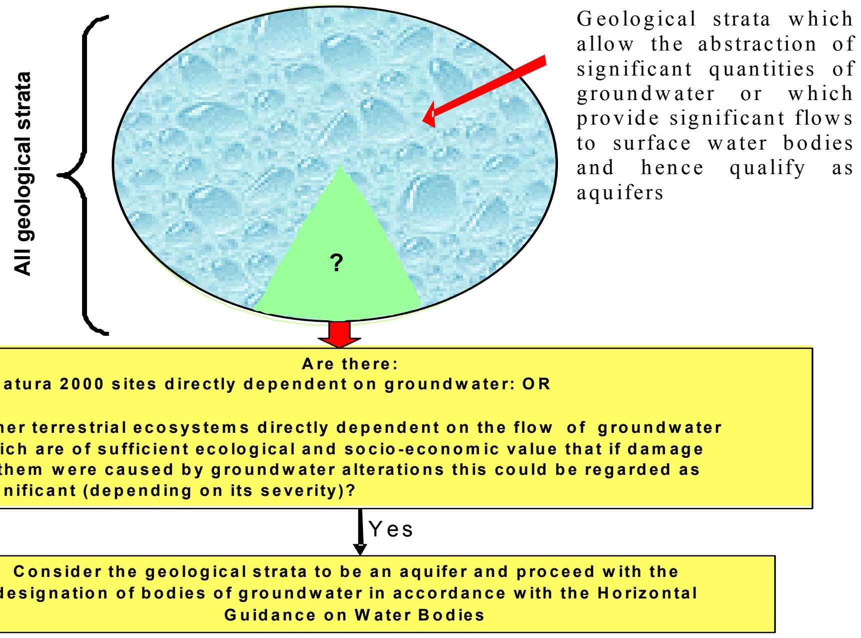

Figure 4: Suggested approach to deciding if a geological stratum qualifies as an aquifer on the basis of the significance of groundwater flow to directly dependent terrestrial ecosystems

The achievement of good groundwater status will require that the groundwater needs of directly dependent terrestrial ecosystems are protected, and where necessary restored to the extent needed to avoid or remedy significant damage to such ecosystems. It will also require that the groundwater needs of surface water bodies are protected and where necessary restored to: (a) ensure the achievement of relevant WFD objectives for surface water bodies; and (b) avoid significant diminution in the ecological or chemical quality of such bodies.

For groundwater quantitative status [Annex V.2.1.2], the WFD requires that:

> *'the level of groundwater is not subject to anthropogenic alterations such as would result in…….*
> *any significant damage to terrestrial ecosystems which depend directly on the groundwater body.'*

For groundwater chemical status [Annex V.2.3.2], good status requires that the concentrations of pollutants:

> *'are not such as would result in failure to achieve the environmental objectives specified under Article 4 for associated surface waters nor any significant diminution of the ecological or chemical quality of such bodies nor in any significant damage to terrestrial ecosystems which depend directly on the groundwater body.'*

These provisions protect dependent terrestrial ecosystems from significant adverse impacts resulting from a reduction in the water table or from groundwater pollution. However, they are not designed to protect terrestrial ecosystems directly dependent on bodies of groundwater from other sources of damage, for example: drainage.

Figure 5 illustrates the general approach, within the river basin management planning process, to considering risks of significant damage to terrestrial ecosystems directly dependent on groundwater as a result of anthropogenic alterations to groundwater quality or levels.

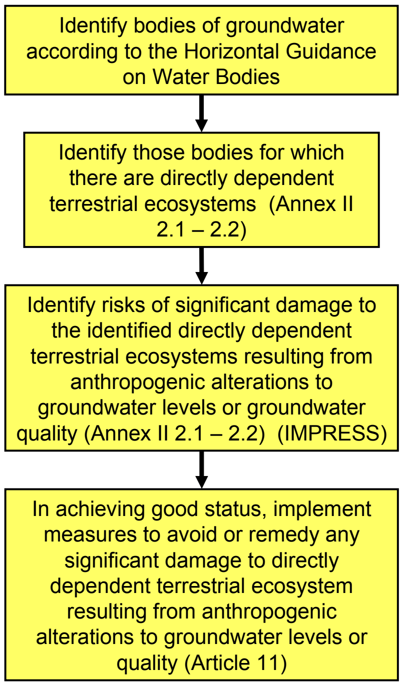

Figure 5: General approach to protecting and restoring the groundwater needs of terrestrial ecosystems directly dependent on groundwater bodies

There are potentially very large numbers of terrestrial ecosystems that are directly dependent on groundwater within the Community. Whilst many support features of value (ecological or socio-economic), a screening tool will be essential to focus action on the most important sites and areas, so that Member States do not face an impossible administrative burden. Member States may use their own, nationally developed criteria for identifying those dependent terrestrial systems which they believe are of sufficient importance that damage to them, as a result of anthropogenic groundwater alterations, could legitimately be described as 'significant'.

The WFD is concerned with significant damage indicating that its intent is to provide a mechanism by which Member States can protect the water needs of wetlands already protected at Community level as part of the Natura 2000 network, and the groundwater needs of other important terrestrial and wetland resources if significantly affected by anthropogenic groundwater alterations. To enable Member States to use their management resources to achieve the greatest benefits for wetland protection and improvement, the practical approach outlined in Figure 6 is recommended.

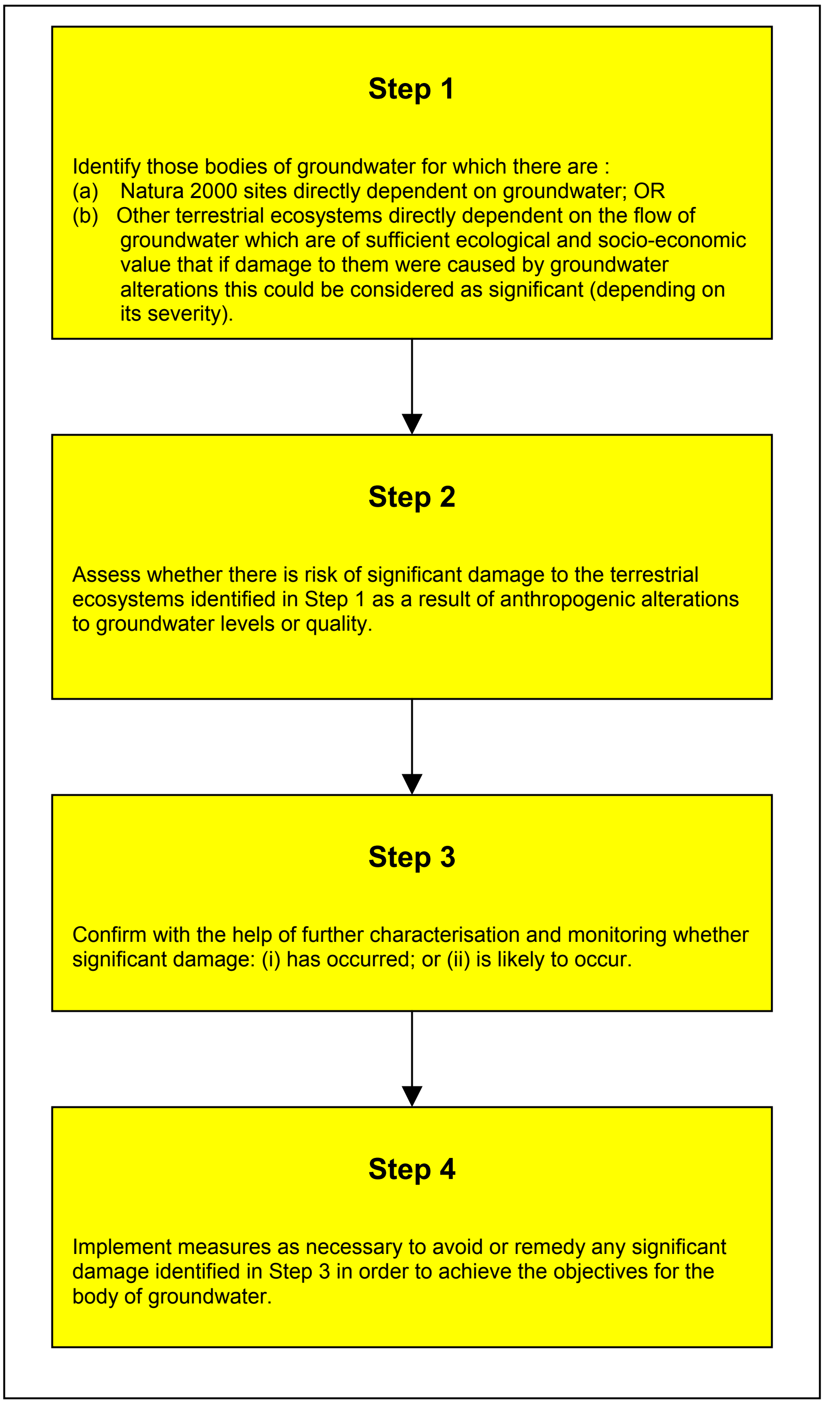

Figure 6: Outline practical approach to identifying terrestrial ecosystems which could be significantly damaged by alterations to groundwater level or quality

An example of how this approach is being implemented in the United Kingdom is illustrated in Figure 7. Because of the limited time available for the 2004 pressures and impacts analysis, work will focus on identifying risks of damage to the most important terrestrial ecosystems in conservation terms. After 2004, other directly dependent terrestrial ecosystems of conservation importance will be considered.

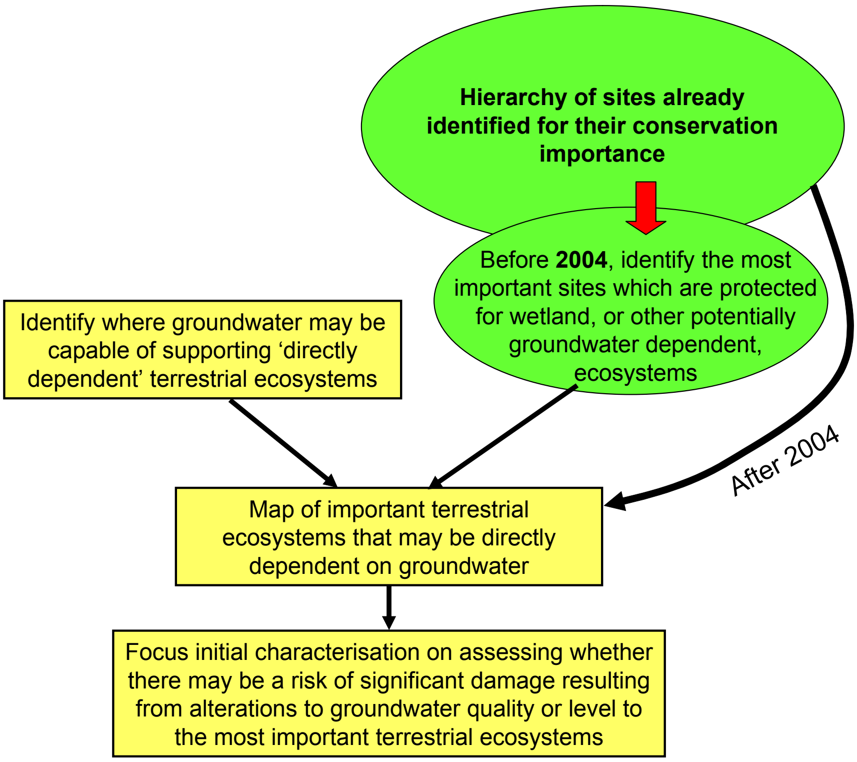

Figure 7: Outline of phased approach being developed in the UK

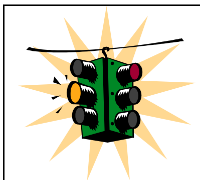
3.3.1 What is significant damage and how should it be measured?

The environmental objectives for groundwater bodies require the protection of dependent terrestrial ecosystems from *significant damage*. However, the WFD does not provide a definition of the term 'significant'. The term '*significant damage'*, should be interpreted primarily with respect to the ecological quality of terrestrial ecosystems that depends on the inter-linkage with groundwater. Beside this, other factors should be taken into account. Existing data held by Member States about the ecological and socio-economic significance of dependent systems could be used to form the basis of a 'significance test' in this context. For example, where a wetland is of conservation importance, impairment of its conservation objectives as a result of alterations to groundwater could be regarded as constituting significant damage. In such a situation Member States may need to assess the risk of incurring into significant damage by relating it to the water needs of critical species and habitats and may determine a boundary of tolerable alteration of groundwater levels defined specifically for each type of ecosystem.



Look out! Wetlands linked to unsaturated strata or karstic systems, may play a crucial role in protecting the saturated zone from pollution. In these cases Member States may need to design specific conservation measures for these ecosystems.

3.4 Wetlands in relation to transitional and coastal waters

Most brackish wetlands fall under the definition of transitional waters given in Article 2.6 of the WFD:

> *Transitional waters are bodies of surface water in the vicinity of river mouths which are partly saline in character as a result of their proximity to coastal waters but which are substantially influenced by freshwater flows.*

The WFD CIS Guidance No. 5 (COAST) recommends that surface waters in the vicinity of river mouths that are ecologically significant in the river basin district be identified as transitional water bodies. The WFD gives no indication of the minimum size of transitional waters to be identified as separate water bodies. The expression '*discrete and significant elements of surface water'*, which is used to help identify significant water bodies (Article 2.10), can be interpreted in terms of the risk of failing to meet good ecological status following assessment by Member States.

Operational needs for the achievement of the main environmental objectives dictate whether a given transitional water should be identified as a discrete surface water body or not. The intertidal area, defined as the discrete area between the highest and the lowest astronomical tides, should be included among water bodies as recommended by Section 2.7.3 of the WFD CIS Guidance No. 5 .

In a similar way, coastal lagoons are defined in respect to the function within the river basin. They fall within transitional waters when they are found *'in the vicinity of river mouths'* and *'substantially influenced by freshwater flows'* (WFD Article 2.6). In other cases, lagoons can be identified as lakes if larger than 0.5 km^2. As suggested in the WFD CIS Guidance No. 5, lagoons smaller than 0.5 km^2 can be included by Member States in the water body definition if they are significant elements of surface water in the context of the purposes of the WFD.

Case Study 7. Groundwater and wetland interactions on a UK floodplain

The River Idle washlands comprise four isolated floodplains covering 84 ha of low lying land in Nottinghamshire and South Yorkshire (UK). The washlands have been designated as a Site of Special Scientific Interest (SSSI) for the wet grassland communities and waterfowl they support.

The River Idle has been subject to modification since the 19th century culminating in the *"River Idle Improvement Scheme"* that saw the construction of flood defence banks and a pumping station which allows drainage to the River Trent during periods of flood and/or high tides when, historically, hundreds of ha of land would have been flooded.

As a result of these modifications the washlands that survive today represent a tiny fragment of the historic wetland landscape and there has been a long-standing concern that even these are subject to drying and degradation.

Initial suspicion fell on the operating regime of pumping station which was thought to be drawing water levels down so quickly after storm events that the period and depth of inundation was insufficient to maintain the shallow water-table depth.

A series of shallow groundwater monitoring boreholes were installed to verify this hypothesis and develop control rules for the pumping station that would restore and maintain the wetland interest. However, the data that was gathered suggests that the shallow water table drops rapidly after flooding to levels below that of the river. This indicates that the fundamental control on the shallow water table in the washlands is the regional aquifer and not the level at which the river is maintained.

While the exact nature of the interaction between river, aquifer and washland is still being investigated, these findings have serious implications for the long-term management of the underlying aquifer, which is heavily exploited for public water supply and has water levels lying below sea level.

4 THE RELATIONSHIP BETWEEN WETLAND SYSTEMS AND HEAVILY MODIFIED WATER BODIES

4.1 Heavily Modified Water Bodies and Wetlands

The HMWBs category of the WFD is the subject of WFD CIS Guidance Document , the principles of which underpin the following discussion (WFD CIS Guidance Document No. 4 on the Identification and Designation of Heavily Modified and Artificial Water Bodies):

> *'Heavily Modified Water Bodies are ones which as a result of physical alterations by human activity are substantially changed in character and cannot, therefore, meet the 'good ecological status' (GES).*
>
> *In this context:*
> - *Physical alterations mean changes to the hydro-morphological characteristics of a water body; and*
> - *A water body that is substantially changed in character is one that has been subject to major long-term changes in its hydro-morphology as a consequence of maintaining the specified uses listed in Article 4(3). In general, these hydro-morphological changes alter morphological and hydro-logical characteristics.'*

If the current specified uses of the water body (i.e., navigation, hydropower, water supply or flood defence) or the wider environment are significantly adversely affected by restoration measures required to achieve GES, and if no other technically feasible and cost effective environmental option exists, then these water bodies may be designated as HMWB. The environmental objectives for such water bodies imply reaching Good Ecological Potential (GEP), which may represent a less stringent requirement than achieving GES.

Riparian, lakeshore or inter-tidal zones, including the wetlands comprised within water bodies, constitute part of the hydro-morphological characteristics of a water body. Where the condition and extent of these is relevant to the achievement of the environmental objectives for the associated water body, modifications to, or destruction of, these wetlands should be taken into account in the HMWB designation process.

The identification of water bodies at risk, and the role of wetlands in this process, is described in the section of this Guidance Document on *Impacts and Pressures* (Section 6). The current chapter considers the relevance of wetlands to the HMWB designation tests and to establishing appropriate values for GEP.

Significant hydromorphological changes which may be judged as incompatible with the achievement of GES, even in the long term, and therefore could prompt HMWB designation may include structural changes such as embankments, drainage, etc., that cannot be removed without significant adverse effects on specified uses or on the wider environment (see WFD Article $4.3_{(a)}$). Actual designation is subject to a series of clear tests outlined in Article 4.3. These are outlined in the following section, along with their relevance for wetland (re)creation, maintenance or enhancement.

4.1.1 Steps in HMWB Designation Process, and their possible relevance to wetlands

There are two key 'designation tests' for HMWBs identified in the WFD and explored in the HMWB Guidance Document (WFD CIS Guidance Document No. 4).

Designation test 4.3$_{(a)}$: Do the restoration measures necessary to achieve GES have significant adverse effects on the wider environment or the 'specified uses'?

In some cases, impacts on wetlands in the riparian, lakeshore or intertidal zones of a water body may result in a risk of failure to achieve GES. Wetland restoration may constitute part or all of the 'measures necessary to achieve GES'. In these cases, the 'designation test' may require an assessment of whether restoration measures can take place without significant impacts on the wider environment or compromising the specified uses. Where this use is flood defence, for instance, wetland restoration linked to the provision of additional flood storage capacity may be possible without significant adverse effects and such a water body would not require designation as an HMWB.

'Designation test 4.3$_{(b)}$: Can the beneficial objectives served by the modifications of the HMWB be achieved by other means, which are a significantly better environmental option, technically feasible and not disproportionately costly?

There may be contexts in which the restoration or creation of wetlands can help to deliver the beneficial objectives in a way that meets the requirements of this designation test. Examples of the roles which wetlands can play in delivering flood defence benefits are described in Chapter 7.

4.1.2 The Establishment of Good Ecological Potential

Following the designation process, Member States will be required to establish environmental objectives for each HMWB. This process is outlined below, identifying where and how the development of a reference condition (MEP) and an appropriate environmental objective (Good Ecological Potential (GEP)) may be relevant to wetland systems.

Table 6. Development of ecological objectives for HMWBs relevant to wetlands

HMWB Ecological Objectives	Relevance to wetlands
Establishment of MEP. Comparison with closest comparable surface water body (Annex V.1.2.5), considering all mitigation measures, which do not have a significant adverse effect on the specified uses or the wider environment.	! Opportunities may exist for restoring relevant wetland function without significant adverse affects on the specified uses or the wider environment. These should be investigated when identifying the closest comparable surface water body. Where no comparable 'natural' system exists (which may be the case when considering heavily modified rivers disconnected from their floodplains), expert judgement may be used to identify the best possible environmental outcome in the context. ! An appropriate reference condition will reflect the restoration of hydro-morphology, in so far as this does not have significant adverse impacts on the wider environment or specified uses.
Establishment of GEP. Only slight changes in the biological elements found at MEP, otherwise measures have to be taken to ensure GEP is achieved (Art. 4.1(a)$_{(iii)}$ and Annex V.1.2.5).	GEP represents only slight changes concerning biological quality elements from MEP, and should therefore provide a driver for the restoration of the physical condition of the water body, in so far as this is compatible with the HMWB designation.

4.2 Artificial Water Bodies and Wetlands

According to the WFD CIS Guidance Document No. 4 (HMWBs), an artificial water body (AWB) is defined as (4.3):

> *'a surface water body which has been created in a location where no significant surface water existed before and which has not been created by the direct physical alteration of an existing water body or movement or re-alignment of an existing water body.'*

A similar, but not identical process to the identification of HMWBs applies to the identification of AWBs and the establishment of MEP and GEP. The potential relevance of this process to wetlands is identified in Table 7 below.

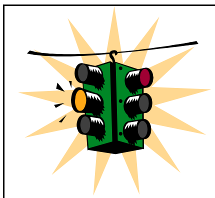
Table 7. Identification of AWBs and their relevance to Wetlands

Is the water body artificial?	Relevance to wetlands
Designation test 4.3(b): Can the beneficial objectives served by the AWB be achieved by other means, which are a significantly better environmental option, technically feasible and not disproportionately costly?	
Establishment of MEP. Comparison with closest comparable surface water body (Annex V.1.2.5), considering all mitigation measures, which do not have a significant adverse effect on the specified uses or the wider environment.	! Care should be taken to ensure that in selecting a natural type for comparison, hydro-morphological condition is properly considered and reflected in the biological standards for maximum ecological potential. Thus, for a relevant lake type, the condition of the lakeshore zone, and of littoral communities associated with it, should help to determine MEP, if mitigation measures could enhance these elements without adverse impacts on the specified uses or the wider environment. This might be particularly relevant to the design or improvement of reservoirs. An appropriate reference condition will reflect the enhancement of hydro-morphology, in so far as this does not have adverse impacts on the wider environment or specified uses.
Establishment of GEP. Only slight changes in the biological elements found at MEP, otherwise measures have to be taken to ensure GEP is achieved (Art. 4.1(a) (iii) and Annex V. 1.2.5).	GEP represents only slight changes in biology from MEP, and should therefore provide a driver for the enhancement of the physical condition of the water body, in so far as this is compatible with the AWB designation.

5 PROTECTED AREAS AND THE WATER FRAMEWORK DIRECTIVE

Article 6 of the WFD requires Member States to establish a register or registers of Protected Areas by 22/12/2004. The Register must include all areas lying within each river basin district that have been designated as requiring special protection under specific Community legislation for the protection of their surface water or groundwater and conservation of habitats and species directly depending on such water. The purpose of the Register is to ensure that the integrated river basin planning system created by the WFD helps to deliver the objectives of other water-related legislation, as it applies to environmentally vulnerable or important parts of the river basin. The Protected Areas register will include some sites designated under the Birds and Habitats Directives as part of the Natura 2000 network.

Under WFD Article 4.1$_{(c)}$, by 22/12/2015, unless otherwise specified in the Community legislation establishing the Protected Area, Member States must achieve compliance with relevant groundwater-related and surface water-related standards and objectives. This requirement concerns areas identified pursuant to Article 6 and Annex IV, designated for the conservation of habitats or species for which the maintenance or improvement of the status of water is an important factor in their protection.



Look out! Under the WFD, "Protected Areas" include areas designated for the abstraction of water intended for human consumption, recreational waters, nutrient-sensitive areas as well as areas for the protection of economically significant aquatic species and areas designated for the protection habitats or species where the maintenance or improvement of the status of water is an important factor in their protection (see Annex IV).

5.1 Ecological criteria for water dependency

Some of these Protected Areas will include wetland habitats and species directly depending on surface water or groundwater.
A crucial part of the development of the Protected Areas Register will therefore be the identification of those habitats and species within the Natura 2000 network which qualify under WFD criteria. The following discussion and criteria offer a starting point for considering how this process might be developed.

Natura habitats include specific surface water habitats, such as oligotrophic to mesotrophic standing waters with vegetation of the *Littorelletea uniflorae* and/or of the *Isoëto-Nanojuncetea,* and Natura species include those that live in surface waters, such as lampreys and Atlantic salmon.

Other Natura habitats and species may depend on saturated conditions, groundwater at or near the surface of the ground, or frequent flooding. Others may depend directly on aquatic processes (e.g. sand dunes reliant on the movement of sediment in adjacent coastal waters) or on increased humidity associated with nearby water (Table 8).

Table 8. Ecological criteria for identifying Natura Habitats and Species that are directly dependent on the status of water

Natura 2000 SPECIES	Natura 2000 HABITATS
1.a Aquatic species living in surface waters as defined in Article 2 of the WFD (e.g. bottle-nose dolphin, freshwater pearl mussel)	**2.a** Habitats which consist of surface water or occur entirely within surface water, as defined in Art. 2 of the WFD (e.g. oligotrophic waters; estuaries; eelgrass beds)
1.b Species with at least one aquatic life stage dependent on surface water (i.e. breeding; incubation, juvenile development; sexual maturation, feeding or roosting - including many Natura bird and invertebrate species)	**2.b** Habitats which depend on frequent inundation, or on the level of groundwater (e.g. alluvial alder wood, blanket bog, fens)
1.c Species that rely on the non-aquatic but water-dependent habitats relevant under 2.b and 2.c in the HABITATS column of this Table (e.g. Killarney fern)	**2.c** Non-aquatic habitats which depend on the influence of surface water - e.g. spray, humidity (bryophyte-rich gorges) should be considered

5.2 Identifying relevant standards and objectives

The WFD requires that any relevant standards and objectives for Protected Areas should be achieved by 2015, unless stated otherwise in the Community legislation under which the sites were designated. The single most significant standard for Natura 2000 sites is the achievement of Favourable Conservation Status for the designated features of interest. This will generally be expressed in biological terms and it is appropriate that this biological outcome remains the final measurement against which WFD obligations are judged. However, it is also widely acknowledged that for the purposes of the pressures and impacts analysis, and the establishment of a PoM, such standards and objectives will need, where practicable, to be understood in terms of relevant physico-chemical or hydro-morphological attributes.

A second, vital step in delivering WFD obligations towards Natura 2000 wetlands is therefore to determine the surface water and groundwater related needs of sites, to the extent required to decide if there is a significant risk of failing to achieve their water-related standards and objectives, and to ensure that measures are taken to address this. The water-related standards needed to meet the objectives for Natura Protected Areas may be more or less stringent than those required to achieve good surface water status, good groundwater status, other Protected Area objectives or other relevant objectives specified under paragraph 1 of Article 4 of the WFD. In accordance with WFD Article 4.2, the most stringent objective will apply.

RBMPs should also include any water management action required to meet the wider provisions of the Birds and Habitats Directives in relation to habitats outside the Natura 2000 network. Article 10 of the Habitats Directive states that:

> *'Member States shall endeavour, where they consider it necessary, in their land-use planning and development policies and, in particular, with a view to improving the ecological coherence of the Natura 2000 network, to encourage the management of features of the landscape which are of major importance for wild fauna and flora. Such features are those which, by virtue of their linear and continuous structure (such as rivers with their banks or the traditional systems for marking field boundaries) or their function as stepping stones (such as ponds or small woods), are essential for the migration, dispersal and genetic exchange of wild species.'*

Where Member States create compensatory habitat (including wetlands), as part of their action to implement the Birds or Habitats Directives, the water needs of such additional habitats will also need to be integrated into the river basin planning process.

5.3 Using GIS to assist with developing the Protected Areas Register

To assist in the river basin management planning process, the register of Protected Areas could be incorporated into a GIS layer, capable of performing complex tasks needed to enhance and support decision-making. Such an approach is being developed by the Danube Ecological Expert Group (DEEG).

6 WETLANDS AND THE IMPACTS AND PRESSURES ANALYSIS

The impacts and pressures analysis required by the WFD is a key part of the River Basin Planning Cycle. The WFD CIS Guidance Document No. 3 (IMPRESS) reviews the action Member States will need to take to identify water bodies at risk of failing their WFD objectives. This section of the Wetlands Guidance builds on the IMPRESS Guidance to establish the relevance of wetlands in assessing risks to the environmental objectives of the WFD.

6.1 Relevant Objectives in the Impacts and Pressures Analysis

The following objectives (Table 9), relevant to wetlands, will be considered during the impacts and pressures analysis:

Table 9. Objectives of the IMPRESS analysis
(Text in italics is based on the WFD CIS Guidance Document No. 3)

Prevent deterioration in the status of all bodies of surface water This will include preventing deterioration in the hydro-morphological condition of water bodies at high status (including the condition of any wetlands in the riparian, lakeshore or intertidal zones). Preventing deterioration in the hydro-morphological condition of water bodies at good status and below, in so far as it is necessary to support the achievement of the relevant standards for biological quality elements.
Prevent deterioration in the status of all bodies of ground water, including preventing significant damage to any terrestrial ecosystem (including wetlands) directly dependent on the groundwater body.
Protect, enhance and restore all bodies of surface water with the aim of achieving good ecological status by 2015. This will include protecting, enhancing or restoring the hydro-morphological conditions of water bodies to the extent necessary to support the achievement of the relevant standards for the biological quality elements The hydrological conditions include the structure and condition of the riparian, shore and intertidal zones. These zones may include wetlands.
Protect, enhance and restore all bodies of ground water including the reversal of significant damage to any terrestrial ecosystem (including wetlands) directly dependent on the groundwater bodies, by 2015.
Protect, enhance and restore all artificial and heavily modified bodies of surface water with the aim of achieving good ecological potential and good surface water chemical status by 2015. This will include protecting, enhancing or restoring the hydro-morphological conditions of artificial and heavily modified water bodies to the extent necessary to support the achievement of the relevant standards for the biological quality elements required at good ecological potential. The hydromorphological conditions include the structure and condition of the riparian, shore and intertidal zones. These zones may include wetlands. NOTE: WFD CIS Guidance Document No. 4 on HMWB states that Member States would not be expected to assess risks to the achievement of GEP in HMWBs before the end of 2004.
Compliance with the standards and objectives for Protected Areas by 2015 at the latest, including the objectives for areas designated for the abstraction of drinking water under Article 7. This will include standards and objectives for wetlands included within the Natura 2000 network, identified in order to implement the Habitats and Birds Directive; similarly consider regulations prescribed by the Drinking Water Directive (see Chapter 5).

6.2 Understanding relevant pressure-impact relationships

The IMPRESS Guidance (WFD CIS Guidance Document No. 3) points out that the achievement of the broad range of objectives established by the WFD will require an understanding of a greater number of impact/pressure relationships than has been required by previous European legislation, or is common practice in most Member States.

> *'The objectives include new ecological objectives, the achievement of which may be compromised by a very wide range of pressures, including point source discharges, diffuse source discharges, water abstractions, water flow regulation, morphological alterations and artificial recharge of groundwater. These and any other pressures that could affect the status of aquatic ecosystems must be considered in the analyses.'*

This is particularly relevant to understanding pressures on wetlands, and their relevance to WFD objectives. Whilst the IMPRESS Guidance (WFD CIS Guidance Document No. 3) recognises that the initial characterisation process (deadline 2004) may rely heavily on existing data, it also emphasises the need for Member States to ensure that this can be refined and supplemented during the river basin planning cycle(s) which follow. Less significant elements of surface waters such as small streams, canals and wetlands, often form networks which play a relevant role in sustaining catchment stability acting as pressure indicators; impacts on these may reveal existing pressures increasing catchment vulnerability.

Table 10 identifies some of the key driver/pressure/impact (DPI) relationships that may need to be better understood, to meet the objectives relevant to wetlands.

Table 10. DPI relationships and wetlands

Pressure	Impact	Information	WFD relevance
Drainage of floodplain wetlands.	Changes to physical extent, biological composition of water body. Changes to condition of the riparian zone and its vegetation. Changes to other hydro-morphological elements of the water body, including flow regime, depth, substrate. Changes to the physico-chemical and chemical quality of water reaching water bodies.	Understanding of the interaction between floodplain wetland condition and the physical, chemical and biological condition of the water body.	Objectives for surface water bodies.
Flood embankments resulting in reduction of floodplain.	Changes to physical extent, biological composition of water body. Changes to condition of the riparian zone and its vegetation. Changes to other hydro-morphological elements of the water body, including flow regime, depth, substrate. Changes to the physico-chemical and chemical quality of water reaching water bodies.	Understanding of the interaction between floodplain extent and connectivity and the physical, chemical and biological condition of the water body.	Objectives for surface water bodies.

Table 10 (continued). DPI relationships and wetlands

Pressure	Impact	Information	WFD relevance
Drainage or destruction of peatlands and other wetland systems in the wider catchment.	Changes to catchment hydrology affecting the quality and quantity of flow reaching downstream water bodies.	Understanding the interactions between wetlands in the wider catchment, hydrological regimes of water bodies, and the elements making up good status.	Objectives for surface water bodies.
Groundwater abstraction.	Reduction in water available to support wetland ecosystems.	Hydrological regime necessary to support relevant components of wetland ecosystems. Interactions between groundwater bodies and wetland hydrology	Preventing deterioration and achieving good status for groundwater bodies.
Groundwater pollution.	Deterioration of quality of water reaching dependent terrestrial ecosystems, including wetlands.	Water quality necessary to support relevant components of wetlands ecosystems. Interactions between groundwater and surface water quality.	Preventing deterioration and achieving good status for groundwater bodies.
Abstraction from surface water bodies.	Reduction in amount of water available to support the achievement of relevant conservation objectives for wetland sites in the Natura 2000 network.	Understanding of the water needs of Natura 2000 wetlands, including interactions with relevant water bodies.	Objectives for Protected Areas.
Pollution of surface water bodies.	Reduction in the quality of water available to support the achievement of relevant conservation objectives for wetland sites in the Natura 2000 network.	Understanding of the water quality needs of Natura 2000 wetlands, including interactions with relevant water bodies.	Objectives for Protected Areas.

6.3 Understanding the impact of future pressures

A key requirement of the impacts and pressures analysis will be to identify future activities in the river basin which may put at risk the achievement of WFD objectives (WFD CIS Guidance Document No. 3 - IMPRESS, Policy Summary):

> *'Accordingly, in assessing risks to the achievement of these objectives, the analyses of pressure and impacts must identify:*
>
> - *Existing pressures and impacts (identified in 2004) likely to be causing the status of water to be lower than good;*
> - *How pressures would be likely to develop prior to 2015, in ways that would cause a failure to achieve good status if appropriate programmes of measure were not designed and implemented.*

These observations also apply to any plan or project likely to cause deterioration in status, from the date at which the 'no deterioration' objective is deemed to apply.

This is particularly relevant when considering the possible impacts on water status of major hydro-morphological modification projects, for example to support agricultural production or the construction of transport infrastructure. Pressure-impact relationships between wetlands and water bodies will need to be investigated, as part of the assessment of such future pressures, if river basin planning is to secure the long-term ecological status of water. The relevance of this point to the protection of Europe's few remaining pristine or near pristine floodplain environments cannot be over stated.

6.4 Pressure screening and threshold values

In order to undertake the analysis of impacts and pressures in a cost effective manner, the IMPRESS Guidance (WFD CIS Guidance Document No. 3) recommends that screening criteria are used in relation to particular pressures. This will lead to the gradual 'narrowing' down of the analysis to those water bodies whose risk of failure is subject to greatest uncertainty, and where it is therefore appropriate to invest resources in investigating pressure-impact relationships.

Member States need to consider risks to the achievement of the Directive's objectives resulting from impacts on hydromorphological quality elements in undertaking the pressure and impacts analysis. This should include consideration risks of deterioration in the type-specific hydromorphological conditions of high status water bodies.

Member States may also find that data acts as a useful bench-mark, from which to develop threshold criteria for the assessment of water bodies likely to fail to achieve GES as a result of hydro-morphological modifications (this is proposed in links between the IMPRESS and HMWB Guidance Documents (WFD CIS Guidance Documents No. 3 and 4 respectively)). These threshold criteria will include a measure of acceptable deviation from reference condition for any wetlands included within the riparian, lakeshore and intertidal zones.

Wetlands outside of these zones will be under pressures that impact on the status of water bodies, broader threshold criteria for assessing such pressures will be needed to undertake a comprehensive impacts and pressures analysis. Wetlands functional evaluation is useful to highlight pressure on the river basin as illustrated in the case study below.

Case Study 8. Impact assessment through wetland functional evaluation: the Cheimaditida case

Functional evaluation, using appropriate physicochemical and biological indicators, may identify the degraded processes, the possible sources of degradation, and the functions that should be restored. The impact assessment through functional evaluation is taking into account the characteristics of the entire watershed, not just the degraded wetland. Activities throughout the watershed can have adverse effects on the aquatic resources. A single wetland management project may not be able to change conditions in the whole watershed. Several methods of functional evaluation have been developed, these are: (a) cost effective, in proportion to the value of information derived; (b) easily interpreted, provide unambiguous information and are easily understood; and (c) policy relevant, address key environmental issues. These methods are used to assess the impacts on wetland ecosystems and furthermore to evaluate proposed management solutions.

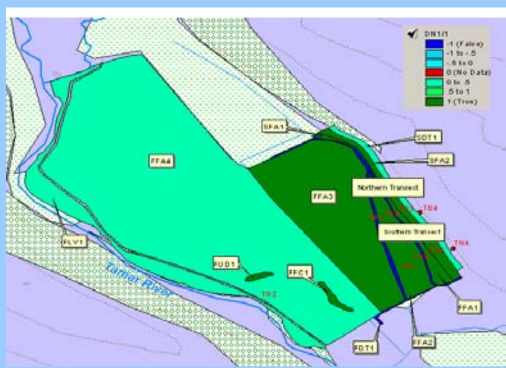
Lake Cheimaditida in Greece is a characteristic case where the functional evaluation at watershed level was used for impact assessment and development of a sustainable restoration plan. Ground water recharge and water storage were found degraded due to water abstraction for agricultural purposes. Although the wetland hosts several rare bird species, the functional evaluation revealed that the foodweb support function was not performed to the desirable degree and biodiversity problems were to arise in the near future if no measures were taken. The poor performance of the above mentioned functions resulted in: i) drop of groundwater levels; ii) shortage of irrigation water; iii) loss of wetland habitats; and iv) gradual decrease of biodiversity. These environmental problems had direct impacts on the local economy. Reduced crop production and deterioration of fisheries led to lower family income and higher social instability. In order to cope with the above-mentioned problems, wetland evaluation was used to set a sustainability reference levels for wetland restoration. Today a program for the restoration of the degraded wetland is under way.

Zalidis G., B. Takavakoglou, and Th. Lazaridou, is part of the work: Zalidis et al., 2001. Study and proposals for restoring the functions of Cheimaditida and Zazari wetaland. Aristotle University of Thessalonki, pages 231,Thessaloniki. (In Greek).

Assessment of wetland function can be performed by means of specific tools and spatial analysis such as the Wetland Evaluation Decision Support System illustrated in Case Study 9.

Case Study 9. A wetland evaluation tool: WEDSS

One of the key outputs of the EVALUWET project is the development of a Wetland Evaluation Decision Support System (WEDSS) (Mode *et al.*, 2002; www.rhbnc.ac.uk/rhier/evaluweb/index.shtml). In simple terms the WEDSS links a functional assessment knowledge base with methods of socio-economic valuation within a GIS environment. The knowledge base carries out assessments of hydrological, biogeochemical and ecological wetland functions using data which can be rapidly gathered in desk studies or field visits. The WEDSS is supported by a simple user interface with input data and outputs being displayed as GIS layers (see Figures below). Users will be able to access the WEDSS online so that they are not required to invest in expensive GIS software. The use of a GIS environment permits decision support at the various scales, from individual wetlands up to catchments. By integrating functional and valuation information within a single tool, decision makers can consider all of the relevant information within wetland management and can fully consider wetlands within integrated catchment management. In this way, the WEDSS will facilitate wetland management in the context of the WFD and support the implementation of other national, European and international policies such as the Habitats Directive, Birds Directive, Convention on Wetlands (Ramsar), Convention on Biodiversity (CBD) and Convention on Sustainable Development (CSD). The WEDSS will be tested in each of the seven study catchments, which represent a variety of wetland types and climatic regions. The WEDSS can be used for a variety of purposes, such as targeting sites for restoration or establishment of buffer zones, comparison of wetland sites and testing of management scenarios.



Figures: WEDSS input layer (left) showing wetland hydrogeomorphic units (HGMUs) to be assessed (blue areas) and output layer (right) showing degree of denitrification occurring in HGMUs (denitrification is an important process improving or maintaining water quality and has higher rates in darker areas).

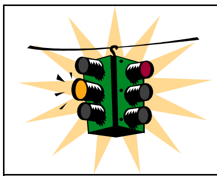
7 THE PROGRAMME OF MEASURES AND WETLANDS

Article 11 of the WFD requires Member States to establish a PoM in order to achieve the objectives stated under Article 4.

As part of the PoM, wetland creation, restoration and management, may prove a cost-effective and socially acceptable mechanism for helping to achieve the environmental objectives of the Directive [WFD Article 11.4; Annex VI, Part B(vii)].

Wetlands have the potential to offer benefits in terms of flood prevention, nutrient and pollutant load abatement, wildlife protection, tourism and recreation. This Section of the document examines the role which wetlands can play in the PoM, in helping to achieve the WFDs environmental objectives.



Look out! The greatest value of measures involving wetland enhancement (creation, restoration, management) is in the multi-purpose solutions they offer.

7.1 Basic and Supplementary Measures

Each programme of measures must include ‘basic’ measures, which are described in detail in Article 11.3, and, where necessary, ‘supplementary’ measures (see WFD Article 11. 2).

7.1.1 Wetlands and Basic Measures

Basic measures may include action directly to protect, enhance or restore wetlands, where:

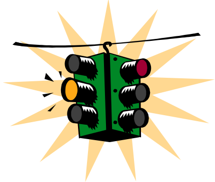
- the wetland is a terrestrial ecosystem that is directly dependent on groundwater (Article 1(a), and the achievement of good groundwater status requires measures to ensure that anthropogenic alterations to groundwater levels and chemical quality are not such as would result in significant damage to that wetland (Annex V.2.1.2 and 2.3.2);
- the wetland concerned is a river, lake, transitional or coastal water body (Article 4.1(a));
- the wetland is part of a hydromorphological quality element of a surface water body and requires protection, enhancement or restoration to ensure that the hydro-morphological conditions of the water body are consistent with the achievement of the relevant good status values for the biological quality elements (Annex V.1.2); and
- the wetland is a Natura 2000 Protected Area and depends, in part, for the achievement of its standards and objectives, on appropriate measures to protect, enhance or restore a surface water body or groundwater body in accordance with Article 4.1(c).

Some measures described in WFD Article 11 might gain benefit from wetland management such as those included under the combined approach principle illustrated in Article 10 (see Section 7.3).

7.1.2 Wetlands and Supplementary Measures

Supplementary measures are those designed and implemented in addition to the basic measures, with the aim of achieving the objectives of the WFD (see Article 11, paragraph 4). Part B of Annex VI of the WFD provides a non-exclusive list of such measures, including *the recreation and restoration of wetland areas*.

In some circumstances, wetland management may be a necessary measure to achieve the objectives of the WFD. In such cases, wetland restoration and recreation may be obligatory. In other circumstances, Member States may choose to use wetland management measures if they judge it would help ensure the most cost-effective approach, or otherwise most appropriate combination of measures. At their discretion, Member States may also choose to use supplementary measures to provide for any additional level of protection or improvement of surface waters or groundwater over and above that required by the WFD.



Look out! Supplementary measures are not always discretionary. Where the achievement of the objectives of the WFD can only be secured with the help of supplementary measures, Member States will be obliged to use them.

7.2 Wetlands and the Concept of Cost Effectiveness

The economic analysis required under Article 5 and Annex III is designed to help Member States make judgements about the most 'cost effective combinations of measures' to achieve the Directive's objectives. The analysis itself should contain enough information in sufficient detail (taking account of the costs of collecting information) to make considered judgements about cost-effectiveness, with a principal focus on basic measures. The comparison of the costs and benefits (including environmental costs and benefits) of measures involving the creation and restoration of wetlands with other options for achieving the WFDs Article 4 objectives may therefore form part of the assessment of cost effectiveness.

In many instances, the appropriate evaluation and costing of wetland management measures may reveal the great value of goods and benefits provided by wetlands. This is illustrated in many of the case studies included in this Chapter of the Guidance.

7.3 Using Wetlands in Programmes of Measures

This Section of the document describes the practical role of wetlands in managing pressures on the water environment. Where wetlands are relevant to the application of a particular basic measure (see Section 7.1 above), the section headings refer to the appropriate provisions of Article 11.3. Otherwise, section headings refer to the *functions* of wetlands, which may help in controlling significant pressures on the water environment (including pollution and the depletion of groundwater resources) and hence assist in the achievement of the WFDs environmental objectives outlined in Article 4.

Throughout, case studies are used to illustrate the role which wetlands can play in managing water status within the river basin.

7.3.1 Measures required to implement Community legislation

WFD Article 11.3(a) refers to measures required to implement Community Legislation for the protection of water, including those specified in Article 10, for instance the use of wetlands to improve water quality (see Section 7.3.4), and part A of Annex VI, which includes the Birds and the Habitats Directives relevant to wetland protection and wetland management.

7.3.2 The role of Wetlands in Cost recovery

WFD Article 11.3 (b) states that basic measures will include those:

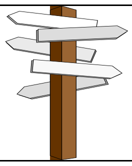
deemed appropriate for the purposes of Article 9

Article 9.1 requires Member States to take account of the principle of the recovery of the costs of water services, including environmental and resource costs, and to ensure, by 2010, that:

- Water pricing policies provide adequate incentives for users to use water resources efficiently;
- An adequate contribution of the different water uses to the recovery of the costs of water services.

Water services are defined in Article 2.38 as all services which provide for households, public institutions or any economic activities:

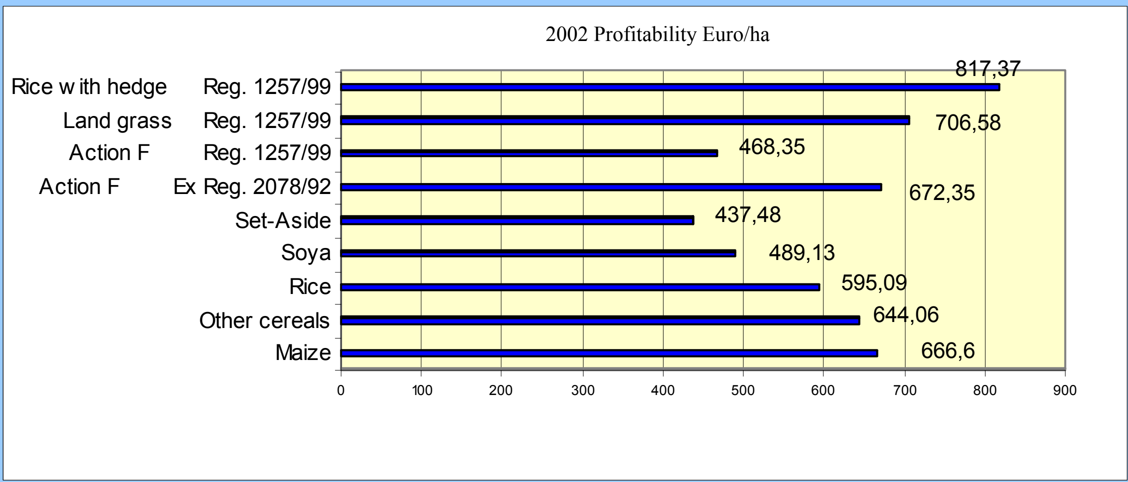
a) Abstraction, impoundment, storage, treatment and distribution of surface water or groundwater;
b) Waste water collection and treatment facilities which subsequently discharge into surface water.



Concerning methods on how to determine the environmental and resource costs readers should refer to the drafting group under WG 2B on Environmental Costs.

Case Study 10. The "wet farm" Cassinazza: interaction between agriculture and water policy

The Cassinazza estate covers approximately 400 ha within the Po floodplain, at the southern edge of the Milan district. Traditional farming patterns included rice, winter cereals, maize, soya beans and sunflowers. Since 1996 intensive production has given way to extensive land management systems aimed at revitalising the natural environment. Under the CAP (Common Agricultural Policy) agri-environment instruments: Regulation 2078/92, the recent Rural Development Regulation 1257/1999, and with the support from the Italian Ministry of Agriculture, a biodiversity enhancing agricultural landscape has been achieved over just 7 years. The farm consists of: marshland (50 ha), wet grassland (15 ha), meadow (100 ha) and woodland (70 ha). Agricultural fields are crossed by a network of streams and 75 km of hedgerows with shrubs and trees planted in double or triple rows. A large pond (11 ha) stores more than 200.000 m^3. Agricultural infrastructures for rice production (dams, bridges, roads) have been restored for agriculture and alternative use. Fifty-nine ha are under traditional farming, while 38 ha developed into "integrated farming". The Figure below illustrates gross margins related to commodities and agri-environment provisions in 2002.



Significant returns are achieved through the sale of small quantities of hay and rice supported through Regulation 1257/99. In comparison to traditional intensive rice cultivation, the Cassinazza rice paddies are smaller in size and contained within hedgerows thus reducing agro-environmental impacts. Under the perspective of direct economic returns extensive rice production revealed to be overall more profitable than intensive farming and than solutions aiming at reducing diffuse pollution supported through 'set-aside' incentives or new Action F.

In November 2002 part of the wet farm was used as a flood prevention basin to collect the stormwater and reduce risk of flooding at a nearby village. Estimated potential storm damages greatly overcome the public funds invested in wetland management at the farm.

CAP agri-environment measures have potential to be much more progressive towards the protection and improvement of water quality and landscape. On the basis of those principles a project called Energy Agriculture and Environment is funded by the Lumbardy Administration to develop an "assembly line", sited at Cassinazza, including wetland recreation from rice fields, cultivation and energy production from biomass. The project wants to overcome typical farmers attitudes whereby "tidiness" equals efficiency, while uncropped areas are seen as wastelands.

The nature of environmental and resource costs, and methods to include them in economic analysis, are highlighted in the WFD CIS Guidance Document No. 1 (WATECO), and discussed in detail in its Annex IV.I, 'Estimating Costs (and Benefits)[4]'.

Where wetland management forms part of a programme of measures, or wetlands are impacted by programmes of measures, relevant environmental and resource costs relating to their functions and values may need to be included in the economic analysis proposed under the WFD.

7.3.3 Managing hydro-morphological impacts

Case Study 11. Heritage value of UK wetlands

The archaeological resource of England's wetlands alone is estimated at 13,400 monuments, of which 11,600 can be found in lowland wetlands (Van der Noort *et al*., 2001). The value of wetlands to England's inhabitants, as far back as the Mesolithic Age, is demonstrated by the large numbers of ritual deposits and monuments they contain (e.g. Roos Carr, Seahenge, Flag Fen, Fiskerton). The anaerobic wetland environment preserves evidence of human activity that is normally lost, particularly the organic remains of buildings and artefacts. Wetlands also preserve long palaeo-environmental sequences. These are the year-by-year accumulations of plants and micro-fauna which tell us how past environments were affected by human influences and climatic change. This rich archaeological storehouse is highly vulnerable, both to habitat destruction and drainage. Even seasonal drying can cause the rapid decay of organic evidence. It is difficult to give statutory protection to archaeological sites in wetlands, because they are hard to locate without disturbing the very environment that preserves them.

Wetlands are a vital component of the evolution of our cultural and historical landscape. This principle has been advocated by the Assynt Crofters Trust's objection to the establishment of forestry on their hard-won in-bye land. In restoring wetland ecosystems, this inheritance should be acknowledged as part of the history of the intimate connections between people, the water cycle and the wetland environment.

The cultural value of wetlands is more than historical. People who live and work around wetlands today celebrate them in the arts, drama, literature, poetry, and folklore, and use them as a valuable educational tool. The recent "Confluence" project, organised by Common Ground for the River Stour in Dorset, promoted the awareness of the importance of rivers and wetlands to the everyday lives of thousands of residents in the Stour catchment from Stourhead to Poole Harbour.

WFD Article 11.3(i) requires controls over any other significant adverse impacts on the status of water bodies not covered by Articles 11.3(a) to (h). In particular, it requires measures to ensure that the hydro-morphological conditions of water bodies are consistent with the required ecological status objectives. Mechanisms for controlling pressures on wetlands within the riparian, lakeshore and inter-tidal zones may be a basic measure where alterations to such wetlands cause a significant adverse impact on the status of water.

The relationship between wetland ecosystems, hydro-morphology (including the condition of the riparian, lake and inter-tidal zones) and ecological status is described in Section 3.2.3.

In order to determine an appropriate controls regime to comply with Article 11.3(i), Member States will need to consider the major pressures on hydro-morphology which may create a risk failing to meet the environmental objectives of the WFD. Assistance in this process is provided in the

[4] Note: WATECO Annexes were not adopted by the Water Directors.

IMPRESS Guidance (WFD CIS Guidance Document No. 3). The following check-list of hydro-morphological pressures is provided in Chapter 4 of the cited Guidance Document. Many of the pressures identified could affect the structure and condition of the riparian shore or inter-tidal zones of water bodies, and that of the wetlands those zones contain.

Table 11. Indicative lists of hydro-morphological pressures relevant to the application of Article 11. 3$_{(i)}$

Flow regulation hydroelectric dams	Fisheries enhancement
Water supply reservoirs	Land infrastructure (road/bridge construction)
Flood defence dams	Dredging
Diversions	Estuarine/coastal dredging due to transitional and coastal management
Weirs	Marine constructions, shipyards and harbours
Physical alteration of channel due to river management	Land reclamation and polders
Engineering activities	Coastal sand suppletion (safety)
Agricultural enhancement	Other morphological barriers

This list of potentially significant pressures includes traditional ‘hard’ engineering solutions to flooding and drought problems (such as the canalisation of rivers, and the construction of walls, culverts and reservoirs), which may have significant impacts on the hydro-morphology of water bodies. They may also prove unsustainable in the long-term on the scale necessary to support people, property and the environment in the context of increased population growth and accelerating climate change. The role which wetland creation can play in offering alternatives to such ‘hard’ solutions is increasingly recognised, and is illustrated in the case studies 12 to 14 below.

Case Study 12. Wetlands for flood mitigation: the Lafnitz River, Austria

The Lafnitz is one of the few remaining natural lowland rivers in Austria. Since the mid 1980s about 220 ha of agricultural land have been purchased and managed more extensively. Another 610 ha have been taken out of intensive agricultural production through compensation payments to landowners. The area is used for natural flood storage. The original plan was to build dams along the river, but this would have caused a higher flood risk for the villages further downstream and it would have been more expensive.

Extensive agricultural management on land surfaces prone to flooding is part of risk avoidance strategies practiced by floodplain peoples since ancient times. Such “soft” solutions are being revived by integrating high quality agricultural products grown under an extensive fashion with integrated river basin management and hold the promise of contributing to a more sustainable future cultural landscape.

The recent update of the UN/ECE *Guidelines on Sustainable Flood Prevention* (*2000*) presented at the Water Directors meeting in Athens, June 2003, provides numerous best practices on flood prevention, protection and mitigation. Non-structural measures such as the storage effect of vegetation, soil, ground and wetlands are vital to mitigate effects of medium scale floods and beneficial in reducing sediment yield. The conservation, protection and restoration of degraded wetlands and floodplains, including river meanders, oxbows, and especially reconnecting rivers with their floodplains is a main preventive non-structural measure.

Case Study 13. Enhancing the effectiveness of coastal flood defence through inter-tidal habitat creation

The Environment Agency of England and Wales assessed the economic impacts of inter-tidal habitat creation in relation to coastal flood defences. 'Managed re-alignment' is the term used to describe the deliberate breaching of current sea defences to allow flooding to a new line, landward of the present structures. The newly created salt marsh or inter-tidal flats can act as a 'buffer' between the sea and the land during high tides and storm floods, dissipating wave energy and allowing the coast to respond more naturally to changes in sea-level.

The economic advantages of managed re-alignment are significant. Re-alignment to rising ground will usually result in a lower and/or shorter length of flood defence, and therefore reduced maintenance costs. In addition, there may be longer-term savings where a natural defence is provided by the newly created area of inter-tidal land. The Environment Agency estimate that where there is an 80 metre width of saltmarsh fronting a flood defence, maintenance costs would be reduced in the order of £3,000 (4,700 euro approximately) per kilometre. This is due to the buffering effects of the inter-tidal habitat in attenuating wave action.
Seas of Change, A report by the RSPB, January 2002. www.rspb.org.uk

Consideration of how wetlands can be used to manage floods and droughts in a manner compatible with WFD objectives could greatly assist Member States with implementation, and in integrating flood management strategies with RBMPs. It is highly likely that a mixed range of flood management options will be part of sustainable flood management in the future.

Case Study 14. Retention zones in Twente, Netherlands

The Twente rural estates located in the basins of the rivers Regge and Dinkel, drain into the Overijsselse Vecht, a transnational river (Germany and the Netherlands) have high cultural historical and natural value. Urbanisation and river channelization have accelerated the discharge of the water. During heavy precipitation, rising water levels, cause flooding in nearby cities; conversely in summer the farmland tends to suffer from drought. A current restoration project aims to store water during periods of heavy precipitation, restore the streams network, control drought, develop natural landscape features, and restore rural estates to their historical condition.

7.3.4 Wetlands and Pollution Control

Achieving the environmental objectives of the WFD will require Member States to take action to control significant impacts of both point source and diffuse pollution pressures on water bodies (Article 10).

It has long been recognised that wetland vegetation and soil processes can play an important role in cycling nutrients, retaining pollutants and trapping suspended solids that 'carry' pollutants into aquatic environments. The reductions in clean-up costs, along with the added biodiversity and leisure benefits accruing from wetland creation, should be considered when assessing the financial viability of options for water treatment in case of both point and non-point source pollution. When considering this function of wetlands, it is also important to safeguard the wildlife and cultural value of existing sites, which might be compromised if these wetlands were treated as nutrient sinks. 'Created' wetlands (constructed wetlands), on the other hand, may provide greater opportunities for nutrient cycling, with areas of increasing nature conservation value potentially 'zoned' around the areas carrying the greatest pollutant loads.

The potential role of wetlands in respect to water supply and pollution management is highlighted in the *Common Text on Wetlands* agreed by the Water Directors in November 2002 and in the 1995 Commission Communication on the *Wise Use and Conservation of Wetlands* to the European Council and Parliament.

The case studies given in this document illustrate the important contribution offered by wetlands in reducing the technical and financial burden of pollutants removal (in particular nutrients).

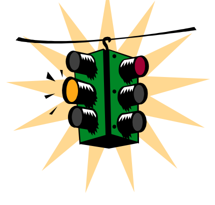
Case Study 15. Nutrient retention value of the lower Morava River

The Morava River is one of the main tributaries of the Danube, extending for some 328 km. Its lower reaches pass through Austrian (right bank) and Slovak (left bank) territory. Of the original 160 km^2 of floodplain on the Slovak side, only about 25% remains, with much of this being under arable agriculture. GIS analysis of historical maps showed that the area of arable land in the functional floodplain had doubled between 1920 and 1999, leading to a corresponding 50% reduction in semi-natural meadows with declines in flora and fauna and in the floodplain nutrient abatement value.

Traditional meadow management in the lower Morava floodplains had an indicative nitrogen retention value of 434 t per year. The monetary value of this natural nutrient removal is equivalent to the operating cost of a wastewater treatment plant for a city of 216,000 citizens – approximately 700,000 Euro per year. Moreover, the initial cost of building such a treatment plant would be around 7 million Euro. These results provided a powerful economic argument in favour of restoring 140 ha of former arable land into meadow. The overall economic investment required in floodplain restoration is far below that for conventional water treatment.

Ongoing restoration of the Morava meadows is enhancing the status of several habitats and species which have declined across Europe, it is improving flood storage through the re-establishment of a more natural flood regime and it fosters tourism/recreation opportunities. Farmers producing hay from the Morava meadows find a ready market across the border in Austria, where the demand for organic products is not currently satisfied by domestic production.

Šeffer, J. and Stanova, V., 1999, Morava River Floodplain Meadows: importance, restoration and management. DAPHNE – Centre for Applied Ecology, Bratislava



Look out! It is recommended that wetlands should be protected from pollution in order to maintain their value. The discharge of anthropogenic wastewaters has to be prevented to maintain the appropriate quality status of wetlands and connected aquatic ecosystems. Such areas should not be compromised by the imposition of an inappropriate pollution control function.

Case Study 16. Le Meleghine, a reconstructed wetland for pollution control

Natural wetlands receive and transform, through biogeochemical processes, large fluxes of water carrying concentrated loads of dissolved and suspended pollutants. In many instances the most efficient way to improve pollution abatement consists of measures aiming at restoring the natural self-purification capacity of the rivers.

Situated in the lower Po valley, near the city of Modena, Le Meleghine consists of 36 ha of shallow ponds and vegetated marshland. The reconstructed wetland, functional since 1994, receives water from the Canalazzo main artificial drainage channel characterised by an average flow of 0,37 m^3/s, draining 8,380 ha of intensively cultivated farmland. The main artificial pond extends over 18 ha with an average depth below 1m.

Before extensive drainage, the area used to host vast marshlands accumulating hydromorphic clayey soils. Today the surrounding farmland has low agricultural potential and can be easily converted into a reconstructed wetland due to a natural impermeable substrate consisting of a 4 m thick layer of impermeable clay deposits which separate surface waters from the underlying shallow sandy alluvial aquifer connected to the Po River system. Spontaneous vegetation includes associations dominated mainly by *Phragmites communis*, species of *Typha, Carex, Scirpus* and alluvial forest. Bird counts totalled 138 including 30 species nesting within the reconstructed wetland.

Ideal conditions for nutrient load abatement are provided by modulating water residence time (nominal maximum residence time is about two weeks) and expanding the vegetated surface. Overall nutrient retention was shown to vary significantly along with changes in hydrological and climatic conditions; nonetheless the wetland demonstrated a distinct capacity to control peaks in nutrient loading due to strong concentration variability at the inlet.

Intensive monitoring programmes show that the wetland is very efficient in reducing nutrient fluxes especially through nitrification and denitrification, as shown in the table below.

	Load abatement
Ammonia	75%
Dissolved Inorganic Nitrogen	64%
Total Phosphorus	63%
Dissolved Phosphorus	94%
Chemical Oxygen Demand	40%
Total Suspended Solids	63%

This reconstructed wetland is the only effective instrument that could have been deployed to control diffuse pollution produced by farming, treated and untreated industrial discharges (including food processing activities) and effluents produced by sewage treatment plants discharging into Canalazzo which drains into the Po River and then further into the highly euthrophic north Adriatic Sea (sensitive area according to Directive 91/271/EEC).

7.3.5 Using wetlands to enhance groundwater recharge.

The achievement of good groundwater status includes requirements to protect and restore the quantitative status of aquifers, in some cases this may be facilitated through the protection and restoration of wetlands.

Case Study 17. Drinking Water from the Danube National Park

The water quality in 45 km stretch of the Danube riverine fringe is high and can provide 250,000 people with clean drinking water. If this area were dammed for hydropower (as was and is suggested), the cost of compensating for the loss in water quality could amount to 6.3 million Euro per year.

(Technical University Vienna 1995)

The winter storage capacity of wetlands can contribute to aquifer recharge. Wetlands retain more water than, for instance, arable land, which is often drained as quickly as possible to aid crop growth. Water from the wetland is thus able to re-infiltrate the aquifer over a longer period, achieving greater re-charge than would be likely where land-drainage and soil conditions direct water rapidly and in greater quantity into main river systems. Infiltration of this kind takes place via infiltration areas in most direct connection to the underlying aquifer, such as ditches, trenches, ponds and lagoons. In this way, wetland creation on flood plains could contribute to improving the quantitative status of alluvial aquifers, as well as alleviating the impacts of flood peaks in winter. It is also possible that small-scale wetland creation in chalk uplands could create a more amenable environment for percolation, and hence aquifer recharge. Further benefits could accrue where more surface water was available in wetlands adjacent to arable land, limiting the agricultural demand for groundwater.

Case Study 18. Wetlands providing drinking water for the Netherlands

As from the 1960s, when most of the rivers in the Netherlands progressively became too polluted to provide sources of drinking water at an acceptable cost; the Dutch government started looking into natural water purification strategies by letting streamwater percolate through sand dunes. The main processes include mechanical filtration through the sand and bacterial remediation within the aquifer. In this way natural landscape features significantly contribute in reducing the technological and financial burden involved in drinking water preparation. Drinking water for the city of The Hague is still pretreated using sand dune infiltration; the same used to occur for the drinking water for Amsterdam until year 2000 when large reservoirs were built.

In some parts of the country such as the South of the Holland Province, there are no sand dunes suitable for water purification. Here the main source is the river Meuse (Maas); a river characterized by an erratic discharge with low summer minima. The natural morphology of the Meuse estuary region was definitely changed by the building of the large Haringvliet dam constructed in 1970 as part of the Delta Plan. A large freshwater basin interrupted the gradual succession between inland freshwater and coastal saline habitats, significantly affecting the estuarine flora and fauna. The project contributed to extend the accessibility of land and water to human uses.

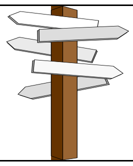
Further inland from Haringvliet, water managers decided to store water to supply the city of Dordrecht and further reclaim land for agriculture. The Biesbosch district, once upon a time a wild shallow coastal zone characterized by estuarine islands, was chosen for the siting of three shallow reservoirs covering an area of 673 ha. Flowing from one reservoir to next, the river water reduces its suspended and dissolved load, reaching values, in the last reservoir, that are close to water fit for human consumption. Today the Biesbosch is a National Park extending over some 7100 ha which forms a very popular recreation resort and artificial aquatic habitats providing a precious resource for wildlife. The reservoirs supply an abundant and high quality source of drinking water.

As part of the Rhine "vision", a look ahead at the condition of the river in a generation's time, the Dutch government is undertaking a series of collaborative projects involving a large number of public organizations. New plans aim at recreating a brackish water zone between the estuary of the Rivers Rhine and Meuse and the North Sea partially restoring a tidal environment in the former sea inlet and in the Biesbosch tidal area which lies behind it. By ultimately opening a third of the Haringvliet sluices permanently, plants and animals that live in fresh and brackish water tidal environments will be able to flourish again and migratory fish such as salmon will be able to swim unhindered from the sea to their spawning areas along the rivers.

Plans are underway in the Netherlands to give the river more space, primarily in the existing and restored winter beds. These recreated wetlands are an opportunity for the development of flood retention areas, water purification schemes, nature conservation areas and other functions provided by natural and restored wetlands.

8 MONITORING AND WETLANDS

Article 8 of the WFD requires the establishment of monitoring programmes (in accordance with Article V) in order to progressively reach a comprehensive overview of water status within each river basin district. The WFD calls for the monitoring of surface water, groundwater and Protected Areas.



CIS WG 2.7 have produced a comprehensive Guidance on Monitoring (WFD CIS Guidance Document No. 7) to which readers are advised to refer to

Section 2.6 of the Monitoring Guidance (WFD CIS Guidance Document No. 7), mentions the relevance of wetlands for the achievement of the Directives environmental objectives but does not focus on wetland monitoring specifically

On the basis of characterisation and impact assessment, Member States are required to set up surveillance and operational monitoring programmes and eventually conduct investigative monitoring activities. Definitions are summarized in Table 12 below, and further details are described in the Monitoring Guidance (WFD Guidance Document No. 7).

Table 12. Definitions of surface water monitoring according to Annex V.

Monitoring	Reference	Objective	Relevance
Surveillance	Annex V, 1.3.1	Provide information for: - supplementing and validating the impact assessment procedure (Annex II); - the efficient and effective design of future monitoring programmes; - the assessment of long-term changes in natural conditions; - the assessment of long-term changes resulting from widespread anthropogenic activity.	Water bodies, at risk and not at risk, of failing the objectives.
Operational	Annex V, 1.3.2	Undertaken to: - establish the status of those water bodies identified as being at risk of failing to meet their environmental objectives; - assess any changes in the status of such bodies from the programmes of measures.	Water bodies identified as being at risk of failing the environmental objectives under Article 4, for those bodies of water into which priority list substances are discharged and bodies at risk of significant hydro-morphological pressure.
Investigative	Annex V, 1.3.3	Required to be carried out: - where the reason for any excedences is unknown; - where surveillance monitoring indicates that the objectives set under Article 4 for a body of water are not likely to be achieved and operational monitoring has not already been established, in order to ascertain the causes of a water body or water bodies failing to achieve the environmental objectives; - to ascertain the magnitude and impacts of accidental pollution.	Case by case.

For surface waters, the results of well designed surveillance, operational and investigative monitoring programmes should help improve understanding of the relationship between the hydro-morphological quality elements (including the structure and condition of the riparian, shore and intertidal zones) and the condition of the biological quality elements. This will enable increased confidence in the results of future pressures and impacts analyses, and improvements to the design of programmes of measures.

The scope of the monitoring programmes applies to wetlands which are designated as water bodies or form part of them (see Section 2.3), as well as for those included in the Register of Protected Areas. Monitoring requirements concerning Protected Areas (*sensu* Annex IV) are to be carried out according to the requirements set by the specific legislation establishing each area.

Wetlands which are river, lake, transitional or coastal water bodies or form part of them (see Section 2.3), as well as for those identified as Protected Areas (see Chapter 5) fall within the scope of the Directive's monitoring programmes. Monitoring requirements concerning Protected Areas (*sensu* Annex IV) are to be carried out according to the requirements set by the specific legislation establishing each area. The amount of monitoring in relation to surface water bodies that is necessary will depend on the information needed to assess risks to, design measures for, and monitor the achievement of, the WFDs environmental objectives.

The monitoring of other wetlands is not required as part of the surface water monitoring programmes. However, in case of uncertainty about water body ecological status, the assessment of the ecological health and functioning of dependent wetlands may be useful in helping to evaluate the likelihood of failing to meet the WFDs objectives.

8.1 Monitoring groundwater bodies and dependent ecosystems

In order to assess groundwater status, information will be required about groundwater levels and quality needed to prevent significant damage to terrestrial ecosystems directly dependent on groundwater (Annex V.2). Once these water needs have been defined, monitoring results for groundwater levels and quality can be used to determine whether the needs of the ecosystems are being met. In many cases an investigation of the typical water requirements of different wetland types and critical species, which are not as yet clearly understood, may be needed. This will mean monitoring wetland habitats and species directly to determine their response to groundwater levels and quality variations, where suitable information to make such estimates is not already available.

Defining the groundwater needs of directly dependent terrestrial ecosystems is likely to require an initial assessment of the typical water requirements of different wetland types and critical species. In many cases, these needs are not yet fully understood. The lack of understanding means that, where a risk has been identified, a direct assessment of the condition of a terrestrial ecosystem may be required to help design appropriate measures for controlling alterations to groundwater quality and levels, and to confirm whether these measures are being effective in avoiding or remedying significant damage to the terrestrial ecosystem (see Figure 8).

Investigations of specific water requirements of individual wetlands are strongly recommended where a body of groundwater is at risk of failing its objectives because of impacts on the water needs of these ecosystems. For example, agricultural drainage disrupting surface water supply to wetlands may significantly reduce recharge in the near groundwater preventing the groundwater body from reaching its environmental objectives. This obligation depends on the potential risk of water needs not being met.

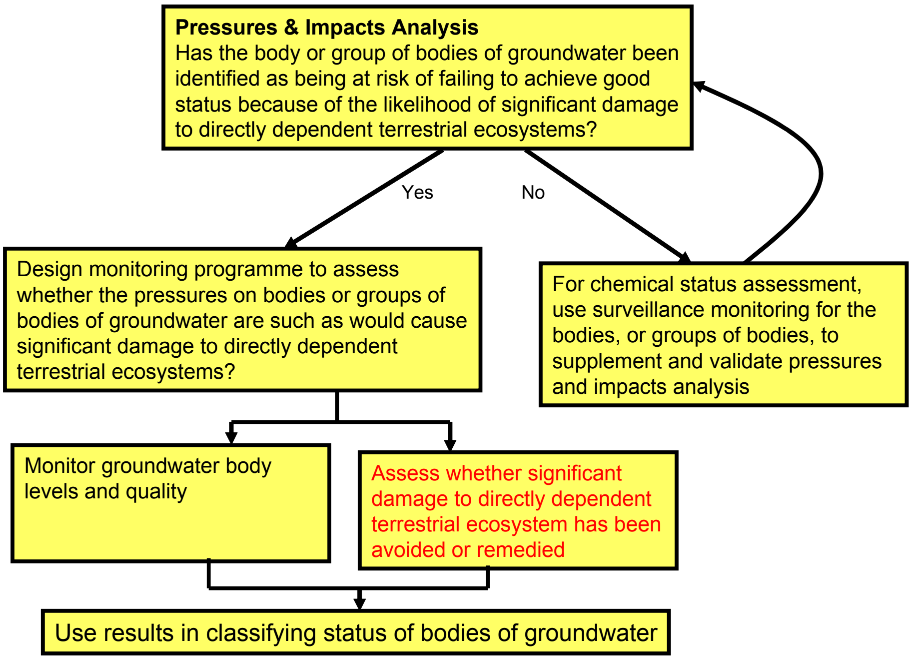


Figure 8: General principles for the design of a monitoring programme and for the assessment of status in relation to the interaction of groundwater and directly dependent terrestrial ecosystems

In the Technical Report on Statistical Aspects of the Identification of Groundwater, Pollution Trends, and Aggregation of Monitoring Results (WFD CIS Technical Report No.1), Annex 2 (Section 6.3) the following elements are listed as essential factors to be considered in the interpretation of groundwater quality data, for the characterisation of groundwater bodies or groups of groundwater bodies (as requested in WFD Annex II):

- Depth to groundwater;
- Annual groundwater level amplitude;
- Hydraulic conductivity;
- Recharge situation;

These indicators are relevant to wetland function and are likely to reveal impacts on wetlands.

Collection of information is required under Annex II of the Directive during the initial characterization and impact assessment phases for the establishment of reference conditions for surface water body types and to describe hydro-morphological quality elements for sites (including riparian, lake and inter-tidal zones) at HES and MEP (Reference Sites). Obtaining information about wetlands may be warranted to improve the understanding of catchment system functions which is a prerequisite for a successful impact and pressures study as highlighted by Section 3.3.2 of the IMPRESS Guidance (WFD CIS Guidance Document No. 3). Targeted monitoring of specific wetland characteristics and ecological processes (nutrients uptake, floodwater retention etc) within reasonable cost, is considered good practice especially in cases when links are not clear and when wetlands protection and restoration is carried out as a supplementary measure.

For water bodies at GES or GEP and below, the WFD will require information about hydro-morphology, where a water body is at risk of failing its biological objectives because of impacts on these quality elements.

Although not specifically requested by the WFD, an investigation of hydrological connectivity, may be useful and could be carried out at the discretion of Member States. Case study 7 in Section 3.4 illustrates this point. In case of evident potential damage to dependent ecosystems or to the degree of connection between these and water bodies, detailed targeted investigations are advisable. The effort required in any assessment should be proportionate to the difficulty in understanding and managing the risks to the WFDs objectives.

9 CONCLUSIONS

Wetlands play a role in the achievement of the environmental objectives of the WFD and help in the fulfilment of the programme of measures and in its adjustment to regional and local conditions.

This Guidance Document introduces recommendations clarifying the role of wetlands in the river basin management process. Case studies provide an illustration of the circumstances under which Member States may choose to use wetland management measures to ensure the most environmental and cost-effective approach.

Some issues could benefit from further development and some topics should be revisited in future activities (e.g. through the Pilot River Basin Testing Exercise). Consideration to be given to:

- Defining more in detail how to include wetlands in the programme of measures when preparing the programme of measures themselves;
- Recognizing the diversity of wetlands in the EU and therefore understanding the different ways in which wetlands restoration may contribute to RBM;
- Setting indicators for assessing the progress achieved regarding wetland restoration as part of the river basin management plan;
- Defining indicators and monitoring methods to establish a relationship between wetland health and groundwater quality and quantity status;
- Identifying wetlands within protected areas;
- Elucidating the contribution of wetlands to the environmental cost recovery; and,
- Investigating links concerning reporting and monitoring for wetland management under both the WFD and the Ramsar Convention.

Finally, it is important to consider that the outcome of the Wetlands Guidance Document testing within the Pilot River Basin Exercise could provide precious practical advice on the role of wetlands in river basin planning.

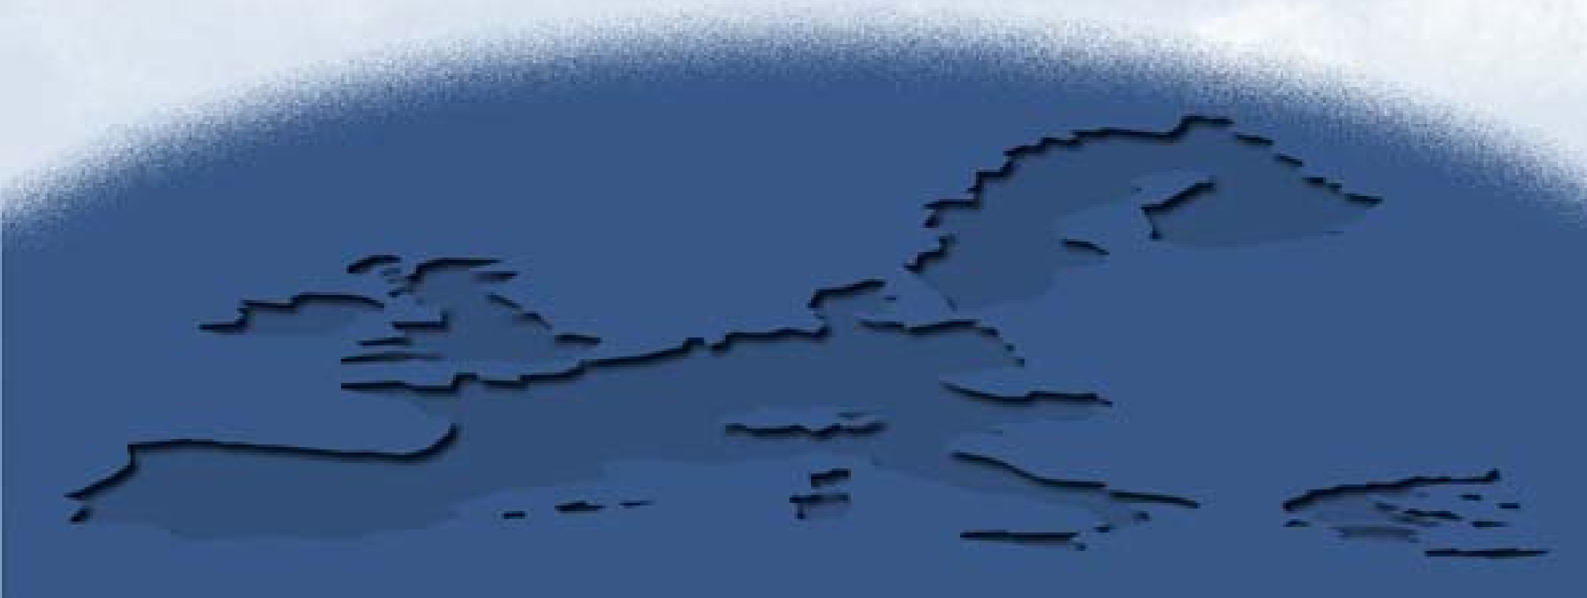
Common Implementation Strategy for the Water Framework Directive (2000/60/EC)

Guidance document n.° 13

Overall approach to the classification of ecological status and ecological potential



COMMON IMPLEMENTATION STRATEGY
FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No 13

Overall Approach to the Classification of Ecological Status and Ecological Potential

Produced by Working Group 2A

ISBN 92-894-6968-4
ISSN 1725-1087

FOREWORD

The Water Directors of the European Union (EU), Acceding Countries, Candidate Countries and EFTA Countries have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC, "establishing a framework for Community action in the field of water policy" (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of the Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

One of the main short-term objectives of the strategy is the development of non-legally binding and practical guidance documents on various technical issues of the Directive. These guidance documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, an informal working group dedicated to the ecological status of surface water bodies within implementation of the Water Framework Directive was set up in November 2002 and named ECOSTAT WG 2.A. Within the current work of the ECOSTAT WG, the United Kingdom and Germany have the responsibility of the secretariat and co-ordination of the activity on the development of guidance on ecological classification which has been developed with the assistance of a drafting group.

The present guidance document contains the output of two drafting group meetings and two meetings of the WG 2.A held in 2003. It summarizes the overall ecological classification rules provided by REFCOND, COAST, HMWB and Monitoring guidance documents (WFD CIS Guidance Document Nos 10, 5, 4 and 7, respectively). Further, this new guidance focuses on certain specific technical issues which had not been resolved in the previous guidance documents, in particular the role of physico-chemical parameters in the ecological status classification.

The development of ecological assessment and classification systems is one of the most important and technically challenging parts of the implementation of the Water Framework Directive. It is the first time such systems have been required under Community legislation and all Member States are in a position of needing to significantly expand their technical knowledge and experience. Consequently, the development and improvement of appropriate systems will involve a learning process. The guidance document provides a starting point for this learning process. It sets out some key principles and ideas on practical approaches. It is hoped these will help Member States build on their existing expertise to develop practical and reliable systems for assessment and classification that satisfy the requirements of the Water Framework Directive.

Much of the guidance document is based on Member States' existing national experiences of assessing and classifying surface waters or on the interim outcomes of some of the development work currently underway. As implementation progresses and Member States begin to monitor and assess the ecological status of water bodies, the richness of Member States' practical experiences with ecological classification in relation to all surface water categories will increase. New ways of dealing with some of the technical challenges, such as controlling the risk of misclassification, may be identified. The sharing of this growing body of experience among Member States will benefit all and should be encouraged.

"We, the Water Directors have examined and endorsed this guidance during our informal meeting under the Italian Presidency in Rome (24/25 November 2003). We would like to thank the participants of the Working Group and, in particular, the leaders, Germany and United Kingdom, for preparing this high quality document.

We strongly believe that this and other guidance documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive. It facilitates the common understanding of ecological classification under the Directive and provides useful tools, in particular as regards the use of physico-chemical parameters in the classification process.

Because of the potentially significant economic consequences of misclassification, this guidance and on-going exchanges of experiences on the assessment and classification of ecological status is important. Therefore, this guidance document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work."

Table of Contents

1. Introduction

1.1 The purpose of this document is to provide general guidance on the assessment of ecological status and potential leading to the overall ecological classification of water bodies for the purposes of the Water Framework Directive (WFD) (see Section 2). The document also provides specific guidance on the role of the general physico-chemical quality elements in ecological classification (see Sections 3 and 4). The guidance document draws on the existing guidance documents REFCOND; COAST; MONITORING and HMWB&AWB (WFD CIS Guidance Document No's 10, 5, 7 and 4, respectively).

1.2 The Directive requires the establishment of classification schemes to reflect the ecological status or potential of surface water bodies as measured by the condition of specific biological, hydromorphological and chemical and physico-chemical quality elements. The relevant elements, and the specific conditions required for these elements in each of the classes of the classification schemes, depend partly on the surface water category and type to which the water body belongs, and on whether the body is artificial or heavily modified.

1.3 Annex II 1.3 of the WFD requires Member States to achieve adequate confidence and precision in classification, and to give estimates of the level of confidence and precision achieved in the River Basin Management Plans. Guidance on getting better conclusions from monitoring data is provided in Annex I of this document.

2. The Ecological Status and Ecological Potential in the Water Framework Directive

2.1 For surface waters the overall aim of the WFD is for Member States to achieve “good ecological status” and “good surface water chemical status” in all bodies of surface water by 2015. Some water bodies may not achieve this objective for different reasons. For example, under certain conditions the WFD permits Member States to identify and designate artificial water bodies (AWB) and heavily modified water bodies (HMWB) in accordance with Article 4(3). Instead of "good ecological status", the principal environmental objective for HMWBs and for AWBs is “good ecological potential” (GEP) and “good surface water chemical status”, which has to be achieved by 2015.

Article 2(17):
”Surface water status” is the general expression of the status of a body of surface water, determined by the poorer of the ecological status and the chemical status.

Article 2(21):
”Ecological status” is an expression of the quality of the structure and functioning of aquatic ecosystems associated with surface waters, classified in accordance with Annex V.

Article 2(23):
”Good ecological potential” is the status of a heavily modified or an artificial body of water, so classified in accordance with the relevant provisions of Annex V.

2.2 The WFD requires surface water classification through the assessment of ecological status or ecological potential, and surface water chemical status. WFD **Annex V, Table 1.1**, explicitly defines the quality elements that must be used for the assessment of ecological status/potential (see Table 1 below). Separate lists are provided for rivers (section 1.1.1), lakes (section 1.1.2), transitional waters (section 1.1.3) and coastal waters (section 1.1.4). Section 1.1.5 specifies that the quality elements for the classification of heavily modified and artificial water bodies are those relevant to whichever of the four surface water categories the heavily modified or artificial water body most closely resembles. The lists of quality elements for each surface water category are subdivided into 3 groups of ‘elements’: (1) **biological elements**, (2) **hydromorphological elements** supporting the biological elements; and (3) **chemical and physico-chemical elements** supporting the biological elements. The chemical and physico-chemical quality elements supporting the biological elements include:

- General physico-chemical quality elements (specified in Annex V, table 1.1 of the WFD);
- Specific non-priority pollutants identified by Member States as being discharged in significant quantities; and
- Specific priority pollutants as being discharged (specified in Annex X of the WFD)

Nevertheless it should be noted that once environmental standards have been adopted at Community level for the priority substances listed in Annex X, these substances should only be taken into account in the classification of surface water chemical status and should not be used as supporting elements for the classification of ecological status (see 2.7 and 3.8).

2.3 WFD **Annex V, Table 1.2**, provides a general definition of ecological status in each of the five status classes. For each relevant quality element more specific definitions for ecological status at high, good and moderate status in rivers (Table 1.2.1), lakes (Table 1.2.2), transitional waters (Table 1.2.3) and coastal waters (Table 1.2.4) are given. In addition, a similar approach has been used for HMWBs and AWBs with definitions for maximum, good and moderate ecological potential being given (Table 1.2.5). For the purposes of mapping and reporting, the two upper classes for HMWBs and AWBs (i.e. maximum and good ecological potential) are combined as "good and above"[1].

2.4 As a basic step, the values of the **biological quality elements** must be taken into account when assigning water bodies to any of the ecological status and ecological potential classes. In order to ensure comparability the results of the biological monitoring systems shall be expressed as ecological quality ratios for the purposes of ecological classification. The ratio shall be expressed as a numerical value between zero (worse class) and one (best class).

2.5 The values of the **hydromorphological quality elements** must be taken into account when assigning water bodies to the high ecological status class and the maximum ecological potential class (i.e. when downgrading from high ecological status or maximum ecological potential to good ecological status/potential). For the other status/potential classes, the hydromorphological elements are required to have "conditions consistent with the achievement of the values specified [in Tables 1.2.1 - 1.2.5] for the biological quality elements." Therefore, the assignment of water bodies to the good, moderate, poor or bad ecological status/ecological potential classes may be made on the basis of the monitoring results for the biological quality elements and also, in the case of the good ecological status/potential the physico-chemical quality elements (see paragraph 2.6 below). This is because if the biological quality element values relevant to good, moderate, poor or bad status/potential are achieved, then by definition the condition of the hydromorphological quality elements must be consistent with that achievement and would not affect the classification of ecological status/potential.

2.6 The values of the **physico-chemical quality elements** must be taken into account when assigning water bodies to the high and good ecological status classes and to the maximum and good

[1] If Member States wish to illustrate all the ecological potential classes, all five classes may be used for mapping and reporting, although this approach is not required by the Directive.

ecological potential classes (i.e. when downgrading from high status/maximum ecological potential to good ecological status/potential as well as from good to moderate ecological status/potential). This is discussed in detail in Section 4. For the other status/potential classes the physico-chemical elements are required to have "conditions consistent with the achievement of the values specified [in Tables 1.2.1 - 1.2.5] for the biological quality elements." Therefore, the assignment of water bodies to moderate, poor or bad ecological status/ecological potential may be made on the basis of the monitoring results for the biological quality elements. This is because if the biological quality element values relevant to moderate, poor or bad status/potential are achieved, then by definition the condition of the physico-chemical quality elements must be consistent with that achievement and would not affect the classification of ecological status/potential.

2.7 The "physico-chemical quality elements" identified in WFD Annex V, Tables 1.2.1 – 1.2.5 mean the "chemical and physico-chemical elements supporting the biological elements" listed in Section 1.1 of Annex V for each surface water category, except those for which an Ecological Quality Standard (EQS) has been set at EU-level.

2.8 The relationships between the biological, hydromorphological and physico-chemical quality elements in status classification are presented in Figure 1 for all natural water categories and types. This is discussed in detail in Section 5.

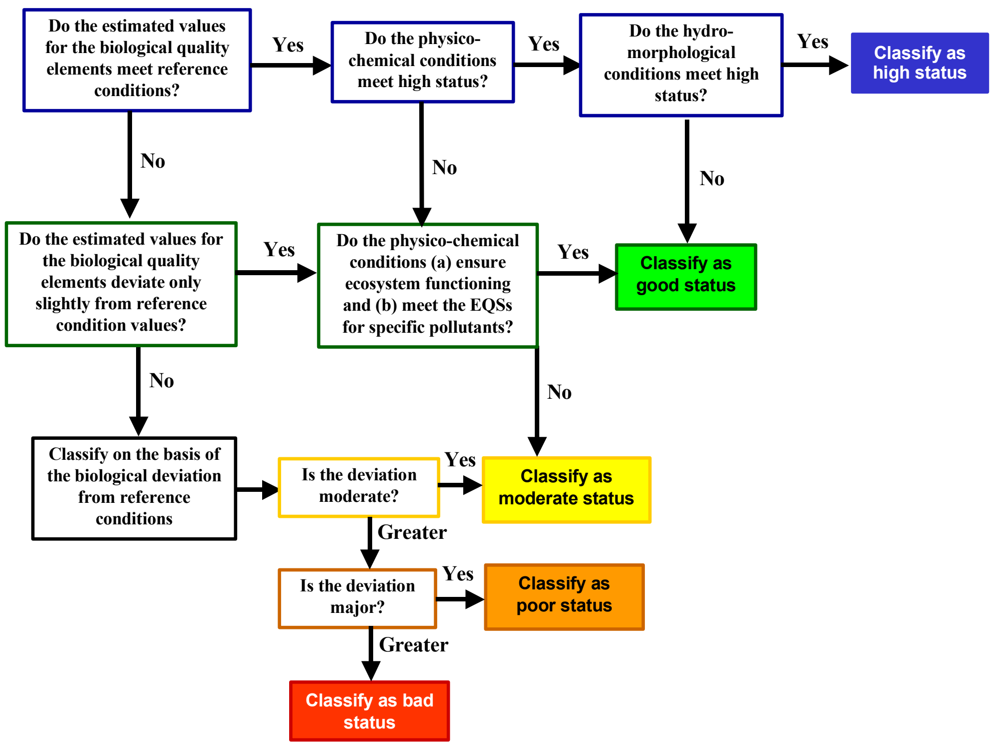

Figure 1. Indication of the relative roles of biological, hydromorphological and physico-chemical quality elements in ecological status classification according the normative definitions in WFD Annex V:1.2. [Note: Figure reproduced from WFD CIS Guidance Documents 10 and 5].

2.9 A comparable approach for HMWB and AWB is shown in Figure 2. The reference conditions of these water bodies mainly depend on the hydromorphological changes necessary to maintain the specified uses listed in Article 4(3)(a). Maximum ecological potential (MEP), as the reference conditions for HMWB and AWB, is intended to describe the best approximation to a natural aquatic ecosystem that could be achieved given the hydromorphological characteristics that cannot be changed without significant adverse effects on the specified use or the wider environment[2]. Accordingly, the MEP values for the biological conditions should reflect, as far as possible, the biological conditions associated with the closest comparable natural water body type at reference conditions, given the MEP hydromorphological and associated physico-chemical conditions (see WFD CIS Guidance Document No. 4 Section 6.2.3).

<u>WFD Annex V No. 1.2.5:</u>

> *[Maximum Ecological Potential (MEP) is defined as the state where] "the values of the relevant biological quality elements reflect, as far as possible, those associated with the closest comparable surface water body type, given the physical conditions which result from the artificial or heavily modified characteristics of the water body."*

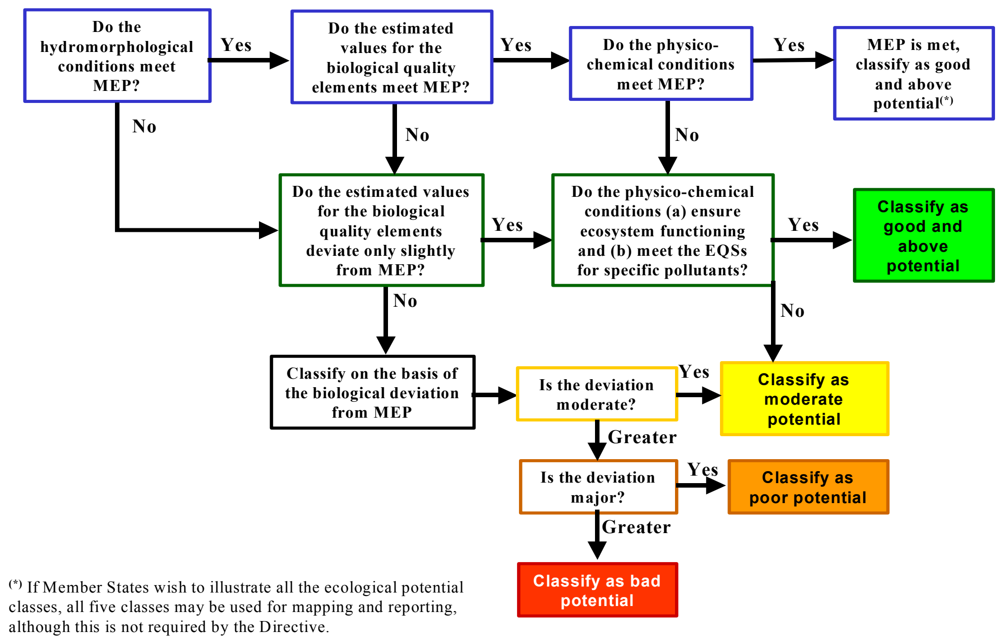

Figure 2. Indication of the relative roles of biological, hydromorphological and physico-chemical quality elements in ecological potential classification according the normative definitions in WFD Annex V:1.2. The two upper classes MEP and GEP are combined for reporting purposes to good and above potential. WFD Annex V (1.4.2) requires that results are presented in equal green/yellow/orange or red (depending on the classification) combined with light grey (AWB) or dark grey (HMWB) stripes.

---

[2] As an illustration, significant adverse effects were calculated by HMWB case studies using local production loss, loss of agricultural land, loss of revenue etc. In general losses of < 1-<10% were considered as insignificant in the case studies, whereas losses of > 30% were considered as significant. For the assessment of the significance of adverse effects on the specified use or the wider environment see WFD CIS Guidance Document No. 4, in particular chapter 5.7.1.

2.10 The WFD requires that Member States achieve an adequate level of confidence that water bodies are assigned to their true status classes. The level of confidence achieved must be reported in the river basin management plans. Further guidance is given in the technical Annex I to this guidance document and may also be found in REFCOND Guidance and specifically in the Monitoring Guidance (WFD CIS Guidance Document 10 and 7).

WFD Annex V, Section 1.3 (3rd paragraph)
In selecting parameters for biological quality elements Member States shall identify the appropriate taxonomic level required to achieve adequate confidence and precision in the classification of the quality elements. Estimates of the level of confidence and precision of the results provided by the monitoring programmes shall be given in the Plan.

WFD Annex V, Section 1.3.4 (3rd paragraph)
[Monitoring] frequencies shall be chosen so as to achieve an acceptable level of confidence and precision. Estimates of the confidence and precision attained by the monitoring system used shall be stated in the River Basin Management Plan.

3. How to Derive the Ecological Status and Potential

3.1 To classify ecological status/potential, the WFD stipulates that the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements should be used (Annex V, 1.4.2. (i)). This implies, de facto, that Member States will need to establish methods/tools for assessing ecological status/potential for both the biological and physico-chemical quality elements. Figures 1 and 2 illustrate that there are separate criteria in WFD Annex V, 1.2, for establishing appropriate ranges for physico-chemcial elements at high and good ecological status and at maximum and good ecological potential.

<u>WFD Annex V, section 1.4.2. Presentation of monitoring results and classification of ecological status and ecological potential</u>

> (i) *For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below. ....*
>
> (ii) *For heavily modified and artificial water bodies, the ecological potential classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below. ....*

3.2 The quality elements for the classification of ecological status/potential are listed in Annex V Section 1.1 of the WFD and reproduced in Table 1 below. WFD Annex V Sections 1.2.1 – 1.2.5 provide definitions of the condition of the quality elements in each status class for each surface water category.

Table 1. Quality elements to be used for the assessment of ecological status/potential based on the list in Annex V, 1.1, of the Directive (for further details see text in 2.2).

Annex V 1.1.1. RIVERS	**Annex V 1.1.2. LAKES**	**Annex V 1.1.3. TRANSITIONAL WATERS**	**Annex V 1.1.4. COASTAL WATERS**
BIOLOGICAL ELEMENTS			
• *Composition and abundance of aquatic flora*[3] • *Composition and abundance of benthic invertebrate fauna* • *Composition, abundance and age structure of fish fauna*	• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora*[4] • *Composition and abundance of benthic invertebrate fauna* • *Composition, abundance and age structure of fish fauna*	• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora*[5] • *Composition and abundance of benthic invertebrate fauna* • *Composition and abundance of fish fauna*	• *Composition, abundance and biomass of phytoplankton* • *Composition and abundance of other aquatic flora*[5] • *Composition and abundance of benthic invertebrate fauna*
HYDROMORPHOLOGICAL ELEMENTS SUPPORTING THE BIOLOGICAL ELEMENTS			
• *Hydrological regime* ➔ *quantity and dynamics of water flow* ➔ *connection to ground water bodies* • *River continuity* • *Morphological conditions* ➔ *river depth and width variation* ➔ *structure and substrate of the river bed* ➔ *structure of the riparian zone*	• *Hydrological regime* ➔ *quantity and dynamics of water flow* ➔ *residence time* ➔ *connection to the ground water body* • *Morphological conditions* ➔ *lake depth variation* ➔ *quantity, structure and substrate of the lake bed* ➔ *structure of the lake shore*	• *Tidal regime* ➔ *freshwater flow* ➔ *wave exposure* • *Morphological conditions* ➔ *depth variation* ➔ *quantity, structure and substrate of the bed* ➔ *structure of the intertidal zone*	• *Tidal regime* ➔ *direction and dominant currents* ➔ *wave exposure* • *Morphological conditions* ➔ *depth variation* ➔ *structure and substrate of the coastal bed* ➔ *structure of the intertidal zone*
CHEMICAL AND PHYSICOCHEMICAL ELEMENTS SUPPORTING THE BIOLOGICAL ELEMENTS			
• *General* ➔ *thermal conditions* ➔ *oxygenation conditions* ➔ *salinity* ➔ *acidification status* ➔ *nutrient conditions* • *Specific pollutants* ➔ *pollution by priority substances identified as being discharged into the body of water* ➔ *pollution by other substances identified as being discharged in significant quantities into the body of water*	• *General* ➔ *transparency* ➔ *thermal conditions* ➔ *oxygenation conditions* ➔ *salinity* ➔ *acidification status* ➔ *nutrient conditions* • *Specific pollutants* ➔ *pollution by priority substances identified as being discharged into the body of water* ➔ *pollution by other substances identified as being discharged in significant quantities into the body of water*	• *General* ➔ *transparency* ➔ *thermal conditions* ➔ *oxygenation conditions* ➔ *salinity* ➔ *nutrient conditions* • *Specific pollutants* ➔ *pollution by priority substances identified as being discharged into the body of water* ➔ *pollution by other substances identified as being discharged in significant quantities into the body of water*	• *General* ➔ *transparency* ➔ *thermal conditions* ➔ *oxygenation conditions* ➔ *salinity* ➔ *nutrient conditions* • *Specific pollutants* ➔ *pollution by priority substances identified as being discharged into the body of water* ➔ *pollution by other substances identified as being discharged in significant quantities into the body of water*

[3] Phytoplankton is not explicitly included in the list of quality elements for rivers in Annex V, 1.1.1, but is included as a biological element in Annex V, 1.2.1. It should therefore be possible to use phytoplankton as a separate element, if needed and appropriate especially in low land large rivers where phytoplankton may be important. The other aquatic flora specifically referred to in the normative definitions for rivers (Annex V 1.2.1) are macrophytes and phytobenthos.

[4] The other aquatic flora specifically referred to in the normative definitions for lakes (Annex V 1.2.2) are macrophytes and phytobenthos.

[5] The other aquatic flora specifically referred to in the normative definitions for transitional waters and coastal waters (Annex V 1.2.3 and Annex V 1.2.4) are macroalgae and angiosperms.

3.3 Member States must monitor parameters indicative of the condition of biological quality elements as part of their monitoring programmes (see WFD Annex V Sections 1.3.1 and Sections 1.3.2). The WFD requires the assessment of the ecological status or /potential class of a water body to be based on the estimate of the condition of the quality element provided by these monitored parameters. In some circumstances, achieving a reliable assessment of the condition of a particular biological quality element may require consideration of the monitoring results for several parameters indicative of that element. A list with all parameters and quality elements is presented in Table 1, but this list could be interpreted in different ways. Therefore in addition Table 1a illustrates, with examples, the understanding of the definitions of parameters, quality elements and groups of quality elements. Further examples of parameters indicative of the condition of the biological quality elements are provided with Table 2.

Table 1a. Examples illustrating the meaning of parameters, quality elements and groups of quality elements, based on the list in WFD Annex V, 1.1; the tables in Annex V, 1.2; and the monitoring requirements in Annex V, 1.3.

Groups of Quality Elements	**Examples of Quality Elements**	**Examples of parameters**
General physico-chemical elements	Oxygenation conditions	COD, BOD, Dissolved oxygen (see point 12 of Annex VIII)
Non-priority, specific pollutants	Copper discharged in significant quantities	Concentrations of copper in water, sediment **or** biota
Hydromorphological elements	Hydrological regime	Quantity of flow, dynamics of flow
Biological elements	Composition and abundance of benthic invertebrate fauna	Composition, abundance (for further examples see Table 2)

3.4 Examples of the sorts of parameters that may be useful in estimating the condition of a biological quality element are given with Table 2. Table 2a provides recommendations on how and under what circumstances monitoring results for parameters indicative of a particular biological quality element may be combined, particularly if pressure related multi metric approaches are used. Further details are given in Annex I of this document.

Table 2: Examples of the sorts of parameters that may be useful in estimating the condition of a biological quality element

(a) Example Biological Quality Element	**(b) Example (type-specific) conditions specified for the element at good status**	**(c) Examples of indicative parameters (metrics) based on measurements of composition and abundance**	
Benthic Invertebrate Fauna (rivers)	THERE MUST BE NO MORE THAN SLIGHT CHANGES IN COMPOSITION AND ABUNDANCE THERE MUST BE NO MORE THAN SLIGHT CHANGES IN THE RATIO OF DISTURBANCE SENSITIVE TAXA TO INSENSITIVE TAXA THERE MUST BE NO MORE THAN SLIGHT SIGNS OF ALTERATION TO THE LEVEL OF DIVERSITY	Presence or absence of particular species or groups of species Overall richness or richness of particular taxonomic groups Relative number of taxa in particular taxanomic groups Abundance of particular species or groups of species Relative abundance of particular species or groups of species Overall diversity, or diversity within particular taxonomic groups	Taxa could be selected and/or grouped by known sensitivity/tolerance, feeding type, habitat preferences, etc

Table 2a. Guidance on combining parameters to estimate the condition of the biological quality element through operational monitoring, if pressure related multi metric approaches are used (i.e. use of multi-metric indices to assess whether the element has been affected by the pressures to which the water body is subject)
(i) Any number of parameters (see column c in Table 2) that are indicative of the biological quality element and relevant to assessing the effects of particular pressures may be combined, for example, by averaging their results. Combining parameters can help reduce the risk of misclassification by improving confidence in the assessment. (ii) Parameters that are sensitive to different pressures should not be combined unless they are also considered independently, since averaging results for non-sensitive and sensitive parameters may conceal failures to meet the relevant type-specific conditions (see column b in Table 2 and point v below). (iii) **The results for parameters likely to respond to a range of pressures may also be combined to estimate the condition of a biological quality element** (iv) The combination of parameters **indicative of the biological quality element** is optional, and the results for individual indicative parameters may be used directly to estimate whether the condition of the biological quality element meets the relevant type-specific conditions. (v) The results for several parameters or groups of parameters, each sensitive to a different pressure, or set of pressures, may be used in estimating the condition of the biological quality element. A one-out, all-out rule, rather than averaging, should be applied in this case such that the condition of the biological quality element is determined by whichever of the grouped or ungrouped parameters sensitive to the different pressures shows the greatest anthropogenic disturbance.

3.5 Figure 3 illustrates the relationship between biological quality elements and indicator parameters and their use in classification decisions. The example in the upper part of the figure illustrates the results for individual parameters of a biological quality element like phytobenthos with general sensitivity to a broad range of pressures (e.g. pressures resulting in morphological and hydrological changes as well as in changes to nutrient conditions). Parameters may be combined by, for example, averaging or weighting (see Section 6 of Annex I to this guidance) to estimate the status of the quality element.

3.6 The second example in Figure 3 illustrates the procedure of combining parameters, if pressure-related, multi-metric approaches are used. Under this approach, individual parameters indicative of the effects of a particular type of pressure on a biological quality element are identified. Where several parameters responsive to the same pressure are identified, these may be grouped and the results for individual parameters in the group combined in order to increase confidence in the assessment of the impact of that pressure on the quality element. If several groups of parameters are identified, each indicating the effects of a different pressure on the quality element, the status of the quality element will be indicated by the results for the group that indicates the greatest impact on the element. However, if the parameters in a group are actually responding to the effects of a range of pressures on the quality element (see paragraph 3.5 above) or there is low confidence in the results for a group of parameters, such pressure-related, multi-metric approaches may not be possible. In such cases, where the groups of parameters are not clearly signalling how the quality element has been affected by different pressures, the approach outlined in paragraph 3.5 and the upper part of Figure 3 may be more appropriate.

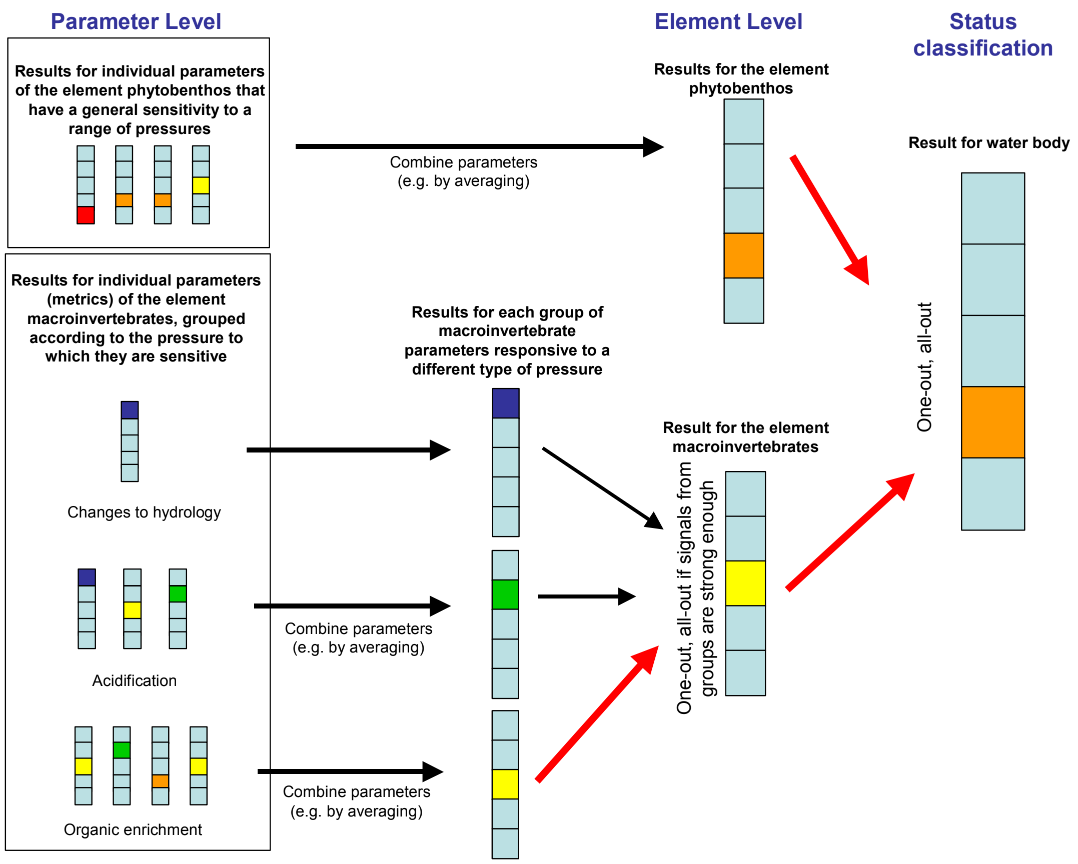

Figure 3. Examples of how indicative parameters may be combined to estimate the condition of the biological quality elements. The one-out all-out principle has to be used on the quality element level as indicated with the phytobenthos example.

3.7 The WFDs normative definitions for ecological status and potential also describe the conditions required for the general physico-chemical quality elements and the specific pollutants at good status/potential. The general physico-chemical quality elements should not reach levels outside the range established to ensure ecosystem functioning and the achievement of the values specified for the biological quality elements [See point (a) in the middle box in Figures 1 and 2]. The concentrations of specific pollutants should not exceed environmental quality standards (EQSs) set in accordance with WFD Annex V, Section 1.2.6 [See Figure 4].

3.8 It has been agreed under the Common Implementation Strategy (CIS) that once environmental quality standards have been adopted at Community-level for the priority substances (WFD Art. 16, Annex X), the concentrations of these substances in water bodies should only be taken into account in the classification of **surface water chemical status** and not in the classification of ecological status/potential. This does not affect the overall classification of a water body because for good surface water status, both ecological and chemical status must be good. However, if any of the biological quality elements are found, from biological monitoring, to be showing adverse effects from exposure to priority substances (e.g. direct ecotoxicological effects), these effects must be taken into account when classifying ecological status/potential.

3.9 Similarly, compliance with EQSs for other substances for which EQSs have been set at Community level (e.g. substances relevant to the Directives listed in Annex IX of the WFD, see Annex V, 1.4.3) should also be taken into account in the classification of surface water chemical status and not in the classification of ecological status/potential.

3.10 For the purpose of assessing ecological status/potential, the specific pollutants listed in WFD Annex V, 1.1 and 1.2 (“specific synthetic pollutants” and “specific non-synthetic pollutants”) must be considered and for good status/potential the environmental quality standards established for them at Member State-level using the procedure set out in Annex V 1.2.6 must be met (like list II substances under the Dangerous Substances Directive (76/464). In addition to the general approach presented in the IMPRESS guidance (WFD CIS Guidance Document No. 3), specific guidance on the selection of those substances may be prepared by EAF Priority Substances.

4. The Role of the General Physico-chemical Quality Elements in the Ecological Classification of Good and Moderate Status/Potential

4.1 For the general physico-chemical elements, the WFD Annex V, Tables 1.2.1 – 1.2.5 specify that for good ecological status/potential to be achieved **the values for the general elements must not reach levels outside the range**[6] **or exceed the levels**[7] established so as to ensure:

(a) The functioning of the (type specific) ecosystem; and

(b) The achievement of the values specified for the biological quality elements.

> **WFD Annex V, Section 1.2**
> General definitions for rivers, lakes, transitional waters and coastal waters for **Good status/potential** for "General Conditions":
> *Temperature (R, L, T, C)*[8]*, oxygen balance (R, L, T, C)*[8] *, pH (R, L)*[8]*, acid neutralising capacity (R, L)*[10] *transparency (L, T, C)*[8] *and salinity (R, L)*[8] *do not reach levels outside the range established so as to ensure the functioning of the type specific ecosystem and the achievement of the values specified above for the biological quality elements.*
> *Nutrient concentrations (R, L, T, C)*[8]*, do not exceed the levels established so as to ensure the functioning of the ecosystem and the achievement of the values specified above for the biological quality elements.*

4.2 The ranges and levels established for the general physico-chemical quality elements must support the achievement of the values required for the biological quality elements at good status or good potential, as relevant. Since the values for the biological quality elements at good status will be type-specific, it is reasonable to assume that the ranges and levels established for the general physico-chemical quality elements should also be type-specific. Several types may share the same ranges or levels for some or all of the general physico-chemical quality elements (Figure 4).

[6] Applies for transparency, thermal conditions, oxygenation conditions, salinity and acidification status
[7] Applies for nutrient conditions
[8] R = applies for rivers; L = applies for lakes; T = applies for transitional waters; C = applies for coastal waters

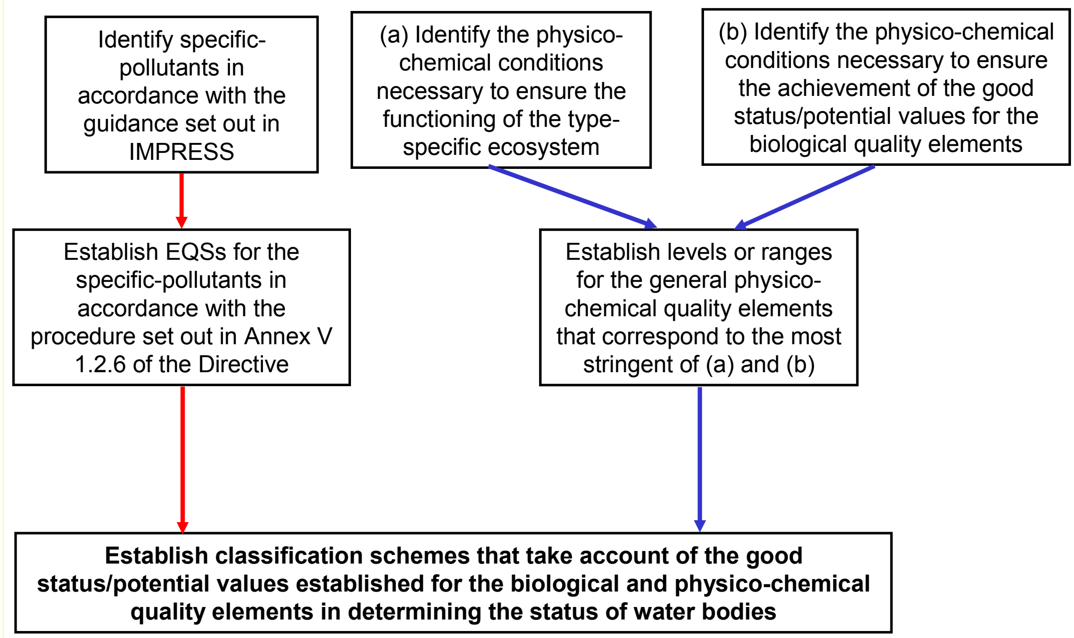

Figure 4. The establishment of ranges and levels for the physico-chemical quality elements at good ecological status/potential. Cases (a) and (b) should be recognised, but from practical reasons it is proposed to establish only one range or level including both aspects.

4.3 If the monitoring results for both the biological quality elements and the general and specific physico-chemical quality elements in a water body meet the conditions required for good ecological status/potential, the overall ecological status/potential of the water body will be good. However, if one or more of the general physico-chemical quality elements or specific pollutants do not meet the conditions required for good ecological status/potential but the biological quality elements do, the overall ecological status/potential will be moderate.

4.4 The following sections outline a checking procedure designed to ensure that the type-specific values established for the general physico-chemical quality elements are no more or no less stringent than required by the WFD, and hence do not cause water bodies to be wrongly downgraded to moderate ecological status or potential. The checking procedures apply only in relation to values for the good-moderate status/potential boundaries. They apply where Member States are confident that there is a real mismatch between the monitoring results for the biological and general physico-chemical quality elements, and not just a mismatch resulting from uncertainties from monitoring. For example, this will usually require evidence that there is a consistent mismatch from a significant number of water bodies in the type. In checking whether the physico-chemical ranges are valid, there is a balance between the scale of the discrepancy that can be demonstrated and the number of sites where the physico-chemical data and the biological data are not compatible. For example, where there are only a few sites monitored, it will be possible only to confirm large discrepancies. Even where the checking procedure applies, it may not be appropriate to revise the level or ranges using the checking procedures if the established levels or ranges are being exceeded because of temporary alterations to the values for the general physico-chemical conditions due to unusual natural conditions, such as prolonged droughts or flooding.

4.5 In individual water bodies, there will be cases where the monitoring results for the biology are good but the results for the general physico-chemical quality elements appear, at face value, to be less than good (i.e. the ranges or levels established for the type appear to have been exceeded). Because of the statistical errors in sampling and analysis described in section 3.3 in Annex I of this document, this situation could be common even though the physico-chemical ranges are thought to be valid. In these cases, Member States may decide to classify the body as less than good only when they have checked that the statistical confidence that the general physico-chemical elements are really less than good is adequate. Where it is not, Member States may take steps to improve confidence, for example, by doing more monitoring.

4.6 The ranges or levels that Member States establish for the general physico-chemical quality elements should be as ecologically relevant as current expert knowledge permits. Specifically, Member States should establish levels or ranges that they consider would, if not exceeded, ensure the functioning of the type-specific ecosystem and the achievement of good status/potential values specified in WFD Annex V, Tables 1.2.1 – 1.2.5 for the biological quality elements.

4.7 In addition to enabling classification, the establishment of ranges or levels for the general physico-chemical quality elements will be needed by Member States to set appropriate controls on discharges liable to adversely affect the general physico-chemical conditions and hence the achievement of the values specified for the biological quality elements at good status/potential or the functioning of the ecosystem.

4.8 The initial levels or ranges established by Member States are likely to be based on an incomplete knowledge of the general physico-chemical conditions needed to ensure the functioning of the type-specific ecosystem and the achievement of the good status/potential values for the biological quality elements. Member States may therefore wish to revise the levels and ranges established for the types as their knowledge improves through the river basin planning cycles.

4.9 There may be cases where the levels or ranges proposed for a general physico-chemical quality element in a type are being exceeded as a result of anthropogenic alterations to the conditions of the general physico-chemical quality elements but no biological impacts are being detected. In such cases, it is recommended that a checking procedure should be undertaken. This procedure should be used to assess whether the established type-specfic levels or ranges for the elements are more stringent than is necessary to ensure the functioning of the ecosystem and the achievement of the values specified for the biological quality elements at good status/potential. An outline checking procedure is presented in Figure 5.

4.10 The mismatch between the biological monitoring results and the general physico-chemical monitoring results may be because the biological methods being used in monitoring are not sensitive to the effects of anthropogenic changes in the condition of the physico-chemical quality element. In such cases, improvements to the biological methods should be made on an on-going basis with the aim of developing methods that are sufficiently sensitive. This improvement work should not stop after the first classification decisions are made.

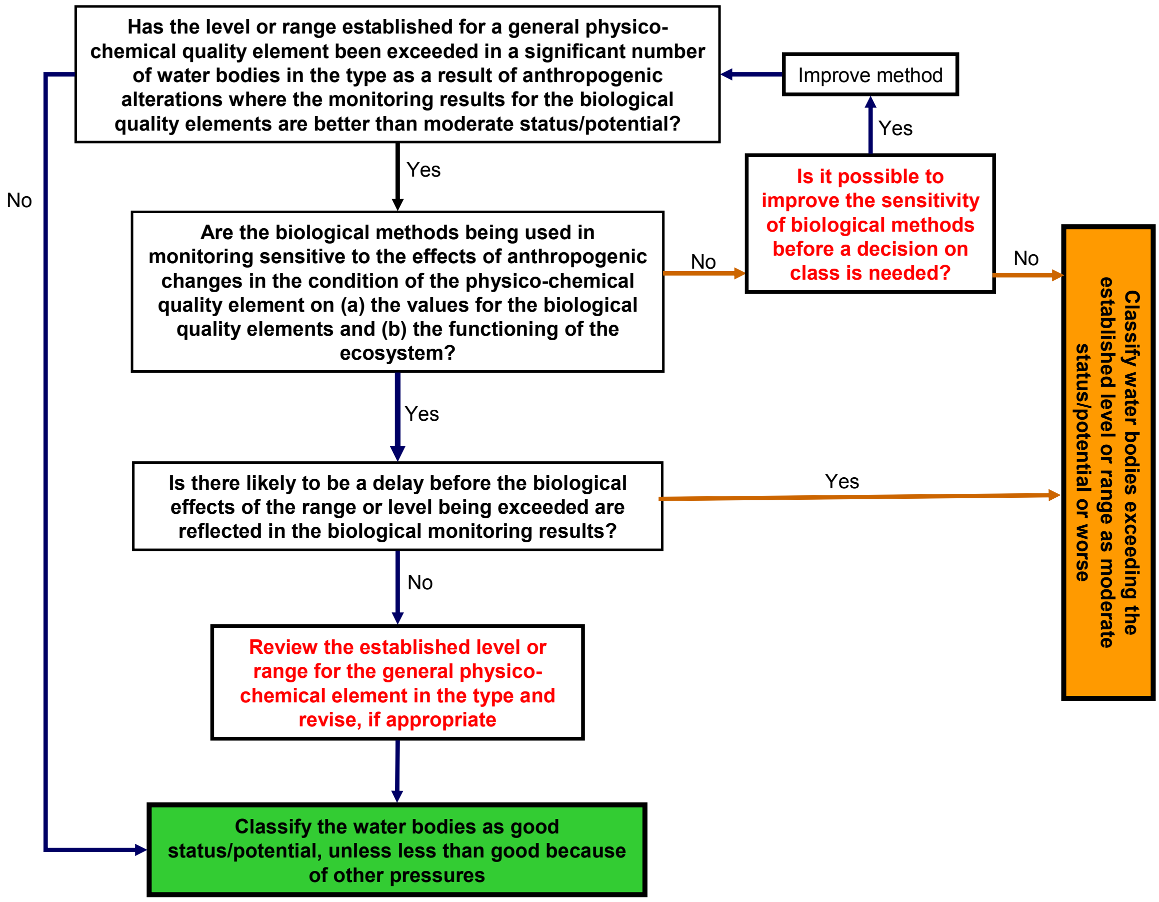

Figure 5. *Checking procedure for assessing whether a level or range established for a general physico-chemical quality element is more stringent than required by the WFD, according to the normative definitions of ecological status/potential.*

4.11 Water bodies in which an established level or range for a general physico-chemical quality element is exceeded should be classified as moderate status/potential or worse unless the established level or range for the type is revised as a result of the checking procedures outlined in Figure 5.

4.12 In establishing and revising the ranges or levels for the general physico-chemical quality elements, Member States should ensure that the same level of protection as provided for under existing Community legislation is guaranteed.

4.13 A checking procedure, such as that illustrated in Figure 6, could be used where the levels or ranges proposed for a general physico-chemical quality element in a type are not exceeded but, because of anthropogenic alterations to the general physico-chemical conditions:

(a) The good status/potential values for the biological quality elements in water bodies in the type are not being met; or
(b) There is evidence of impairment to ecosystem functioning in water bodies in the type.

In this case, the checking procedure would assess whether the established levels or ranges for the general physico-chemical quality elements:

(a) Met the Directive's requirements; or
(b) Were insufficiently stringent to ensure the functioning of the ecosystem and the achievement of the good status/potential values for the biological quality elements.

The procedure would not be applicable where temporary alterations to the physico-chemical conditions had occurred because of unusual natural conditions, such as prolonged droughts or flooding.

4.14 The purpose of the procedure is to check whether there is a need to review the ranges or levels established for the type. If a review is initiated, this may not always indicate that a revision of the established levels or ranges is appropriate. For example, it may not be appropriate to revise the ranges or levels where:

(a) The biological monitoring results are detecting the effects on the biology of intermittent anthropogenic alterations to the physico-chemical conditions but the actual alterations to the physico-chemical conditions are not being detected by monitoring of the general physico-chemical quality elements. Instead, it may be appropriate to change the sampling design; or

(b) The biological elements are responding to the combined effects of alterations to a number of different general physico-chemical quality elements (e.g. the combined effects on the biological elements are greater or lower than would be the effects of alterations to only one of the physico-chemical quality elements). In such cases, however, it may be possible to devise a level or range for the general physico-chemical quality element that takes account of combination effects.

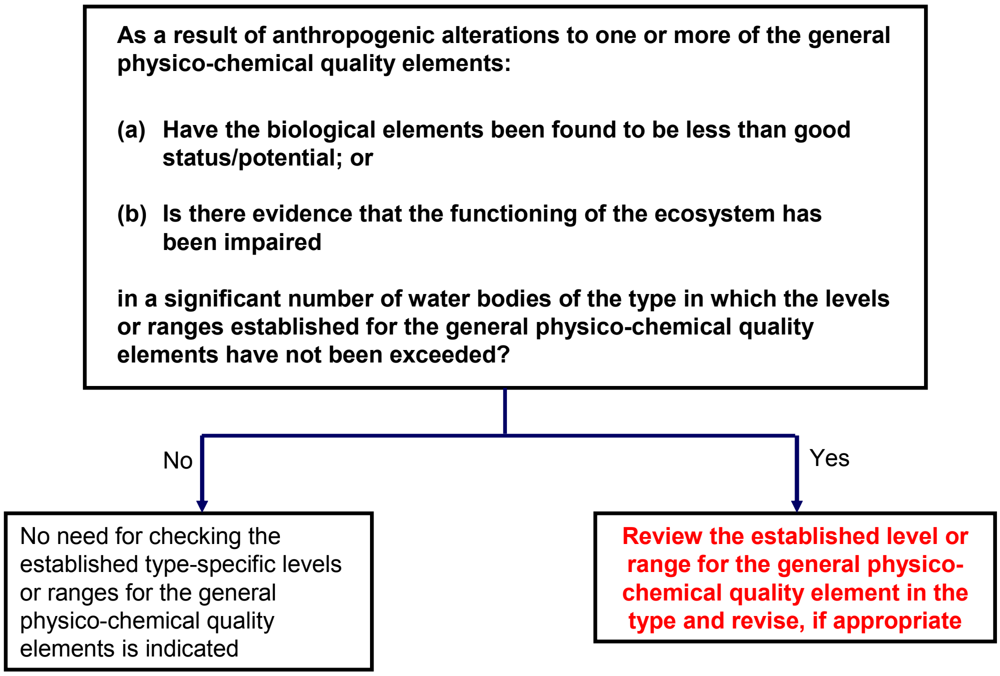

Figure 6. *Checking procedure to assess whether a level or range established for a general physico-chemical quality element is insufficiently stringent to meet the Directive's requirements, according to the normative definitions of ecological status/potential.*

4.15 Member States are recommended to keep in mind when applying the checking procedures that physico-chemical methods have been developed over a long period of time and may, at first stage, give a better, more reliable indication of ecological impact than some less well tried and tested biological methods. This does not mean that physico-chemical methods can ever replace biological methods. Both are required by the WFD.

4.16 For each planning cycle, it is recommended that Member States should complete the checking procedures in sufficient time to enable the classification of water bodies and the design of suitable programmes of measures.

4.17 To support the proposed practical approach, the relevant box in the general Figures 1 and 2 on ecological classification should be expanded for clarification as illustrated in Figure 7 below:

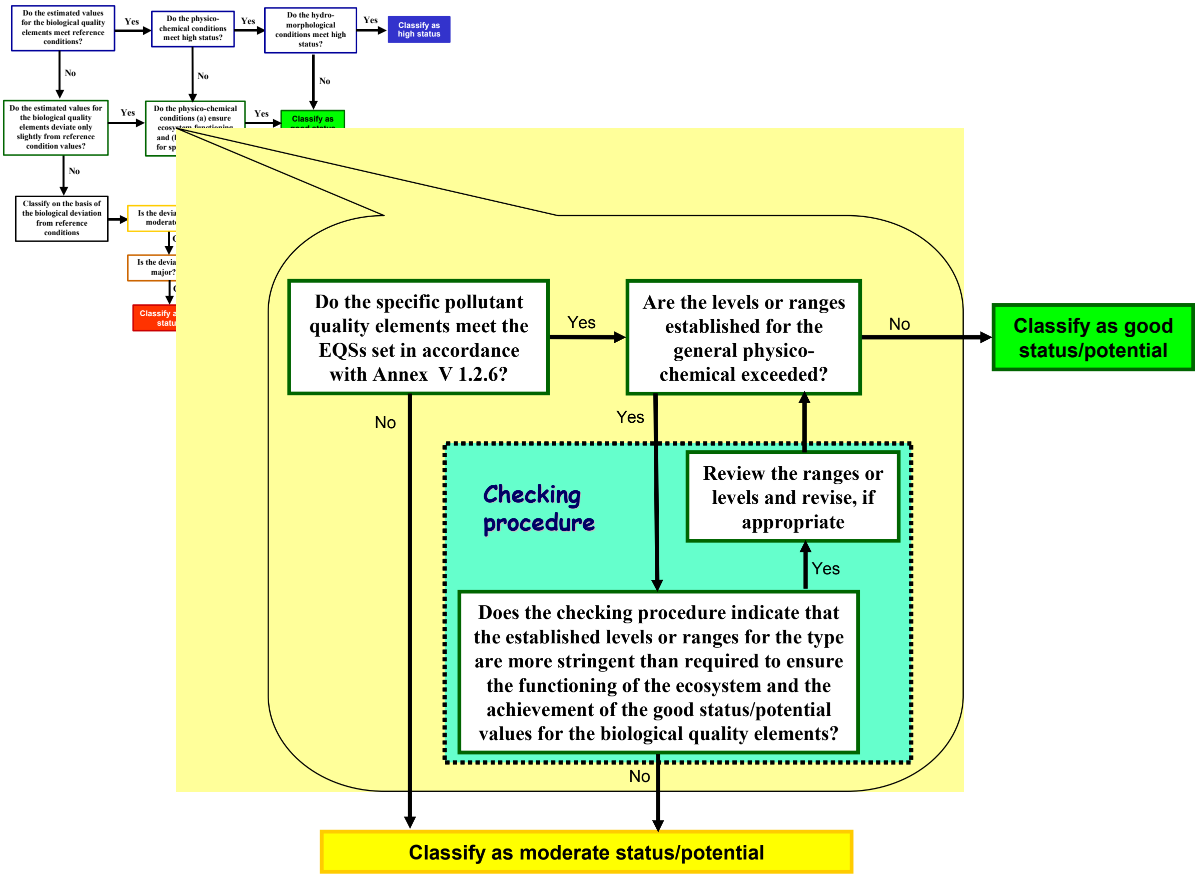

***Figure** 7. Elaboration of second box in the good status/potential line of the ecological classification diagrams (see Figures 1 and 2). Details of the checking procedure are given in Figure 5 and paragraphs 4.3 – 4.9.*

4.18 It is important to note that the use of non-biological indicators for estimating the condition of a biological quality element may complement the use of biological indicators in groups of bodies, as for example in the way described below, <u>but it cannot replace it</u>. Representative biological monitoring is required by the WFD (see WFD CIS Guidance Document No. 7). Where a reliable dose response relationship has already been established between the condition of a biological element and that of a general physico-chemical quality element, monitoring results for the physico-chemical quality element could, in certain circumstances, provide for a reliable estimate of the condition of the biological element. For example, imagine groups of similar water bodies subject to pressures that may affect their pH, such as lakes in Norway, Scotland, Finland and Sweden. If the dose response relationship between pH and the condition of a biological element is well established and there are no confounding effects of other pressures, it may be possible to estimate the condition of the biological elements in the water bodies in the group by monitoring (a) biological parameters in a few of the water bodies to check the dose response relationship is correct for that group, and (b) by monitoring pH in a sufficient proportion of the bodies in the group to obtain sufficient data to enable the bodies to be classified as resource-efficiently as possible but still with an adequate level of confidence and precision.

5. Stepwise Approach for the Ecological Classification

5.1 Step 1: High Ecological Status (HES) and Maximum Ecological Potential (MEP)

5.1.1 WFD Annex II 1.3 requires Member States to establish type-specific biological, hydromorphological and physico-chemical conditions representing the values defined in Tables 1.2.1 – 1.2.5 of Annex V for HES or MEP.

5.1.2 A slightly different approach has to be used for natural and HMWBs or AWBs according to Figures 1 and 2. Generally, the assessment of whether a HMWB or an AWB is at MEP should start with an assessment of whether the condition of the hydromorphological quality elements is consistent with the condition expected for them if all mitigation measures were taken to ensure the best approximation to ecological continuum.

5.1.3 The mitigation measures must be compatible with the use for which the water body is designated (see Section 4.1.3), making them and the resulting values for MEP hydromorphology potentially very specific to particular water bodies or groups of water bodies. Since the MEP hydromorphology dictates the MEP biological and physico-chemical conditions, it is appropriate in the case of those HMWBs and AWBs that may be at MEP to check if their hydromorphology is at MEP before considering the condition of the other quality elements.

5.1.4 Only if the values for all the biological, hydromorphological and physico-chemical quality elements reflect their type-specific conditions can the resulting class be high ecological status or MEP.

Biological Quality Elements

5.1.5 For natural water bodies, the values of the relevant biological quality elements at high status reflect those normally associated with that type under undisturbed conditions, and show no, or only very minor, evidence of distortion; i.e. the biological quality elements correspond totally, or nearly totally, to undisturbed conditions (HES).

5.1.6 For HMWBs and AWBs, the values of the relevant biological quality elements at MEP, reflect, as far as possible given the MEP values for the hydromorphological and associated physico-chemical conditions, those of the closest comparable surface water body type.

Physico-chemical Quality Elements

5.1.7 For natural water bodies, the values for the **general physico-chemical quality elements** at high ecological status correspond totally or nearly totally to undisturbed conditions. A further qualification specifies that the values for the physico-chemical quality elements must remain within the ranges normally associated with undisturbed conditions.

5.1.8 For HMWBs and AWBs, the MEP values for the general physico-chemical quality elements are derived from the ”undisturbed conditions” for the surface water body type most closely comparable to the HMWB or AWB concerned, given the MEP values for the hydromorphological conditions. The CIS guidance on HMWBs and AWBs (WFD CIS Guidance Document No. 4) recognises that in the case of some MEP values for the hydromorphological conditions, the values for some of the general physico-chemical quality elements will be very different to those of the closest comparable type. The guidance therefore suggests that, provided the differences are an inevitable and direct result of the MEP values for the hydromorphological conditions, they may be taken into account when establishing the MEP values for the general physico-chemical quality elements. The following example illustrates how to define MEP physico-chemical reference conditions: The hydromorphological characteristics of impoundment created for hydropower and water supply can dictate the oxygen and temperature conditions in the impounded water and the downstream river. These may be different from those in a natural water body. These differences can be taken into account when defining MEP.

5.1.9 The specific pollutant quality elements have been subdivided into **specific synthetic pollutants** and **specific non-synthetic pollutants**. For HES/MEP to be achieved the concentrations of the specific synthetic pollutants must be close to zero and at least below the limits of detection of the most advanced analytical techniques in general use. The concentrations of the specific non-synthetic pollutants must be within the range normally associated with undisturbed conditions. IMPRESS provides guidance on the identification of specific pollutants (WFD CIS Guidance Document No. 3).

Hydromorphological Quality Elements

5.1.10 For **HES,** the values for the hydromorphological quality elements correspond totally or nearly totally to undisturbed conditions.

5.1.11 For **MEP,** the hydromorphological conditions are consistent with the only impacts on the surface water body being those resulting from the characteristics of the HMWB or AWB once all mitigation measures have been taken to ensure the best approximation to ecological continuum, in particular with respect to migration of fauna and appropriate spawning and breeding grounds. The mitigation measures should not include those that would have a significant adverse effect on the specified uses of the water body or the wider environment.

5.2 Step 2: Good Ecological Status (GES) and Good Ecological Potential (GEP)

5.2.1 For natural and HMWBs or AWBs the same approach has to be used according to Figures 1 and 2.

5.2.2 Only if the values for the biological and physico-chemical quality elements reflect, as relevant, the values defined for GES or GEP should a water body be classified as GES or GEP.

Biological Quality Elements

5.2.3 For natural water bodies, the values of the relevant biological quality elements for the surface water body show low levels of distortion resulting from human activity, but deviate only slightly[9] from those normally associated with the surface water body type under undisturbed conditions (HES).

5.2.4 For an HMWB or AWB to be classified as being at GEP there must be no more than slight changes in the values of the relevant biological quality elements as compared to their values at MEP.

Physico-chemical Quality Elements

5.2.5 For a water body to be classified as being at GES/GEP, the values for the **general physico-chemical quality elements** must comply with the ranges or levels established so as to ensure:

(a) the functioning of the type specific ecosystem; and

(b) the achievement of the values specified for the relevant biological quality elements.

5.2.6 Where the levels or ranges proposed for a general physico-chemical quality element in a type are being exceeded, a checking procedure should be used to assess whether the established levels or ranges for the elements are more stringent than is necessary to ensure the functioning of the ecosystem and the achievement of the values specified for the biological quality elements at good status/potential. An outline checking procedure is presented in Figure 5. Similarly, where the levels or ranges proposed for a general physico-chemical quality element in a type are not exceeded but, because of anthropogenic alterations to the general physico-chemical conditions:

(a) The good status/potential values for the biological quality elements are not being met; or

(b) There is evidence of impairment to ecosystem functioning

A second checking procedure could be used as a means of assessing whether the established levels or ranges meet the WFDs requirements or are insufficiently stringent to ensure the functioning of the ecosystem and the achievement of the good status/potential values for the biological quality elements. An outline checking procedure is presented in Figure 6.

[9] The meaning of slight deviation is being considered as part of the intercalibration exercise.

5.2.7 GES/GEP also requires that the concentrations of the **specific pollutant quality elements** are not in excess of the EQS set at Member State level in accordance with the procedure laid down in WFD Annex V, Section 1.2.6.

Hydromorphological Quality Elements

5.2.8 The conditions of the hydromorphological quality elements at GES and GEP must be consistent with the achievement of the values specified for the relevant biological quality elements at GES/GEP level.

5.3 Step 3: Moderate Ecological Status and Moderate Ecological Potential

5.3.1 For natural, HMWBs or AWBs the same approach has to be used according to Figures 1 and 2. A water body should be classified as moderate status/potential where:

(a) The values for the biological quality elements differ moderately[10] from the type specific communities;

(b) The values for the biological quality elements differ moderately and the physico-chemical quality element values are less than good or;

(c) The values for the biological quality elements are better than moderate but the physico-chemical quality element values are less than good.

5.3.2 If the biological quality elements are at moderate status or potential, the condition of the physico-chemical and hydromorphological quality elements must, by definition, be consistent with the achievement of those biological values.

5.3.3 If the biological quality elements reflect GES/GEP, but the values of the general physico-chemical quality elements do not ensure the functioning of the type specific ecosystem or the concentrations of one or more of the specific pollutant quality elements are not in compliance with relevant EQSs, the resulting ecological status/potential is "moderate" (see chapter paragraph 5.2.6).

[10] The meaning of moderate deviation is being considered as part of the intercalibration exercise.

5.4 Step 4: Poor Ecological Status (PES) and Poor Ecological Potential (PEP)

5.4.1 For natural, HMWBs or AWBs the same approach has to be used according to Figures 1 and 2.

5.4.2 In accordance with WFD Annex V, Section 1.2, if the values for the relevant biological quality elements show evidence of major alteration from their type specific values [i.e. the relevant biological communities deviate substantially from those normally associated with the surface water body type under undisturbed conditions], the water body must be classified as ”poor”. The decision on whether a water body is at PES/PEP or not is dictated by the condition of the biological quality elements. The condition of the physico-chemical and hydromorphological quality elements only affects that decision indirectly through their influence on the condition of the biological elements.

5.5 Step 5: Bad Ecological Status (BES) and Bad Ecological Potential (BEP)

5.5.1 For natural, HMWBs or AWBs the same approach has to be used according to Figures 1 and 2.

5.5.2 In accordance with WFD Annex V, Section 1.2, if the values for the relevant biological quality elements show evidence of severe alteration from their type specific values [i.e. large portions of the relevant biological communities normally associated with the type are absent], the water body must be classified as bad”. The decision on whether a water body is at BES/BEP or not is dictated by the condition of the biological quality elements. The condition of the physico-chemical and hydromorphological quality elements only affects that decision indirectly through their influence on the condition of the biological elements.

6. Presentation of Monitoring Results and Mapping of the Ecological Status and Ecological Potential

6.1 WFD Annex V, Section 1.4.2 (i, ii) requires that the ecological status/potential classification for a body of surface water be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements as indicated in Figures 1 and 2. The monitoring results for the physico-chemical quality elements must therefore be taken into account when classifying surface water bodies.

6.2 WFD Annex V, Section 1.4.2 (iii) requires Member States to also indicate, by a black dot on the map, those bodies of water where failure to achieve good status or good ecological potential is due to non-compliance with one or more environmental quality standards (EQS) which have been established for that body of water in respect of specific synthetic and non-synthetic pollutants (in accordance with the compliance regime established by the Member State). So for example, if a water body is classified as moderate ecological status/potential because of a failure to achieve an EQS for a specific pollutant, this must be reported by (a) colouring the water body yellow in the maps included in the river basin management plan and (b) indicating, using a black dot, that the reason for classifying the body as moderate status/potential is non-compliance with the requirements for specific pollutants.

6.3 The analysis set out in the sections above concludes that the WFD requires the establishment of, and compliance with, specific values for the physico-chemical quality elements for the HES and GES classes as well as for the MEP and GEP. For the lower ecological status/potential classes (i.e. moderate, poor and bad status/potential) it only appears to require the establishment of, and compliance with, values for the biological quality elements. Where monitoring results indicate that the condition of the physico-chemical quality elements is worse than good, the status/potential class assigned to the water body must also be less than good, and should be determined with reference to the type specific condition of the biological quality elements as outlined in Figures 5 and 6.

WFD Annex V, Section 1.4.2: Presentation of monitoring results and classification of ecological status and ecological potential

(i) *For surface water categories, the ecological status classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below:*

Ecological Status Classification	***Colour Code***
High	*Blue*
Good	*Green*
Moderate	*Yellow*
Poor	*Orange*
Bad	*Red*

(ii) *For heavily modified and artificial water bodies, the ecological potential classification for the body of water shall be represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements classified in accordance with the first column of the table set out below:*

Ecological Potential Classification	***Colour Code***		
		AWBs	***HMWBs***
Good and above	*Equal green and…*	*light grey stripes*	*dark grey stripes*
Moderate	*Equal yellow and…*	*light grey stripes*	*dark grey stripes*
Poor	*Equal orange and..*	*light grey stripes*	*dark grey stripes*
Bad	*Equal red and…*	*light grey stripes*	*dark grey stripes*

(iii) *Member States shall also indicate, by a black dot on the map, those bodies of water where failure to achieve good status … is due to non-compliance with one or more environmental quality standards which have been established for that body of water in respect of specific synthetic and non-synthetic pollutants (in accordance with the compliance regime established by the Member State).*

7. Conclusions

1. The normative definitions of the WFD (Annex V, Table 1.2) provide the basis for classifying the ecological status or potential of surface water bodies, and each Member State must develop classification systems that conform to these definitions. Biological as well as supporting hydromorphological and physico-chemical quality elements are to be used by Member States in the assessment of ecological status/potential. The relative roles of these elements are illustrated in Figures 1 and 2. The estimates of the condition of the biological quality elements provided by the monitored parameters should be used in classification decisions. The monitoring results for several parameters may be combined, where appropriate, to provide these estimates.

2. The use of non-biological indicators for estimating the condition of a biological quality element may complement the use of biological indicators but it cannot replace it.

3. Deciding if a particular ecological status or potential class can be assigned to a water body depends on whether the quality element worst affected by anthropogenic alterations matches its normative definition for that class. In short, the classification scheme is a one-out, all-out scheme at the level of the quality elements.

4. The condition of a biological element, such as benthic invertebrates, may be estimated using one or more parameters that are indicative of that element, bearing in mind the normative definitions for the element. Where more than one parameter is monitored, the results for each may be combined to estimate the condition of the element. This may be achieved by averaging, unless the parameters are sensitive to different pressures. In the latter case, the condition of the element should be estimated by the results for the worst affected parameter, or group of parameters, indicative of the effects of different pressures on the element.

5. The condition of the biological element estimated to be worst affected by anthropogenic alterations will dictate the class that can be assigned to the water body, unless the monitoring results for the physico-chemical or hydromorphological quality elements indicate a lower class (see Figures 1 and 2).

6. A decision to assign a water body to the good status/potential class rather than the moderate status/potential class should be made on the basis of the relevant biological and physico-chemical results. The ecological status/potential class is represented by the lower of the values for the biological and physico-chemical monitoring results for the relevant quality elements.

7. Where the levels or ranges proposed for a general physico-chemical quality element are being exceeded as a result of anthropogenic alterations to the conditions of the general physico-chemical quality elements but no biological impacts are being detected in a significant number of water bodies in a type, it is recommended that a checking procedure should be undertaken. This procedure should be used to assess whether the established type-specific levels or ranges for the elements are more stringent than is necessary to ensure the functioning of the ecosystem and the achievement of the values specified for the biological quality elements at good status/potential. In some cases it may be that the biological method is insufficiently sensitive. An improvement in the biological methods may be appropriate rather than a revision of the range or level established for the general physico-chemical quality element (Figure 5). Similarly, where the levels or ranges are not exceeded but, for example, the good status/potential values for the biological quality elements are not being met as a result of anthropogenic alterations to the general physico-chemical conditions, a second checking procedure could be used as a means of assessing whether the established levels or ranges are insufficiently stringent and consequently need to be revised to meet the WFDs requirements (Figure 6).

8. The specific synthetic and non-synthetic pollutants relevant to the classification of bodies at HES/MEP or GES/GEP (see Figures 1 and 2) do not include those pollutants for which relevant environmental quality standards have been established at Community-level. Guidance on identifying specific pollutants is provided in IMPRESS Guidance (WFD CIS Guidance Document No. 3)**.**

Annex I: Technical Approach on Achieving and Reporting Adequate Confidence and Precision in Classification

1. Introduction

1.1 This annex provides guidance on getting better conclusions from monitoring data by using general statistical principles to manage errors. The approach deals mainly with the use of numeric data from operational monitoring in classification decisions. Appendix 1 looks at the surveillance monitoring programmes.

1.2 Information on the confidence and precision that can be achieved using particular methods and monitoring designs is not provided in this guidance. Other international initiatives focused on specific issues or monitoring methods may include such information [e.g. OSPAR (www.ospar.org); FAME (www.fame.boku.ac.at); AQEM (www.aqem.de); STAR (www.eu-star.at); ECOFRAME (Contact Brian Moss, Liverpool University UK); CEN (http://www.cenom.be/cenom/index.htm)]

1.3 In an ideal world with comprehensive monitoring data containing no errors, water bodies would always be assigned correctly to their true class with 100 per cent confidence. But estimates of the truth based on monitoring data are subject to error if monitoring is not done everywhere and all the time, and because monitoring systems, equipment and people are less than perfect. A key recommendation of this guidance is that Member States estimate and report (see Section 9) the risk that a water body is assigned to the wrong class because of the errors in monitoring data.

1.4 Managing the risk of misclassification is important because of the potential to waste resources on water bodies that have been wrongly downgraded or to fail to act because a water body has been wrongly reported as better than it is.

2. Background

2.1 In general, the risk of misclassification is likely to be lower if the quality element is in truth, nearer the middle of the class than the class boundaries. The consequence of this is that enhanced monitoring is likely to be needed for water bodies close to the good-moderate class boundary.

2.2 The results of the pressures and impacts analysis will be used to help design, and subsequently refine, the monitoring programmes and, in turn, information from the monitoring programmes will be used to improve the analysis of which bodies are at risk of failing to achieve their objectives (see Section 2.1.2 WFD CIS Guidance Document No 3 & Section 2.2 WFD CIS Guidance Document No. 7).

2.3 One of the reasons a water body may be identified as being at risk is if the pressures and impacts analysis suggests that it is currently less than good status. Once identified as being at risk, the water body must be considered within the operational monitoring programme for the river basin district, although it may be grouped with other bodies at risk for this purpose under certain conditions. The results of operational monitoring programme must be used to establish the status of the body.

2.4 If the results of monitoring subsequently provide adequate confidence that the status of the body is good or better and there is no significant risk of deterioration in the body's status, the body would no longer need to be considered as being at risk of failing to achieve its status objectives. The results of the pressures and impacts analysis could be updated accordingly. If, on the other hand, the results of operational monitoring confirmed, with adequate confidence, that the water body is less than good status the water body would remain at risk, and be subject to on-going consideration within the operational monitoring programme. It would also be subject to the application of suitable measures aimed at restoring its status to good.

2.5 The confidence in the results of operational monitoring may not always be adequate, and a Member State could find itself uncertain as to whether the body is at good status or not. An adequate level of confidence should be achieved in time to enable the achievement of the WFDs objectives.

3. Sources of error and their management

3.1 An estimate of the confidence and precision provided by the methods used in monitoring is necessary for assessing the confidence in the results of monitoring and the confidence that the class assigned to a water body is the true class. The need for such estimates should be an important consideration in the development and the application of methods.

3.2 There are several ways in which errors in a method can be estimated, one of which is to test the method using replicate sampling and simulations to produce quantitative estimates. In other cases, it may be appropriate to ask independent experts to provide a suitable estimate.

3.3 A water body can be subject to some or all of the following variations (or ways of describing variation), for whatever mixes of natural or other causes:

(a) Apparent random variations from second to second, minute to minute, or hour by hour;
(b) Diurnal patterns;
(c) Seasonal patterns;
(d) Longer term trends, cycles and random influences, including year to year variation;
(e) Step changes (random, regular or permanent);
(f) Variation with depth of water;
(g) Variation with location (spatial variation);
(h) Correlations with physical and other biological properties (though these can be thought of as causing the above);
(i) Serial correlation, for example, clusters of bad months or bad years;

(j) Bias and random errors from equipment; and

(k) Human error.

3.4 Subsequently in this Annex, where we refer to "error and uncertainty", we mean the outcome of all the factors listed in paragraph 3.3 that is produced when a monitoring programme is applied to a water body. This may take the form of a total error in the numerical results from monitoring and in the EQRs that are calculated from those results. The errors might be quantified as the standard deviation, standard error, error bands or confidence limits, or other in other ways by which scientists normally assign a range to the numerical values produced by monitoring. As discussed later (in paragraph 4.3 and Table 1), the probability that a water body is in a particular class is estimated as the proportion of the range in error that is cut by the boundaries of the class.

3.5 If measured everywhere and continuously, with an error-free monitor operated by infallible people, we get the full picture of the property and perfectly true and exact estimates of temporal and spatial distributions, or summary statistics like the mean and variance.

3.6 For any particular water body property one or more of variations may be large and others may be known to be absent. There is no need to determine all errors, only the dominant ones. For all monitoring systems, it is recommended that sources of error are analysed and quantified, for example, by replicate sampling programme, by the examination of long or extensive series of historic data, or by simulations.

3.7 For some biological parameters, we will be able to exploit the natural averaging that means we need not worry much about short term fluctuations and cycles [variations (a), (b) and (c) above] that do not damage the biology. For chemical parameters it will be more important to demonstrate lack of bias due to unrepresentative sampling against diurnal and seasonal cycles [variations (b) and (c) above], and to manage random temporal variation [variation (a) above] through statistical estimation of confidence limits on summary statistics like means and percentiles. Where the source of potential error is, for example, seasonal variation, [variation (c) above] this may be managed by selecting appropriate monitoring frequencies.

3.8 The spatial errors [variations (f) and (g) above] should also be quantified and managed, as far as possible, by an informed selection of monitoring sites. Failure of a sampling method and operator to capture or detect species actually present may produce errors that dominate. This source of error can be reduced by precisely defining sampling seasons, sampling methods, sorting procedures and identification levels supported by training and analytical quality control. Errors may also result if the biological method used is based on a taxonomic level that is, for example, insufficiently sensitive to the pressures.

4. The use of estimates of confidence in class

4.1 Information on confidence and precision in monitoring results will help quantify the uncertainty from errors and gaps in data, allowing an estimate to be made of the confidence, or probability, that the true class of a water body is:

(a) As reported;
(b) Worse than reported; or,
(c) Better than reported.

4.2 The main recommendation of this paper is that the estimates for (a), (b) and (c) should always be made. Such an outcome for data with errors is shown in Table 1. In this hypothetical example the error leads to a range of uncertainty that spans the classes from High to Bad.

Table 1	
Class	Probability of Class (per cent)
High	10
Good	60
Moderate	25
Poor	4.9
Bad	0.1

4.3 In Table 1, there is confidence of 70% for the result of good or better status. The confidence that the class is less than good is 30 per cent. These percentages are calculated in the following way. Suppose that the upper and lower class limits for the good class are ecological quality ratios of 0.9 and 0.7 respectively. Suppose further that the measured ecological quality ratio is 0.78. At face value this would place the water body in the good class. Because of errors in monitoring, the value of 0.78 may actually be associated with a range, say, 0.62 to 0.92. This range crosses the class limits of 0.9 and 0.7, leading to a probability that the true class is worse than good, or better than good.

4.4 Technically it is best if the error band, 0.62 to 0.92, is a pair of confidence limits; say the pair of 95 per cent confidence limits. The facility to estimate these confidence limits relies on the fact that the error band is two points from a probability distribution, sometimes called the error distribution. The confidence that the water body is in any class is calculated by looking at where the class limits cross this distribution. In Table 1, 60 per cent of the distribution falls between the good class boundaries, 25 per cent falls between the moderate class boundaries, and so on.

4.5 Ideally, we would like to get closer to the position illustrated in Table 2. In this case there is 100 per cent confidence that the water body is in the good class. This outcome occurs if the error bands on the estimated EQR are small. To continue with the example in the last paragraph, the confidence limits about the estimate of 0.78 might have been 0.75 to 0.85, lying entirely within the good class boundaries of 0.9 and 0.7

Table 2	
Class	Probability of Class (per cent)
High	0
Good	100
Moderate	0
Poor	0
Bad	0

4.6 We might expect to move from Table 1, towards an outcome like that in Table 2, by getting better or more appropriate data. It should be noted that in doing this we might find that a water body which starts out having a probability of only 4.9 per cent of being in the poor status class ends up being classed as poor status with near 100 per cent confidence when better data is taken into account.

4.7 We have to decide how to use information on the error in monitoring results, and in particular whether and how to be influenced by the error in assigning and reporting the status class of a water body. Where the errors are small, and consequently the confidence that the water body is in a particular class is high and therefore clearly adequate, classification decisions will be straightforward (see Section 8).

4.8 In the example given in Table 1, the most likely class is good status (60 per cent confidence). Generally most old classification systems, including those that ignored errors, would report this as the outcome if required to answer the question: "What is the class?" The data in Table 1 could then be used to decide if the water body should still be identified as being at risk of failing good status because of the 30 per cent chance that its class is worse than good compared to the 70 per cent chance that it is at least good.

4.9 The subsequent sections of this annex describe the ways in which errors can be reduced so that more water bodies can be assigned a class with high confidence. But even if these techniques are used, Member States are likely to end up with lots of water bodies like the one in Table 1, and will need to reach a view on how to answer to the question "What is the class?" in such cases.

5. Summary of possible approaches to managing the risk of misclassification

5.1 Figure 1 represents a generalised view of the WFDs classification scheme. The number of quality elements (QEs) relevant in principle in classification will vary, depending on, for example, the number of specific pollutants being discharged in significant quantities. Under the scheme, the class of a water body is determined by the condition of the quality element most affected by the pressures to which the water body is subject. In shorthand, classification is based on a one-out all-out system.

5.2 Based on experience with existing classification schemes, the error and uncertainty in monitoring results (see paragraph 3.4), coupled with the fact that a proportion of waters will, in truth, be close to a class boundary, tends to lead to a risk that about 20 per cent of assignments of class will be wrong. Where water bodies are, in truth, extremely HIGH or extremely BAD, this risk will be very much lower. The risk of wrongly deciding that the class of a water body has changed (i.e. that a deterioration in status has occurred) tends to be closer to 30 per cent[11].

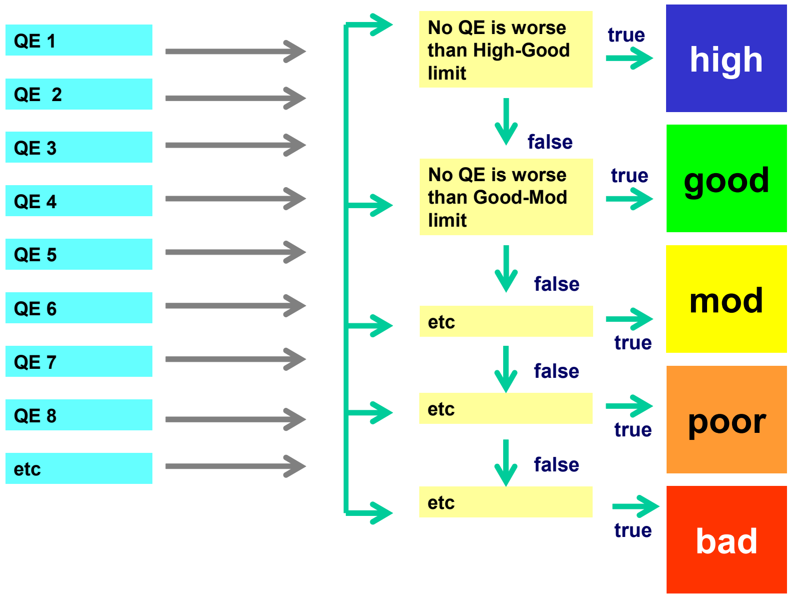

Figure 1: Representation of the WFDs classification scheme for ecological status. The ecological potential classification scheme for HMWBs and AWBs operates according to the same principles. Note that the number of relevant elements (e.g. benthic invertebrates, specific pollutants, etc) depends on (a) the status class (see Section 2 of the main guidance document); and (b) factors such as the number of specific pollutants being discharged in significant quantities.

5.3 Low confidence and precision leads to a risk of misclassification. The main components of a strategy for reducing the risk of misclassification by managing errors are outlined in following section and summarised below:

(i) Estimate the errors in the monitoring results for each quality element (e.g. quote the value of the classification variable as, say, plus or minus X % - see paragraph 3.4). This will enable the probability that a water body is in a particular class to be estimated;

[11] Given an estimate of the errors and uncertainty in monitoring results, the risk of misclassification can be calculated by, for example, Monte Carlo simulation for any classification system and are recommended to be calculated for the classification procedures set up for the purposes of the Directive.

(ii) Decide what level of confidence is adequate for assigning a water body to a particular class. There will be many cases where there is less that 100 per cent probability that a water body is in any of the classes. In Table 1, for example, there is only 60 per cent probability that the class is good. It is necessary to decide the level of confidence that is considered adequate in order to declare that a water body is in a particular class;

(iii) If the errors in the results of monitoring are too large to achieve adequate confidence about the class that should be assigned, reduce them through, for example, more monitoring[12], the use of more reliable monitoring systems, better monitoring design[13], improved assessment and modelling, and/or by combining the monitoring results for different indicative parameters to estimate the condition of the quality element;

(iv) Minimise the number of different quality elements used in making classification decisions by only taking into account the monitoring results for those elements most sensitive to the pressures to which the water body is subject (i.e. by excluding the monitoring results for elements that are NOT among the most sensitive to the pressure).

5.4 There will be clear cut situations where the class is clear even though the confidence in biological monitoring results, if considered on their own, would be low. For example, it may be clear that the entire river length upstream of a weir that is not equipped with a fish ladder will be worse than good ecological status until improvements to river continuity are made, even though the monitoring results for the fish fauna themselves are equivocal because of errors in the method used.

6. Managing errors in monitoring data for individual elements

6.1 The risk of error in classification cannot be assumed to be zero just because a method of calculating it has not been developed. Monitoring results that do not include an estimate of their errors should not be used in classification. If they were, it would not be possible to estimate the level of confidence achieved in classification, as required by the WFD.

6.2 The measurements for any quality element will involve error. For example, the mean from 12 samples can have an uncertainty of plus or minus 50 per cent[14]. A monitoring result that detects 12 species might need to be qualified by an error ranging from 11 to 15[15]. Such errors can be reduced in a predictable way if they are preventing the achievement of an adequate level of confidence in classification by, for example, extra monitoring and assessment, improved monitoring design[16], the use of better monitoring systems or by combining the

12 At its simplest increasing the number of samples by n reduces errors by the square root of n.
13 Controlling the variability contributed by the natural environment allows anthropogenic contributions to changes in quality elements to be detected with increased confidence.
14 50% is a typical figure where the standard deviation equals the mean.
15 The quoted figures are derived from an assessment of errors in monitoring for the UK river invertebrate monitoring system, RIVPACS. There were random errors and biologists missed, on average, two species of invertebrates in sampling.
16 Natural sources of environmental variation and measurement error can contribute significantly to uncertainty in estimates of a quality element. These can be controlled by sampling design, allowing anthropogenic influences to be more readily detected.

results for different parameters that are indicative of the condition of an element into an index for that element.

6.3 The sensitivity of biological elements and of the parameters monitored to estimate their condition may be considered in terms of (a) their actual sensitivity to the pressure; and (b) the degree of confidence that can be achieved in monitoring results. For example, a fish species might be sensitive to a particular toxin but it might not be possible to obtain low error monitoring data for that species using existing sampling methods.

6.4 Figure 2 illustrates how metrics A, B and C are combined, perhaps by averaging, to assess the condition of element 1 (see also Section 3 of the main guidance document). Combining the metrics can produce a smaller error in the estimate of the quality element than that provided by the original metrics. For this reason, combining metrics may allow a number of individually weak indicators of impact to come through as a statistically significant conclusion.

6.5 The term "averaging" may involve taking the arithmetic average, or a weighted average, median or percentile of the monitoring results for a number of parameters and using this statistic to classify rather than the individual ecological quality ratios calculated for each parameter. There need be no restriction in how the data are combined provided the outcome is ecologically sensible and provided the error in the resulting summary statistic can be estimated.

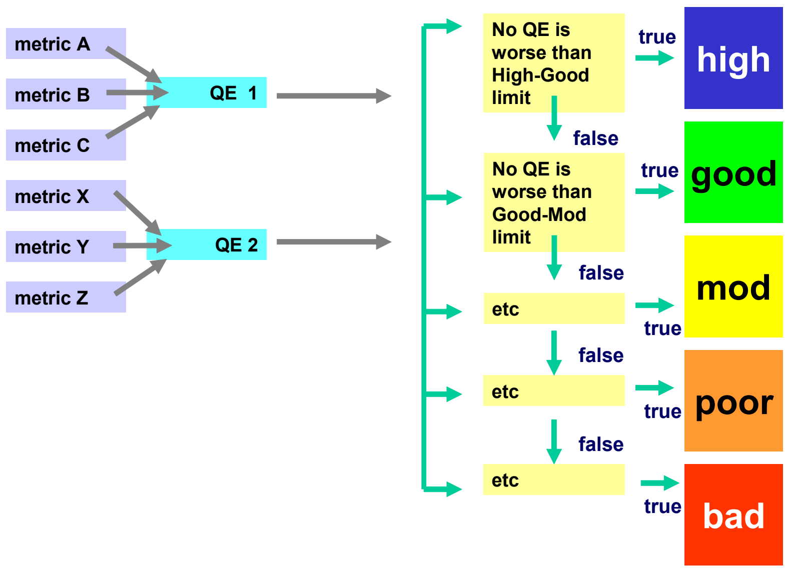

Figure 2: Representation of the WFDs ecological classification scheme, using multiple indicative parameters, or metrics, to estimate the condition of individual elements

6.6 The average for five independent metrics, each with 30 per cent error, will come through as an error of around 13 per cent. The reduction from 30 per cent to 13 per cent is the result of the Central Limits Theorem and applies to all sets of data that are independent. This would be a good reduction but the error should still to be taken into account in estimating the risk that the assigned class is not the true class (i.e. in assessing confidence in class). Care is needed where the metrics are correlated as, for example, in the use of the same set of data to calculate several metrics. In the case of 100 percent correlation, the reduction in error vanishes.

6.7 Averaging the results for a parameter with low error with those for parameters with much bigger errors could increase the risk of misclassification rather than reduce it, and would therefore defeat the purpose of combining results for different parameters. Similarly, averaging the results for parameters that are sensitive to a pressure with those that are relatively insensitive to that pressure could conceal failures to meet the conditions specified in the WFDs normative definitions of ecological status (Annex V, Section 1.2.1 – 1.2.5).

6.8 It should be noted that different types of metrics are differently affected by errors. The most stable results are usually delivered by metrics whose derivation includes a step involving averaging taxa, such as Saprobic Indices or Average Score Per Taxon. Metrics reflecting the proportion of taxa with particular preferences, such as feeding or microhabitat preferences, will also tend to have lower errors than metrics such as taxonomic richness (e.g. number of Ephemeroptera taxa).

7. Managing the effect of combining results for individual elements

7.1 The potential for misclassification is amplified by the number of quality elements that are taken into account in the one-out all-out system. If a water body is truly in the high status class and the monitoring results for any quality element included in the classification scheme can place the water body wrongly in a lower class, the probability of misclassification multiplies up with increasing numbers of quality elements. This is illustrated in Figure 3 below. The outcome is dominated by the quality elements with the biggest errors – the biggest probability of putting the water body in the wrong class.

7.2 The dotted line in Figure 3 occurs as follows. Suppose, for simplicity, that there are 10 quality elements and each is associated with a risk of 10 per cent that it will assign a class that is worse than the true class. In reality the risk may differ for each quality element. It may be zero for some and very large for others. If all the risks are zero there is no problem and the dotted line would run along the full line.

7.3 For 10 quality elements each with 10 per cent risk, the risk of declaring a wrong class increases as each quality element is introduced. It is 10 per cent for the first quality element, 19 per cent for two, 27 per cent for three, rising to 65 per cent for all 10.

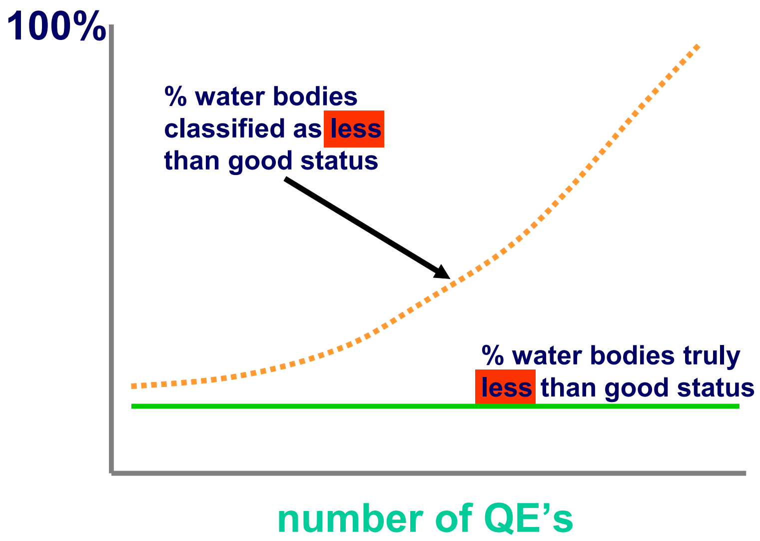

Figure 3: Effect of increasing the number of different elements in a one-out, all-out classification scheme

7.4 WFD Annex V, Section 1.3.2 specifies that, for operational monitoring, Member States should monitor among other things parameters indicative of the biological quality element, or elements, most sensitive to the pressures to which the water bodies are subject[17] and pollutants discharged in significant quantities. The Directive specifies that the results of operational monitoring are to be used in establishing the status of bodies at risk of failing to achieve environmental objectives.

7.5 WFD Annex II, Section 1.3 (paragraph VI) also says that where it is not possible to establish reliable reference conditions due to high natural variability, a quality element may be excluded from the assessment of ecological status. The number of quality elements that need to be considered in classifying bodies at risk can be reduced according to these provisions.

7.6 When making difficult classification decisions for bodies at risk (i.e. deciding the status of bodies which may be less than good status but which are not obviously very bad), Member States should focus on obtaining, and basing their decisions on, reliable operational monitoring programme results for those elements most sensitive to the pressures to which the water body is subject. The AQEM[18] system for example, aims to use only metrics that show a dose-response across a gradient of human influence that is "reliable, interpretable and not obscured by natural variation". Figure 4 represents how the principle of minimising the number of quality elements considered in any one classification decision can be applied using the results of operational monitoring.

17 Annex V 1.3.2 Design of Operational Monitoring.
18 http://www.aqem.de

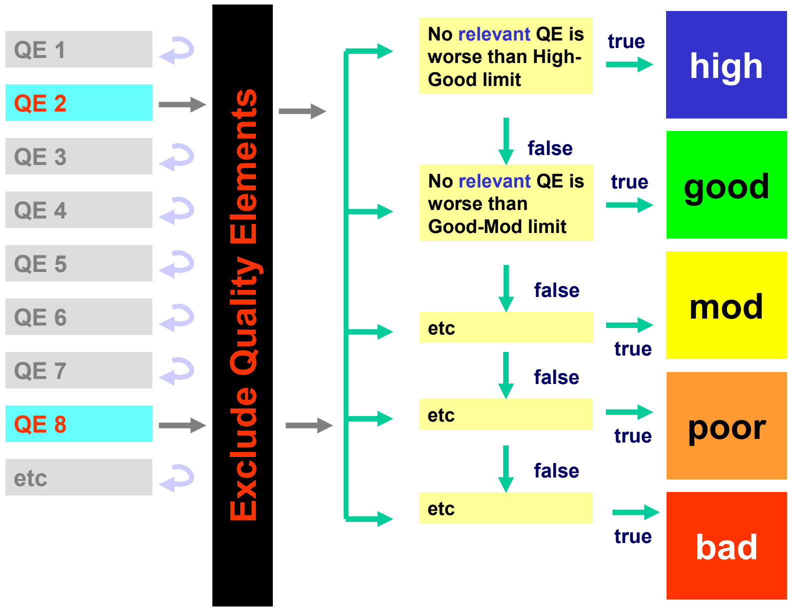

Figure 4: Representation of the WFDs ecological classification scheme, taking account only of operational monitoring results for those elements (a) most sensitive to the pressures to which the water body is subject; and (b) for which reliable type-specific reference conditions can be established.

7.7 As illustrated in Figure 5, when deciding the class of a water body (a) minimising the number of quality elements considered in the decision [See Section 7]; (b) the use of averaging of multiple indicative parameters in estimating the condition of the individual elements that are considered [See Section 6]; (c) obtaining results for the indicative parameters from well designed and operated monitoring [See Monitoring Guidance]; and (d) ensuring appropriate consideration is given to the statistical confidence in the final assessment will help ensure that the class assigned (the short blue line) can be made to stay close to the green line (the truth).

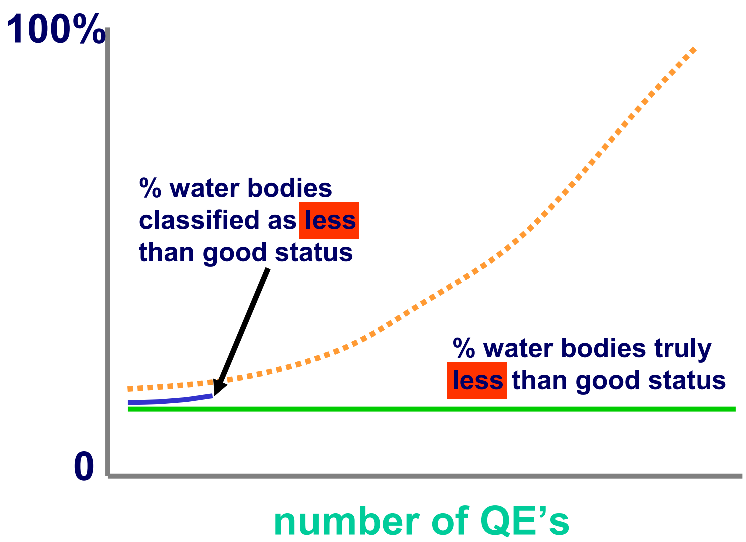

Figure 5: Illustration of the objective of managing the risk of misclassification

8. Deciding on the level of confidence that can be considered adequate

8.1 The following guidance on confidence and precision is reproduced from Section 2.5 (see paragraphs 8.2 – 8.4 below) and Section 2.8.1 (see paragraphs 8.5 – 8.7 below) of the CIS Monitoring Guidance (WFD CIS Guidance Document No. 7). The status of water bodies must be classified in time to enable a presentation in map form in the River Basin Management Plans of the results of the monitoring programmes for the status of surface water. The first Plans must be published by the end of 2009. This means that by this date, Member States will have to have achieved an acceptable level of confidence and precision for assigning water bodies to an appropriate class. Estimates of the level of confidence and precision of the results provided by the monitoring programmes must also be given in the Plan.

8.2 Choosing levels of precision and confidence will set limits on how much uncertainty can be tolerated in the results of monitoring programmes. The level of acceptable risk of misclassification will affect the amount of monitoring required to estimate a water body's status. In general terms, the lower the risk of misclassification desired, the more monitoring (and hence costs) required to assess the status of a water body. It is likely that there will have to be a balance between the costs of monitoring against the risk of a water body being misclassified. Misclassification may mean that measures to improve status could be inefficiently and inappropriately targeted. It should also be borne in mind that in general the cost of measures for improvement in water status would be orders of magnitude greater than the costs of monitoring. The extra costs of monitoring to reduce the risk of misclassification might therefore be justified in terms of ensuring that decisions to spend larger sums of money required for improvements are based on reliable information on status. Further, from an economic point of view, stronger criteria should be applied to avoid a situation where water bodies fulfilling the objective are misjudged and new measures applied.

8.3 The Directive does not specify the levels of precision and confidence required from monitoring programmes and status assessments. This perhaps recognises that demanding a too rigorous level of precision and confidence may entail a much-increased level of monitoring for some, if not all, Member States. On the other hand the actual precision and confidence levels achieved should enable meaningful assessments of status in time and space to be made. Member States will have to quote these levels in RBMPs and will thus be open to scrutiny and comment by others. This should serve to highlight any obvious deficiencies or inadequacies in the future.

8.4 The starting point for many Member States will probably be an assessment of existing monitoring programmes to see what level of precision and confidence they are achieving. It is likely that this will have to be an iterative process with modification and revision of monitoring programmes to achieve levels of precision and confidence that allow meaningful assessments and classification.

Key Question For operational monitoring, what is the acceptable level of risk of a body being wrongly classified?

8.5 The answer partly depends on what action is likely to be required if the objective is failed. Expensive measures would require higher certainty of failure to obtain environmental quality objectives to justify them than would low cost measures. Because the implications of misclassification could be serious for water users, there should be a high level of confidence in the estimates produced from operational monitoring data. In some cases failing objectives can be serious for water users, but in many cases implementation of unnecessary measures have more serious consequences for the community and therefore it is important to judge whether or not a water body is fulfilling its objectives.

8.6 Thus the required confidence in establishing the status of a water body will be highest where the implications of a misclassification to below good status are high with costs potentially being wrongly imposed on a water user. Similarly there needs to be high confidence in ensuring that water bodies of less than good status are not misclassified as good. In short a high level of confidence will be required close to the boundary of good/moderate status.

8.7 The more water bodies identified as being at risk of failing to achieve an environmental objective, the more operational monitoring will be required. Put more accurately: the more significant pressures there are upon the water environment, the more monitoring will be required to provide the information for managing those pressures. Generally it should be easier to achieve high levels of confidence in status classification where the pressure is very high and well identified, than at sites that lie close to the good/moderate status boundary.

9. Options for reporting confidence and precision in monitoring results

9.1 The WFD does not specify how the level of confidence and precision achieved in the results of monitoring should be reported in the river basin management plans. It is recommended that the confidence and precision in the status class assigned to water bodies or groups of water bodies be reported, and appropriate information on the reasons for classification as less than good be given.

9.2 It is recommended that the main sources of uncertainty in the class assigned should be identified, with particular reference to monitoring frequencies and taxonomic resolution and how these have been used to achieve adequate confidence. As discussed above (paragraph 3.4) this is done using the normal methods by which scientists estimate the errors and confidence limits in the numerical results produced by their monitoring.

10. Conclusion

10.1 To control misclassification, Member States are recommended to apply the following principles to help achieve an adequate level of confidence in classification, as required by the WFD:

- Only use procedures (e.g. monitoring and analysis) for classification that quantify their errors and use the information on errors to calculate the risk of misclassification;

- Aim to reduce errors in the status assigned to a water body by minimising the number of different quality elements used in making the classification decision. This can be done by using only the operational monitoring results for those elements most sensitive to the pressures to which the water body, or group of bodies, is subject; and

- Aim to reduce errors, where necessary, in the results for individual quality elements by using more and better monitoring and assessment, and by estimating the condition of the biological elements using more than one indicative parameter, and then combining the results for these parameters by, for example, averaging.

11. Appendix 1: Confidence and precision in the surveillance monitoring

11.1 The objectives of surveillance monitoring are to provide information for:

a. Supplementing and validating the impact assessment procedure detailed in Annex II;
b. The efficient and effective design of future monitoring programmes;
c. The assessment of long term changes in natural conditions; and
d. The assessment of long term changes resulting from widespread anthropogenic activity.

11.2 For surveillance monitoring, Member States must monitor parameters indicative of each of the biological, physico-chemical and hydromorphological quality elements [Annex V Section 1.3.1]. This means that a larger number of different quality elements may need to be monitored in surveillance monitoring compared with operational monitoring. Suppose we monitor all the quality elements in a water body that has been declared not at risk on the basis of the pressures and impacts analysis. An initial view of the data, ignoring errors, and looking at the worst quality element might indicate the possibility that the water body is less than good status/potential and therefore at risk.

11.3 If this happens the water body should be reviewed in the pressures and impacts analysis, and if appropriate identified as being at risk. For this review, we could:

- Look at which of the results of surveillance monitoring for the different quality elements appear to dominate the result;
- Check the confidence in these particular results;
- Review the identification of pressures to see if there are any pressures that could affect these elements [Where an impact indicated by the surveillance monitoring results does not appear to be related to any known pressures, investigative monitoring may be appropriate]; and,
- Decide if the water body should be identified as being at risk and therefore subject to operational monitoring to determine its status.

11.4 The basic principles recommended in this paper for operational monitoring apply to other forms of monitoring. Monitoring results that do not include an estimate of their errors should not be used.

FOREWORD

The Water Directors of the European Union (EU), Acceding Countries, Candidate Countries and EFTA Countries have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC, “establishing a framework for Community action in the field of water policy” (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of the Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

In November 2002 the Water Directors endorsed the document ‘Towards a guidance on establishment of the Intercalibration network and on the process of the Intercalibration exercise’ (CIS Guidance Document nr. 6; “Intercalibration Guidance”).

The Intercalibration Guidance contains a detailed description of a two-step procedure for the establishment of a network of intercalibration sites in 2002-4. As a first step, water body types, pressures and quality elements were selected to focus the intercalibration. As a second step, Member States and Accession Countries selected sites representing their interpretation of the high-good and the good-moderate class boundaries. For all intercalibration sites, metadata on typology, reference conditions, and biological and physico-chemical monitoring results was provided, together with information on the criteria used for classification. According to the timetable required by the Water Framework Directive (WFD), a draft register of sites for the intercalibration register was established in December 2003, and the final register will be established by December 2004.

The Intercalibration Guidance contains a preliminary description of the process of the intercalibration exercise in 2005-6. This section was not complete, because at the time the guidance was written, it was uncertain to what degree the sites in the intercalibration network would represent an agreed view of the high-good and the good-moderate class boundaries. It was also unclear what data would be available from the sites. A “metadata analysis” was executed to make this information available, and to enable a realistic planning for the intercalibration exercise.

The purpose of the present document is to provide further guidance for the intercalibration process, which started in 2004 and will continue up to the end of 2006, The document is based on the Intercalibration Guidance, taking into account the results of the metadata analysis, ongoing discussions in Working Group A Ecological Status (WG A), and the recommendations of the expert networks on lakes, rivers, and coastal and transitional waters.

The document was edited by Wouter van de Bund (EC-Joint Research Centre), and has been developed between December 2003 and September 2004 by a drafting group consisting of Peter Pollard (UK), Ulrich Irmer (DE), Pierre-Jean Martinez (FR), Jean-Gabriel Wasson (FR), Gisela Ofenboeck (AT), Andrea Buffagni (STAR project), Kari Nygaard (EEA), Jose Ortiz-Casas (ES), Manuel Toro (ES), Anna-Stiina Heiskanen (JRC), and Wouter van de Bund (JRC).

The Water Directors have examined and endorsed this guidance during our informal meeting under the Dutch Presidency in Amsterdam (2/3 December 2004)[1].”

[1] “The Water Directors endorsed the intercalibration guidance while taking note that the parts of the text and the annexes which refer to the upcoming Commission decision on the register of sites will need to be updated when the formal decision is taken”

CONTENTS

1. Key Principles of the intercalibration process

1.1 The intercalibration process is aimed at consistency and comparability of the classification results of the monitoring systems[2] operated by each Member State for the biological quality elements[3]. The intercalibration exercise must establish values for the boundary between the classes of high and good status, and for the boundary between good and moderate status, which are consistent with the normative definitions of those class boundaries given in Annex V of the WFD[4].

1.2 The essence of intercalibration is to ensure that the high-good and the good-moderate boundaries in all Member State's assessment methods for biological quality elements correspond to comparable levels of ecosystem alteration. Intercalibration is not necessarily about agreeing common ecological quality ratio (EQR) values for the good status class boundaries as measured by different assessment methods. Common EQR values only make sense, and are only possible, where very similar assessment methods are being used or where the results for different assessment methods are normalised using appropriate transformation factors. This is because different assessment methods (e.g. using different parameters indicative of a biological element) may show different response curves to pressures and therefore produce different EQRs when measuring the same degree of impact.

1.3 The first phase of the process is the establishment of an intercalibration network for a limited number of water body types consisting of sites representing boundaries between the quality classes High-Good and Good-Moderate, based on the WFD normative definitions. The WFD requires that selection of these sites is carried out "using expert judgement based on joint inspections and all available information[5]".

1.4 The Intercalibration Guidance states that "some artificial or heavily modified water bodies could be considered to be included in the intercalibration network, if they fit in one of the natural water body types selected for the intercalibration network. Artificial and heavily modified water bodies that are not comparable with any natural water bodies should only be included in the intercalibration network, if they are dominant within a water category in one or more Member States; in that case they should be treated as one or several separate water body types". An artificial or heavily modified water body is considered to fit in a natural water type if the maximum ecological potential of the artificial or heavily modified water body is comparable to the reference conditions of the natural type for those quality elements considered in the intercalibration exercise[6].

[2] The term 'monitoring system' in the way it is commonly used includes the whole process from sampling, measurement and assessment including all quality elements (biological and other). In the context of WFD Annex V, 1.4.1, the term 'monitoring system' only refers to a biological assessment method, applied as a classification tool, the results of which can be expressed as ecological quality ratios. This guidance uses the term 'WFD assessment method' in place of the term 'monitoring system' that may be misleading in this context.

[3] The WFD intercalibration as described in Annex V, 1.4.1 does not concern the monitoring systems themselves, nor the biological methods, but the classification results

[4] WFD Annex V, 1.4.1 (ii), (iii), (iv), (vi)

[5] WFD Annex V, 1.4.1 (v)

[6] This is not the case for those quality elements that are significantly impacted by the hydromorphological alteration that has led to the water body to be designated as heavily modified.

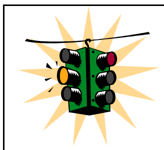
1.5 In the second phase of the process, each Member State's assessment method must be applied to those sites on the register that are both in the ecoregion (or, as pointed out in section 1.8, in the Geographical Intercalibration Group (GIG)) and of a surface water body type to which the system will be applied. The results of the second phase must be used to set the EQR values for the relevant class boundaries for each Member States' biological assessment system. The results of the exercise will be published by the Commission by 22 December 2006 at the latest.

1.6 Intercalibration sites are selected by the Member States, and represent their interpretation of the WFD normative definitions of high, good and moderate status. There is no guarantee that different Member States will have the same views on how the normative definitions should be interpreted. Differences in interpretation are reflected in the intercalibration network[7]. A common interpretation of the normative definitions should be the main outcome of the intercalibration exercise. At the end of the intercalibration exercise the intercalibration network may need to be revised according to this common interpretation.

1.7 The Intercalibration Exercise is focused on specific type/biological quality element/pressure combinations[8]. The selection of these combinations is based on the availability of adequate data within the time constraints of the exercise. This means that the exercise will not identify good status boundary EQR values for all the type/biological quality element/pressure combinations relevant for the implementation of the WFD. However, the Intercalibration Exercise will identify, and test the use of, a procedure and criteria for setting boundaries in relation to any such combinations[9].

1.8 The intercalibration process described in this guidance is aimed at identifying and resolving:
  (a) Any major/significant inconsistencies between the values for the good ecological status class boundaries established by Member States and the values for those boundaries indicated by the normative definitions set out in Section 1.2 of Annex V of the WFD; and,
  (b) Any major/significant incomparability between the values established for the good status class boundaries by different Member States.

1.9 The process will identify appropriate values for the boundaries of the good ecological status class applicable to the EQR scales produced by the Member States' assessment methods.



The EQR values appropriate for the good ecological status class boundaries will depend on the particular characteristics of each assessment method. This means that the Intercalibration Exercise may identify unique boundary EQR values for each national assessment method. These different values will nevertheless, after the Intercalibration Exercise, reflect a comparable level of anthropogenic alteration to the biological quality element

[7] Intercalibration Guidance, section 3.5
[8] as described in the document' Overview of common Intercalibration types' (available at the intercalibration site submission web pages, http://wfd-reporting.jrc.cec.eu.int/Docs/typesmanual)
[9] If the results of the method are significantly affected by biogeographical or other ecological differences within the intercalibration type, different boundary EQR values may be appropriate for different parts of the type

1.10 The Intercalibration Exercise will be undertaken within GIGs rather than the ecoregions defined in Annex XI of the WFD. This is to enable intercalibration between a maximum number of Member States.

1.11 The Intercalibration Exercise assumes that all Member States will have developed their national WFD assessment methods to a sufficient extent to enable the consistency with the normative definitions, and the comparability between Member States, of the good status boundary EQR values for those methods to be assessed during 2005. It was recognized however that this assumption might be problematic. An inventory on the state-of-the-art in the developments of WFD compliant methods is carried out during the process of finalisation of the intercalibration network[10].

1.12 The Intercalibration Exercise will set boundary EQR values for the biological quality elements using parameters, or combinations of parameters Member States intend to use in their WFD assessment methods. For better readability, the term ‘metric’ is used in this guidance as an alternative to the WFD term ‘parameter indicative of a biological quality element’.

1.13 The Intercalibration Exercise should be carried out for all agreed common intercalibration types[11]. If this is not possible, the reasons for not including a type should be reported by the GIG to WGA, which will make recommendations to Strategic Co-ordination Group (SCG) and/or WFD Committee, as appropriate.

[10] The metadata questionnaire is available at the intercalibration site submission web pages, http://wfd-reporting.jrc.cec.eu.int/Docs/ metadata
[11] As described in the document’ Overview of common Intercalibration types’ (available at the intercalibration site submission web pages, http://wfd-reporting.jrc.cec.eu.int/Docs/typesmanual)

2. Process options for intercalibration

2.1 This Section outlines different options for the process of intercalibration. Subject to the conditions for their use as outlined, each option could provide an appropriate means of ensuring the consistency and comparability of the values established for the good status class boundaries.

2.2 Taking account of the requirements of the options, and their strengths and weaknesses, GIGs should identify the most appropriate approaches for the different common intercalibration types. These approaches should then be harmonised and agreed by WG A.

2.3 All three options as well as any hybrid options require agreement on principles to derive type-specific reference conditions, and the establishment of data sets illustrating gradients of biological alteration, if possible along a pressure gradient, and at least including the two relevant class boundaries. These data sets do not necessarily need to be limited to sites from the Intercalibration Network. The normative definitions for the ecological quality classes are then applied to these data. The main difference between the options is whether this is done at Member State level using national metrics (option 3), or at GIG level using common metrics (option 1 and 2).

2.4 An outline of the main components of such a class boundary setting procedure is presented in Annex I. In the course of the intercalibration process, the GIGs should regularly report the progress. To facilitate this, the EC Joint Research Centre (JRC) will establish a simple web-based reporting system, where GIGs can report the progress made in each of the steps of this procedure on a regular basis. This makes it possible to check whether approaches followed in different GIGs are sufficiently comparable. WG A is responsible for the consistency and harmonisation of the process between GIGs and between categories (lakes, rivers, and coastal and transitional waters).

2.5 An overview of Option 1 for the intercalibration process is provided in Figure 2.1 and Table 2.1.

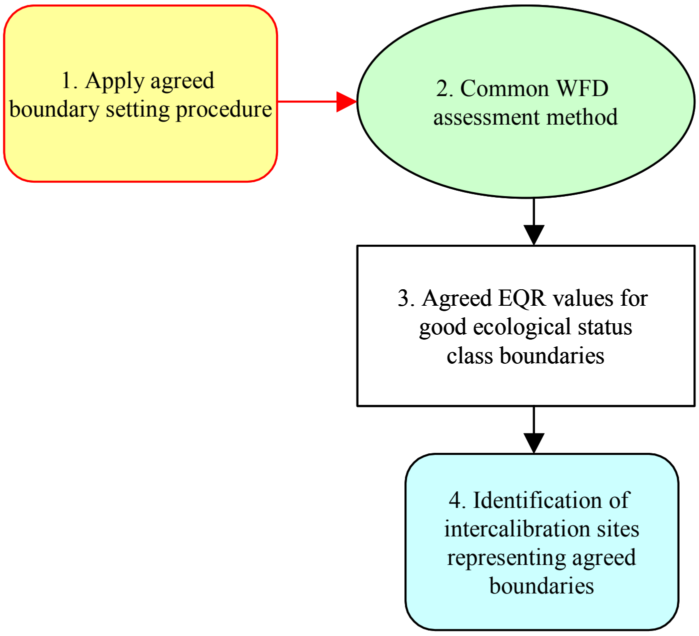


Figure 2.1. Outline of Option 1: Member States in a GIG area are using the same WFD assessment method

Table 2.1. Information on Option 1

Conditions for use	All Member States in a GIG agree to use the same method as their national assessment method for a quality element considered in the intercalibration exercise - based on the same metrics and the same means of identifying reference conditions. The metrics are calculated in the same way from data collected and analysed according to a standard procedure.
Application	Where a common assessment method is the best WFD assessment method available in the GIG area, this should always be the preferred option. For quality elements for which most Member States have not sufficiently established national assessment methods, and where a common assessment method is available[12] Where the Member States in a GIG have not sufficiently established their national WFD assessment methods for the purposes of the intercalibration exercise but can identify an interim common WFD assessment method for the purposes of the intercalibration exercise (i.e. a partial application of option 2)
Features	Does not require intercalibration of the results of different WFD assessment methods. It only requires agreement on high-good and good-moderate class boundaries of the EQR scale for the common method, by applying the class boundary setting procedure[13]

[13] e.g. (a) Reference conditions; (b) Type characteristics; (c) data on the biological quality element and the condition of

Role of the intercalibration network	Intercalibration sites are not directly used in the process of setting the boundaries. After setting the class boundaries, sites in the Intercalibration Network representing the boundary conditions will be identified.
Data requirements	Data requirements are limited to those required to apply the boundary setting procedure (i.e. the minimum requirement for setting boundaries consistent with the normative definitions). To ensure sufficient statistical confidence of the results it is recommended that the data should include a range of quality from high to at least moderate but preferably also including classes of worse status[14].
Advantages	The most straightforward option since the difficulties and uncertainties involved in comparing the results of different assessment methods are avoided. Comparability between Member States is assured. WG A can readily monitor the application of the agreed boundary setting procedure. WG A can easily make refinements to the boundary setting procedure.
Disadvantages	The opportunity to use this approach is likely to be very limited as few Member States are planning to use common WFD assessment methods.

the supporting elements across the range of status classes; (d) a means of taking into account the effects of any differences in the way biological information in the data set has been collected and analysed (the effect of bias)

[14] This condition is unlikely to be satisfied using only data from Intercalibration Sites.

2.6 An overview of Option 2 for the intercalibration process is provided in Figure 2.2 and Table 2.2.

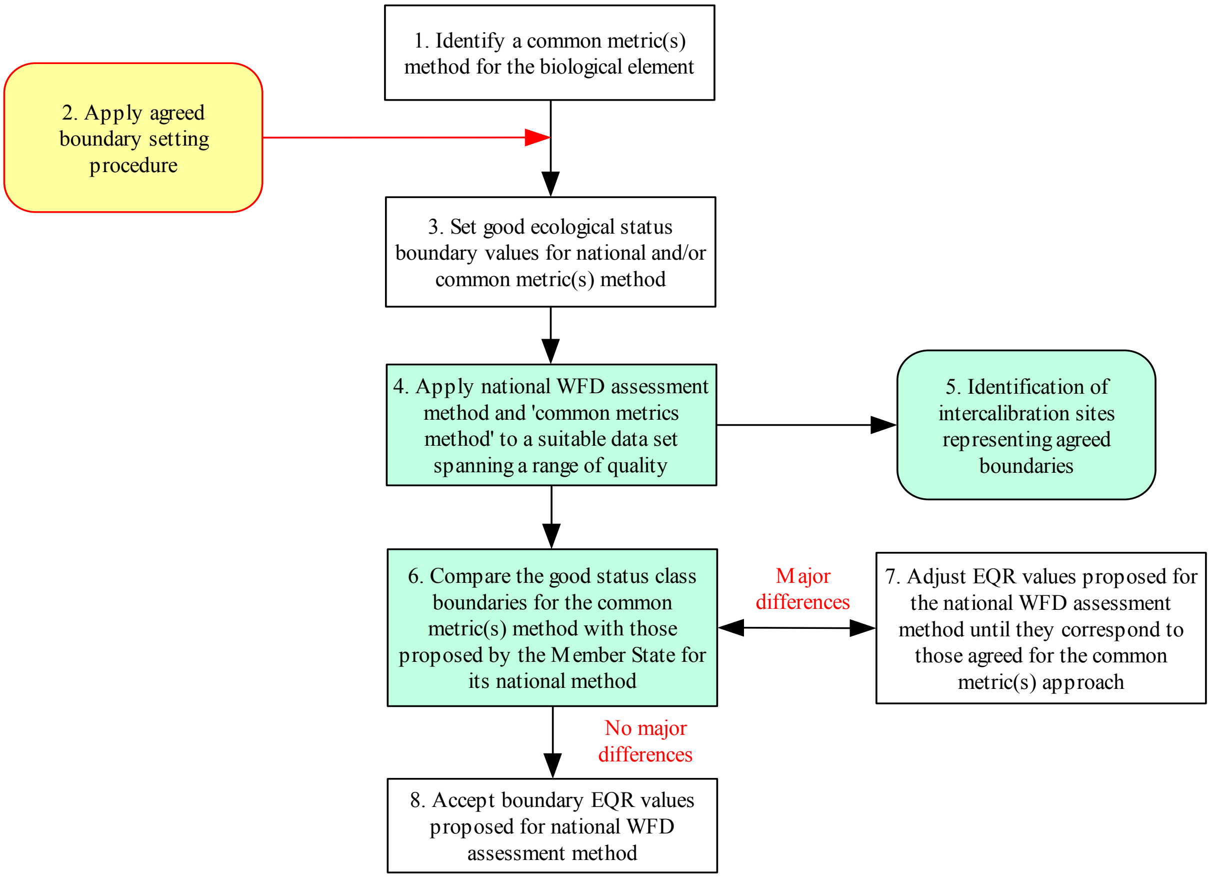

Figure 2.2. Outline of Option 2: Use of a common metric(s) method identified specifically for the purposes of the intercalibration exercise

Table 2.2. Information on Option 2.

Conditions for use	Suitable common metrics should be identified. These metrics should be indicative of the relevant biological quality element and sensitive to the pressure that is assessed. Common metrics may be selected from one of the Member State's existing assessment methods, if acceptable for the other Member States in the GIG. Availability of a suitable data set from which these common metric(s) can be calculated to enable reliable application of the agreed boundary setting procedure[15] (or the possibility to establish such a data set in the given timetable). Availability of data sets relating Member State's assessment methods to the common metric (or the possibility to establish such data sets in the given timetable). Availability of a means of estimating and taking into account differences in the bias of the methods when applied to the data set referred to above[16].

[15] e.g. (a) Reference conditions; (b) Type characteristics; (c) data on the biological quality element and the condition of the supporting elements across the range of status classes; (d) a means of taking into account the effects of any differences in the way biological information in the data set has been collected and analysed (the effect of bias)
[16] e.g. if the data set has been collected using different sampling and analysis procedures to the standard procedures

Application	Where option 1 is not possible Where suitable common metrics can be agreed upon within GIGs
Features	Involves the agreement on a common WFD method by the Member States in a GIG for the purposes of the intercalibration exercise. Such methods can be specifically developed in the GIGs, but also existing methods can be used[17]. For the common method, type-specific good status boundary values are established in the GIGs following the application of the agreed boundary setting procedure using a data set assembled for the purposes of the intercalibration exercise. The results of the common assessment method are used as the basis for adjusting the boundary EQR values of the national assessment methods. This is done by establishing quantitative relationships between common and national metrics, enabling to directly translate agreed boundary values for the common metrics into EQR values of the national assessment methods.
Role of the intercalibration network	Intercalibration sites are not necessarily used in the process of setting the boundaries. After setting the class boundaries, sites in the intercalibration network representing the boundary conditions will be identified.
Data requirements	Common metric data set for application of the boundary setting procedure for each common intercalibration type[18]. Data establishing quantitative relationships between common metrics and each national WFD assessment method[19]. To ensure sufficient statistical confidence of the results it is recommended that the data should include a range of quality from high to at least moderate but preferably also including classes of worse status[20].
Advantages	WG A can readily monitor the application of the boundary setting procedure because it is applied to one common dataset rather than to many national data sets. The expert judgements needed in the application of the boundary setting procedure are made by experts from across a GIG area. Refinements to the boundary setting procedure can be readily made by WG A. The process of agreeing on class boundaries (using common metrics) is clearly separated from the checking/adjusting of the EQR values of national assessment methods within a GIG. The approach has been at least preliminarily tested for rivers by the STAR/AQEM project The effects of random errors on the identification and adjustment of boundary values can be adequately controlled, for example, by using sufficiently large data sets

intended for the common assessment method, any significant effects of this on the results for the common method must be resolved

[17] for some water categories such common methods have already been developed (e.g. metrics developed in research projects as AQEM and STAR)

[18] The data set should be adjusted for any bias that may result from methodological differences in sampling and analysis between countries in a GIG

[19] In some cases, such relationships may already be available. E.g., the STAR project has already established relationships between many national assessment methods and a proposed common metric for rivers.

[20] This condition is unlikely to be satisfied using only data from Intercalibration Sites.

Disadvantages	Relies on the ability of each GIG to collate suitably quality assured and large data sets for the purposes of applying the agreed boundary setting procedure and setting class boundary values for the common assessment method. The quality of the data used for the boundary setting procedure to the common method may be lower than that which Member States could assemble nationally for applying the procedure directly to their national assessment methods (see Option 3).

2.7 An overview of Option 3 for the intercalibration process is provided in Figure 2.3 and Table 2.3.

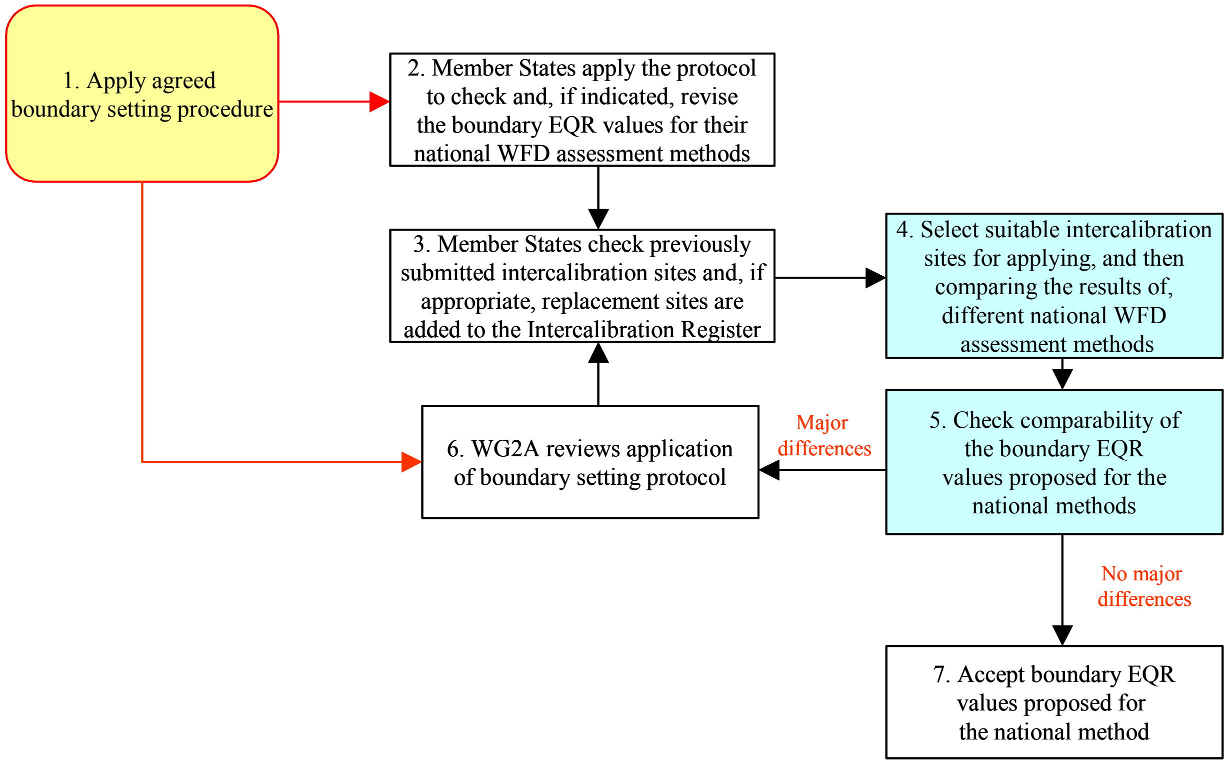

Figure 2.3. Outline of Option 3: Use of a common metric(s) method identified specifically for the purposes of the intercalibration exercise

Table 2.3. Information on Option 3.

Conditions for use	All Member States in a GIG have sufficiently developed their national WFD assessment methods for application in 2005. Availability of suitable data sets for each Member State's assessment method to enable reliable application of the agreed boundary setting procedure[21] (or the possibility to establish such data sets in the given timetable). Availability of data from intercalibration sites relating different Member State's assessment methods to each other (or the possibility to establish such data sets in the given timetable). Availability of a means of estimating and taking into account differences in the bias of the methods when applied to the data set referred to above[22].
Application	Except where Option 1 is available

[21] e.g. (a) Reference conditions; (b) Type characteristics; (c) data on the biological quality element and the condition of the supporting elements across the range of status classes; (d) a means of taking into account the effects of any differences in the way biological information in the data set has been collected and analysed (the effect of bias)]
[22] e.g. if the data sets have been collected using different sampling and analysis procedures, any significant effects of this on comparability of the results must be resolved

Features	Member States apply the boundary setting procedure using their own data sets and identify intercalibration sites representing the high-good and good-moderate class boundaries. It is assumed that all Member States within a GIG possess sufficiently developed assessment methods for the biological quality elements. The proper application of the procedure is tested by checking whether there are major differences in the results given by different Member States' assessment methods when applied to the same intercalibration sites WG A has a major role in ensuring comparability. Where there are major differences, WG A would check the application of the procedure in relation to the Member States' data sets and propose adjustments to those boundary EQR values not in line with the boundary setting procedure.
Role of the intercalibration network	Unlike Options 1 and 2, selected intercalibration sites play a central role in checking consistency and comparability of Member State's WFD assessment methods.
Data requirements	For each national assessment method included in the intercalibration exercise, Member States need to compile data sets for application of the boundary setting procedure for each common intercalibration type. To ensure sufficient statistical confidence of the results it is recommended that the data should include a range of quality from high to at least moderate but preferably also including classes of worse status[23]. For the intercalibration sites representing the high-good and good-moderate boundaries, data is needed allowing to compare the results of different Member State's assessment methods within a GIG. Collection of additional data may be needed where existing data from the selected intercalibration sites are insufficient for the purposes of applying one or more of the relevant Member States' national WFD assessment methods Information to enable expert judgements to be made about whether apparent differences between the results of Member States' methods are caused by real differences in the level of anthropogenic alteration represented by the boundary EQR values they have proposed for their national assessment methods[24]
Advantages	Simpler in principle than Option 2 in that it does not require the development of, and calibration of the results of, a common metric(s) assessment method Most clearly follows the procedure specified by the WFD. Adjustments to the good status boundary EQR values of Member States' WFD assessment methods are dictated directly by the application and refinement of the agreed boundary setting procedure rather than indirectly via a common metric(s) method (see Option 2).

[23] This condition is unlikely to be satisfied using only data from Intercalibration Sites.
[24] e.g. estimates of the errors produced by the assessment methods; information on biogeographical differences between the intercalibration sites and the sites to which the national methods are normally applicable or other ecological differences such as those that may be associated with differences in site characteristics; information on the condition of the supporting elements

Disadvantages	Relies on each Member State within a GIG being able to find at least some intercalibration sites that are considered, with adequate confidence, to be on, or close to, the good status class boundaries – or which will at least allow interpolation of the boundaries. Consistent application of the class boundary setting procedure between Member States may be difficult because this is done separately by each Member State using different data sets (using a common procedure) rather than jointly in the GIG. Iterative refinement of the boundary setting procedure may be less easy to achieve in a coordinated way than under Option 2 where a common data set is available. Organisation of the data flow may be complicated. Although WGA would not be required to hold the national data sets used for the application of the boundary setting procedure, it would need access to these data sets to check the application of the procedure, should major differences in the boundaries set by Member States be identified.

2.8 A number of hybrid options may be possible; for example:

- It may be possible to identify a simple common metric(s) method (see option 2) to underpin the development of the boundary setting procedure, but to follow Option 3 for the application of the procedure to each Member State's data, establishing boundary EQR values. This would have the advantage compared to option 3 of allowing WG A to more readily monitor the application of, and iteratively refine, the setting of the class boundaries;
- Boundary values are first established with national classification assessment methods (as in Option 3). The subsequent comparison of the boundary values could then be done with the help of a common metrics method (as in Option 2). An example of this approach, that is presently being tested in the Alpine, Central/Baltic and Mediterranean river GIGs, is presented in Annex III.

3. Contents of the final intercalibration report

3.1. According to the timetable set out in the WFD[25], the final report of the Intercalibration Exercise should be published before 22 December 2006 by the Commission. This chapter gives an outline of the expected key elements of this report.

Section 1 Overview of GIGs and Common Intercalibration Types considered in the intercalibration exercise[1]

Section 2 Results of the intercalibration for each common intercalibration type

1. Description of the Common Intercalibration Type
2. List of Member States in which the type is present
3. Biological element(s) considered in Intercalibration Exercise for the type
   e.g. Benthic invertebrates
4. Pressure(s) considered in the Intercalibration Exercise for the type
   e.g. Nutrient enrichment
5. Summary description of the 'procedure and criteria that were agreed to derive reference conditions and good ecological status class boundary values from the normative definitions for the type ('class boundary setting procedure'), with a reference to the data used in the application of the procedure for the common intercalibration type[1].
6. Intercalibration register sites representing (a) the high-good boundary; and (b) the good-moderate boundary [+ reference to where data from site can be found]
7. Overview of quantitative relationships established between common and national metrics (option 2) or between different national metrics (option 3), including an estimate of statistical uncertainty
8. Boundary EQR values established for the type/quality element/pressure combination for the common metric (where applicable) and each national WFD assessment method

For example:

Member State	Classification Method	EQR High-Good boundary	EQR Good-Moderate boundary
	Common metric	0.85	0.65
MS1	Method 1	0.85	0.60
MS2	Method 2	0.85	0.75
MS3	Method 3	0.70	0.60
MS4	Method 4	0.90	0.75
MS5	Method 5	0.85	0.60

Section 3 Conclusions stating what is achieved and what is not achieved in the intercalibration exercise

[25] WFD Annex V, 1.4.1, ix

4. Organisation of the work and timetables

4.1 The intercalibration process will be carried out under the umbrella of WG A. The Lakes, Rivers, and Coastal/Transitional Waters expert groups are subdivided in GIGs that will carry out the practical work. An Intercalibration Steering Group consisting of the JRC and representatives of the water category expert groups will summarise the results of the different GIGs and water categories and present those to WG A. An overview of the organisational structure is given in Figure 4.1.

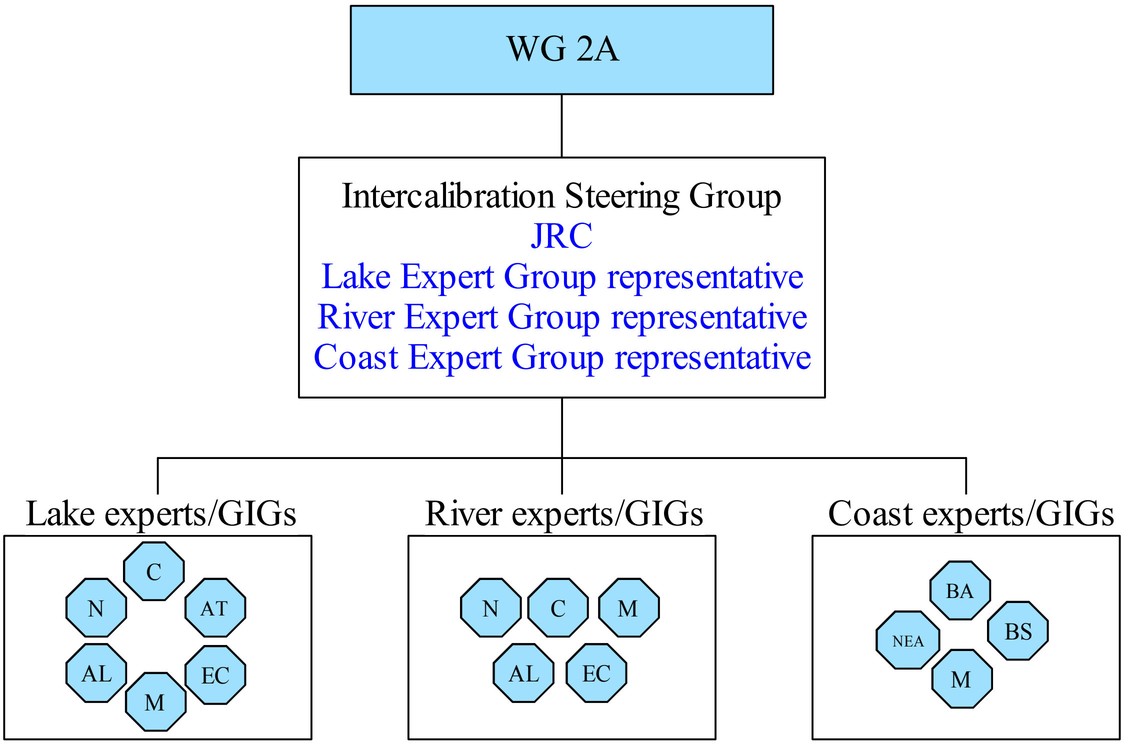

Figure 4.1: Overview of the organisational structure for the intercalibration process.

4.2 WG A is responsible for evaluating the results of the intercalibration exercise and making recommendations to the SCG or WFD Committee, as and when appropriate.

4.3 The practical work will be carried out in the GIGs, following the timetables set out in this guidance document. One of the Member States in each GIG will act as an informal GIG co-ordinator[26]. An overview of the GIGs including the participating Member States and the informal co-ordinators is given in Annex 2.

4.4 The process needs to be transparent and the results need to be coherent and consistent between GIGs and between water categories.

[26] Co-ordination of larger GIGs (e.g. Central rivers and Central lakes) may be too large a task for a single Member State. In those cases, a GIG steering group of several Member State experts could be formed.

4.5 An intercalibration steering group consisting the JRC and representatives of the water category expert groups will be established that will summarise the progress of the different GIGs and evaluate inconsistencies within and between GIGs, and report those to WG A. It is the task of WG A to resolve such inconsistencies.

4.6 The intercalibration process is facilitated by the JRC. JRC will establish a simple reporting structure where GIGs can report and update the results of the different steps of the boundary setting procedure for the different intercalibration types, and will compile the draft final report of the intercalibration exercise.

4.7 In principle, only the final results of the intercalibration procedure (as specified in Section 4 of this guidance document) are centrally reported to JRC using uniform templates. These results will be discussed in WG A, presented to the SCG and WFD Committee, and included in the final intercalibration report.

4.8 The Member States in the GIGs have the collective responsibility to bring together the data to set and/or illustrate the class boundaries, and the data enabling comparison of the classification results of different countries within the GIG. Additional sampling during the Intercalibration Exercise may be considered in the GIGs. The GIGs are free to specify the aggregation level and format for this data. To ensure transparency of the intercalibration process the original data source(s) should be specified, and the data should be made publicly available in such a form that the correct application of the boundary setting procedure can be verified.

4.9 JRC is responsible to regularly report the progress of the intercalibration process to the SCG, the Water Directors, and the WFD Committee.

Figure 4.2: General timetable including GIG milestones (M1-M5), WGA, and draft (D1-D2) and final (F) reports of the intercalibration exercise

4.10 The general timetable of the Intercalibration Exercise (Figure 4.2) is constrained by the legal deadline to finalise the intercalibration report by December 2006. This requires that WG A agrees on the report in June 2006. A first and second draft of the intercalibration report will be prepared in October 2005 and February 2006, respectively. WG A will meet twice every year and regularly provide progress reports and recommendations to the SCG and the WFD Committee.

4.11 Table 4.1 presents the different steps of the timetable for the Intercalibration Exercise in more detail, with the tasks of the GIGs, the complete. If needed, GIGs can propose modifications to this timetable depending on their specific needs (e.g. the options chosen, data availability, possibility to collect additional data, etc.), provided that this does not affect the overall process. Such modifications require agreement of WGA.

4.12 The principle milestones of the work of the GIGs are further specified in Table 4.2. The milestones are linked to the meetings of WGA. GIGs are expected to report two weeks before each WG A meeting. The Intercalibration Steering Group will then summarise the reports and present the results to WG A.

Table 4.1: Proposed overall timetable for the Intercalibration exercise

	GIGs	JRC / Steering Group	WG A
June-July 04	Agree on first suggestions on intercalibration options and carry out pilot work where possible		
July 04	**M1** Report of progress to WG A: - Composition and co-ordination - First suggestions re. options - First results if pilot work	Establishment of steering group	Meeting 7-8 July 04: - Discussion on guidance - Discussion on GIG organisation - Discussion on GIG options and pilot work
July-Sept	Meet and agree on: - Options & common metrics - Boundary setting procedure - Comment on draft guidance - New data collection needs and possibilities - Timetable of the work	Prepare template for GIG work plan	- Comments on guidance (deadline 7 September) - Drafting group on intercalibration process finalises guidance
Sept - Oct 04	**M2** Preparation GIG work plan: - Proposed option(s) - Proposed common metrics (if applicable), identify needs for new data collection - First proposal boundary setting procedure - Outline of timetable	Summarises GIG work plans and presents this to WG A	Meeting 7-8 October 04: - Agreement on guidance - Agreement on options for the GIGs and common metrics (where applicable) - Agreement on GIG timetables
Oct 04-Jan 05	- Development of boundary setting procedure[27] - Agreement on data needs for intercalibration types (depending on option chosen[28]) - Agree on principles of reference condition setting, e.g. by collating and comparing methods and values for national type-specific reference conditions for selected quality elements	- Establishment of a simple internet-based reporting structure where GIGs can report and update different steps of BSP for the different intercalibration types - Develop specific proposals for comparability checking depending on options and metrics chosen	
Feb-Mar 05	**M3** Report GIG progress (using internet reporting structure) - First report of boundary setting procedure (including principles to set reference conditions)[29] - Overview of data requirements	Summarise GIG progress reports and prepare WG A meeting	Meeting March 05: - Agreement on boundary setting procedures and data requirements
Feb-Aug 05	- Collate data sets to apply boundary setting procedure at GIG level (option 1/2) or at Member State level (option 3) for all types - Apply boundary setting procedure for all types (including setting values for reference conditions and good ecological status boundary values for common metrics (Option 1/2) or national metrics (Option 3) - Identify intercalibration sites		

[27] At this stage, GIGs may decide to focus on specific common intercalibration types/pressures/quality elements
[28] Option 1/2 – data quantifying the relations between common and national metrics. Option 3 – data directly comparing assessment methods between Member States using intercalibration sites
[29] For this first report GIGs may choose to focus on specific common intercalibration types, pressures and/or quality elements

	representing agreed class boundaries (all options) and start compiling data for assessing comparability between Member States using those sites (Option 3) - Collate data sets relating common metrics with Member State's national metrics and propose EQR values for national metrics using these data (Option 2)		
Sep-Oct 05	**M4** Report GIG progress - Report on ongoing application of boundary setting procedure - Identification of intercalibration sites representing agreed class boundaries	Summarise GIG progress reports and prepare WG A meeting	Meeting October 05: - Identify inconsistencies between MS classification results

M5	Report GIG progress - Report on ongoing application of boundary setting procedure (using internet reporting structure) - Identification of inconsistencies within the GIG	2 weeks before WG A meeting	February 2006
M6	Type-specific reports including EQR boundary values and identification of sites representing good status boundaries	2 weeks before WG A meeting	June 2006

[30] For this first report GIGs may choose to focus on specific common intercalibration types, pressures and/or quality elements

Annex I. Framework for deriving class boundary values consistent with the WFD normative definitions

[To be implemented iteratively with the expert groups at water category or GIG level]

The table below sets out a procedure designed to ensure that, if applied correctly, the good status boundary EQR values established for an assessment method will be consistent with the WFD Annex V normative definitions. The procedure relies on the establishment of data illustrating the degradation of biological quality element for a common intercalibration type.

GIGs are expected to apply this boundary setting procedure for each of the common intercalibration types, and to report how they have applied the different steps to WG A on a regular basis. The steps do not necessarily need to be completed in the order indicated. It should be rather thought of as an iterative process. However, GIGs should complete all steps before the end of the intercalibration exercise (2006),

Outline components of a boundary setting procedure	
1. Describe type-specific reference conditions for biological quality elements	*Reference conditions are the starting point of WFD classification. Agreement on reference conditions for the common intercalibration type is a requirement for intercalibration of the classification outcome. GIGs should describe a procedure and criteria for deriving reference conditions, and apply this to their common intercalibration types.* *A comparison of Member States views on what very minor disturbance means in practice is likely to highlight any potentially significant differences between Member States view of the class boundaries*
2. Agree rules for deriving high-good boundary for biological quality element consistent with the normative definitions	*An explicit description of what constitutes a 'slight deviation from reference conditions' should be given.* *Intercalibration requires agreement on the way the high-good biological boundary value is derived[31]. This may include a relation to the physico-chemical and hydromorphological conditions.* *A comparison of Member States' approaches should highlight any potentially significant differences*
3. Establish a data set illustrating reference conditions and the degradation of the biological quality element along a pressure gradient[32]	*The ecological status classes represent different degrees of degradation from reference conditions in the condition of biological quality elements. Data about on the degradation path is needed to interpret and illustrate the normative definitions.* *The description of the degradation path should be relatable to the criteria specified in the normative definitions. The descriptions should be in terms of metrics derived from the*

[31] If a spatial network of reference sites is used to quantify reference conditions and/or class boundaries using statistical criteria, the criteria used to select sites for this reference network should be specified (e.g. pressure criteria, 'best available, etc.)
[32] Using common metrics (Option 1-2) or Member State's assessment methods (Option 3)
[33] The pressure gradient does not need to be quantified – although it would be useful for the purposes of checking comparability if it was

		basic biological data. The pressure gradient itself should preferably be quantified in relation to the biological changes, since this is necessary to arrive at certain pressure reductions required to reach good status for the biological element[33]
4.	Describe criteria for good status and moderate status classes derived from the normative definitions and related to the way in which the quality element degrades from reference conditions with increasing pressure	*Boundary setting has to be based on a common understanding of what the normative definitions of high, good and moderate class mean in the context of each intercalibration type/quality element/pressure combination.*
5.	Method/criteria used to derive good-moderate status boundary values	*The criteria developed in point 4 may be translated into a framework of rules for setting boundaries – the final component of the boundary setting procedure*
6.	Apply the criteria to the data set(s) established in step 3 and establish EQR values for the high-good and the good-moderate ecological status boundaries	*The outcome of the boundary setting procedure is reference values and good status boundary EQR values established consistent with the WFD normative definitions.*

Annex II: List of Geographical Intercalibration Groups (GIGs)

Informal GIG co-ordinator(s) (Steering Group members for Central Lakes and River GIGs) indicated in **bold**

Geographical Intercalibration Groups

1) Rivers

Name of the GIG	Countries comprising rivers GIGs
Northern	Finland Ireland Norway **Sweden** United Kingdom
Central/Baltic	Austria Belgium Czech Republic Denmark Estonia **France** **Germany** Ireland Italy Latvia Lithuania Luxemburg Netherlands Poland Spain Sweden **United Kingdom**
Alpine	**Austria** France Germany Italy Slovenia Spain
Eastern Continental **(ICPDR)**	Austria Bulgaria Czech Republic Greece Hungary Romania Slovakia

Mediterranean	Cyprus France Greece Italy Malta **Portugal** Spain

2) Lakes

Name of the GIG	Member States comprising lakes GIGs
Northern	Finland Ireland Norway **Sweden** United Kingdom
Central/Baltic	Belgium **Denmark** Estonia France Germany Hungary Latvia Lithuania **Netherlands** **Poland** **United Kingdom**
Atlantic	**Ireland** Portugal Spain United Kingdom
Alpine	**Austria** France Germany Italy Slovenia
Mediterranean	Cyprus France Greece Italy Malta Portugal Romania **Spain**

3) Transitional and coastal waters

Name of the GIG	Member States comprising coastal GIGs

Baltic	Denmark Estonia Finland Germany Latvia Lithuania Poland Sweden
North-East Atlantic	Belgium Denmark France Germany Ireland Netherlands Norway Portugal Spain Sweden **United Kingdom**
Mediterranean	Cyprus France Greece Italy Malta Slovenia Spain
Black Sea	Bulgaria **Romania**

Annex III: Example of a hybrid intercalibration option

An example of a hybrid intercalibration approach is given in Figure III.1. In this approach boundaries are initially set by the Member State (as in Option 3), then compared to a common metric (as in Option 2), and harmonised where necessary). Common metrics enable a GIG-wide comparison of classification results. Several river GIGs identified this as the most promising option, and tested it in the autumn of 2004. For this approach to be successful it is essential that there is agreement within the GIG on criteria to derive reference conditions.

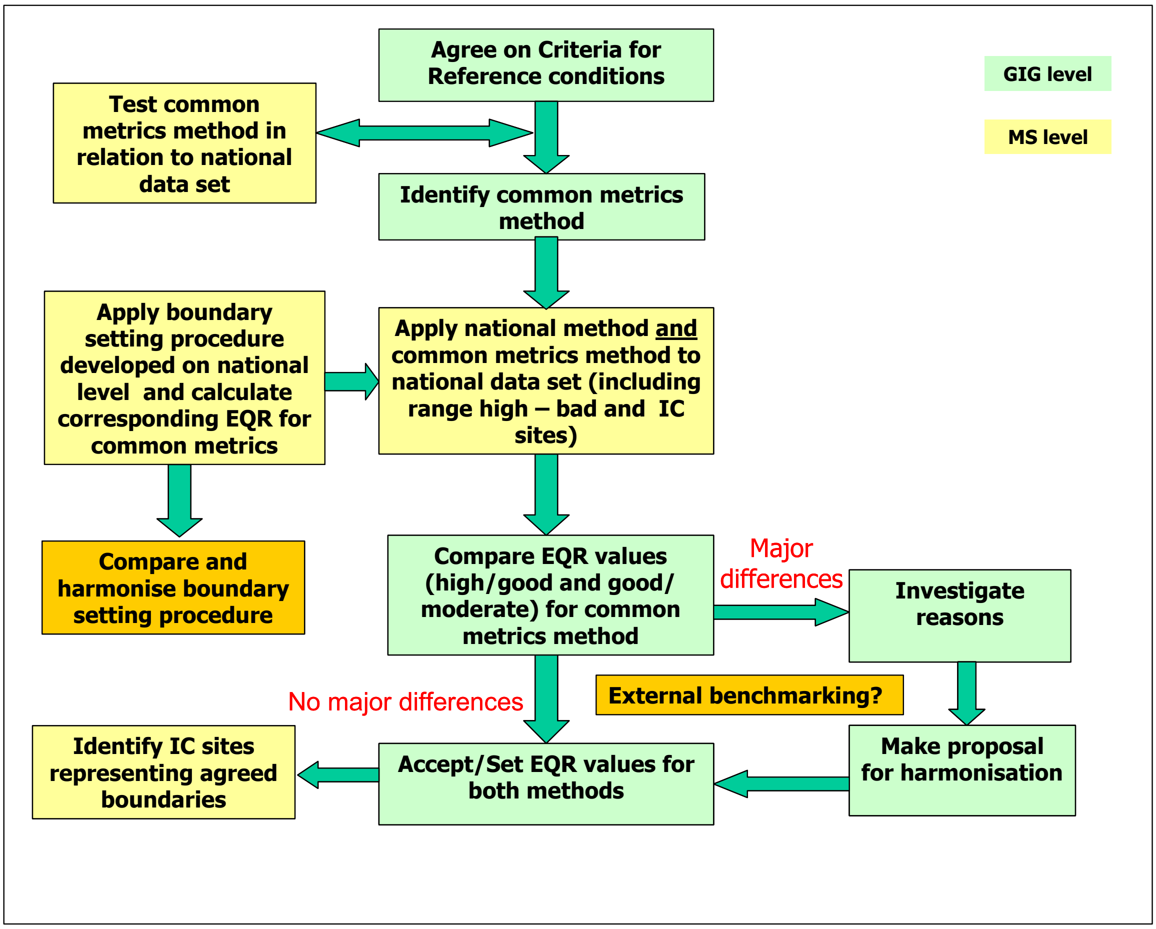

Figure III.1: Example of a hybrid intercalibration approach, combining elements of Options 2 and 3.

In this approach it is not necessary to compile a single data set at the GIG level, avoiding the problem of collating data from different countries applying different methods. Instead, Member States apply a common metric to their own data sets, and compare this to their national assessment results. This approach is especially suitable in cases where Member States have relatively well-developed assessment methods in place at the start of the intercalibration exercise (e.g. macroinvertebrate assessment methods for rivers), and where a robust common metric is available. This procedure is undergoing testing in the Alpine, Mediterranean, and Central/Baltic river GIGs, with very promising results.

Because initially the class boundary setting procedure is only applied by Member States using their own data and methods, it will be necessary to compare and harmonise the different steps of the class boundary setting procedure within the GIG. If the comparison of Member State's classification results using the common metric show that there are no major differences between countries this should be a relatively trivial task; if there are major differences that cannot be resolved within the GIG it may be necessary to directly apply the class boundary setting procedure to a benchmarking data set (best available classification)

COMMON IMPLEMENTATION STRATEGY FOR THE WATER FRAMEWORK DIRECTIVE (2000/60/EC)

Guidance Document No. 15

Guidance on Groundwater Monitoring

FOREWORD

The Water Directors of the European Union (EU), Acceding Countries, Candidate Countries and EFTA Countries have jointly developed a common strategy for supporting the implementation of the Directive 2000/60/EC, "establishing a framework for Community action in the field of water policy" (the Water Framework Directive). The main aim of this strategy is to allow a coherent and harmonious implementation of the Directive. Focus is on methodological questions related to a common understanding of the technical and scientific implications of the Water Framework Directive.

In particular, one of the objectives of the strategy is the development of non-legally binding and practical Guidance Documents on various technical issues of the Directive. These Guidance Documents are targeted to those experts who are directly or indirectly implementing the Water Framework Directive in river basins. The structure, presentation and terminology is therefore adapted to the needs of these experts and formal, legalistic language is avoided wherever possible.

In the context of the above-mentioned strategy, a guidance document "Monitoring under the Water Framework Directive" has been developed and endorsed by the Water Directors in November 2002 (CIS Guidance Document Nr. 7). This document provides Member States with Guidance on monitoring of inland surface water, transitional waters, coastal waters and groundwater, based on the criteria provided in Annex V of the Water Framework Directive.

As a follow-up, and in the context of the development of the new Groundwater Directive under Article 17 of the Water Framewortk Directive, Member States have expressed the need to clarify issues of groundwater monitoring related to e.g. quantitative and chemical status monitoring, protected area monitoring, or monitoring linked to prevent/limit measures. A project to develop a guidance document complementing the CIS Guidance Document Nr. 7 has, therefore, been designed in 2004, and an informal drafting group has been established under the umbrella of the CIS Working Group on Groundwater (WG C). This drafting group has been coordinated by Austria and the United Kingdom, and involved a range of experts from other Member States and from stakeholder organisations.

The present Guidance Document is the outcome of this drafting group. It contains the synthesis of the output of discussions that have taken place since December 2004. It builds on the input and feedback from a wide range of experts and stakeholders that have been involved throughout the procedure of Guidance development through meetings, workshops, conferences and electronic media, without binding them in any way to this content.

"We, the water directors of the European Union, Norway, Switzerland and the countries applying for accession to the European Union, have examined and endorsed this Guidance during our informal meeting under the Finnish Presidency in Inari (30 November-1st December 2006). We would like to thank the participants of the Working Group C and, in particular, the leaders of the monitoring drafting group, Austria and the United Kingdom, for preparing this high quality document.

We strongly believe that this and other Guidance Documents developed under the Common Implementation Strategy will play a key role in the process of implementing the Water Framework Directive and the newly adopted Groundwater Directive.

This Guidance Document is a living document that will need continuous input and improvements as application and experience build up in all countries of the European Union and beyond. We agree, however, that this document will be made publicly available in its current form in order to present it to a wider public as a basis for carrying forward ongoing implementation work.

We also commit ourselves to assess and decide upon the necessity for reviewing this document in the light of scientific and technical progress and the experiences gained in the monitoring programmes of the Water Framework Directive".

Monitoring Guidance for Groundwater

THE COMMON IMPLEMENTATION STRATEGY (CIS) OF THE WFD

The Water Framework Directive (2000/60/EC)[1] is a comprehensive piece of legislation that sets out, *inter alia*, “good status” objectives for all waters in Europe. The Directive provides for a sustainable and integrated management of river basins including binding objectives, clear deadlines and comprehensive programme of measures based on scientific, technical and economic analysis including public information and consultation. Soon after its adoption, it has become clear that the successful implementation of the Directive will be equally as challenging and ambitious for all countries, institutions and stakeholders involved.

In order to address the challenges in a co-operative and coordinated way, the Member States, Norway and the Commission agreed on a Common Implementation Strategy (CIS) for the Water Framework Directive only five months after the entry into force of the Directive. Furthermore, the Water Directors stressed the necessity to involve stakeholders, NGOs and the research community in this joint process as well as to enable the participation of Candidate Countries in order to facilitate their cohesion process.

In the first phase of the joint process, a number of guidance documents were prepared and these documents were tested in Pilot River Basins across Europe in 2003 and 2004. In the new Work Programme 2005/2006, the four Working Groups (Ecological Status, Integrated River Basin Management, Groundwater and Reporting) have continued addressing the key issues for implementation. In addition, new groups on ‘WFD and Agriculture’, ‘GIS’ and ‘Chemical Monitoring’ are sharing experiences in this area and a new Pilot River Basin network is supporting the technical activities in all working groups.

1 PURPOSE AND SCOPE OF THE GUIDANCE

This guidance has been drafted in response to a mandate from the WFD Groundwater Working Group (Working Group C). This mandate required the development of practical guidance and technical specifications for groundwater monitoring that builds on, and complements existing WFD guidance[2]. Its primary focus is on the requirements of the Water Framework Directive (WFD), and in particular the obligations set out in Article 8. In addition, it will meet the requirements of the daughter Groundwater Directive (adopted at the end of 2006)[3]. The guidance also forms one of the elements of the WFD Chemical Monitoring Activity.

This document provides guidance on establishing groundwater monitoring programmes to meet the requirements of the WFD and of the new Groundwater Directive. These programmes include both quantitative and chemical (quality) monitoring for status and trend assessment, monitoring to support (ground)water body characterisation and drinking water protected area objectives.

The establishment of high quality long-term monitoring programmes is essential if the implementation of the WFD and the daughter Groundwater Directive is to be effective. It is recognised that monitoring can be very expensive and so the guidance presented here aims to establish cost-effective, risk-based and targeted groundwater monitoring across Europe that enables WFD objectives to be met. However, inadequate investment in monitoring, including network infrastructure and data quality and management will result in a significant risk of failure to meet the WFD’s environmental objectives.

[3] European Parliament and Council Directive on the protection of groundwater against pollution and deterioration (adopted in December 2006)

Recommendations expressed in this guidance paper will help to implement consistent monitoring across Europe. The guidance provides useful elements for the development and maintenance of networks at high standards and thereby provide the necessary information to assess (ground)water status, identify trends in pollutant concentrations, support establishment and assessment of programmes of measures and the effective targeting of economic resources.

2 BACKGROUND

Article 8 of the WFD requires the establishment of programmes for the monitoring of groundwater. WFD groundwater monitoring is focussed primarily on the groundwater body as a whole but it also supports the overall management of the river basin district and the achievement of its environmental objectives.

The groundwater monitoring programmes must provide the information necessary to assess whether relevant Article 4 environmental objectives are met, in particular the assessment of groundwater quantitative status, chemical status and significant, long-term trends in natural conditions and trends in groundwater bodies resulting from human activity. In addition, these may need to be supplemented by additional monitoring programmes to meet requirements relevant to Protected Areas (e.g. Drinking Water Protected Areas) and to support the validation of the Article 5 characterisation and risk assessment procedures. Programmes meeting these requirements must be operational by 22 December 2006 at the latest.

The WFD sets out the requirements for the different groundwater monitoring programmes in Annex V (2.2 and 2.4) and Annex II (2.3), which must include:

- A **quantitative monitoring network** to supplement and validate the Article 5 characterisation and risk assessment procedure with respect to risks of failing to achieve good groundwater quantitative status in all groundwater bodies, or groups of bodies. Its principal purpose is therefore to facilitate quantitative status assessment.
- A **surveillance monitoring network** to: (a) supplement and validate the Article 5 characterisation and risk assessment procedure with respect to the risks of failing to achieve good groundwater chemical status; (b) provide information for use in the assessment of long-term trends in natural conditions and in pollutant concentrations resulting from human activity and; (c) to establish, in conjunction with the risk assessment the need for operational monitoring.
- An **operational monitoring network** to: (a) establish the status of all groundwater bodies, or groups of bodies, determined as being ‘at risk’, and (b) establish the presence of significant and sustained upward trends in the concentration of pollutants.
- Appropriate monitoring to support the achievement of Drinking Water Protected Area (DWPA) objectives.

The results of the monitoring must be used to:

- establish the chemical and quantitative status of groundwater bodies (including an assessment of the available groundwater resource);
- assist in further characterisation of groundwater bodies;
- validate the risk assessments carried out under Article 5;
- estimate the direction and rate of flow in groundwater bodies that cross Member States’ boundaries;
- assist in the design of programmes of measures;
- evaluate the effectiveness of programmes of measures;
- demonstrate compliance with DWPA and other protected area objectives;
- characterise the natural quality of groundwater including natural trends (baseline); and
- identify anthropogenically induced trends in pollutant concentrations and their reversal.

Specific provisions concern those bodies of groundwater which cross the boundary between two or more Member States. Bilateral agreement should be reached on monitoring strategies, which requires coordination of conceptual model development, the exchange of data and QA and QC aspects (in line with the requirements of Article 13(2) of the WFD). The provisions for the surveillance monitoring require transboundary groundwater bodies to be monitored for those parameters which are relevant for the protection of all uses supported by the groundwater flow.

An overview of the objectives for each monitoring programme described in detail in this guidance document is shown in Table 1.

The WFD stipulates that surveillance monitoring must be undertaken during each planning cycle, and operational monitoring must be carried out during periods not covered by surveillance monitoring. No minimum duration or frequency is specified for the surveillance programme. Operational monitoring must be carried out at least once a year during periods between surveillance monitoring. Member States should undertake sufficient surveillance monitoring during each plan period to allow adequate validation of Article 5 risk assessments and obtain information for use in trend assessment, and sufficient operational monitoring to establish the status of bodies at risk and the presence of significant and sustained upward trend in pollutant concentrations.

Table 1: Overview of the relationship of monitoring objectives for each monitoring programme defined by, or to support, the WFD and the daughter Groundwater Directive

	WFD Specified Monitoring Programmes			**Drinking Water Protected Area (DWPA) Monitoring**	**Prevent and Limit Monitoring**
Monitoring objective(s)	**Quantity Monitoring**	**Surveillance Monitoring**	**Operational Monitoring**

Assess the effectiveness of Programmes of Measures	✓		✓	✓	✓

[1]) Results will support characterisation in future RBMP cycles

[2]) Assumes new Groundwater Directive will require DWPA objectives to he met for good status

3 GENERAL PRINCIPLES

The monitoring programmes must provide the information necessary to assess whether the WFD environmental objectives will be achieved. This means that a clear understanding of the environmental conditions required for the achievement of the objectives, and of how these could be affected by human activities, is essential for the design of effective monitoring programmes. The monitoring programmes should therefore be designed on the basis of the results of the Article 5 characterisation and risk assessment procedure and the **conceptual model/understanding** of the groundwater system in which the general scheme of ‘recharge-pathway-discharge’ is known. Detail and importance of such models is already laid down in relevant CIS guidance[4]. Chapter 3.1 outlines the principles and relationship of the model to the monitoring programme.

[4] Guidance Document No. 3: Analysis of Impacts and Pressures – Working Group 2.1 IMPRESS (2003)
Guidance Document No. 7: Monitoring under the Water Framework Directive – WG 2.7 Monitoring (2003);

Considering the principles described in this guidance should allow for the establishment of a monitoring network which is **representative** for the groundwater body. The amount of monitoring required (number of points and sampling frequency) will be proportional to the difficulty in (a) judging the status of the groundwater body, (b) the presence of adverse trends, and (c) the implications of errors in such judgements, in particular with regard to setting up programmes of measures.

It should be emphasised that the WFD monitoring programme is intended to focus on phenomena affecting the **overall state of the groundwater body**. Local scale pollution processes which do not affect the overall state of the groundwater body should be the target of different monitoring activities run by the appropriate competent authorities (e.g. a regulatory, local authority etc.) responsible for the relevant legal provisions. Such local impacts are not relevant at the groundwater body scale unless their evolution in time and space endangers the environmental objectives of the groundwater body. They may, however, be relevant with respect to assessments linked to 'prevent/limit' measures covered by Article 11 of the WFD and Article 6 of the daughter Groundwater Directive, which are discussed in a separate guidance document.

The application of the term 'body of groundwater' must be understood in the context of the hierarchy of relevant definitions provided under Article 2 of the WFD. Accordingly, a *body of groundwater* means a distinct volume of groundwater within an aquifer or aquifers. *Groundwater* means all water, which is below the surface of the ground in the saturated zone and in direct contact with the ground or subsoil and *aquifer* means a subsurface layer or layers of rock or other geological strata of sufficient porosity and permeability to allow either a significant flow of groundwater or the abstraction of significant quantities of groundwater. Furthermore, **groundwater bodies may be grouped** i.e. for the purpose of monitoring.

The design of a monitoring network should take into account the **three-dimensional** nature of the groundwater system and both, **spatial and temporal variability**, especially when determining the location of monitoring sites and the selection of appropriate monitoring site types. The network should have a spatial and temporal density which considers the natural characteristics of the groundwater body (conceptual understanding) and the pollution risks, to help focus monitoring activities in areas where significant pressures combined with higher vulnerability exist.

In order to contribute to a three-dimensional representative monitoring network an advanced conceptual understanding of hydrogeological characteristics and pressures is essential, especially where there is evidence of significant vertical variation in the aquifer characteristics and stratification of groundwater quality.

The **selection/location** of appropriate sampling sites and the selection of appropriate site density should be based on the conceptual understanding (hydrogeological characteristics and pressures) and might be supported by using existing information such as:

- existing quality and/or quantity data (length, frequency, range of parameters);
- construction characteristics of existing sites and the abstraction regime;
- the spatial distribution of existing sites compared to the scale the groundwater body; and
- practical considerations relating to easy and long-term access, security, health and safety.

The selection of appropriate monitoring **site types** within a monitoring network at groundwater body level should be based on an understanding of the objectives of monitoring and the understanding (conceptual or otherwise) of travel times and/or groundwater ages that the monitoring site may typically sample. This understanding may be enhanced by groundwater age dating where appropriate.

Detailed information on the site should be available and be routinely reviewed. This information should be used to assess the suitability of the site to be used in the relevant monitoring programme. Elements for characterising sampling sites are summarised in Annex 2 as well as the advantages and disadvantages of different monitoring installations/points (types and uses) in Annex 3.

Integrated monitoring will contribute significantly to cost-efficient monitoring by making best use of appropriate components of existing monitoring networks serving different objective and by designing and operating integrated groundwater and surface water monitoring networks.

3.1 CONCEPTUAL MODELS AS BASIS FOR MONITORING

Conceptual models/understanding are simplified representations, or working descriptions, of the hydrogeological system being investigated. Their development underpins much of the work carried out as part of the characterisation process. As the amount of, and confidence in, the available environmental information increases, the accuracy and complexity of the model improves, so that they become more effective and reliable descriptions of the system.

The conceptual model will represent the current understanding of the groundwater system based on the knowledge of its natural characteristics (e.g. the aquifer type, three-dimensional structure, dynamics and boundary conditions), perceived pressures and knowledge of impacts.

In this guidance, two types of conceptual model/understanding are used:

- the regional conceptual model – an understanding of the factors at groundwater body scale that identifies the need to establish a monitoring network/point and how the data will be used;
- the local conceptual model – an understanding of the local factors influencing the behaviour, both in chemical and quantitative terms, of individual monitoring points.

Within (inter)national river basins large differences may and do occur in the geochemical and hydrogeological characteristics of groundwater bodies. Therefore conceptual models may differ between regions within a(n) (inter)national river basin. A regional conceptual model/understanding will identify the specific requirements for establishing a monitoring network and the degree of monitoring, in terms of number of sites, site density and frequency of monitoring. This model/understanding will be consistent with that developed and used as part of the characterisation and risk assessment process.

Figure 3.1 outlines the principles and relationship of the model to the monitoring programme.

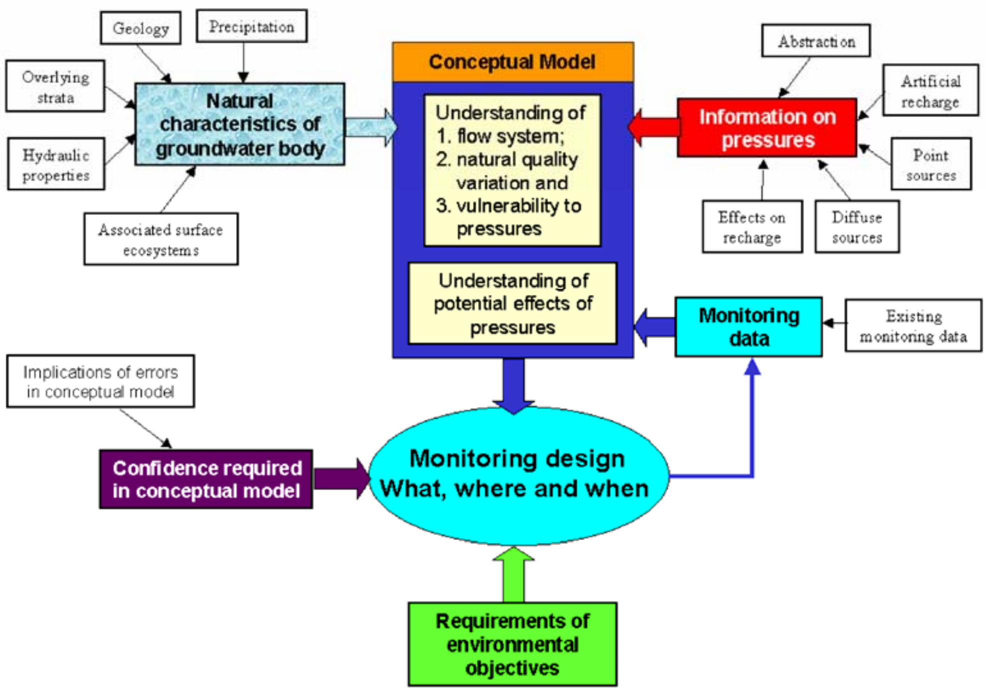

Figure 3.1: Link between the conceptual model/understanding and monitoring (from CIS WG 2.7 Monitoring Guidance)

The selection of groundwater monitoring points also requires knowledge of the local factors influencing the behaviour of the monitoring point. This enables an assessment to be made of the point's suitability for providing representative information and data to support the objectives of the monitoring programme. This conceptual understanding is vital for the effective operation of the monitoring programme.

In developing the local conceptual understanding, information on local hydrogeological and environmental conditions is required. This information includes:

- monitoring point construction details;

- hydrogeological setting;
- understanding of recharge sources and patterns;
- local groundwater flow pattern(s) and regime within the catchment area;
- abstraction impacts;
- existing hydrochemical data;
- approximate size of catchment area;
- land use and pressures within the catchment area.

Information about travel times and/or or groundwater age distribution may be a very useful input to the conceptual model/understanding as well as for validating the model. Monitoring data obtained from the WFD monitoring programmes should be used to test, validate and refine the conceptual model(s). This process should be started before the first data are available and continued until there is adequate confidence in its/their reliability. Testing may include using the conceptual model and measured values of chemistry and/or water level to predict conditions at locations elsewhere within the groundwater body that are not monitored and then installing monitoring to check these predictions to confirm the model or identify what refinements are needed.

In addition to assisting with the design of the monitoring network the conceptual model is also extremely important for understanding and interpreting the monitoring data.

3.2 AQUIFER TYPES

A consideration of the different types of aquifers is an essential part of the conceptual model/understanding. A diverse range of hydrogeological settings and aquifer types is found across Europe. This broad variation has major implications for the suitability of different types of sampling installation and how effectively they represent changes in groundwater systems, and monitoring design needs to be tailored accordingly.

For all groundwater bodies, there is a need to consider the characteristics of the strata forming the aquifers with regard to flow paths and flow mechanisms, storage, unsaturated zone thickness, groundwater recharge and discharge, before determining the most appropriate means of monitoring. The scale of the groundwater body i.e. whether there are local and rapid flow paths or much longer and slower regional ones, and the nature of the geological material, in particular whether groundwater movement is dominantly through the intergranular spaces between the grains of sedimentary rocks or via the fractures in consolidated rocks are key factors in this respect.

Hence a clear understanding is needed of what each monitoring point represents in terms of the groundwater bodies in which they are located, and the response times of the groundwater both to pressures imposed upon them and to measures to control their impacts.

A summary of the range of aquifer settings found across Europe and the range of likely response times is given in Annex 1.

3.3 GROUPING OF GROUNDWATER BODIES

As proposed by the CIS guidance on the Identification of Water Bodies[5], groundwater bodies may be grouped for monitoring purposes provided that the monitoring information obtained provides a reliable assessment of the status of each body in the group and the confirmation of any significant upward trends in pollutant concentrations.

In grouping groundwater bodies, the monitoring programmes must be designed and operated to ensure that the environmental and monitoring objectives for each of the component bodies making up the group can be reliably achieved.

Where groundwater bodies are determined to be **not at risk** according to the Article 5 review process, bodies may be grouped if they are sufficiently similar in terms of aquifer characteristics, pathway susceptibility(ies), pressure(s) and confidence in the risk assessment(s).

In undertaking the grouping:

- bodies do not necessarily need to be adjacent to each other;

---

[5] Guidance Document No. 2: Identification of Water Bodies (2003).

- a monitoring point is not required in each of the component bodies within the group provided there is sufficient overall monitoring in the group as a whole to meet the requirements of operational surveillance, quantitative or protected area monitoring, as appropriate.

Where groundwater bodies are determined to be **at risk** according to the Article 5 review process, bodies may be grouped if they are sufficiently similar in terms of aquifer characteristics, pathway susceptibility(ies), pressure(s) and confidence in the risk assessment(s). In undertaking the grouping:

- bodies should be adjacent to each other except in exceptional circumstances (e.g. numerous small comparable groundwater bodies; islands);
- it is recommended that each component body should have at least one monitoring point to determine the relationship between the bodies. However the number of monitoring points will depend on the aquifer characteristics, pathway susceptibility(ies), pressure(s) and confidence in the risk assessment(s);
- operational monitoring may be focused on one or more component bodies selected on the basis of the conceptual model, e.g. the most sensitive body(ies). This prioritised monitoring is designed to deliver cost-effective targeted environmental monitoring.

3.4 INTEGRATED MONITORING

The WFD considers the water environment as a continuum. This is reflected in the groundwater status definition and through the recognition of the role played by groundwater in maintaining the flow, quality and ecology of dependent surface waters and vice versa. Therefore as well as providing an overview of the distribution of contaminants in the body of groundwater, monitoring should be able to provide an understanding and assessment relating to groundwater flows between groundwater bodies and surface water bodies and between groundwater bodies and terrestrial ecosystems. The extent of this monitoring will depend on the significance of the dependency of the surface water bodies and/or terrestrial ecosystems on groundwater and the extent of the risks.

Monitoring programmes for surface water and groundwater should therefore be designed and operated in an integrated way where the environmental objectives of surface waters and groundwater are dependent on each other. Surface waters with a large proportion of groundwater derived base flow can be used to indicate the quality of groundwater and monitoring data from surface water bodies may support the assessment of groundwater body status. In many cases, the correct location of a surface water sampling point, e.g. close to an aquifer discharge point, may function as a monitoring point for both programmes.

The integration of available wells and springs already used for other purposes (monitoring or abstractions) has several advantages as it contributes to a representative reflection of the state of groundwater. It can also contribute significantly to cost-effective monitoring but has to be done carefully in order to avoid bias. Boreholes in regular operation have the advantage of less need of purging before sampling. However, a network dominated by drinking water abstractions might not adequately reflect the overall environmental quality of the groundwater across the whole body. This is because they are often situated in locations where the groundwater quality is good, e.g. away from recharge areas, or abstract only from deeper parts of the aquifer. It is important to note that when drinking water abstraction sites are used for monitoring, it is raw water quality that should be sampled and analysed. A representative monitoring network should ideally be based on a balanced mixture of different sampling site types as well as sampling site uses. The advantages and disadvantages of different monitoring points (types and uses) are summarised in Annex 3.

3.5 NETWORK REVIEW AND UPDATE

As the conceptual model is refined and the understanding of the hydrogeology and hydrochemistry of the groundwater system improves, the network design should be reviewed and adapted if required. The monitoring results obtained from the network should be interpreted regularly and the monitoring network and its operation reviewed at least once every six years, but ideally more frequently.

Updating of the network should take into account the observed variations in the natural processes and/or anthropogenic impacts influencing groundwater quantity and quality, trends and emerging phenomena. As knowledge improves, it can be seen as a network optimisation process. Review and updating of the network should be performed every time the factors influencing the observed phenomena change significantly, and should take account of the likely response times of the aquifers, in relation to the expected ages of the groundwater being sampled.

However, when updating the network, it is important to remember that deleting a monitoring site will lead to a potential loss of useful information and that to correctly assess trends, it is important to keep sampling sites with long time series. It is easier to add a site than delete one. It is also important to maintain the data for sites taken off the network to enable audit and review of previous decisions/management plans based on these data.

The removal of site from the network may also introduce bias. Any changes to the network must be assessed in terms of the impact this will have on the information being derived from the monitoring programme and the decisions being made.

4 CHEMICAL STATUS AND TREND MONITORING

Groundwater monitoring programmes are required to provide a coherent and comprehensive overview of water status within each river basin, to detect the presence of long-term anthropogenically induced trends in pollutant concentrations and ensure compliance with Protected Area objectives. As stressed in the daughter Groundwater Directive, reliable and comparable methods for groundwater monitoring are an important tool for assessment of groundwater quality (and this is applicable to quantity as well).

A groundwater body will be at good chemical status if the following criteria are satisfied:

- *General water quality*: The concentrations of pollutants should not exceed the quality standards applicable under other relevant Community legislation in accordance with Art. 17;
- *Impacts on ecosystems*: The concentration of pollutants should not be such as would result in failure to achieve the environmental objectives specified under Article 4 for associated surface waters nor any significant diminution of the ecological or chemical quality of such bodies nor in any significant damage to terrestrial ecosystems which depend directly on the groundwater body*;*
- *Saline intrusion*: The concentrations of pollutants should not exhibit the effects of saline or other intrusions as measured by changes in conductivity.

The WFD requires both surveillance and operational programmes to be established to provide the information needed to support the assessment of chemical status and identification and monitoring of pollutant trends.

Monitoring programmes specifically for addressing protected areas and prevent and limit objectives are covered separately in sections 6 and 7 respectively.

4.1 DESIGN OF THE SURVEILLANCE MONITORING PROGRAMME

Surveillance monitoring is focusing on the groundwater body as a whole. A ‘surveillance monitoring’ programme is required to:

- *Validate risk assessments:* supplement and validate the characterisation and risk assessment procedure with respect to risks of failing to achieve good groundwater chemical status;
- *Classify groundwater bodies:* confirm the status of all groundwater bodies, or groups of bodies, determined as not being at risk on the basis of the risk assessments; and
- *Assess trends:* provide information for use in the assessment of long-term trends in natural conditions and in pollutant concentrations resulting from human activity.

Surveillance monitoring is required in bodies or groups of bodies both at risk and not at risk of failing WFD objectives. The programme must be carried out during each River Basin Management cycle, irrespective of whether the groundwater body (or group of bodies) is at risk.

Surveillance monitoring should be undertaken in each plan period and to the extent necessary to adequately supplement and validate the risk assessment procedure for each body or group of bodies of groundwater.

The surveillance monitoring programme will also be useful for defining natural background levels (as defined in the daughter Groundwater Directive) and characteristics within the groundwater body. This will enable future changes in conditions to be assessed, reference data to be acquired and typologies to be investigated. This information will be useful for characterising transboundary water bodies and as a basis for European-wide reporting.

In designing a surveillance programme, the required confidence in the monitoring results must be defined in order to achieve sufficient confidence in the assessment. The required confidence in surveillance monitoring depends upon the variability of the groundwater or aquifer properties in question. In principle, the uncertainty from the monitoring process should not add significantly to the variability of the monitoring data.

The acceptable risk of not identifying a new pollution pressure or a trend change should also be established and this information used when establishing the objectives for the monitoring, managing the monitoring programme(s) and assessing data quality and variability.

4.1.1 Selection of surveillance monitoring determinands

The recommended core set of determinands comprises dissolved oxygen, pH-value, electrical conductivity, nitrate, ammonium, temperature and a set of major and trace ions. Parameters such as temperature and a set of major and trace ions are not formally required by the WFD but may be helpful to validate the Article 5 risk assessment and the conceptual models. Selective determinands (e.g. heavy metals and relevant basic radio nuclides) will be needed for assessing natural background levels.

Additional indicators of anthropogenic contaminants typical of land use activities in the area and with the potential to impact on groundwater will also be required on an infrequent basis (see below) to provide additional validation of WFD risk assessments and to check for any new identified pressure.

In addition at all sites monitoring of the water level is recommended in order to describe (and interpret) the 'physical status of the site' and to interpret (seasonal) variations or trends in chemical composition of groundwater.

Further information on both core and selective determinand suite selection is provided in Annex 3.

4.1.2 Selection of representative surveillance monitoring sites

The selection of sampling sites and their operation is of major importance for the results of the later assessment procedure especially as contaminants are often unevenly distributed across a body of groundwater. The spatial distribution of contaminants is related to the location of different pressures e.g. point and diffuse sources (different types of land use). Additionally a body of groundwater is three dimensional and the concentration of contaminants may vary significantly in vertical and lateral direction. Common variations of hydrodynamic and hydro-geochemical characteristics inside a body of groundwater can have significant impact on the parameter specific spreading of contaminants and should be taken into account during the selection of monitoring sites. Furthermore the physico-chemical parameters (e.g. electrical conductivity, temperature and contaminant concentrations) in shallow aquifers sometimes reveal a distinct variation over the year.

The selection process should be based on three main factors:

- the conceptual model(s) including assessment of the hydrological, hydrogeological and hydrochemical characteristics of the body of groundwater including characteristic travel times, distribution of different types of land uses (e.g. settlement, industry, forest, pasture/farm land), pathway susceptibility, receptor sensitivity and existing quality data;
- assessment of risk and the level of confidence in the assessment; including the distribution of key pressures[6] and;
- practical considerations relating to the suitability of individual sampling points (see Annex 3). Sites need to be easily accessed, secure and be able to provide long-term access agreements.

An effective monitoring network will be one in which the sites are able to monitor for the potential impacts of identified pressures and the evolution of groundwater quality along the flow paths within the body.

---

[6] It should be noted that the risk assessment – as carried out under Article 5 of the WFD – and the identification of key pressures should enable identification of specific pollutants that contribute to the determination of groundwater bodies as being "at risk". Under the new Groundwater Directive, consideration will need to be given for establishing threshold values (groundwater quality standards) for these substances by the end of 2008. They should therefore be considered in the list of parameters to be monitored.

Where risk issues relate to specific receptors such as ecosystems, additional sampling points can be focussed in areas that are close to these receptors. In these cases, where the location of pressures (point sources) is well known, sampling points will often be used to help isolate impacts from different pressure types, assess the areal extent of impacts and determine contaminant fate and transport between the pressure and the receptor. In some cases this may involve the use of multi-level samplers although, as noted in Annex 3, such installations can be very expensive.

Site selection factors must be assessed on a site by site basis, but key principles are as follows:

- *Suitable types of site:* Selection should be based on the regional conceptual model of the groundwater bodies (or group of bodies) and a review of existing and candidate monitoring sites, the local conceptual model. Surveillance monitoring is not, on its own, required to isolate the impact of individual pressures and the effectiveness of programmes of measures, but should give an overview of the water quality within the groundwater body or group of groundwater bodies. Large abstractions and springs may therefore provide suitable sampling sites, as they draw water from a large area and volume of aquifer particularly in homogeneous systems. Springs are particularly recommended in karstic or shallow fracture flow dominated aquifers. However, a representative monitoring network should ideally be based on a balanced mixture of different sampling site types as well as sampling site uses (e.g. abstraction, monitoring etc.). In some hydrogeological systems where the groundwater contributes significantly to the (base)flow of the surface water course, then sampling of the surface water may provide a representative groundwater sample.
- *Representativity:* In some aquifer systems, stratification may occur. In this case the location of monitoring points must be focussed on those parts of the groundwater body that are most susceptible to pollution. This will often be the upper parts. However to provide a representative assessment of the distribution of contaminants for the groundwater as a whole additional monitoring in other parts of the groundwater body is also required.
- *'At risk' bodies*: Surveillance monitoring sites will provide the basis for the operational monitoring i.e. based on the results the network can be adapted accordingly. Sites could be used for both programmes.
- *'Not at risk' bodies where confidence in the risk assessment is low:* The number of monitoring points should be sufficient to be representative of the range of pressure and pathway conditions in the groundwater body (or group of bodies) with the aim of providing the data necessary to supplement the risk assessment, i.e. increase confidence. The location of sampling points may therefore be focussed on the most susceptible areas of the groundwater body(ies) for each pressure/pathway combination. The final distribution per grouping will depend on availability of suitable surveillance sites and the distribution of pressures. As a general guide, a minimum of 3 points in a groundwater body or group of bodies is recommended. However where groundwater bodies are large and heterogeneous, it is likely that significantly more monitoring points will be needed to meet the monitoring objectives.
- *Groups of groundwater bodies where pressures are limited (low or absent):* In groups of groundwater bodies that are defined as 'not at risk' and confidence in the risk assessment is high, sampling stations will be required primarily to assess natural background levels and natural trends. Locations should therefore be selected accordingly.

4.1.3 Monitoring frequency

The selection of appropriate monitoring frequency will generally be based on the conceptual model and existing groundwater monitoring data. Where there is adequate knowledge of the groundwater system and a long-term monitoring programme is already established this should be used to determine an appropriate frequency for surveillance monitoring. Where knowledge is inadequate and data are not available, Table 2 suggests frequencies for surveillance monitoring that can be adopted for different aquifer types. Of major importance is the change of concentration patterns with time which influences the selected monitoring frequency as does the increased knowledge of the conceptual understanding. In general, shallow groundwater bodies are rather dynamic with respect to water quantity and quality variation. If such variability occurs, monitoring frequency has to be selected accordingly in order to characterise this variability adequately.

In less dynamic groundwater systems two samples per year may be sufficient initially for surveillance monitoring. If this monitoring shows no significant variation over a river basin cycle (six years) a further reduction of sampling frequency may be appropriate.

Due to possibly time-related changes of concentration patterns, especially in rather dynamic groundwater flow systems, sampling per monitoring location must be executed at the same distance of time (frequency-related). This guarantees comparable monitoring results and a proper trend assessment.

The results of surveillance monitoring should be reviewed on a regular basis and frequencies adjusted accordingly to ensure that the information requirements are fully met and a cost-effective programme maintained.

Table 2: Proposed monitoring frequencies for surveillance monitoring (where understanding of aquifer systems is inadequate).

Note: This table proposes monitoring frequencies that can be used as a guide where the conceptual understanding is limited and existing data are not available. Where there is a good understanding of groundwater quality and the behaviour of the hydrogeological system, alternative monitoring frequencies can be adopted as necessary.

		Aquifer Flow Type				
		Confined	**Unconfined**			
			Intergranular flow significant		**Fracture flow only**	**Karst flow**
			Significant deep flows common	**Shallow flow**		
Initial frequency – core & additional parameters		Twice per year	Quarterly	Quarterly	Quarterly	Quarterly
Long term frequency – core parameters	**Generally high-mod transmissivity**	Every 2 years	Annual	Twice per year	Twice per year	Twice per year
	Generally low transmissivity	Every 6 years	Annual	Annual	Annual	Twice per year
Additional parameters (on-going validation)		Every 6 years	Every 6 years	Every 6 years	Every 6 years	-

4.2 DESIGN OF THE OPERATIONAL MONITORING PROGRAMME

Operational monitoring is focusing on the groundwater body as a whole. An ‘operational monitoring’ programme is required to establish:

- the chemical status of all groundwater bodies, or groups of bodies, determined as being ‘at risk’;
- the presence of any long term anthropogenically induced upward trends in the concentration of any pollutant; and
- it can also be used to assess the effectiveness of programmes of measures implemented to restore a body to good status or reverse upwards trends in pollutant concentrations.

Operational monitoring is required only in bodies 'at risk’ of failing to meet WFD objectives. It should be carried out during the periods between surveillance monitoring. In contrast to surveillance monitoring, operational monitoring is highly focussed on assessing the specific, identified risks to the achievement of the Directive’s objectives.

In designing an operational monitoring programme, the required confidence in the monitoring results must be defined. The required confidence in operational monitoring depends upon the variability of the impact source and the groundwater or aquifer properties in question, as well as the risk in case of error. In principle, the uncertainty from the monitoring process should not add significantly to the uncertainty of controlling the risk.

The acceptability of not identifying a new risk or controlling a known risk should be established, used for setting objectives for the variability of the properties in question and used for control of the monitoring quality with respect to data variability.

4.2.1 Selection of operational monitoring determinands

In most cases, both core and selected determinands will be required at each sampling station (see footnote 6 concerning the requirement to establish groundwater threshold values under the daughter

Groundwater Directive). Guidance on selection of core and selective determinands is provided in Annex 3.

The selection process will be based on:

- Characterisation and conceptual model(s) including an assessment of groundwater pathway susceptibility, receptor sensitivity, the time taken for any programme of measures to be effective and the ability to differentiate between the effects of different measures .
- Assessment of risk and the level of confidence in the assessment; including the distribution of key pressures identified in the characterisation process and which may cause the body to be classified as at poor status.
- Practical considerations relating to the suitability of individual sampling points.

4.2.2 Selection of representative operational monitoring sites

When selecting monitoring sites, their locations should be prioritised on the basis of:

- Availability of suitable existing sites (e.g. from the surveillance monitoring programme) that provide representative samples.
- Potential for supporting different WFD monitoring programmes (e.g. suitable springs can act as quality, quantity and surface water sampling stations).
- Potential for integrated multi-purpose monitoring, e.g. combining requirements for Nitrates Directive monitoring, Drinking Water Protected Area monitoring, monitoring linked to registration of plant protection or biocidal products[7], IPPC Directive monitoring and Groundwater Directive compliance.
- Potential linkages with existing/planned surface water monitoring sites.

Where risk issues relate to specific receptors such as ecosystems, additional sampling points can be focussed in areas that are close to these receptors. This monitoring, as well as contributing to status and trend assessment can also help to distinguish the impacts from different pressure types, assess the spatial extent of impacts and determine contaminant fate and transport between the source and the receptor. This information will be important to the risk assessment and characterisation process. It may include monitoring of the upper parts of the aquifer and possibly water draining from soils, e.g. multi-level samplers, lysimeters and field drain sampling.

Where pressures and risk issues relate to the groundwater itself, e.g. diffuse pressures, sampling points will be more distributed across the body, and will be focussed on the different pressures and their distribution within the groundwater body. Where necessary it may be appropriate to focus resources on the most representative or sensitive combinations of pressures and groundwater susceptibility.

4.2.3 Monitoring frequency

Monitoring frequency selection will generally be based on the conceptual model and in particular, the characteristics of the aquifer and its susceptibility to pollution pressures. Table 3 proposes monitoring frequencies for operational monitoring for different aquifer types where the conceptual understanding is limited and existing data are not available. Where there is a good understanding of groundwater quality and the behaviour of the hydrogeological system, alternative monitoring frequencies can be adopted as necessary.

Sampling frequency and sample timing at each monitoring location should furthermore consider:

- requirements for trend assessment;
- whether the location is upgradient, directly below, or downgradient of the pressure. Locations directly below a pressure may require more frequent monitoring;
- the level of confidence in Article 5 risk assessments, and changes in the assessments over time;

---

[7] See recommendations formulated by the Forum for the Co-ordination of pesticide fate models and their use (FOCUS). Final report of the Ground Water Group of Focus, European Commission, DG SANCO, 2006

- short term fluctuations in pollutant concentrations, e.g. seasonal effects. Where seasonal and other short-term effects are likely to be encountered, it is essential that sampling frequencies and timings are adjusted (increased) accordingly and that sampling takes place at the same time(s) each year, or under the same conditions, to enable comparable data for trend assessment, accurate characterisation and status assessment; and
- land use management patterns, e.g. the period of pesticides or nitrate application. This is especially important for rapid flow system like karstic aquifers and/or shallow groundwater bodies.

Sampling for operational monitoring must be continued until the groundwater body is determined, with adequate confidence, to be no longer at poor status <u>or</u> at risk of being at poor status <u>and</u> there is adequate data to demonstrate a reversal of trends.

Table 3: Proposed frequencies for operational monitoring.

		Aquifer Flow Type				
		Confined	**Unconfined**			
			Intergranular flow significant		**Fracture flow only**	**Karst flow**
			Significant deep flows common	**Shallow flow**		
Higher vulnerability groundwater	**Continuous pressures**	Annual	Twice per year	Twice per year	Quarterly	Quarterly
	Seasonal / intermittent pressures	Annual	Annual	As appropriate	As appropriate	As appropriate
Lower vulnerability groundwater	**Continuous pressures**	Annual	Annual	Twice per year	Twice per year	Quarterly
	Seasonal / intermittent pressures	Annual	Annual	As appropriate	As appropriate	As appropriate
Trend assessments		Annual	Twice per year	Twice per year	Twice per year	-

5 QUANTITY MONITORING

A quantitative monitoring network is required to assist in characterisation, to determine the quantitative status of groundwater bodies, to support the chemical status assessment and trend analysis and to support the design and evaluation of the programme of measures.

A groundwater body will be at good quantitative status if:

- the available groundwater resource is not exceeded by the long-term annual average rate of abstraction; and
- the groundwater levels and flows are sufficient to meet environmental objectives for associated surface waters and groundwater dependent terrestrial ecosystems; and
- anthropogenic alterations to flow direction resulting from level change does not cause saline or other intrusion.

As with other networks, the monitoring design should be based on a conceptual understanding of the groundwater system and the pressures. The key elements of the quantitative conceptual understanding will be:

- assessments of recharge and water balance; and/or
- existing groundwater level or discharge assessments and relevant information on the risks for groundwater dependent surface waters and groundwater dependent terrestrial ecosystems.
- the degree of interaction between groundwater and related surface and terrestrial ecosystems where this interaction is important and could potentially cause the surface water body status to be affected.

The development of a quantitative monitoring network can be iterative; data collected from new monitoring points being used to enhance and refine the conceptual model used to locate each monitoring point in the groundwater body as a whole and the operation of the quantitative monitoring programme.

Implementation of a numerical groundwater model or a hydrological model integrating groundwater and surface water are useful tools in compiling and interpreting quantitative monitoring data and identifying resources and ecosystems at risk. Furthermore, the uncertainty estimates that can be obtained with a numerical model can help identify parts of a groundwater body where additional data points will add most to the description of groundwater quantity and flow.

5.1.1 Monitoring parameters

Although the Directive identifies groundwater level as the metric for determining quantitative status, in practice, the requirements of status assessment mean that additional supporting information will be required. Recommended parameters for the purposes of quantitative assessment of groundwater include:

- groundwater levels in boreholes or wells;
- spring flows;
- flow characteristics and/or stage levels of surface water courses during drought periods (i.e. when the flow component directly related to rainfall can be neglected and discharge is sustained substantially by groundwater);
- stage levels in significant groundwater dependent wetlands and lakes.

Selection of the monitoring points and parameters must be based on a sound conceptual model of the water body to be monitored.

Additional monitoring to support groundwater characterisation and classification may include:

- chemical and indicator parameter (e.g. temperature, electrical conductivity) monitoring for saline or other intrusions. For island aquifers it may also be appropriate to monitor the fresh/saline water transition zone. This may include;
- rainfall and the components required to calculate evapo-transpiration (to calculate groundwater recharge);
- ecological monitoring of groundwater dependent terrestrial ecosystems (including ecological indicators); and
- groundwater abstraction (and artificial recharge).

Specific requirements for the supportive monitoring data, to supplement the knowledge gained from groundwater level monitoring will largely be determined by the tools/methods that will be employed to support the assessment of risk or status and the confidence required in this assessment.

Key to parameter selection is how representative the parameter is of the hydrogeological setting being monitored and the significance of its role in determining risk or status.

In some hydrogeological settings monitoring groundwater levels in a borehole may be inappropriate for the purposes of the Directive and in some cases highly be misleading. In these circumstances the flow characteristics of associated watercourses or springs may provide better data with which to undertake an assessment. This is most likely to be the case in low permeability/fractured aquifers. There are cases, when the water level remains more or less stable but water from other aquifers, surface waters or even seawater is intruding. Specific conditions should be considered for groundwater bodies on islands. If there is the risk of waters intruding, then appropriate water quality indicators should be monitored, e.g. electrical conductivity and water temperature.

5.1.2 Selection of monitoring density

Monitoring may be required at two different scales to meet the various requirements of the Article 4 objectives. Firstly, where possible, groundwater levels and flows across a groundwater body should be assessed. These may be related to the water balance assessment for the body as a whole. Secondly, more focussed ‘local’ monitoring of levels and flows that relate to relevant local groundwater supported receptors, i.e. surface water bodies (rivers, lakes, estuaries) and groundwater dependent terrestrial ecosystems, may be needed. The latter may include supporting information e.g. salinity monitoring (with respect to saline intrusions) or supporting information from ecological monitoring as already performed under other relevant community legislation (as evidence of impact on ecosystems from groundwater abstractions).

In groundwater bodies or groups of groundwater bodies assessed as being 'not at risk', the monitoring can be minimised. Indeed, monitoring need not be located in each body within a group, provided that the groups are hydrogeologically comparable.

In groundwater bodies or groups of groundwater bodies assessed as being 'at risk', the distribution of monitoring points will reflect the need to understand the hydrogeological conditions that relate to the receptors identified as being 'at risk' and to their perceived importance. Monitoring density must be sufficient to ensure proper assessment of impacts due to abstractions and discharges on groundwater level.

Specific provisions concern those bodies of groundwater which cross the boundary between two or more Member States, such as the location of groundwater abstraction points providing more than 10 m³ a day or serving more than 50 persons, the abstraction rates, direct discharges to groundwater etc. The number of sampling sites should be sufficient to be able to estimate the direction and rate of groundwater flow across the Member State boundary.

5.1.3 Monitoring frequency

The amount and frequency of monitoring will be determined by the data needed to determine risk and status, and where necessary to support the design and assessment of a programme of measures.

Frequency of monitoring predominantly depends of the characteristics of the water body and the monitoring site respectively. Sites with significant annual variability should be monitored more frequently than sites with only minor variability. In general monthly monitoring will be sufficient for quantity monitoring where variability is low but daily monitoring would be preferred (particularly when measuring flows). The frequency should be revised as knowledge of the aquifer response and behaviour improves and in relation to the significance of any changes in pressures on the groundwater body. This will ensure that a cost-effective programme is maintained.

6 PROTECTED AREA MONITORING

Member States are required to meet the standards and objectives of any Protected Areas established under other relevant community legislation and identified in Annex IV of the WFD. Where these specify a requirement for the monitoring of groundwater it is assumed that as part of the implementation process Member States are complying fully with these requirements and following any relevant guidance. The guidance contained here only addresses the requirements for the WFD.

Further details regarding protected areas are described in the guidance document on 'Groundwater Protected Areas'.

To ensure monitoring programmes are as efficient and as effective as possible, it would be appropriate to ensure that the quantitative and the chemical monitoring programmes described above complement, and are integrated with, the programmes established for Protected Areas so that the groundwater monitoring networks are as far as possible multi-purpose.

6.1 DRINKING WATER PROTECTED AREA MONITORING

The WFD requires that monitoring programmes are able to assess the achievement of Drinking Water Protected Area (DWPA) objectives defined under Article 7. Unlike surface water bodies defined as DWPAs, the WFD does not introduce any additional specific monitoring criteria for DWPAs. However, the DWPA objectives require that any monitoring is also able to provide accurate and reliable data to support DWPA management and assessment. For example this information will be needed to identify any deterioration in the quality of abstracted groundwater that may potentially lead to an increase in the level of purification/treatment. It will not be necessary to monitor for all the parameters specified by the Drinking Water Directive (80/78/EEC as amended by 98/83/EC). Only those parameters that are directly related to the quality of the groundwater (raw water) need to be considered. The list of the parameters will be based on the results of the risk assessment, existing knowledge of groundwater quality and the purification treatment regimes in place at drinking water sources.

Monitoring in groundwater DWPAs should therefore be carried out in accordance with the programmes set out for surveillance and/or operational monitoring as relevant to that groundwater body in order to meet Article 4 objectives, with the added requirement to ensure compliance with

DWPA objectives (Article 7(3)) and the information requirements of ‘further characterisation’ set out in Annex II (2.3c) of the WFD.

The Article 7(3) objective of aiming to prevent deterioration in the water quality of DWPAs in order to reduce treatment implies that there are background quality data for DWPAs at the date of implementation of this objective, against which any subsequent deterioration can be assessed. No specification for this is provided so it may be assumed that only monitoring sufficient to assess this objective is needed. It seems clear that raw water quality data are needed and it is logical to assume that this should be focused on potable abstraction sources.

Regular monitoring of all potable sources would not be practical or necessary where the characterisation processes has indicated no risk. In water bodies or groups of bodies not at risk of meeting DWPA objectives it is recommended that there should be sufficient monitoring of a representative selection of significant potable sources (those to which the Drinking Water Directive applies – see note below[8]) to confirm the risk assessment. This should be incorporated into and may in practice already be part of the surveillance monitoring programme or another national monitoring programme. The relevant criteria for surveillance monitoring therefore apply. It should be noted that the Drinking Water Directive also includes a requirement to meet standards for microbiological parameters and radioactivity and these may need to be include in any DWPA monitoring programme where these may potentially lead to a failure of DWPA objectives.

In water bodies at risk of not meeting DWPA objectives, it is recommended that significant potable sources should be monitored, as a minimum, at least once before and at least once within each RBMP period. Where appropriate, this monitoring may be focussed on, or restricted to, areas where the pressures and/or impacts that are giving rise to the risk are relevant to the quality of abstracted water. Safeguard zones may be used to focus such monitoring (and subsequently to focus any necessary protection measures). If data from drinking water (raw water) monitoring already exist, these can be used as well.

In many cases potable abstraction sources will form part of the surveillance and operational monitoring programmes. In these cases, the specific requirements of the surveillance and operational monitoring programmes will take precedence over the monitoring outlined above. Where sources are part of surveillance and/or operational monitoring programmes, more frequent data than indicated above will be available and should be used for assessing compliance with Article 7 objectives.

In some cases individual groundwater abstraction points may form part of a group of sources that effectively abstract water from the same zone of contribution or safeguard zone within the DWPA. In such cases, providing that the monitoring regime is consistent and representative, not all individual sources may need to be monitored to adequately assess compliance with Article 7 objectives.

---

[8] A significant potable source is defined as one intended for human consumption that comes within the requirements of the Drinking Water Directive (Directive 80/778/EEC as amended by Directive 98/83/EC). That is a source where;

- water abstracted from an individual supply provides 10 m³ a day or more as an average or serves at least 50 persons, unless supplied as part of a commercial or public activity in which cases the thresholds do not apply;

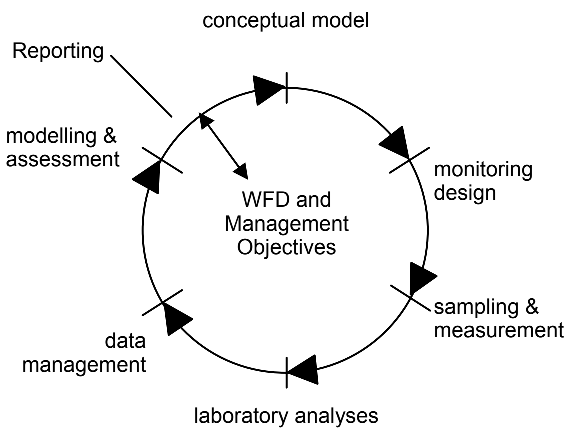
and that is not:

- a natural mineral water recognised as such by the competent national authorities, in accordance with Council Directive 80/778/EEC of 15 July 1980 on the approximation of the laws of the Member States relating to the exploitation and marketing of natural mineral waters; or
- water which is a medicinal product within the meaning of Council Directive 65/65/EEC of 26 January 1965 on the approximation of provisions laid down by law, regulation or administrative action relating to medicinal products.

7 PREVENT AND LIMIT MONITORING

Groundwater quality monitoring is required to assess the effectiveness of the measures introduced to prevent or limit the inputs of pollutants and/or the deterioration of the status of groundwater (in accordance with Article 11(3) of the WFD and Article 6 of the daughter Groundwater Directive). Although surveillance and operational monitoring programmes will contribute significantly to this, there may be a need for specific additional monitoring programmes aimed at point source pressures. Therefore, this guidance distinguishes between surveillance and operational monitoring focused on the groundwater body as a whole and **prevent and limit monitoring** focused on point sources.

Prevent and limit monitoring of this type is designed primarily at ensuring compliance with site conditions and authorisations in the cases of regulated activities or for site specific investigation, i.e. compliance monitoring, or for the purposes of characterising site specific impacts and designing and assessing remedial action programmes, i.e. investigation monitoring.



These programme requirements may already be defined by specific regulation aimed at preventing or limiting the input of pollutants to groundwater, e.g. Landfill Directive requirements for landfill monitoring or Groundwater Regulations requirement for requisite surveillance. It may also be designed specifically to investigate other localised issues, e.g. contaminated land or accidental spillages.

Although prevent and limit monitoring is not explicitly requested in the WFD, the information derived from this monitoring should be used for characterisation and the investigation of specific issues, as well as ensuring that Programmes of Measures are being effective. It should not be used specifically for status and trend assessment, although some monitoring sites may potentially be used for surveillance and/or operational monitoring. However, where such sites are used, they must fully conform to the quality assurance requirements of WFD monitoring programme sites. Where sites do not comply they should be rejected.

8 ENSURING QUALITY OF MONITORING DATA

The quality required for groundwater monitoring depends upon the purpose but must be defined for each step in the entire process which consists of:

- conceptual modelling,
- monitoring design,
- field sampling and measurements,
- laboratory analysis,
- transfer, storage, modelling,
- interpretation of data,
- result reporting

The required quality should be obtained by defining sets of verifiable quality requirements for each step in the process. The quality requirements should not be defined independently from each other, in order to avoid setting higher quality standards for one step than can be accommodated by the others. The variability of the system to be monitored, the uncertainty associated with sampling and analysis, the risks involved in case of error and the costs should be considered in setting quality requirements that are fit for purpose.

8.1 QUALITY REQUIREMENTS

Quality requirements for a **conceptual model** can be defined in terms of the acceptable deviations of measured from predicted properties (frequency and extent). This can be achieved by formulating questions that must be answered by the monitoring data and other relevant information with defined certainty based upon the conceptual model. The conceptual model and changes therein should be documented and subject to peer review.

Quality requirements for a **monitoring design** can be formulated in terms of required maximum allowable confidence interval for the relevant compliance criteria (e.g. average value) in time or space of a parameter within a groundwater body or a group of groundwater bodies. The design should be documented and subject to peer review.

Quality requirements for **sampling** must be formulated in terms of the maximum acceptable uncertainty of sampling.

Quality requirements for the **analysis** must be formulated in terms of the maximum acceptable uncertainty of analysis and the required analytical detection limit.

Quality requirements for **transfer, storage, modelling and interpretation of data** are clear documentation of data management, interpretation and decision rules based on good modelling practices.

8.2 QUALITY CONTROL

During the monitoring process, the achievement of the quality requirements shall itself be monitored. If the defined quality requirements are not met for one or more of the steps during monitoring, as demonstrated by the quality control measures taken, the monitoring must be re-evaluated and if required, improved and repeated.

Controlling the quality of the **conceptual model** against the requirements is best done as an iterative process during the entire monitoring programme and in relation to the required confidence; see Figure 8.1.

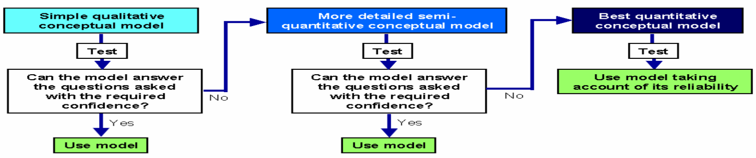


Figure 8.1: Iterative control of the conceptual model against set quality requirements

The control of the quality of the **monitoring design** will ensure that the required confidence intervals are not exceeded.

These confidence intervals may be calculated based upon the established quality requirements or they may be based upon expert judgment that takes into account the expected variability. In either case, the compliance of the monitoring design in relation to the quality requirements should be verifiable. It should be emphasized that the variability of the data will include components from the monitoring design, sampling and analytical methods and the natural variability of the medium. The former components should be considered when improving the quality of the monitoring design, as these can be controlled, whereas the natural variability can not.

For **sampling and analysis**, appropriate quality assurance procedures will enable minimisation of errors in sampling and analysis. Minimum elements to be covered by quality assurance procedures are:

- Identification and records for samples, devices and operators
- Sampling methods, sampling plan and sampling field reports
- Sample transportation, receipt, storage and preservation

- Validation of methods, including uncertainty estimation
- Analytical measurement procedures
- Internal quality control of methods
- Participation in external QC schemes (proficiency testing schemes etc)
- Expression of results
- Traceability of documents
- Traceability of measurements

The user of sampling and analytical data should always request documented information on the quality of the services received and ensure that the necessary quality criteria have been met. The sampling and analysis should be done with third party assessment of the quality procedures applied. For laboratory analysis, accreditation according to the international standard ISO 17025 is recommended, whereas for sampling, laboratories and other sampling service suppliers could choose either accreditation according to ISO 17025 or personnel certification according to ISO 17024. For sampling procedures, see Chapter 9.

For parameters where field measurements are most suitable, field measurements should be subject to method validation and quality control as required for laboratory measurements.

In control of **transfer, storage, modelling and interpretation of data**, spot checks of data consistency (transfer and storage) are mandatory. Model validation with data not included in model development and calibration should be done.

9 METHODS FOR SAMPLING AND ANALYSIS

As the starting point, sampling strategies, sampling techniques, sample treatment, analysis, calculations and reporting should be considered integral parts of the overall monitoring process (monitoring supply chain). A detailed description of the wide-range of tools, techniques and methods for groundwater sampling and analysis is beyond the scope of this guidance. This section therefore only provides a brief overview of the key aspects. For more detailed guidance on methods and instructions, the reader is referred to international and national standards, guidelines and textbooks (reference to ISO 5667 series for sampling and to the Chemical Monitoring Activity). For sampling and analysis, validated methods should be used which also address the issue of fitness-for-purpose (Section 8). Sampling and analysis should be carried out in accordance with published international and national standard methods, unless explicitly justified not to do so due to e.g. the absence of suitable standard methods.

Due to the technical difficulties in accessing groundwater and the rapid changes in chemistry that can take place once the water has been removed from its point of origin, **sampling** for groundwater monitoring requires careful planning and the selection of the most suitable equipment and methods.

Standard methods for sampling are generally less precise than analytical methods, in part because of the varying field conditions at different sites and the varying purposes of sampling, and in part because the process of standardising sampling is presently less advanced than that for chemical analysis. Therefore, even with national and international standards there is a need of harmonisation of approaches and methods to ensure the comparability and representativeness of sampling.

Sampling methods for groundwater monitoring must take into account the regional and the local conceptual model:

- the hydrogeological conditions (layered aquifer, porous/fissure/fracture flow, permeability etc)
- physico-chemical properties (volatility of substances, adsorption properties, reactivity etc) of determinands sampled for;
- the type of parameters being measured (chemical, biological, physical) and;
- the characteristics of the sampling point (e.g. well diameter, screen length, depth of sampling, static/flowing).

Unstable parameters such as pH, temperature, conductivity, dissolved oxygen and where necessary, redox potential and turbidity must be **measured in the field**, as quickly as possible. For this, special calibrated equipment with clear operating instructions and procedures is required.

Similarly, **sample treatment** such as preservation or filtration of water samples must be done in the field without aeration and as rapidly as possible in order to avoid changes in the distribution between dissolved and particulate phases within the sample.

New analytical methods and parameters should be applied to the monitoring programmes to improve the quality of monitoring and to deliver efficiencies. For those emerging analytical methods and new parameters, standard methods may not yet be available. In those cases, 'in-house' validated methods are required (see Section 8 for requirements) and their application must be documented accordingly and the performance of new methods regularly evaluated.

10 REPORTING

Elements of the monitoring programme are subject to reporting under Article 15(2) of the WFD.

Estimates of the confidence in the monitoring results should be determined and reported in accordance with WFD requirements. The reported confidence must as a minimum describe the uncertainty arising from the monitoring processes and the variability (in time or space) of the parameters monitored. If the initially required confidence has not been obtained, the consequences for the monitoring objectives must be evaluated and the need for adjustment of the monitoring programme specified.

Documentation of monitoring programme, operation, and status/trend reporting should be further discussed considering the development of the 'Reporting Sheets' elaborated in WG D. It comprises summary information in 'verbal' form like investigated parameters and monitoring frequency and information in table structure.

GLOSSARY

Groundwater means all water, which is below the surface of the ground in the saturated zone and in direct contact with the ground or subsoil.

Aquifer means a subsurface layer or layers of rock or other geological strata of sufficient porosity and permeability to allow either a significant flow of groundwater or the abstraction of significant quantities of groundwater.

Body of groundwater means a distinct volume of groundwater within an aquifer or aquifers.

Drinking Water Protected Area (DWPA) means areas designated for the abstraction of water for human consumption under Article 7 of the WFD.

Raw water means groundwater in its natural state prior to any treatment or purification.

ANNEX 1 - AQUIFER TYPES

The European land mass embraces the whole spectrum of geological rock types, ages and histories. Consequently, a diverse range of hydrogeological settings and aquifer types is found across Europe covering e.g.:

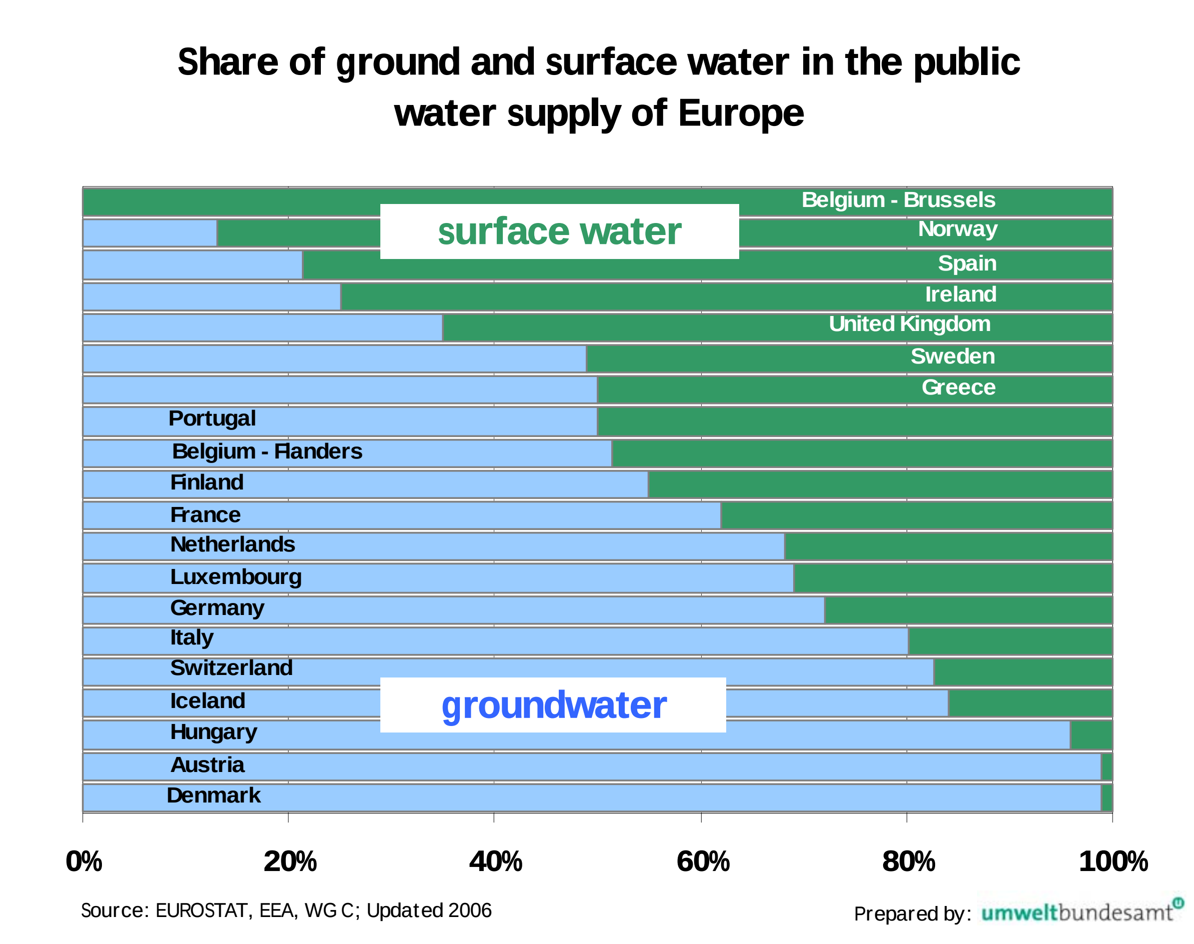
- major alluvial and coastal plain sediments where the relations with surface water systems might be complex;
- intermontane colluvial systems, discharging mainly to springs and/or directly to the base flow of rivers;
- consolidated sedimentary aquifers – limestones, chalk and sandstones;
- karstic (mountain or plain) areas with or without external inflow;
- marls and clays with local aquifers made of limestones or sands;
- recent coastal calcareous formations and islands;
- glacial and associated small alluvial formations;
- extensive volcanic terrains;
- weathered and fresh crystalline basement (including metamorphic rocks such as gneisses and schists).

This broad variation has important implications for the suitability of different types of sampling installation and how effectively they represent changes in groundwater systems, and monitoring design needs to be tailored accordingly. Further, the information obtained, and in particular any changes observed, is required to be reported at national and European levels regularly over several decades. Hence a clear understanding is needed of what each monitoring point represents in terms of the groundwater bodies in which they are located, and the response times of the groundwater both to pressures imposed upon them and to measures to control their impacts. A summary of the range of aquifer settings found across Europe and their response times is shown in the table below.

*Table 4: Summary of groundwater situation in EU Member States (*Proportion of groundwater in public water supply) (based on EEA, 1999, amended by WG C).*

Country (*)	**Principal aquifers**	**Response times**
Finland (55%) Norway (13%) Sweden (49%)	Small, thin, shallow aquifers in fractured crystalline bedrock and glacio-fluvial sands and gravels	Fast to moderate
Denmark (99%)	Some Chalk and recent sands and gravels, mostly shallow with thin unsaturated zone	Fast to moderate
Netherlands (68%) Belgium (52%)	Thick alluvial sequences with water table very close to surface – thin unsaturated zone	Fast
United Kingdom (35%)	Important aquifers are consolidated Chalk, sandstone and limestone in the south, centre and east, some alluvium	Ranges from fast to slow
France (62%)	Some Chalk in the north , thick alluvial plains, limestones in the centre and south, crystalline basement rocks in the West, in the Centre and in mountain areas	Ranges from fast to slow
Germany (72%)	Thick alluvial plains in the north, consolidated sediments in the centre and south	Fast to moderate
Ireland (25%)	Main aquifers are limestones (karstified to varying degrees), fissured sandstones, volcanics and small shallow fluvioglacial sand/gravel deposits. Poorly productive aquifers (muddy limestones, granites, metamorphic rocks) underlie 65% of the country.	Fast
Austria (99%)	Karstic limestones and some alluvial basins and river plains, some older fractured rocks in Alpine regions	Mostly fast

Country (*)	**Principal aquifers**	**Response times**
Spain (21%) Greece (50%) Portugal (50%) Italy (80%)	Karstic limestones, sandstones, coastal alluvial plains and some large alluvial basins (Po, Guadalquivir, Tagus), volcanic aquifers (Italy, Portugal).	Mostly fast. Moderate in alluvial basins and volcanic aquifers
Luxembourg (69%) Switzerland (83%) Iceland (84%)		
Hungary (96%)	Thick alluvial basin in the east and northwest, karstic aquifers in the centre, north and south, consolidated sediments in the west, some fractured rocks in mountain areas	Fast to slow



ANNEX 2 - INFORMATION REQUIREMENTS FOR MONITORING POINTS

Detailed information on the site should be available and routinely reviewed. This information should be used to assess the suitability of the site to be used for the relevant monitoring programme. Elements for characterising sampling sites are summarised below.

Table 5: Monitoring point information – essential and desirable factors

Factor	Chemical monitoring points	Quantitative monitoring points	Reporting Requirement (to be finalised)
Aquifer(s) monitored	E	E	✓
Location (grid reference), name of monitoring point and unique identifier	E	E	✓
Groundwater body that monitoring point is within	E	E	✓
Purpose(s) of monitoring site	E	E	✓
Type of monitoring point – farm borehole, industrial borehole, spring, etc	E	E	✓
Depth and diameter(s) of boreholes/wells	E	D	
Description of headworks – grouting integrity, slope of ground around borehole	E	E	
Depth of screened/open sections of boreholes/wells	D	D	
Vulnerability or indication of subsoil thickness and type at monitoring point	E	D	
Visual appraisal of recharge area (including land use and pressures, potential sources of point pressures)	E	D	
Construction details	E	E	
Amount abstracted or total discharge (at springs)	E	E	
Pumping regime (qualitative description – e.g., intermittent, continuous, overnight, etc.)	D	E	
Drawdown (pumped water level)	D	E	
Zone of contribution/recharge area	D	D	
Pump depth	D	D	
Static or rest water level	D	E	
Datum elevation and description of datum	D	E	
Artesian/ overflowing	E	E	
Borehole log (geological)	D	D	
Aquifer properties (transmissivity, hydraulic conductivity etc)	D	D	

E…Essential, D … Desirable

For quantitative monitoring sites:

- Monitoring points should not be pumped or should only be pumped for very short periods at well-defined times, such that measured water levels reflect natural conditions.
- The locations should be outside the immediate hydraulic influence of the pressure such that day-to-day variations in pumping will not be evident in the data.
- Large springs may be suitable where total flows are in excess of 1 litre/sec.

Note that data from stations which function as continuous abstraction wells may be acceptable if accompanied by detailed (e.g. hourly) pumping records.

ANNEX 3 - ADVANTAGES AND DISADVANTAGES USING AVAILABLE WELLS

Many national monitoring programmes, especially those that have developed overt time depend to a large extent on sampling from existing discharge points. Of these, public supply boreholes have the advantage of being operated more or less continuously. Purging is therefore not required, and sampling from the supply pump (often from a side tap) is easy, relatively inexpensive, and determination of field parameters is usually straightforward. Private domestic, industrial and irrigation boreholes are also widely used, and have many of the same advantages, except that they may be used less regularly.

In some aquifers, dug wells may be plentiful and accessible, but may be open to direct infiltration or shallow pollution pathways, difficult to purge satisfactorily and also shallow and only representative of the uppermost parts of the aquifer.

Where there are spring discharges from groundwater, these may be cheap and easy to sample, and should always be considered, especially for those bodies of groundwater defined by Article 7.1 of the WFD. Large springs may be particularly suitable in mountain and karstic areas, where suitable boreholes intersecting the major fissured flow paths are difficult to find or construct. Smaller springs may have shallow flow paths vulnerable to localised pollution, be unrepresentative of the main body of deeper groundwater, and subject to unreliable or intermittent flow during droughts, or even seasonally. Sometimes spring flow paths may be so short and shallow that they draw only from superficial deposits, rather than the underlying and more extensive aquifers. Where aquifers discharge directly into rivers integration with the surface water monitoring network is advised, and surface water quality may provide the best indication of groundwater quality.

If the groundwater is used for drinking water abstraction, the monitoring network design should take account of this. A representative selection of drinking water wells/springs could be included in the network or existing drinking water monitoring results can be used, but only if they are based on raw water samples and preferably from individual wells rather than those taken from within the distribution system.

Sampling from supply boreholes produces a sample drawn from the screened or open section of the borehole, which may be quite large. The sample may integrate water of different ages over the whole vertical interval in uniform, intergranular sedimentary aquifers or, in fractured aquifers, drawn from separate groundwater flow horizons that the borehole has intersected. Except in the most well-studied and documented public supply boreholes, the true depth origin of the sampled groundwater is uncertain, while vertical variations in groundwater quality can be expected. If the operating supply boreholes are deep, but the upper aquifer horizons are known or expected to have poorer quality water, then sampling from the supply boreholes may provide an over-optimistic picture of groundwater quality.

Where the hydrogeological conditions indicate major vertical variations in aquifer types and characteristics, and an analysis of pressures or of existing quality data suggest the presence of stratified groundwater quality, then adequate monitoring may require discrete sampling points. Several approaches can be used for this, but they all require sound knowledge of the groundwater conditions, specialised construction techniques and are increasingly costly, especially in aquifers with thick unsaturated zones and fissured rocks. In these situations the use of observation wells has the drawback of requiring a dedicated sampling pump or a pump to be brought to the site each time and adequate purging to ensure that the sample is not standing water from within the installation. Therefore, sampling visits are longer and need more and better experienced staff. In situations with shallow granular aquifers with shallow water tables, however, monitoring networks solely made up of observations wells can be cost-effective. For example, a monitoring network of a spatially representative mixture of multi-level and single-level observation wells designed using information on specific land use and hydrogeological characteristics can be effective in aquifers with a large spatial variability in groundwater quality. In all cases, selection of springs, pumping wells or observation wells requires evaluation of flow paths and characteristic travel times, and water sampled should be relatively young in order to give an indication of impacts from pressures being considered as part of the WFD characterisation and risk assessment process.

Monitoring networks may include a variety of types of the installations and facilities described above. Their characteristics for sampling groundwater are summarised in the following table. Decisions about types of sampling installations to be used can also have important implications for the cost of monitoring and some information about relative costs is given in the table.

Table 6: Summary of the characteristics of groundwater sampling facilities

Type of sampling point	**Character of discharge**	**Discrete vertical sampling points**	**Quantitative measurements**	**Hydraulic testing**	**Inert materials**	**Costs**			**Notes**
						Drilling	**Materials**	**Sampling**	
Existing groundwater sampling points									
Public supply borehole	Usually high and continuous	Integrates over screen interval	Usually disturbed by pumping	Data may exist	No	None	None	Very low	
Private supply borehole	Often low and intermittent	Integrates over screen interval, but may be shallow	Sometimes disturbed by pumping	Data may exist	No	None	None	Low	Purging may be problematic/time consuming for irregularly used boreholes
Irrigation borehole	High but may be intermittent or seasonal	Integrates over screen interval	Possible in non-pumping seasons	Data may exist	No	None	None	Low	Purging may be time consuming when boreholes not used
Dug well	Usually intermittent	No	Yes, usually	Unlikely	No	None	None	Low	Large storage in well, difficult to purge with sampling pump
Large springs	High and continuous	No	Yes, discharge	No	No materials	None	None	Low	May have large catchments and good in karst areas
Small springs	May be low and seasonal or irregular	No	Yes, discharge	No	No	None	None	None	May have shallow, vulnerable flow paths
Purpose-constructed observation or monitoring boreholes									
Single piezometer	Low and needs portable pump	One, usually a short screen near bottom	Yes	Yes	Yes	Moderate	Low	Moderate, but needs pump	
Cluster of single piezometers	Low and needs portable pump	Several distinct depths	Yes	Yes	Yes	Very high	High	High, needs pump	
Nest of piezometers in single borehole	Very low, needs portable pump	Two to five	Yes	Yes	Yes	High	High	High	
Multi-port sampling systems	Very low, needs specialist pump	Many	Some types	Some types	Yes	Moderate	High	High	Requires specialist techniques and expertise for installation and operations

ANNEX 4 - INITIAL GUIDANCE ON THE SELECTION OF DETERMINAND SUITES

SURVEILLANCE MONITORING

The following core determinands are mandatory:

- oxygen content (DO),
- pH-value,
- electrical conductivity (EC),
- nitrate, and
- ammonium.

In addition, the WFD requires that this core determinand list must be supplemented by parameters that are indicative of the impact of pressures identified through the characterisation and risk assessment process. It should be noted that chemical substances or indicators related to identified risks should be considered for the establishment of groundwater threshold values (quality standards) under the daughter Groundwater Directive, and surveillance and operational monitoring will represent key steps in this respect. This also means that monitoring should be carried out for all substances which characterise groundwater (groups of) bodies as being at risk.

Although not required by the WFD, the core list should also be supplemented by suites of inorganic parameters to provide data for QA purposes and information on the natural background level of groundwater, temperature and water level. It will also provide necessary information to support verification of the conceptual model/understanding of the groundwater body and contribute to improved confidence in the assessment of status.

Further generic indicator species may also be added to supplement the risk assessment process. These may include indicators of general industrial activity, e.g. TCE and PCE and urban areas, e.g. Zn and B. These parameters are however only necessary where a pressure has been identified that may give rise to potential impact at the groundwater body scale.

For surveillance monitoring it is therefore recommended that:

- The core suite will comprise DO, pH, EC, nitrate, ammonium, temperature, a suite of major and trace ions plus, where appropriate, selected indicators.
- Parameters indicative of the risks to and impacts on groundwater from pressures identified through the Annex II characterisation process where relevant taking into account the indicative list of pollutants identified in Annex VIII. At this stage it is very important to use the conceptual model. In order to identify each pressure influencing each sampling site, it is necessary to take into account of information provided by the conceptual model.
- Temperature, DO, EC, pH should be measured in the field (at the sampling point), while the other parameters should be measured/analysed in the laboratory. Additional field parameters may also be included as necessary, e.g. redox potential (Eh) and turbidity.
- It is not necessary to monitor each of the 33 priority substances mentioned in Annex X of the WFD. Among these parameters, those that should be included in the surveillance programme must be chosen on the basis of the characterisation and potential risks to groundwater and other associated receptors, e.g. surface waters.
- Consideration is also given to both emerging substances and those that have been phased out and are no longer used.

OPERATIONAL MONITORING

In addition to the core parameters, selective determinands will need to be monitored at specific locations, or across groundwater bodies, where the risk assessments carried out as part of the characterisation process of groundwater bodies indicate that they are at risk of failing to achieve relevant objectives.

As mentioned above, these determinands will have to be considered when establishing groundwater threshold value and the monitoring results used in the assessment of status classification.

The selection of parameters will be made on a case-by-case basis and be influenced by WFD characterisation work supplemented, where necessary, by other information including existing water quality data and local knowledge. The chemical monitoring suites must be reviewed on a regular basis to ensure that they provide representative information and data on groundwater quality and fully support the risk assessment process.

Broad land use/cover categories can be used as a basis for initial determinand selection. A careful analysis of the types of land use/cover and the nature and approximate amounts of chemicals being used should be made in cooperation with competent local bodies and be used for the identification of potential determinands. Further targeting and optimisation of determinand suites should be based on information from the characterisation process.

APPROACHES FOR THE SELECTION OF ADDITIONAL DETERMINANDS

The following approaches may be considered when selecting additional determinands for monitoring. An indicator representative of background industrial anthropogenic pressure may be included in monitoring programmes (e.g. hydrocarbons, organochlorides). For the selection of substances the following criteria can be considered. They will take into account the hydro-geological characteristics of the groundwater body and its interaction with surface water bodies and with connected terrestrial ecosystems. The criteria are:

- Ecotoxicological and toxicological properties of pollutants
- Intrinsic characteristics of pollutants
- Anthropogenic pressures
- Contamination pathways
- Quantitative aspects

Ecotoxicological and toxicological criteria: the prioritising of the substances should be based on the evaluation of the direct risk for aquatic organisms and the indirect risk for human health due to the consumption of drinking water, fresh water organisms and vegetables. The risk for the aquatic organisms due to the interaction with surface water bodies should be evaluated through the use of ecotoxicological data, when available, in particular, using acute and chronic bioassays for local aquatic organisms of different trophic levels.

Intrinsic characteristics of pollutants: The chemical-physical properties of chemicals, in particular organic chemicals, among which water solubility, relative density, persistence, as measured by soil and water degradation parameters, and the whole set of partition parameters, included soil adsorption coefficient and BCF, improve the knowledge of their environmental fate in surface and subsurface soil layers and water bodies. On this basis, a rough screening of mobile or potentially mobile and persistent molecules can be made, also by the application of screening indexed or more complex models which allow for estimating the groundwater pollution potential of chemicals and their tendency to distribute in environmental compartments. Chemical-physical and chemical-dynamic properties can be found in the scientific literature. For plant protection products and biocides, which have undergone a registration procedure, comprehensive sets of data including risk assessments for the active ingredients, as well as for relevant metabolites and degradation products, are contained in the respective registration dossier and are available to the competent authorities.

Anthropogenic pressures: The following non-exhaustive list of anthropogenic pressures could be taken into consideration when identifying determinands. The presence and significance of a pressure will be determined through the WFD risk assessment process. Some of the activities may also refer to old, disused infrastructure (industrial-municipal-agriculture).

- Agriculture, livestock breeding (fertilizer constituents, plant protection products and biocides and related breakdown products and metabolites, pollutants from sludge and manure spreading and pharmaceuticals (antibiotics, hormones, etc.).
- Industrial activities (polishing and degreasing of metal manufacturing, tissues, paints, dyes, detergents, galvanization, tannery, mining, hydrocarbon fuel extraction and fuel additives including production and use and sludge spreading)
- Municipal activities (management of sewage pipelines, management of recreational areas: fertilizers, plant protection products, biocides and related breakdown products and metabolites, management of urban sludge and waste.
- Waste disposal sites, dumps, landfills: leakage of the above mentioned categories
- Transport
- Groundwater overexploitation: salt content enrichment, concentration and abstraction of pollutants from neighbouring polluted waters

Contamination pathways:

- Leaching processes from diffuse sources
- Accidental spills, leakages due to point sources
- Polluted surface waters which feed aquifers
- Saltwater intrusion

- Atmospheric deposition

Quantitative aspects: When selecting additional determinands, high priority should be given to those substances with large total amounts used in the recharge zone of a groundwater body. Quantification of loads of pollutants, information on chemical production volumes, indirect evaluation through sales data etc.; collection of historical monitoring data which may confirm the environmental relevance of selected pollutants; availability and practicability of analytical methods.

CASE STUDY - NETHERLANDS

Background information
Title/Name of case study: Frequency of groundwater quality monitoring.
Type of case study: the Netherlands National Groundwater Quality Monitoring Network
Web-Link: http://www.rivm.nl/milieuStoffen/milieumeting/Meetnetten/lmg/index.jsp#tcm:4-587
Objective of case study The objective of this case study is to show that frequency of sampling of monitoring sites for groundwater quality is dependent on the overall monitoring strategy, the site characteristics and acquired experience in the course of monitoring.
Contribution to…
WFD focus: monitoring, groundwater quality
Specific contributions: sampling frequency, monitoring strategy, conceptual model

Characterisation

In principle, the Netherlands consist of one single sandy aquifer. This aquifer was divided into 20 GW-bodies based on the consideration of the hydrogeological situation, the status, protection and finally water management aspects. In the clay and peat areas the upper layers (about 3 m) are treated as separate groundwater bodies which are closely associated with surface water bodies.

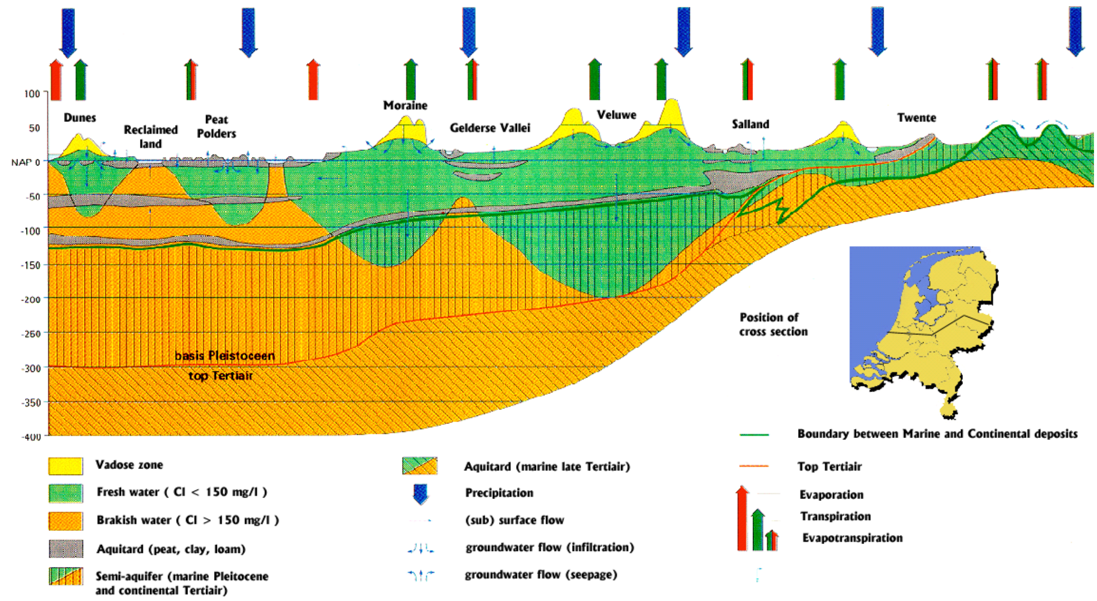


Figure 1: Schematic East-West cross section of the subsoil of the Netherlands. The subsoil is characterised by marine and continental deposits of mainly Pleistocene and late Tertiary origin (Source: Dufour, 1998).

The Netherlands National Groundwater Quality Monitoring Network (LMG), established between 1979 and 1984, comprises about 360 locations divided over the whole country (Van Duijvenbooden, 1987). The main criteria for site selection were type of soil, land use and hydrogeological state. At each location groundwater is sampled at depths of approximately 10 and 25 m below the surface level using special designed observation wells with screens of 2 m length. From 1984 to 1998 locations were sampled annually, results have been published by Reijnders et al., (1998), Fraters et al. (2004) and by Pebesma & De Kwaadsteniet (1997). After an evaluation of the network design in 1998 (Wever & Bronswijk, 1998), the frequency of sampling was decreased for certain combinations of soil type and depth. Shallow screens in sand regions are still sampled every year; shallow screens in other regions (clay and peat) are sampled every two years; deep screens are sampled every four years; shallow screens with high chloride concentrations (more than 1000 mg l^{-1} due to marine influence) are also measured every four years. Finally, well-screen combinations dominated by local conditions (e.g. nearby rivers and local sources of pollution) have been eliminated. In this way, the number of screens to be sampled every year has been reduced from 756 to about 350.

Experiences gained - Conclusions - Recommendations

The quality of groundwater in Dutch groundwater bodies shows a large variability in space (both in the horizontal and in depth) relative to the variability in time, even in the upper five meter of the groundwater, see Figure 1. A sampling frequency of once per year was established in the design phase of the network, based on a conceptual model of groundwater flow. Given the Dutch net yearly precipitation a net vertical infiltration rate of 1 m·a^{-1} was assumed, which yields minimum groundwater ages of about 10 and 25 years at the two monitoring depths. These ages were later confirmed by tritium measurements. A vertical transport velocity of 1 m a^{-1} and 2 m long screens yields a replacement rate of water around the screen every two years. Given this replacement rate, an annual monitoring frequency is sufficient for trend detection purposes. Over ten years of data showed that under certain hydrological and soil conditions the sampling frequency could be lowered from once a year to once every two or every four years without loss of information. After optimisation of the networks, a specific set of locations is used for *trend assessment* using a high sampling frequency, i.e. assessment of effects of measures. The complete sets of locations are used for *status assessment* using a measurement frequency of once every 4 years (Broers, 2002). In addition, frequencies might differ for different chemical parameters, for example, a lower frequency for metals that show a slower displacement in the soil environment.

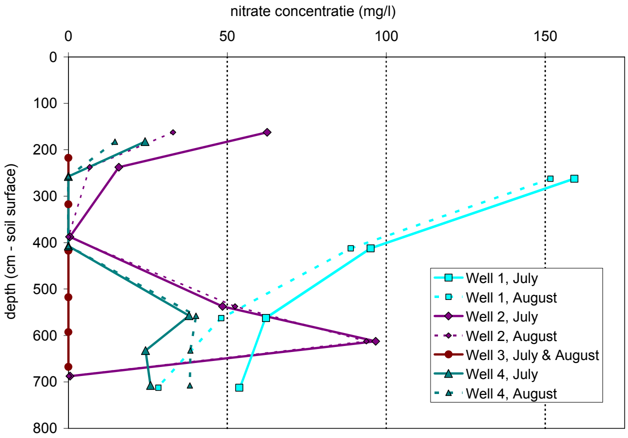

Figure 2: Nitrate concentration in upper five meter of groundwater in four multi-screen wells at one 40 ha dairy farm in the Netherlands. Wells with screens of 0.25 m length are sampled in July and August 2005 (RIVM, unpublished data).

The design and operation of a monitoring network is an iterative process. A conceptual model of transport velocities and an analysis of the sources of variances for the parameters of interest are a prerequisite for effective and efficient monitoring. It forms the basis for the determination of the number of sites, type of wells, number, type and depths of screens, and the frequency of sampling. All these aspects of the design have to be considered coherently.

CASE STUDY - AUSTRIA

Background information
Title/Name of case study: National Water Quality Monitoring in Austria
Type of case study: National Water Quality Monitoring Network
Web-Link: http://gis.umweltbundesamt.at/austria/wasser/Default.faces
Objective of case study: Demonstrate the business rules of monitoring and the QA aspects
Contribution to…
WFD focus: Groundwater Quality Monitoring
Specific contributions Organisation, Procedure, Costs, Quality Assurance

Characterisation

In Austria standardised water quality monitoring based on legal provisions started in 1991. The monitoring programme covers groundwater in porous media, groundwater in karst and fractured (fissured) rock and running waters.

Water quality monitoring is carried out in periodical cycles for the whole of Austria. The main goals are to assess the current status of the Austrian waters on the basis of a sound and reliable database and to detect negative developments at an early stage. Based on this programme, measures can be introduced to reverse a negative development.

Groundwater sampling sites are distributed all over the groundwater areas. A distinction is made between groundwater in porous media and groundwater in karst and fractured rock. Regarding groundwater in porous media continuous groundwater bodies and discontinuous groundwater-bodies are distinguished. Continuous groundwater bodies can mainly be found in flat regions and valleys along rivers. Small, discontinuous groundwater bodies were grouped in so-called “groundwater regions“. Groundwater in karst (carbonate rock) and in fractured rock (crystalline rock) is distinguished due to hydrochemical criteria.

Experiences gained - Conclusions - Recommendations

Procedure / Business rules

The implementation of the Austrian Water Quality Monitoring Network is the shared responsibility of Federal and Provincial Authorities:

At the Federal level the Federal Ministry for Agriculture, Forestry, Environment and Water Management, Department Water Management Register, is responsible for:

- the integrative assessment of data,
- the yearly publications of results,
- ensuring uniform procedures all over Austria, and
- covering the main part of costs.

The provincial governor is responsible for

- operational management (call for tender, tendering, inspection of contractors during sampling and analyses, quality check of received data, data delivery to the federal level),
- covering parts of the costs, and
- co-operation regarding elaboration and amendment of guidance papers.

Based on an agreement the Federal Environmental Agency is responsible for

- IT-development and data management,
- technical co-operations regarding analytics and data assessment,
- Reporting/writing the biannual reports in co-operation with the Federal Ministry for Agriculture, Forestry, Environment and Water Management.

Monitoring Cycle / Frequency / Parameter sets

The monitoring is a cyclic procedure of 6 years:

- One year initial investigation period (extended parameters) and
- five years period of repeated investigation (minimum requirement based on the results from the initial investigation period).

Groundwater is monitored four times a year and sometimes only twice a year in groundwater bodies without pollution.

The parameters monitored in groundwater and running waters are split into three sets comprising about 100 different parameters.

Call for tender

Usually the parameter sampling and analysis are executed by private accredited laboratories (EN 45000). The contract is awarded according to price and quality criteria ('principle of best cost/benefit offer') in order to get best quality at reasonable costs.

Tendering is done by Provincial Authorities based on groundwater bodies und parameter sets.

Budget / Financial distribution of monitoring costs

All costs for Water Quality Monitoring in Austria are covered by the public authorities. According to the Hydrography Act the Federal Authorities bear all costs concerning the monitoring network. The costs for sampling and analytics are met two-thirds by Federal and one-third by Provincial Authorities.

From 1990 up to 2005 in total 43 Million Euro were spent for the Water Quality Monitoring in Austria:

- 2.7 Million Euro for selection and establishing sampling sites and
- 2.2 to 3 Million Euro per year for sampling and analytics.

The mean costs for a groundwater sample (70 up to 100 parameters) are about 300 Euro.

Quality assurance

For best quality assurance of analytical results, various elements of quality assurance were introduced in the monitoring programme as there are:

- nationwide standardised tendering documents (declaration of analytical figures of merit in the offers);
- accredited laboratories;
- provision of key figures of the analytical procedures within the bidding files;
- standardised procedure (guidelines) including sampling methods
- laboratory control visits (inspection before awarding of contracts and during the monitoring periods);
- compulsory participation in sampling courses;
- compulsory participation in (international) round robin tests;
- control system (proficiency testing scheme for water analyses) in routine work with spiked samples – performed by the Institute for Agrobiotechnology (IFA-Tulln); and
- minimum requirements for limit of quantification and limit of detection.

Outlook - Next steps – Accessibility of results

The monitoring network is currently been adapted by end of 2005. The new monitoring network has to be operative by Dec 2006.

CASE STUDY - FINLAND, SWEDEN, NORWAY

Background information

Title/Name of case study: INFORM – **In**tercalibration of **F**enn**o**scandian **r**eference **m**onitoring of groundwater in Finland, Sweden and Norway

Type of case study: Regional study, organizations involved

Finland –	Finish Environment Institute, SYKE
	Geological Survey of Finland, GTK
Sweden –	Geological Survey of Sweden, SGU
Norway –	Geological Survey of Norway, NGU
	Norwegian Water Resources and Energy Directorate, NVE

Web-Link:

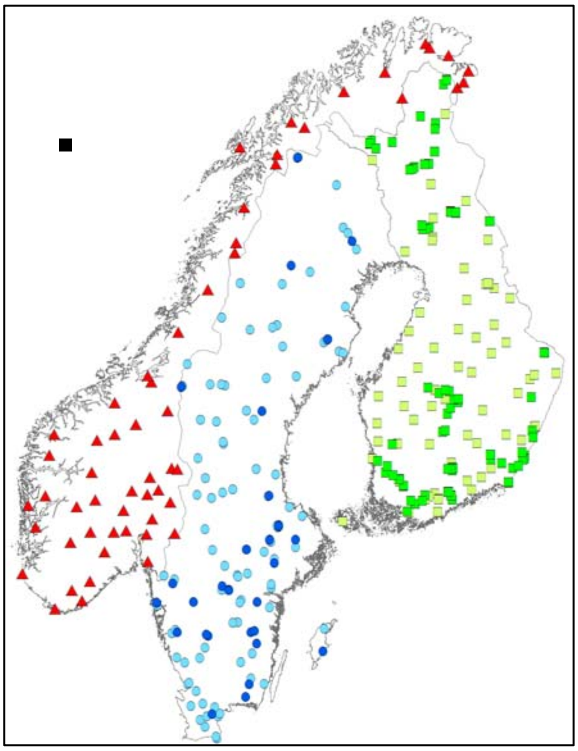
Objective of case study: The study will include an evaluation of monitoring system design and operation, of representativeness with regard to groundwater typology and other natural parameters, and of effectiveness and cost efficiency with the objective to recommend a common Fennoscandian reference network for groundwater monitoring

Contribution to…

WFD focus: reference monitoring, natural background levels, natural trends

Specific contributions: Fennoscandian aquifer typology, intercalibration of strategies, methods and networks, common Fennoscandian reference network

Characterisation:



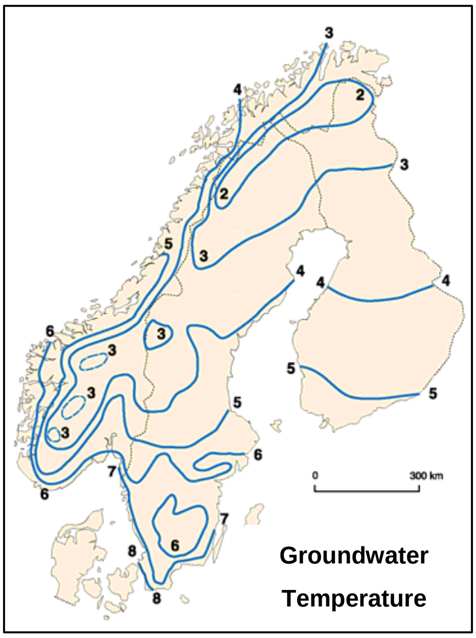
The combined networks for reference monitoring of groundwater in Finland, Sweden and Norway total about 230 stations, or 1 station per 4665 km^2. The responsible government agencies in these countries will carry out this joint project in 2006-7 with the following objectives:

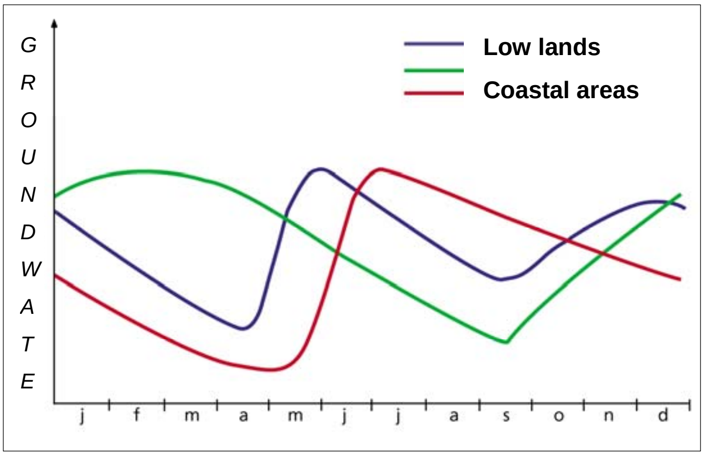
- Intercalibration of *system* design and operation for reference monitoring of groundwater in Finland, Sweden and Norway, incl. groundwater typology and representativeness of monitoring stations.
- Intercalibration of groundwater *quality* for reference monitoring in each of the three countries (e.g. comparability of water quality for groundwaters with comparable hydrogeological origin, interlaboratory comparison etc.).
- Producing a common dataset for reference groundwater quality in Finland, Sweden and Norway, for scientific analysis and for use in practical aspects related to the WFD (e.g. baseline values, monitoring transboundary aquifers, determination of threshold values etc.).
- Evaluation of, and recommendation for a common Fennoscandian network for reference ground-water monitoring related to the WFD, with the objective to produce a more effective and cost-efficient common network in comparison with the current three reference networks in Finland, Sweden and Norway.

Experiences gained - Conclusions – Recommendations:

With regard to groundwater, Finland, Sweden and Norway have been collaborating since 2002 on work carried out in each country for the implementation of the WFD, arising from a common basis in natural conditions, such as geology, climate and demography, and the wish to exchange experience both on a national level and with regard to the EU. In addition to WFD-related issues, the collaboration has generated scientific topics that warrant joint activities. The relevant topic of interest here is the variation in groundwater chemical composition across the three countries, both as a function of the bedrock geology and of the younger Quaternary geology.

Earlier collaboration has resulted in, e.g., a regional overview of groundwater temperature and of variations in groundwater level which is controlled by the recharge-discharge mechanism which in turn is highly dependent on climate.





Outlook - Next steps – Accessibility of results:

Project activities fall into two main categories – **A**, a documentation part and **B**, a data-collection part.

A - This work consists of an analysis of existing documentation for the design and operation for the monitoring system in each country, including

- the criteria for locating monitoring stations and for the density of stations, i.e., typology and representativeness,
- the content, methods and frequencies for collecting both quantitative and qualitative data,
- the method and exchangeability of data storage (databases),
- evaluation and selection of a common dataset for reference groundwater quality, following the completion of part B, and
- evaluation and recommendation of a common Fennoscandian network for reference groundwater monitoring related to the WFD.

B - This activity involves the collection and analysis of a timed batch of groundwater samples from all monitoring stations in each country, including one common batch of samples for intercalibration of laboratory analyses.

The project will publish its results in national reports, international publications and as digital maps showing results for groundwater quality data across the Fennoscandian region.

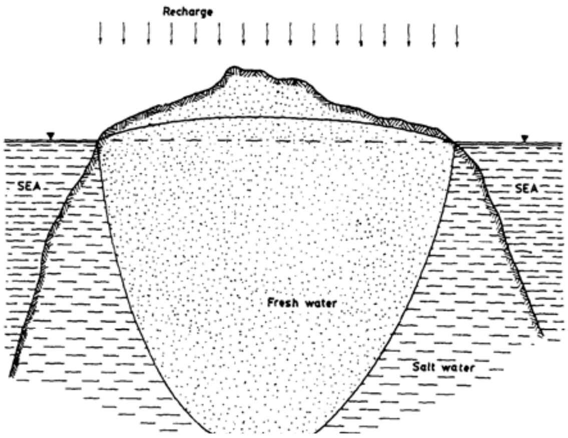
CASE STUDY - MALTA

Background information
Title/Name of case study: Monitoring for Quantitative Status in small islands
Type of case study: Testing the reliability of groundwater level as an indicator of groundwater volume
Web-Link: http://www.mra.org.mt/wfd_introduction.shtml
Objective of the case study: Investigating the utilization of groundwater levels as a metric for status determination
Contribution to…..
WFD focus: Groundwater Quantitative Status Monitoring
Specific Contributions: Best practice in quantitative status monitoring

Characterisation

The Malta Main Mean Sea Level Groundwater Body is sustained in the Lower Coralline Limestone aquifer and is in free contact with sea-water. This groundwater body extends over the whole southern and central parts of the island and is by far the major groundwater body in the Maltese islands, yielding an estimated 66 % of the total groundwater abstracted in the country.

The groundwater body can be compared to a lens shaped body of fresh-water floating on more saline water, having a convex piezometric surface and conversely a concave interface sloping towards the land. The thickness of the lens below sea level is roughly thirty-six times its piezometric height above sea level following closely the Ghyben-Herzberg model.



Scheme showing a Ghyben-Herzberg (floating) groundwater body in an island. It should be noted that the vertical dimensions are highly exaggerated relative to the horizontal dimensions. In fact if the situation in Malta is considered, for an island width of app. 13km, the lens reaches a maximum thickness of around 100m (Source: UNESCO)

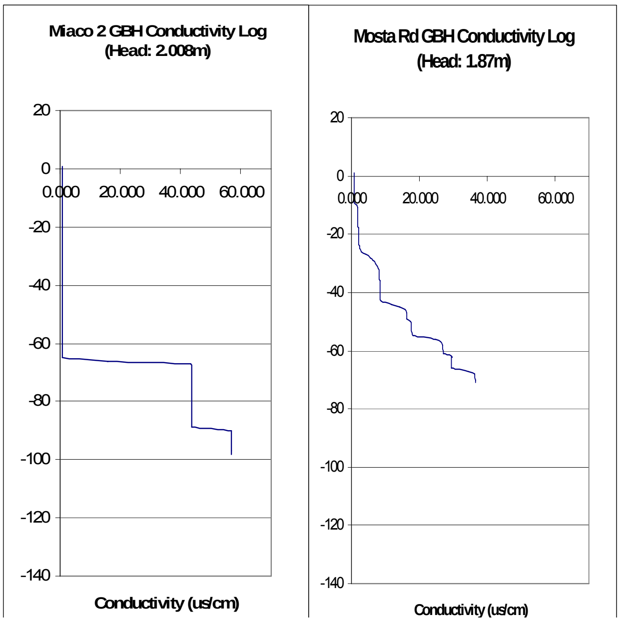
However, in reality, the underground interface that separates the freshwater from the saltwater is not a sharp boundary line. This interface is in fact a mixing zone, whose limits are generally defined by the 1 and 95 % sea water content, called the Transition Zone. The thickness of this zone depends both on the hydro-dynamic characteristics of the aquifer and the fresh and sea water fluctuations.

Experiences gained – Conclusions – Recommendations

The quantitative status of such a mean sea level–island–groundwater body is dependent not only on the hydraulic head but also on the vertical distribution of the chloride content throughout the body. The sole measurement of the piezometric head might therefore not be enough to effectively monitor status. This is particularly so in cases where the hydro-dynamic characteristics of the aquifer supporting the groundwater body favour the occurrence of a wide transition zone.

A pilot project was initiated in Malta involving five deep gauging boreholes in which conductivity logs were taken twice every year. The depth of these boreholes was such that it exceeded the theoretical position of the interface. The process involved taking conductivity readings with a probe at 1 m successive intervals down the borehole.

Reference is made to the results obtained from two of these boreholes, the Miaco 2 and Mosta Road Gauging Boreholes which are located in the southern and north/central regions of the island respecitvely. Both gauging boreholes register almost the same hydraulic head above mean sea level, which is 2.0 m for the Miaco 2 GBH and 1.9 m for the Mosta Road GBH. This data alone would imply that these two monitoring stations are representing regions of the groundwater body having the same quantitative status. However, the results from the conductivity logs indicate that the quantitative status is significantly different.



Conductivity Logs from Miaco 2 and Mosta Rd GBH

In the case of the Miaco 2 GBH; a sharp interface between fresh and salt water was encountered, and the depth of freshwater exceeded 60 m below mean sea level. On the otherhand, results from the Mosta Road GBH indicated that disturbance of the groundwater body has led to the formation of a transition zone, the thickness of which was estimated to exceed 40 m. The depth of freshwater in this case was in the region of 10 to 20 m below mean sea level.

These results indicate that the metric identified by the WFD for the determination of quantitative status may in such cases, where groundwater quantitative and qaulitative status are interlinked, be not sufficient for an effective assessment of status.

Outlook – Next steps – Accessibility of Results

Proposals are currently being formulated for the adaptation of groundwater monitoring in Malta in line with WFD requirements. In the case of sea level groundwater bodies, it is being proposed that, initially, a basic geometrically based water level monitoring network is established, in which groundwater level will be continually monitored. These monitoring stations will subsequently be deepened to enable the collection of quarterly groundwater conductivity profiles in all monitoring stations. It is planned that the basic network will be operational by December 2006; whilst the time-table for the subsequent upgrading of the network is still being formulated.

The monitoring proposals formulated by the MRA will be open to public consultation on the Authority's web-site. The final monitoring plan and an evaluation of its effectiveness following the first monitoring results will also be subsequently available on the same website.

CASE STUDY - NORTHWEST AND CENTRAL EUROPE

Background information

Title/Name of case study: Monitoring effectiveness of Nitrates Directives Action Programmes

Type of case study: regional study; organisations involved: environmental and agricultural institutes from Austria, Belgium, Denmark, Germany, Ireland, Sweden, the Netherlands, the United Kingdom

Web-Link: http://www.rivm.nl/bibliotheek/rapporten/500003007.html

Objective of case study

To show that monitoring of effectiveness of programmes of measures, as required by the WFD (Annex VII, B.2), needs special attention; for example by designing "early warning" monitoring programmes.

Contribution to…

WFD focus monitoring, programme of measures, environmental objectives

Specific contributions. effect monitoring, conceptual model, selection of sampling sites

Characterisation

The Water Framework Directive requires all Member States to make a plan of measures for each river basin, taking account of the characterisation and review of the environmental impact of activities, in order to achieve the WFD objectives. The first update of the river basin management plan (2015) shall also include an assessment of the progress made towards the achievement of the environmental objectives.

Operational monitoring, required to establish the chemical status and presence of long term anthropogenically induced trends in pollutants concentrations, can also be used to assess the effectiveness of programmes of measures. For the design of an operational programme for WFD monitoring experiences can be gained from existing Nitrate Directive monitoring programmes designed for effect monitoring.

The Nitrates Directive (91/767/EEC) requires all Members States to make Action Programmes for Nitrate Vulnerable zones and to monitor not only groundwater and surface water quality, but also the effectiveness of these Action Programmes. In several EU Member States special designed monitoring programmes are operational to monitor the effectiveness of the Nitrate Directive Action Programmes. In 2003 a workshop has been organised to exchange experiences and identify common goals, problems and solutions for improving monitoring programmes and, possibly, for improving comparability.

Experiences gained - Conclusions – Recommendations

When focusing on monitoring effects of measures on water quality we can evaluate the pros and cons of each of these possibilities. Three main factors have to be considered, these are:

1. the time between the implementation of the measure and the moment that a change in water quality will occur as a consequence of this measure, this we call the lag time;
2. the ability to distinguish between the effects of different measures, actions and/or sources of pollution, this we term resolution power;
3. the occurrence of interfering processes in soil or water system, for example, denitrification lowers the nitrate concentration during transport of water through the soil and/or the surface water system.

The table below gives an overview of the importance of these factors for each of the main monitoring possibilities (see Figure). It is evident that the closer to the source of pollution the shorter the time between measure and effect and the smaller the chances that other sources of system processes may influence water quality.

In studying the relationship between the effects of agriculture and water quality, collection of data should preferably be on the same scale for both agriculture and water quality.

The choice for a certain level of scale for effect monitoring depends, amongst others, on the scale used in existing monitoring networks and level of scale of data collection by regional and/or national authorities for other purposes.

The study made clear that water quality is not only influenced by agricultural practice but by other factors as well. Soil type, hydro(geo)logical characteristics of sediments or rocks, or of the surface differences in water quality between locations or in time. The type and structure of the farm, the educational level of the farmer, and whether the farmer has a successor or not are examples of "farm factors". These farm factors influence the way policy measures are implemented in farm practice.

Table: *Overview of the merits and demerits of different types of water quality monitoring for monitoring the effects of changes in agricultural practice.*

Type of monitor	Lag time	Resolution power	Importance of interfering processes
Soil moisture	Short	high	little
Tile drains	Short	high	little
Shallow groundwater	short – moderate	moderate – high	little – moderate
Deep groundwater	moderate – long	low – moderate	moderate – significant
Ditches & brooks	short – moderate	moderate	moderate
Regional & main waters	Long	low	significant

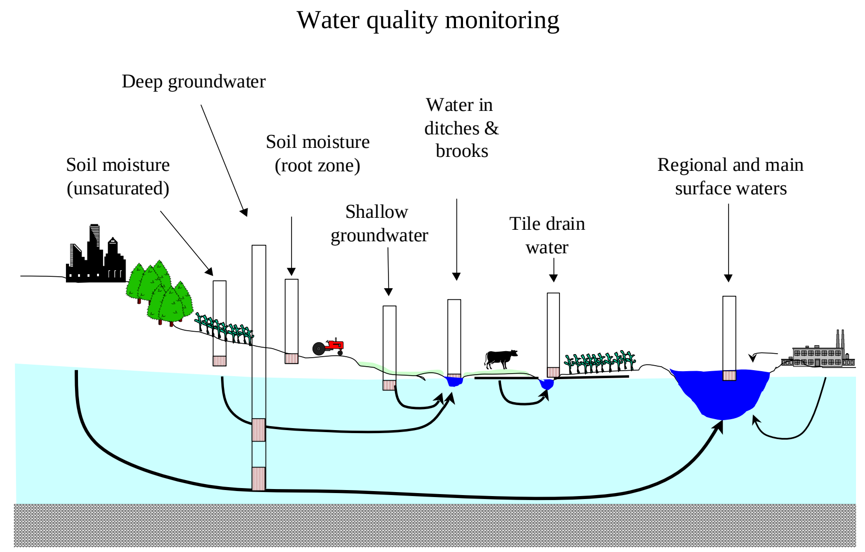


Figure: range of possibilities of water quality monitoring

Two different approaches − upscaling and interpolation − for describing the effect of Action Programmes on a national scale were defined. The upscaling approach uses the results of studies on the effects of change in agricultural practice on nitrate leaching (and water quality) on experimental sites (e.g. homogeneous plots or parcels). Numerical process models and data on agricultural practice covering national-scale change are used to upscale the experimental-site results. This allows Member States to describe the effect of the Action Programme on nitrate leaching and water quality on the national scale. The interpolation approach uses the results on monitoring agricultural practice and nitrate leaching (and water quality) for a random sample of locations, e.g. farms. Statistical models based on knowledge of processes and national-scale monitored changes in agricultural practice are used on the national scale to describe the effect of their Action Programmes on nitrate leaching and water quality.

Outlook - Next steps – Accessibility of results

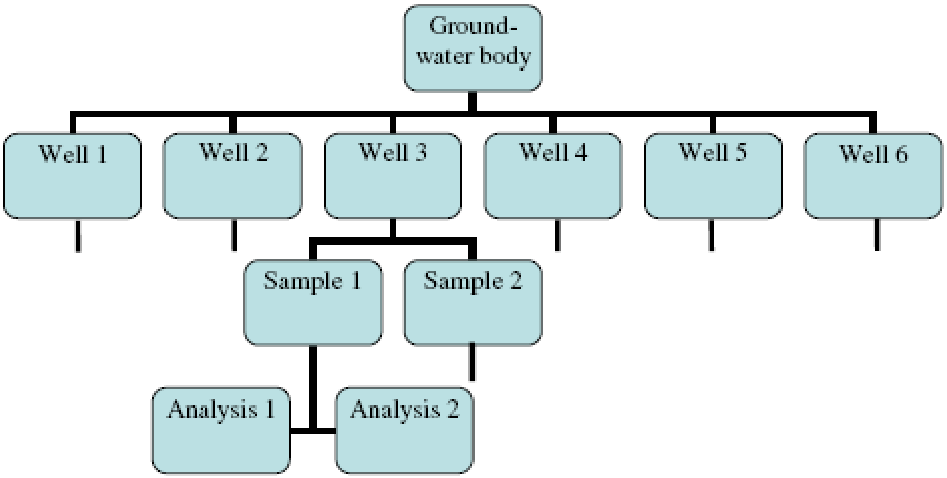
After the workshop effect monitoring programmes have been adapted and/or efforts have been increased, for example, in England and the Netherlands.

England: http://www.bluesky35.adas.co.uk/record/display_index.html?podlet_id=39&article_id=21

The Netherlands: http://www.rivm.nl/bibliotheek/rapporten/680100001.html (Dutch)

CASE STUDY - ÅRHUS COUNTY (DENMARK)

Background information
Title/Name of case study: Estimation of groundwater monitoring uncertainty
Type of case study: Local monitoring study as part of international guidance cooperation
Web-Link: http://www.samplersguide.com
Objective of case study: Demonstration of the use of simple methods for estimation of monitoring uncertainty and for monitoring quality control
Contribution to…
WFD focus: Groundwater quality monitoring
Specific contributions: Uncertainty from analysis, sampling and aquifer heterogeneity, methods for estimation of uncertainty, use of uncertainty estimates to identify points of improvement as well as fitness for purpose (compliance with set quality objectives)
Characterisation: A group of groundwater bodies that are an important drinking water resource for the city of Århus, the second largest city of Denmark, has through surveillance monitoring been identified as at risk for deterioration of the quality due to intensive drinking water abstraction. An operational monitoring program was established in order to control the trend in water quality development. The groundwater body is in glacial outwash sands with Miocene sands and clays below and glacial till above. The natural quality of the groundwater is anaerobic without nitrate, with sulphate and reduced iron, but without hydrogen sulphide and methane. One of the threats to the groundwater bodies is oxygen intrusion into the aquifer as the result of the water abstraction and concomitant groundwater table draw down. One groundwater body representing the group, 2 km x 2 km x 10 m, starting 20–30 m below the surface, was selected for the operational monitoring. In the operational monitoring planning, it was decided to use dissolved iron as a target parameter that would be a sensitive indicator of aquifer oxidation (decreasing iron concentration with increasing oxidation). It was further decided to aim at monitoring one well twice per year and the objective of the operational monitoring was set to having a 95 % probability of recognising a 20 % quality deterioration. This requires a measurement uncertainty including both sampling and analysis of not more than 10 % (comparison of two means each for two samples, 95 % confidence interval, two sided test) corresponding to an expanded measurement uncertainty of 20 %. To ensure the compliance of the monitoring program with this stated objective, a sampling validation study was initially conducted including all wells available and based upon the results from this, a routine sampling quality control program was set up for implementation with the monitoring program for the selected monitoring well.
Experiences gained - Conclusions – Recommendations: The empirical approach was selected as study design in order to provide estimates of heterogeneity in the groundwater body (between-target variation well to well or over time) and measurement uncertainty, split into sampling uncertainty and analytical uncertainty. The basic principle of the empirical approach is to apply replicate measurements. Sampling was done using the groundwater monitoring sampling protocol developed by the county. Analyses were performed at an independent, accredited (ISO 17025) laboratory using accredited methods subject to the required quality assurance and analytical quality control. Estimates of laboratory uncertainty and analytical detection limits were obtained from the laboratory quality control scheme and evaluated with the data from the monitoring validation and quality control. The objective of the validation study was to ensure that measurement uncertainty meeting the set quality objective could be obtained and to describe the components of uncertainty in order to identity points of improvement, if required. The validation study was set up with sampling of the 6 wells, two independent samplings per well and 2 sub-samples per sample analysed, see overleaf figure. The validation study thus included one sampling round with a total of 12 samples taken and 24 sub-samples sent for analysis.



The objective of the quality control programme for the operational monitoring was to ensure that measurement uncertainty did not increase over time during the monitoring. The quality control programme was set up after careful evaluation of the results from the validation study and was designed including duplicate sampling on one of the two annual sampling occasions of the monitoring programme.

The replicate data were treated using the range method (ISO 3085), see below table for results. The applied calculation methods are demonstrated in the guide on uncertainty from sampling, calculations are easily done using standard spread sheets, and an example can be downloaded from http://www.samplersguide.com. The data treatment provided estimates of analytical, sampling and total measurement uncertainty, in addition to the uncertainty due to heterogeneity (in space or time). Only random errors were included, whereas the occurrence of systematic sampling errors was not assessed quantitatively, but the consistency of the obtained results for different chemical parameters was used as a qualitative control of systematic errors.

Dissolved iron	**Expanded uncertainty, coverage factor 2**			**Between-target**
in groundwater	**Analysis**	**Sampling**	**Measurement**	**heterogeneity**
Validation	2.1 %	10 %	10 %	35 %[1]
Quality control			4.0 %	9.9 %[2]

[1)] In the validation study, between-target variability was between wells
[2)] In the quality control, between-target variability was between sampling occasions, first 6 sampling occasions included

The data show that the requirement for less than 20% expanded measurement uncertainty could be fulfilled for dissolved iron (sampling validation), and that the required measurement uncertainty was in reality achieved during the routine monitoring (sampling quality control). Furthermore, the data show that if an improvement of the certainty of monitoring was required, the obvious point of improvement would be increased monitoring density (between-target heterogeneity dominating).

Outlook - Next steps – Accessibility of results

In planning groundwater monitoring, fitness for purpose (monitoring uncertainty corresponding to set quality objectives) can be ascertained by a simple monitoring validation approach. If required, points of improvement of monitoring can be identified from the contributions to monitoring uncertainty (analysis, sampling, heterogeneity). With a simple and cost efficient quality control, it can be ascertained that the routine monitoring uncertainty remains as required for the purpose.

Considering the total costs of groundwater monitoring and the costs associated with decisions on measures taken from monitoring data, the costs of including an initial monitoring validation during planning and a subsequent monitoring quality control during routine monitoring seem justified.

The principles applied are described in the Eurachem/EUROLAB/CITAC/Nordtest Guide

“Estimation of measurement uncertainty arising from sampling”.

CASE STUDY - TEVERE, COLLI ALBANI (ITALY)

Background information

Title/Name of case study: Studies and management of a volcanic aquifer in an area subject to different pressures. Colli Albani volcanic structure (Lazio-central Italy)

Type of case study:

The case study is being conducted as part of phase II of the PRB testing activity and it is coordinated by the Tevere River Basin Authority with the support of the Italian Ministry of the Environment, the Italian National Institute of Health (ISS), the Italian National Environment Protection Agency and Technical Services (APAT), the Regional River Basin Authority of Lazio, ARPA Lazio (Regional Environment Agency), the National Research Council - Water Research Institute (Cnr Irsa), and the Department of Geological Sciences of "Roma3" University. Testing of the methodologies set up within the FP6 Bridge project will be carried out in the same area.

Web-Link: http://www.abtevere.it/prb_2/

Objective of case study:

The management of aquifers subject to intense overexploitation for household, agricultural and industrial uses requires specific and complex plan measures. The case study of the Colli Albani volcanic structure located in the south of the city of Rome has been given as an example. Other aspects of interest in this area are the presence of protected areas and dependent terrestrial and aquatic ecosystems. The identification of thresholds, especially in relation to quantitative aspects and natural background levels will be taken into account during the phase related to the Bridge project.

The scheme of this case study is as follows:

- description of the water circulation in the Colli Albani
- identification of the natural background levels
- key elements of the pressures and impacts analysis
- identification of areas that require specific protection
- safeguard measures
- analysis of existing monitoring activities
- steps needed for the monitoring network to comply with the WFD objectives

Contribution to…

WFD focus: monitoring, protected areas, risk assessment, programme of measures, volcanic aquifer, saline intrusion

Specific contributions: groundwater-surface water interaction, natural background levels, programme of measures

Characterisation:
The Colli Albani volcanic structure is situated south of the city of Rome. It is constituted by an isolated relief with a characteristic truncated cone shape that surmounts the Roman countryside with an altitude of 970 m asl. During the final phases of the volcanic activity, the top of the structure was subject to violent explosions, which created a vast caldera with a diameter of about 10 km. Today, two secondary craters, formed in a subsequent phase within the calderic ring, are filled by the Albano lake and Nemi lake.

This territory has an important value from a landscape, historical and cultural point of view and has been widely exploited since the Roman epoch. It comprises important natural protected areas of local, national and European interest.

The Colli Albani structure's water circulation develops in radial direction from the center to the periphery following complex patterns and it is characterized by a substantial interaction between groundwater and surface water circulation. The geological setting originated an aquifer in the central area, sustained by low permeability volcanic rocks and a basal aquifer, sustained by marine pre-volcanic clay deposits and contained in the more ancient volcanic rocks. Water circulates also through the lakes from the superior to the basal aquifer complexes. The characteristic springs in this system are linear springs that feed the perennial surface water circulation at the bottom of the riverbed. The water circulation was subdivided into four sectors delimited by potential levels, where it was possible to carry out water balance calculations.

Furthermore, some areas where the water enters into contact with the surfacing magma fluids from the later phases of the volcanic activity are characterized by the presence of thermal springs and water with particular chemical compositions.

In the last 50 years this area has been subject to growing pressures due to the expansion of urban settlements, scattered houses, industrial activity and agriculture (water-demanding crops). The water demand was mainly satisfied by groundwater abstraction from wells, facilitated by the development of drilling techniques and by the relative shallowness of the water.

Experiences gained - Conclusions - Recommendations

The first step was to carry out a hydrogeological study in order to allow the calculations to be made.

Hydrogeological balance calculations were carried out analyzing the spatial and temporal variability of precipitations and climatic conditions on a monthly basis, analyzing the effects of morphological, lithological, pedological conditions, vegetation and land use on runoff and evapotranspiration with elevated spatial detail, estimating the withdrawals.

The most important results of the hydrogeological study carried out on the Colli Albani aquifer showed how in the last years, also due to a decrease of rainfall, especially during the winter season, the base flow in surface watercourses dropped by 50%. In particular, the water level of Albano lake, which is in direct contact with the aquifer, dropped by about 2 m.

Considering that surface base flow is fundamental in sustaining aquatic ecosystems and that the flow of water bodies receiving wastewater discharge determines the quality status of water bodies, it is very important to maintain the base flow at a compatible level with the life of aquatic ecosystems and the achievement of good quality status.

Another issue that merits attention regards the ratio between estimated withdrawals and effective infiltration.

The balance units have different withdrawal/recharge ratios and can be considered as four water bodies.

For the purpose of the study a methodology was designed for the identification of sectors where the withdrawals and consequently the major critical situations are concentrated. This methodology is based on seven indexes regarding both causes (withdrawals) and effects (alterations to the aquifer's equilibrium), calculated spatially on a grid with 250 m wide cells.

The necessity emerged of urgent interventions through the application of safeguard measures that set rules for groundwater use on the basis of the different levels of attention that were detected.

Outlook - Next steps – Accessibility of results

An efficacious management of the water in the Colli Albani volcanic structure must be aimed at fulfilling general characteristics, such as the preservation of an acceptable level of equilibrium of the aquifers and specific objectives, such as the protection of particular areas.

In particular, regarding the quantitative aspects it is necessary to:

- verify the exploitation trends of the aquifer by measuring the piezometric levels
- verify the trends of the surface base flow through measures of peripheral watercourses
- verify the trends of intakes by means of rainfall and temperature measurements

regarding qualitative aspects, it is necessary to:

- define the basic and specific chemical parameters in particular conditions
- define the interaction between discharge water and freshwater in the perennial network
- define the suitability of lakes for bathing

CASE STUDY - EMILIA-ROMAGNA REGION (ITALY)

Background information

Title/Name of case study: Groundwater monitoring network of the Regione Emilia-Romagna (Italy).

Type of case study: Groundwater level and chemical monitoring network of the Regione Emilia-Romagna alluvial plain (part of the Po Plain - Italy). Regione Emilia-Romagna (Servizio Geologico, Sismico e dei Suoli; Servizio Tutela e Risanamento Risorsa Acqua); ARPA Regione Emilia-Romagna.

Web-Link: http://www.arpa.emr.it/acquarer/

Objective of case study: support of groundwater management

Contribution to…

WFD focus: Monitoring of groundwater. Presentation of groundwater status.

Specific contributions: Hydrogeological structure of the aquifer. Monitoring network features and optimising.

Characterisation:

Emilia-Romagna alluvial plain is 12,000 km² large, here is located a Pleistocene alluvial aquifer up to 700 m thickness. It is divided in three main hydrostratigraphical units, each one divided in four or five sub-units. Inside the units we recognise three different groundwater bodies (appenninic rivers alluvial fans, appenninic rivers alluvial plain, deltaic and alluvial river Po plain). According to the greatest quantitative and chemical features, the appenninic rivers alluvial fans could be considered as the priority groundwater bodies. Recharge areas are located in the southern margin, where all the aquifers are amalgamated and unconfined, toward north aquifers become multilayers and confined.

In Emilia-Romagna plain aquifer the groundwater monitoring network started in 1976 with level and electrical conductivity measures, the chemical measures started in 1988. Network is now composed by 575 wells (about 1–25 km²); 112 measure the quantity, 143 the quality and 320 measure both.

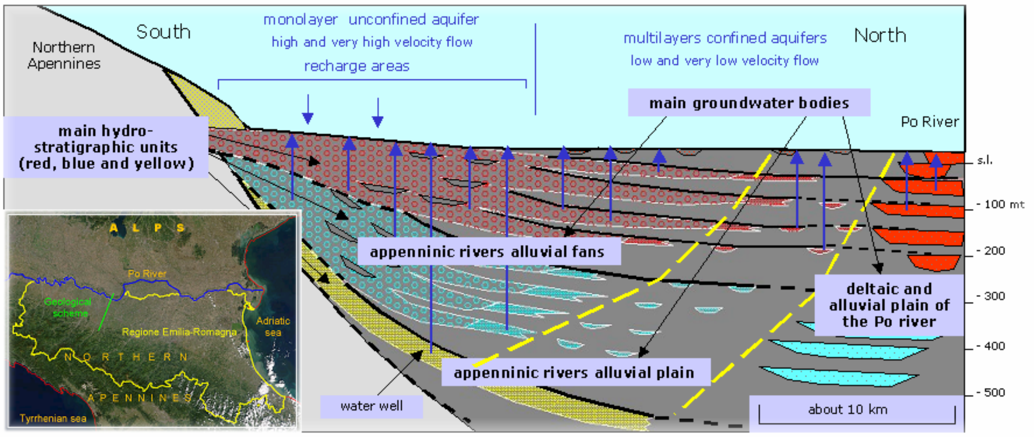


Figure 1: Schematic cross section and simplified conceptual model of the Emilia-Romagna alluvial plain aquifer.

Experiences gained – Conclusions - Recommendations

Monitoring network features

Main objective of the network. Classify groundwater according to Italian and European law. Verify the groundwater status. Define quantitative and qualitative capacity of the aquifer. Control the natural status of the aquifer.

Network design. In 1976 network started with a regular distribution of the monitoring wells. During time we reduced the density where no appreciable quantitative or chemical variations was clear, and we increased monitoring wells:

- where water level is low due to main withdrawal and near to the pumping station for drinking water;
- in the recharge areas, and where the piezometrical gradient is higher (ex. 6–8 ‰);
- where pollutants (first of all nitrates) are present, and in vulnerable areas;
- in priority groundwater bodies (alluvial fans), where we arrange wells along flow line to

consider chemical variations.

Therefore density of monitoring wells is higher in alluvial fans areas (1–15 km²) than in alluvial plain areas. In any case we adapted monitoring network to hydrogeological conceptual model in order to have information in each unit and in every groundwater bodies (see the figure 2 for the wells distribution). Depth of monitoring wells varies from 5 to 700 m (mean about 100 m).

Quantitative monitoring frequency. From 1976 to 1998 we took 4 measures per year. After statistical study of available data, we understood that 2 lecture per year are sufficient to realise multiyears trend. On the other hand, in case of high piezometrical gradient (strong withdrawal, nearness to river, recharge areas), 4 lectures per year are not sufficient to understand the situation. So from 1998 we have been continuing with 2 lecture per year on the great number of wells (400 about), and 12 lecture per year in the most stressed areas (on 30 monitoring wells).

Chemical monitoring frequency and type. Frequency is every six month. After a geostatistical approach we optimised the numbers of parameters to analyse. Now we have 4 wells groups, where related to their importance we analyse from 67 to 27 chemical and microbiological parameters.

Costs (level measures, sampling and analyses) in 2003 was about 550,000 Euro.

Groundwater status

From piezometrical trend value we calculated water deficit volume, as the volume of the water needed to achieve the equilibrium in the water balance aquifer. Therefore quantitative status is assigned considering value of the water deficit. Chemical status is assigned on the basis of the concentration of 7 main parameters and 33 additional parameters. Then we attributed groundwater status at each monitoring well by superposition of quantitative and chemical status data. The worse classes with biggest human impact (red and yellow dots in Figure 2) are located principally in the recharge alluvial fans areas. At the same time in the main alluvial fan areas are also present green dots, indicating good status, due to the high aquifer transmissivity and high dilution with clean fresh river water. Grey dots in Figure 2 represent particular conditions (no human impact, but poor chemical status due to natural condition), they are present in the northern side, where aquifers are extremely confined, groundwater velocity is reduced, and the exchange between groundwater and sediments is higher.

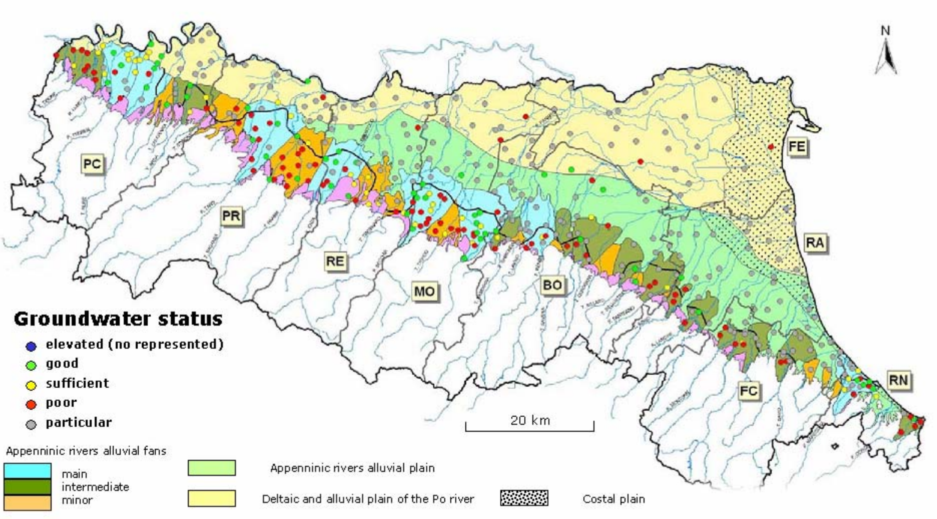

Figure2: Groundwater status taken from Water Plan (Piano di Tutela delle Acque) of the Regione Emilia-Romagna. Each dot represents a monitoring well.

Outlook - Accessibility of results

Data are available at http://www.arpa.emr.it/acquarer/ (Italian language), http://www.regione.emilia-romagna.it/geologia/ (Italian and English language), http://www.arpa.emr.it/ (Italian language)http://www.ermesambiente.it/ermesambiente/acque/servizio_acqua/ (Italian language), http://www.ermesambiente.it/PianoTutelaAcque/ (Italian language).

Next steps:

- Installation of 50 instruments for continuous groundwater level measurements.
- Identification of network for evaluation of the measure programmes.

Prólogo

Los Directores Generales del Agua de la Unión Europea (UE), los países de la Adhesión, los países candidatos y los países de la EFTA, han desarrollado conjuntamente una estrategia común para apoyar la aplicación de la Directiva 2000/60/CE, “por la que se establece un marco comunitario de actuación en el ámbito de la política de aguas” (Directiva Marco del Agua). Esta estrategia tiene como principal objetivo permitir una aplicación coherente y uniforme de la Directiva. La atención se ha centrado en las cuestiones metodológicas relacionadas con una comprensión común de las repercusiones técnicas y científicas de dicha Directiva.

En particular, uno de los objetivos de la estrategia es el desarrollo de documentos guía, de carácter práctico y jurídicamente no vinculantes, sobre varios aspectos técnicos de la Directiva. Estos documentos guía van dirigidos a los expertos que, directa o indirectamente, son los responsables de aplicar la Directiva Marco del Agua en las demarcaciones hidrográficas. En consecuencia, se ha adaptado la estructura, la presentación y la terminología a las necesidades de estos expertos, y, en la medida de lo posible, se ha evitado la utilización de un lenguaje formal y legalista.

En este contexto, los Directores Generales del Agua elaboraron y adoptaron el documento guía *Identification of Water Bodies* en noviembre de 2002 (ECI[*], Documento guía nº 2). Este documento ofrece a los Estados miembros una comprensión común de la definición de masas de agua e indicaciones específicas de carácter práctico para su identificación de acuerdo con la Directiva Marco del Agua.

A modo de continuación y en el contexto del desarrollo de la nueva Directiva relativa a las aguas subterráneas, tal como establece la Directiva Marco del Agua en su artículo 17, los Estados miembros han expresado la necesidad de aclarar algunos aspectos relacionados con las aguas subterráneas en zonas protegidas y, en particular, en Zonas protegidas para el abastecimiento de agua potable (ZPAP). En este sentido, en 2004 se inició un proyecto para desarrollar un documento guía que completara el Documento guía nº 2 de la CIS, y se creó un grupo informal de redacción al amparo del Grupo de Trabajo sobre Aguas Subterráneas de la CIS (WG-C). El Reino Unido y la EUREAU (Unión Europea de Asociaciones Nacionales de Suministradores de Agua y Servicios de Aguas Residuales) han sido los coordinadores de dicho grupo de redacción, y en él han participado varios expertos procedentes de otros Estados miembros y de organizaciones interesadas.

Este documento guía es el resultado de los trabajos del grupo de redacción. Contiene la síntesis de los resultados de los debates celebrados desde diciembre de 2004. Está basado en las aportaciones y las reacciones de una amplia variedad de expertos y partes interesadas que han participado a lo largo de todo el procedimiento del desarrollo de la guía a través de reuniones, talleres, conferencias y medios electrónicos, sin que por ello resulten vinculados en modo alguno con el contenido del presente informe.

“Nosotros, los Directores Generales del Agua de la Unión Europea, Noruega, Suiza y los países que han solicitado la adhesión a la Unión Europea, hemos examinado el presente Documento guía y lo hemos respaldado en el transcurso de nuestra reunión informal bajo la Presidencia alemana en Dresde (18-19 de junio de 2007). Deseamos expresar nuestro agradecimiento a los participantes del Grupo de Trabajo C y, en particular, a los jefes del grupo de redacción, al Reino Unido y a la EUREAU por la elaboración de este documento de gran calidad. Creemos firmemente que éste y otros documentos guía elaborados en el marco de la Estrategia común para la aplicación de Directivas tendrán un papel destacado en el

[*] CIS: Common Implementation Strategy, Estrategia común para la Implantación

proceso de aplicación de la Directiva Marco del Agua y de la Directiva relativa a las aguas subterráneas, adoptada recientemente.

Esta guía es un documento vivo que necesitará aportaciones y mejoras continuas a medida que avanza la aplicación y crece la experiencia en todos los países de la Unión Europea y en otros países. Hemos acordado, no obstante, que este documento se haga público en su forma actual con el fin de presentarlo al gran público como la base para seguir avanzando en los esfuerzos de aplicación en curso. Asimismo, nos comprometemos a evaluar y a decidir sobre la necesidad de revisarlo a la luz de los avances científicos y técnicos, así como de las experiencias acumuladas en la aplicación de la Directiva Marco del Agua y de la nueva Directiva relativa a las aguas subterráneas."

ÍNDICE

1. Objeto y alcance

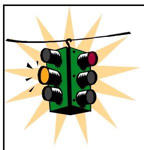
1.1 Introducción

Este documento guía explica las obligaciones de carácter normativo aplicables a las aguas subterráneas que se encuentran en zonas protegidas y, en particular, los requisitos para las Zonas protegidas para la captación de agua potable (en adelante, ZPAP) que establece el artículo 7 de la Directiva Marco del Agua (en adelante, DMA). No se incluyen aquí los requisitos recogidos en otras Directivas, en virtud de las cuales se designan las zonas protegidas. El documento explica asimismo la relación que existe entre los objetivos para las zonas protegidas y otros objetivos de la DMA. En particular, aclara los requisitos relativos a las ZPAP.

El presente documento debe leerse conjuntamente con otras de las guías de la ECI (estrategia común para la implantación, CIS en las siglas inglesas), tales como: la guía de carácter horizontal sobre la designación de masas de agua[1] y los documentos guía elaborados por el Grupo de Trabajo C de la ECI – Aguas subterráneas y, en particular, la guía de seguimiento de las aguas subterráneas[2].

1.2 Finalidad de la guía

- Contribuir a una visión común de las repercusiones técnicas y científicas de la DMA en lo que respecta a las zonas protegidas;
- Contribuir a que se formule en términos que sean comprensibles tanto para los organismos reguladores como para los que se vean afectados por la aplicación de la Directiva;
- En lo relativo a las exigencias de la DMA para las zonas protegidas, aclarar los aspectos relativos a las aguas subterráneas que no hayan sido tratados en otra parte, incidiendo especialmente en las exigencias para las ZPAP y los perímetros de protección asociados;
- Poner de relieve las cuestiones que puedan afectar a la gestión de acuíferos y masas de agua transfronterizos.



¡Atención! La metodología que propone esta guía deberá adaptarse a las circunstancias regionales y nacionales

El documento guía propone un enfoque pragmático global. Considerando la diversidad de circunstancias que se da en el territorio de la Unión Europea, los Estados miembros podrán aplicar las guías con flexibilidad, para responder a problemas que serán diversos en las distintas cuencas hidrográficas; por ello las guías deberán adaptarse a las circunstancias específicas de cada caso.

[2] CIS Guidance Document No. 15 on groundwater monitoring, Comisión Europea, 2006

2. Requisitos generales para zonas protegidas de la Directiva Marco del Agua

2.1 Zonas definidas con arreglo a la DMA

El artículo 4 de La DMA establece que los objetivos medioambientales de la Directiva se dividen en: objetivos para las aguas superficiales, para las aguas subterráneas y para las zonas protegidas. Los objetivos para las zonas protegidas son los que recoge la legislación comunitaria en virtud de la cual hayan sido establecidas dichas zonas, con el objetivo adicional de que "*Los Estados miembros habrán de lograr el cumplimiento de todas las normas y objetivos"* a más tardar en diciembre de 2015, a menos que se especifique de otro modo en el acto legislativo comunitario.

El anexo IV de la DMA define las zonas protegidas como:

1. zonas designadas para la captación de agua destinada al consumo humano con arreglo al artículo 7 de la DMA – Zonas protegidas de agua potable (ZPAP);
2. zonas designadas para la protección de especies acuáticas significativas desde un punto de vista económico;
3. masas de agua declaradas de uso recreativo, incluidas las zonas declaradas aguas de baño en el marco de la Directiva 76/160/CEE;
4. zonas sensibles en lo que a nutrientes respecta, incluidas las zonas declaradas vulnerables en virtud de la Directiva 91/676/CEE y las zonas declaradas sensibles en el marco de la Directiva 91/271/CEE; y
5. zonas designadas para la protección de hábitats o especies cuando el mantenimiento o la mejora del estado de las aguas constituya un factor importante de su protección, incluidos los puntos Natura 2000 pertinentes designados en el marco de la Directiva 92/43/CEE y la Directiva 79/409/CEE.

Respecto a las zonas protegidas para la captación de aguas subterráneas, exceptuando las ZPAP:

Los Estados miembros tendrán facultad discrecional respecto a su designación cuando:

- formen parte de una masa de agua subterránea;
- se extiendan sobre partes de dos o más masas de agua subterránea;
- incluyan zonas que no contengan en sí mismas aguas subterráneas o aguas superficiales, pero que comprendan hábitats o especies que dependen directamente de dichas aguas (p.ej. algunas zonas Natura 2000, que están protegidas); o
- coincidan con los límites de las masas de agua subterránea.

Dichas zonas figurarán designadas en los planes hidrológicos de cuenca.

La designación de ***ZPAP*** con arreglo a los artículos 6.2 y 7.1 de la DMA se presta a diferentes interpretaciones, las cuales han sido objeto de debate en el transcurso de la redacción del presente documento. Una primera interpretación es que las ZPAP podrán designarse como "zonas", mientras que la segunda interpretación es que deben designarse como masas de agua, como se recoge en el artículo 7.1. Esta divergencia de opiniones procede principalmente de las terminologías que a nivel interno utilizan los Estados miembros; es posible que éstos hayan percibido que el empleo de una terminología determinada tiene consecuencias en las medidas de protección. Estas pueden resumirse como sigue:

- En la primera interpretación, una ZPAP puede ser una zona que forme parte de una masa de agua subterránea, que se extienda a otras partes de dos o más masas de agua o que corresponda a los límites de la masa de agua subterránea. En este sentido, puede que no sean necesarios los perímetros de protección definidos en el artículo 7.3, además de la ZPAP. De hecho, las ZPAP se convierten en perímetros de protección en los que se centran las medidas.
- En la segunda interpretación, las ZPAP abarcan en su totalidad las masas de agua subterránea. Las medidas de protección necesarias podrán centrarse en el área circundante a los puntos reales de captación previstos (aunque no tienen por que limitarse solamente a dicha área), es decir, en los perímetros de protección que, por consiguiente, son similares a las ZPAP definidas en la primera interpretación.

Independientemente de la interpretación que se adopte, será aplicable el objetivo del artículo 7.3 de evitar el deterioro de su calidad y deberá otorgarse la protección necesaria a las zonas que estén en riesgo de sufrir un deterioro.

En el presente documento guía se ha adoptado la segunda interpretación como base de trabajo. Esto implica, en definitiva, que:

1. las ZPAP son las masas de agua en su conjunto;
2. las ZPAP comprenden las zonas de extracción de agua propiamente dichas (perímetros de protección) y otras zonas de captación potenciales;
3. las medidas de protección se centran en los perímetros de protección, normalmente ligados a los puntos de extracción de agua potable que estén en riesgo de sufrir un deterioro, lo cual no descarta otras medidas más amplias para toda la ZPAP, cuando un Estado miembro desee garantizar la protección, por ejemplo, de una zona que haya sido designada para la captación de agua en un futuro;
4. como especifica la nueva Directiva relativa a las aguas subterráneas, los perímetros de protección podrán incluir una masa de agua subterránea (es decir, una ZPAP), comprender partes de dos o más masas de agua o abarcar todo el territorio de un Estado miembro.

La designación de masas de agua subterránea (incluidas las masas de agua declaradas como ZPAP), que son unidades de gestión creadas para facilitar la consecución de los objetivos de la DMA, dependerá exclusivamente de la facultad discrecional de los Estados miembros. Los requisitos asociados a las ZPAP podrán ser una de las consideraciones para la designación de una masa de agua subterránea. Como se resalta más arriba, también podrán designarse **perímetros de protección** en los que centrar las medidas de protección necesarias para cumplir los objetivos del artículo 7 y de conformidad con el artículo 4.2.

	***¡Atención!* La terminología existente en los Estados miembros para la protección de zonas o áreas de captación de agua potable puede no concordar con la del artículo 7. En algunos Estados miembros, estas zonas son sinónimo de “perímetros de protección”. No será necesario modificar las designaciones existentes siempre que la relación con la terminología de la DMA sea inequívoca y se apliquen los objetivos y medidas de la DMA.**

2.2 Calendario para la consecución de los objetivos

La DMA establece en su artículo 4.1.c) que, para las zonas protegidas:

“Los Estados miembros habrán de lograr el cumplimiento de todas las normas y objetivos a más tardar quince años después de la entrada en vigor de la presente Directiva, a menos que se especifique otra cosa en el acto legislativo comunitario en virtud del cual haya sido establecida cada una de las zonas protegidas.”

Los objetivos y normas de otros actos de la legislación comunitaria quedan así integrados en los planes hidrológicos de cuenca con arreglo a la DMA.

La DMA introduce la fecha del 22 de diciembre de 2015 para alcanzar las normas y objetivos para la zona protegida, a menos que la legislación comunitaria en virtud de la cual haya sido establecida dicha zona protegida especifique una fecha alternativa.

2.3 Relación entre la zona protegida y otros objetivos de la DMA y de la nueva Directiva relativa a las aguas subterráneas

Los objetivos dirigidos a aplicar las medidas necesarias para evitar o limitar la entrada de contaminantes en las aguas subterráneas, recogidos en el artículo 4.1.b),i), y a invertir toda tendencia significativa y sostenida al aumento de la concentración de cualquier contaminante, con arreglo al artículo 4.1.b),iii), son aplicables a todas las aguas subterráneas. Los objetivos relativos al estado de las aguas, según se especifica en el artículo 4.1.b), i) y ii) de la DMA, son aplicables a las masas de agua subterránea. Los objetivos para zonas protegidas recogidos en el artículo 4.1.c) son aplicables a las zonas declaradas en virtud de las Directivas de referencia (es decir, aquellas que se han mencionado en el apartado 2.1).

Las normas y objetivos para las zonas protegidas difieren de los objetivos relativos al estado de las aguas. Las medidas encaminadas a cumplir los objetivos para una zona protegida podrán centrarse en dichas zonas protegidas, aunque sin limitarse necesariamente a las mismas. Las medidas para cumplir los objetivos relativos al estado de las aguas se aplicarán, en caso necesario, a toda la masa de agua subterránea.

La DMA establece en su artículo 4.2 que cuando sea aplicable a una masa de agua más de un objetivo, se utilice el más riguroso. Dentro de una zona protegida se aplicaría el objetivo más riguroso y, por ejemplo, aquél relativo al estado de las aguas. Aun cuando sea más riguroso, un objetivo para una zona protegida no será aplicable fuera de la zona protegida declarada.

Las exenciones y excepciones aplicables a cada uno de los objetivos medioambientales de la DMA, incluidos los objetivos para las zonas protegidas, serán sometidas a debate en el grupo de expertos de la ECI sobre Excepciones y, en este sentido, la ECI formulará recomendaciones claras en un Documento guía aparte.

De conformidad con el artículo 11 de la DMA, los Estados miembros velarán por que se establezca un programa de medidas con el fin de alcanzar los objetivos establecidos en el artículo 4, incluyendo los relativos a las zonas protegidas.

Por último, hay que mencionar que la nueva Directiva relativa a las aguas subterráneas, Directiva 2006/118 CE (en adelante, DAS), hace referencia a la necesidad de investigar con el fin de obtener mejores criterios relativos a la calidad y a la protección del ecosistema de las aguas subterráneas. Se pone así de relieve que las aguas subterráneas deben ser consideradas como un ecosistema, al tiempo que se reconoce que los conocimientos disponibles actualmente no son suficientes para establecer medidas claras de protección. De acuerdo con el considerando 20 de la Directiva, debe tenerse en cuenta la información adquirida a la hora de aplicar o revisar dicha Directiva, lo que significa que también deben actualizarse los documentos guía pertinentes.

2.4 Registros de zonas protegidas

La DMA establece en su artículo 6 que los Estados miembros velarán por que se establezca un registro de las zonas protegidas. El registro (o registros) se limitará a:

- *las zonas incluidas en cada demarcación hidrográfica….*

- *que hayan sido declaradas objeto de una protección especial <u>en virtud de una norma comunitaria específica</u>….*
- *para la <u>protección</u> de sus aguas superficiales o <u>subterráneas</u> o…*
- *para la conservación de los hábitats y las especies que dependen directamente del agua.*

Estos registros se completarán a más tardar el 22 de diciembre de 2004 y se revisarán y actualizarán regularmente. En el caso de las ZPAP que no hayan sido establecidas anteriormente en virtud de otros actos de la legislación, esto implica que deben haber sido establecidas antes de la fecha citada.

3. Aguas subterráneas en zonas protegidas para la captación de agua potable

3.1 Terminología

La DMA introduce en su artículo 7 algunos términos, aunque no los define. A continuación se ofrece orientación sobre los mismos:

- **captación de agua destinada al consumo humano**

A efectos del presente documento, son las aguas extraídas de una masa de agua subterránea cuyo destino sea para beber, cocinar, preparar alimentos o para otros fines domésticos. Asimismo, son todas las aguas utilizadas en empresas alimentarias para fines de fabricación, tratamiento, conservación o comercialización de productos o sustancias destinados al consumo humano, a menos que a las autoridades nacionales competentes les conste que la calidad de las aguas no puede afectar a la salubridad del producto alimenticio final.

Observación: Esta definición ha sido tomada de la Directiva sobre Agua Potable (98/83/CE). Incluye las aguas extraídas para el abastecimiento público y privado de agua potable, para su inclusión directa en productos alimenticios (por ej. en la fabricación de cerveza y el enlatado), pero no las aguas destinadas a usos indirectos como el riego por aspersión.

- **perímetro de protección (“safeguard zone”)**

Por regla general, es una zona situada dentro de una masa de agua subterránea (declarada ZPAP) que puede ser considerablemente más pequeña que dicha masa de agua, en la que se puedan centrar las medidas para impedir que se deteriore la calidad de las aguas subterráneas captadas para el consumo humano (véase apartado 3.4). En algunas circunstancias, por ejemplo en acuíferos kársticos, la extensión de los perímetros de protección puede ser la misma de la masa de agua subterránea o incluso mayor (véanse más detalles sobre los perímetros de protección en el apartado 3.7). Estos perímetros de protección pueden llegar a abarcar todo el territorio de un Estado miembro (considerando 15 de la Directiva 2006/118/CE).

3.2 Identificación y delimitación de las ZPAP

El artículo 7.1 establece que los Estados miembros especificarán dentro de cada demarcación hidrográfica:

“todas las masas de agua utilizadas para la captación de agua destinada al consumo humano que proporcionen un promedio de más de 10 m^3 diarios <u>o</u> que abastezcan a más de 50 personas, <u>y</u>

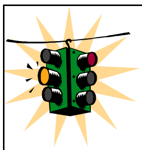
todas las masas de agua destinadas a tal uso en el futuro.”

En virtud de dicha disposición, así se designarán las masas completas de agua subterránea y así lo confirma el apartado 4 de la Referencia 1.

Observación: Como se ponía de relieve en el apartado 2.1, esto no significa que el objetivo mencionado en el artículo 7.3 de la DMA deba cumplirse en todos los puntos situados sobre una masa de agua subterránea, ni que deban aplicarse por igual medidas sobre toda la masa de agua (véanse apartados 3.4-3.8 de esta guía).

El enunciado *"un promedio [de más] de 10 m^3 diarios"* induce a pensar que la masa de agua en su conjunto debe poder proporcionar 10 m^3 diarios. La calificación alternativa, abastecer a más de 50 personas, confirma dicha interpretación (*Observación: este enunciado es similar al de la Directiva sobre Agua Potable (DAP), aunque el contexto en el que se utiliza es diferente*). Teniendo en cuenta las variaciones en el consumo y el tamaño de los hogares que existen en la Comunidad, estos límites son cercanos al abastecimiento de agua potable, procedente de la masa de agua subterránea, para entre 10 y 20 hogares.

La DMA no fija ningún límite respecto al tamaño que pueden tener las masas de agua subterránea – son unidades de gestión cuya designación es competencia de los Estados miembros, como se observa en la Referencia 1. No obstante, los requisitos administrativos con arreglo a la DMA, incluida la notificación, favorecen la creación de masas de agua subterránea o grupos de masas de agua subterránea de gran tamaño. Por lo general, estas masas de agua alcanzan muchas decenas y hasta muchos centenares de kilómetros cuadrados. La necesidad de proteger el agua potable es sólo uno de los numerosos factores entre los que habrá que elegir y que podrán ser tenidos en cuenta en la designación de masas de agua subterránea.



¡Atención! **De acuerdo con la DMA, puede que deban designarse como ZPAP muchas de las masas de agua subterránea de un Estado miembro. Esto no significa que sea necesario aplicar medidas de protección para cumplir los objetivos del artículo 7 a toda la extensión terrestre de dichas ZPAP. Podrán utilizarse los perímetros de protección para centrar las medidas a fin de proteger las aguas subterráneas que se extraen para el consumo humano y cumplir así los requisitos de los artículos 7.3 y 4.1.c).**

Las zonas de protección existentes (previas a la DMA) que hayan sido establecidas con arreglo a la legislación u orientaciones de los Estados miembros podrán ser similares a los perímetros de protección y podrían ser utilizadas para cumplir los objetivos del artículo 7.

Las exigencias de establecer masas de agua subterránea que estén "destinadas a tal uso en el futuro" con arreglo al artículo 7.1 y de crear un registro de dichas zonas de acuerdo con el anexo IV de la DMA, indican que los Estados miembros deben declarar dichas masas de agua como un recurso hídrico destinado al consumo humano en el futuro. Es posible que en la actualidad no exista dicho uso o que la captación total existente sea inferior a los límites mencionados anteriormente. Cuando, dentro de las perspectivas de planificación de la DMA, pueda preverse razonablemente dicho uso (tomando como base las propiedades hidrogeológicas del acuífero así como su uso potencial), las masas de agua subterránea deberán especificarse como destinadas a tal uso en el futuro.

3.3 Cumplimiento de los requisitos de la Directiva sobre Agua Potable (DAP)[3]

El artículo 7.2 de la DMA reza: *"además de cumplir los objetivos del artículo 4……los Estados miembros velarán por que, en el régimen de depuración de aguas que se aplique y*

[3] Directiva 98/83/CE del Consejo relativa a la calidad de las aguas destinadas al consumo humano.

de conformidad con la normativa comunitaria, el agua obtenida cumpla los requisitos de la Directiva 80/778/CEE, modificada por la Directiva 98/83/CE."

Observación: en la práctica, la Directiva 98/83/CE sustituye a la Directiva 80/778/CEE).

Esto confirma que:

- los objetivos del artículo 4 (es decir, el estado del agua, el objetivo de prevenir o limitar, aplicar la inversión de la tendencia y otros objetivos para las zonas protegidas) deberán cumplirse independientemente del cumplimiento del objetivo del artículo 7.2 ; y
- deberán cumplirse los requisitos de la Directiva sobre Agua Potable (DAP). Se incluye aquí el requisito general de garantizar que el agua esté libre de toda contaminación que pueda constituir un peligro para la salud humana **y** el requisito de cumplir las normas establecidas en la DAP en el punto de suministro a los consumidores (es decir, el grifo).

Observación: todas las demás referencias al cumplimiento de las normas de la DAP de esta guía, se interpretarán igual que el cumplimiento de estos dos requisitos.

No todas las captaciones de agua destinada al consumo humano están sujetas a la DAP. Tal como permite la propia Directiva, algunos Estados miembros han optado por eximir de su cumplimiento a fuentes **individuales** que proporcionan un promedio de menos de 10 m^3 diarios o que abastecen a menos de 50 personas; por ello, no todas las captaciones dentro de una ZPAP están sujetas al cumplimiento de la DAP y, por consiguiente, del artículo 7.2 de la DMA.

Observación: esta excepción de fuentes individuales es, de hecho, muy diferente de la aplicación del enunciado del artículo 7.1, descrito más arriba, que define qué masas de agua son ZPAP.

El punto de cumplimiento para el artículo 7.2 es el mismo que el mencionado en la DAP, es decir, el punto en el que se utiliza el agua potable para el consumo humano. En virtud de la legislación comunitaria, las normas de calidad mencionadas en la DAP no son aplicables al agua sin tratar captada de la masa de agua subterránea. No obstante, los Estados miembros podrán tener legislación propia sobre las normas de calidad aplicables a las aguas subterráneas sin tratar en tales circunstancias y, en la práctica, son numerosos los abastecimientos dentro de la UE en los que las aguas subterráneas se extraen y utilizan para el consumo humano sin ser sometidas a ningún tratamiento de purificación.

Los requisitos del artículo 7.2 no introducen ningún objetivo nuevo para los Estados miembros, y el calendario para el cumplimiento de los requisitos lo fija la Directiva sobre Agua Potable.

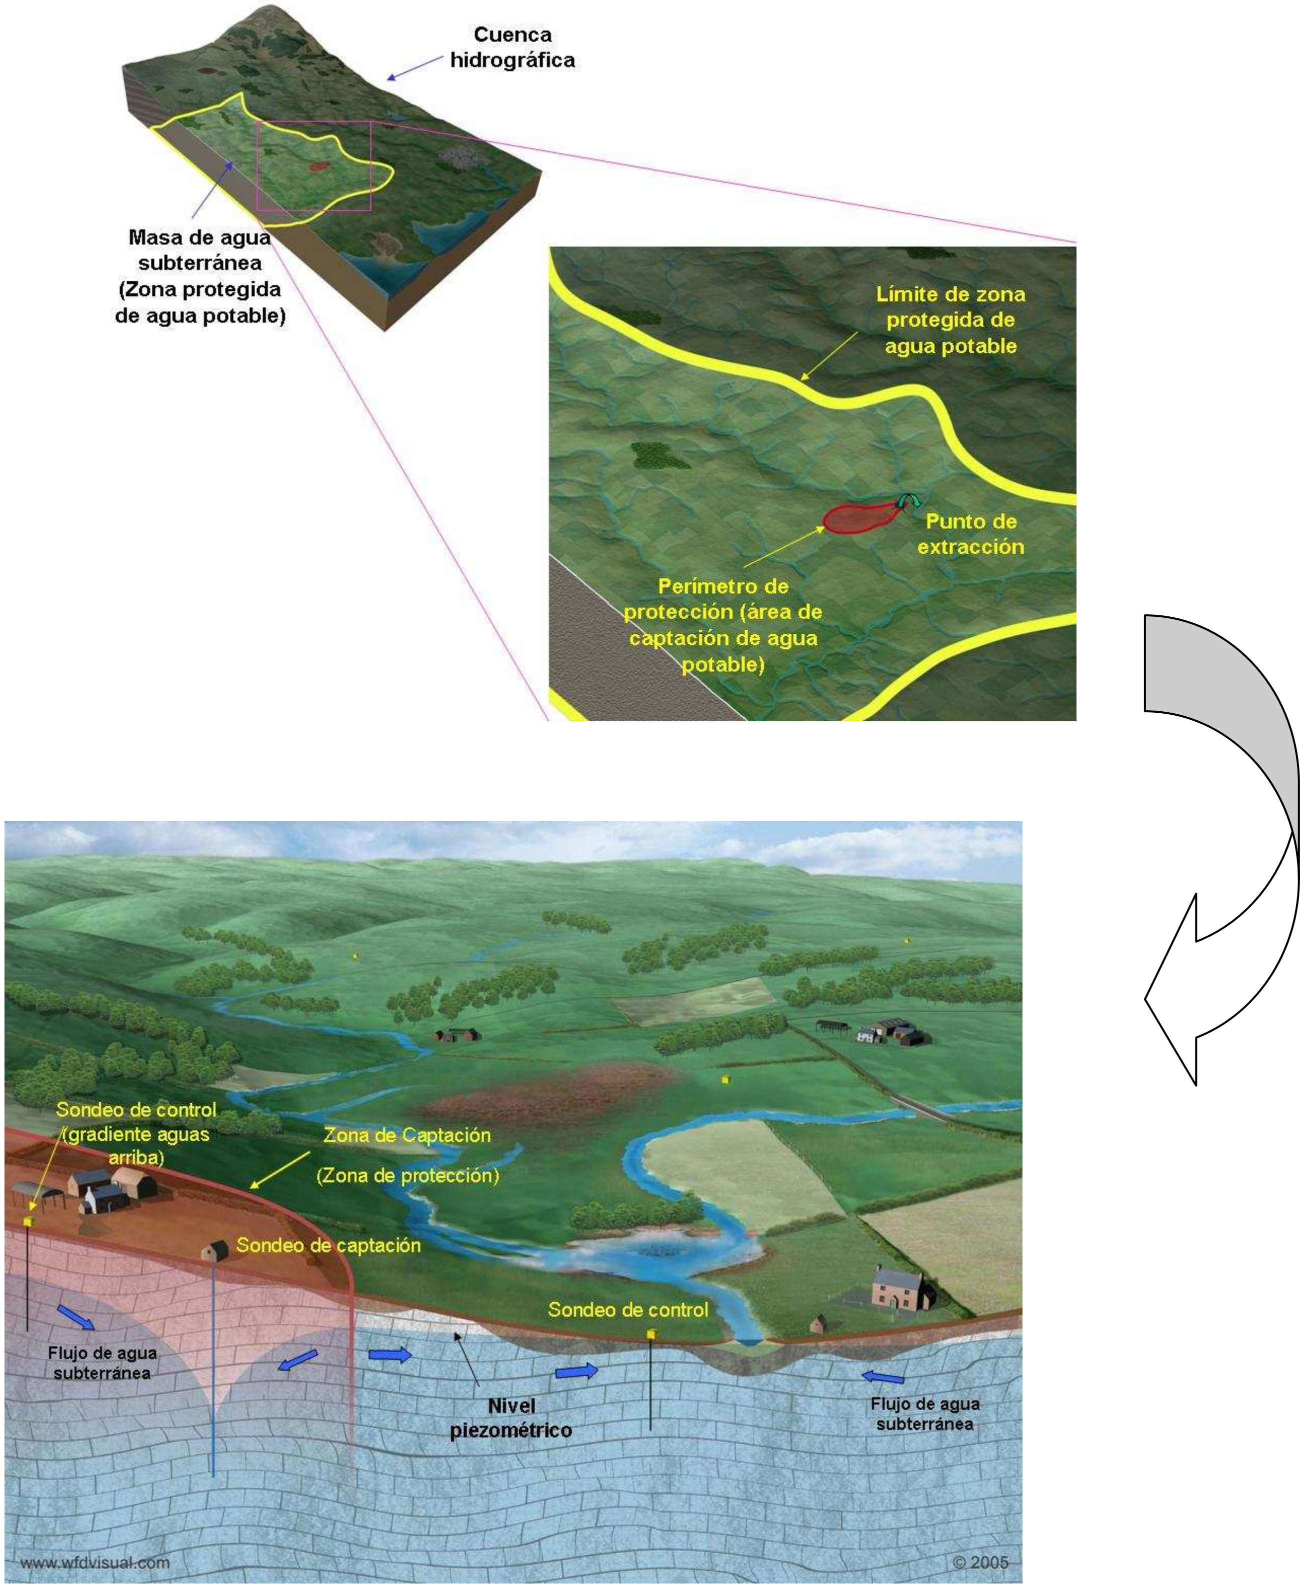


Figura 1: Posible relación entre una zona de aguas subterráneas protegida para la captación de agua potable y un perímetro de protección.

3.4 Protección necesaria y cómo evitar el deterioro

En virtud del **artículo 7.3** de la DMA, los Estados miembros velarán por la necesaria protección de las masas de agua subterránea especificadas como ZPAP *"con objeto de evitar el deterioro de su calidad, contribuyendo así a reducir el nivel del tratamiento de purificación necesario para la producción de agua potable. Los Estados miembros podrán establecer perímetros de protección para esas masas de agua."*

En la práctica, evitar el deterioro de la calidad de una masa de agua subterránea no necesariamente tendrá como resultado una reducción del nivel del tratamiento de purificación que pueda ser necesario para producir agua potable. Para reducir el tratamiento sería necesaria una mejora de la calidad. Existe, sin embargo, la clara intención de, al menos, evitar el deterioro de la calidad de las aguas subterráneas. En el mejor de los casos, la protección debería ser suficiente para que, con el paso del tiempo, pueda reducirse el tratamiento de purificación. La segunda frase del artículo 7.3 establece que los Estados miembros tendrán facultad discrecional para establecer perímetros de protección dentro de los cuales se centre la protección necesaria. En algunos Estados miembros, estos perímetros de protección se conocen comúnmente como "zonas de protección de captación de agua potable". Estas se tratan con mayor detenimiento en el apartado 3.8 y en el anexo 1.

¿Cuándo puede hablarse de deterioro significativo?

Serán necesarios valores de referencia sobre la calidad de las aguas subterráneas existente respecto de los cuales pueda evaluarse el deterioro. Estos valores podrán obtenerse de los datos existentes y de los programas de seguimiento creados con arreglo a la DMA, como se describe a continuación en el apartado 3.6. Habida cuenta de que un solo contaminante que exceda los niveles establecidos por las normas para el agua potable puede hacer necesario un tratamiento de purificación, cabe deducir que la evaluación del deterioro debe llevarse a cabo para parámetros individuales. Será necesario un valor de referencia para aquellos contaminantes que supongan un riesgo de deterioro, respecto al cual puedan evaluarse las tendencias en el futuro. El objetivo es prevenir el deterioro derivado de las presiones antropogénicas en cualquier contaminante que pueda necesitar un tratamiento adicional para cumplir las normas relativas al agua potable.

La figura 2 ilustra un caso en el que ya se ha instalado un tratamiento para corregir un problema existente de calidad del agua -cuyo origen puede estar relacionado con causas naturales o con la actividad humana-, de manera que se cumpla la norma sobre agua potable respecto al contaminante 1. Este tratamiento podría corregir asimismo un futuro deterioro en el contaminante 2. Sin embargo, este sistema oculta el hecho de que se ha producido un deterioro significativo de la calidad del agua sin tratar. El objetivo de prevenir el deterioro no se ha cumplido.

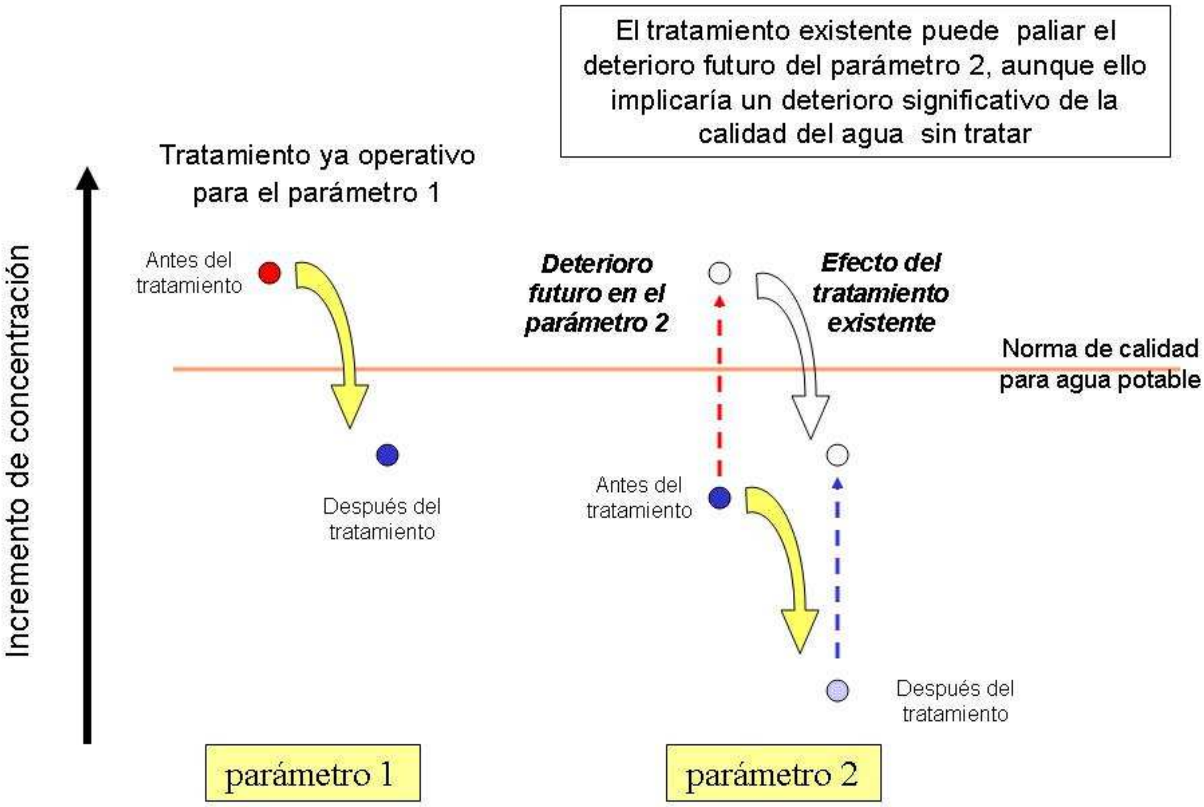

Figura 2: Deterioro significativo de la calidad de aguas subterráneas en una captación tras haberse instalado un tratamiento de purificación.

Mejoras de la calidad

La imposibilidad de abastecer a la población con agua salubre y limpia tiene consecuencias graves tanto para el abastecedor como para el consumidor de agua potable. En la práctica, una pequeña mejora de la calidad del agua sin tratar no reducirá necesariamente el nivel del tratamiento. Una vez que se haya instalado el tratamiento de purificación, es probable que sea necesaria una mejora sostenida de la calidad para infundir al abastecedor -y al consumidor- confianza suficiente de que dicho tratamiento ya no es necesario y puede abandonarse.

La DMA observa en su artículo 11.3.d) que las medidas básicas de un programa de medidas para una demarcación hidrográfica deben incluir:

"las medidas para cumplir lo dispuesto en el artículo 7, incluyendo las destinadas a preservar la calidad del agua con el fin de reducir el nivel del tratamiento de purificación necesario para la producción de agua potable"

A pesar de que esto indica claramente una aspiración a reducir el nivel del tratamiento, no supone en sí mismo la obligación absoluta a hacerlo.

El término "con objeto de evitar" del artículo 7.3 de la DMA indica que los Estados miembros deben intentar por todos los medios garantizar la protección necesaria de las aguas subterráneas. Sin embargo, es posible que a pesar de que lo intenten por todos los medios, no puedan evitar un deterioro de la calidad del agua debido a las influencias antropogénicas. Este caso puede darse cuando exista un desfase temporal entre la fuente de contaminación y cualquier impacto en un receptor, como consecuencia de la lentitud del flujo en el subsuelo. Es posible que la fuente de contaminación date de una fecha anterior a la DMA u otra legislación que exija su control, y que esta fuente no haya sido eliminada, sino que aún exista contaminación residual en las aguas subterráneas. Es posible asimismo que la tarea de eliminar la contaminación en las aguas subterráneas sea técnicamente inviable o que su coste sea desproporcionadamente oneroso.

En tales circunstancias no sería razonable esperar que los Estados miembros adoptaran nuevas medidas para proteger la captación de agua potable, una vez que todas las medidas viables ya han sido adoptadas. Aún podrá ser necesaria la instauración de tratamiento o de un nivel adicional del tratamiento para garantizar el abastecimiento continuado de agua potable y para cumplir los requisitos de la DAP.

Cualquier otra opción – el cierre de la captación de agua potable – debería considerarse en sí misma como indicio del posible incumplimiento de los objetivos del artículo 7.3, pero únicamente cuando exista un deterioro de la calidad debido a los efectos antropogénicos. En muchos casos, el cierre de un punto de abastecimiento de agua potable puede no ser viable si no existe un abastecimiento alternativo; puede que el tratamiento de purificación resulte inevitable.

Protección necesaria

Es posible que no sea necesario aplicar por igual las medidas de protección a toda la masa de agua subterránea para cumplir los requisitos del artículo 7.3. La DMA prevé la utilización de perímetros de protección dentro de los cuales podrán centrarse las medidas adoptadas con este fin (apartado 3.8).

Los Estados miembros disponen de amplia libertad para designar y hacer operativos los perímetros de protección, pero, en principio, estas zonas deberán basarse en los riesgos, de manera que cualquier medida necesaria sea lo más eficaz posible para reducir el impacto de la actividad humana sobre la calidad de las aguas subterráneas que se extraen. La cartografía de vulnerabilidad y/o los métodos para calcular el tiempo de tránsito ya son utilizados en numerosos Estados miembros para designar las zonas con diferentes niveles de riesgo, en las que pueden centrarse medidas específicas de protección.

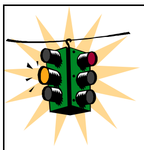
Observación: *existen propuestas, que están siendo objeto de debate, sobre la introducción de Planes de seguridad del agua en el marco de la DAP que incluyan procedimientos integrados que garanticen su calidad desde el punto de extracción hasta que llega al consumidor. En cuanto a su efecto, las propuestas son similares a los requisitos del artículo 7 de la DMA, aunque deben aclararse los vínculos que existan entre ambos*.

	***¡Atención!*** **Existe una relación potencial entre la identificación de una ZPAP y, en particular, la designación de perímetros de protección y las medidas de protección necesarias, por un lado, y los Planes de seguridad del agua propuestos en el marco de la Directiva sobre Agua Potable, por otro.**

Puntos de cumplimiento

Es necesario designar un punto de cumplimiento para valorar si se ha previsto la protección necesaria. Si este punto estuviera en el punto de utilización del usuario (el grifo), sería posible mezclar múltiples fuentes de agua de una extensa zona antes del suministro, ocultando así cualquier deterioro de la calidad de las aguas subterráneas y cualquier medida de protección inadecuada.

Sería asimismo poco práctico vigilar y evaluar el cumplimiento en todos los puntos dentro de la masa de agua subterránea. Puesto que el objetivo es evaluar el deterioro de la calidad del agua extraída, el punto de cumplimiento debe situarse en las inmediaciones del lugar de captación de las aguas subterráneas y antes de ser sometidas a cualquier tratamiento de purificación. Puede ser aceptable o inevitable una cierta cantidad de mezcla para compensar la calidad del agua sin tratar en un campo de pozos, debido a la naturaleza de la infraestructura utilizada para la extracción. Sin embargo, la mezcla de agua procedente de diferentes campos de pozos o lugares de producción podría ocultar alteraciones significativas y sostenidas de la calidad de las aguas subterráneas.



***¡Atención!* Los Estados miembros deben velar por que la vigilancia de la calidad del agua sin tratar sea representativa y suficiente para garantizar que se detectan las alteraciones significativas y sostenidas de la calidad de las aguas subterráneas causadas por las influencias antropogénicas, y que se toman las medidas oportunas al respecto. Los puntos de cumplimiento deben fijarse en los lugares adecuados para poder detectar dichas alteraciones.**

Aplicación a futuras captaciones

Cuando no se estén utilizando las aguas subterráneas para la captación de agua potable pero esté prevista su utilización en un futuro, resulta poco práctico evaluar si es necesario un tratamiento de purificación y cuál debe ser su nivel antes de efectuar las pruebas oportunas en el lugar de captación propuesto. Por consiguiente, se aconseja que se determine una base de referencia y el nivel del tratamiento necesario para corregir las influencias antropogénicas en el momento de instalar el abastecimiento previsto para la producción de agua potable y que se efectúen pruebas iniciales en ese momento. El cumplimiento con el objetivo reseñado en el artículo 7.3 debe evaluarse con respecto a esta base de referencia.

Interpretación resumida de los requisitos del artículo 7.3

Mediante la adopción de medidas de protección de las aguas subterráneas que sean técnicamente viables y proporcionadas, los Estados miembros velarán para que la calidad de las aguas subterráneas no experimente ningún deterioro en el punto de extracción para la producción de agua potable, para que no sea necesario incrementar el nivel del tratamiento de purificación.

Debe evaluarse el riesgo de deterioro para todos los parámetros individuales. Si se ha instalado tratamiento para un parámetro, no debe permitirse el deterioro de otros parámetros que también puedan controlarse con dicho tratamiento hasta el punto de que necesiten también tratamiento.

Puede existir un tratamiento de purificación instalado para corregir la mala calidad natural del agua y las alteraciones de su calidad causadas por la actividad humana. Los Estados miembros deben velar por la protección de las aguas subterráneas al objeto de infundir confianza suficiente a los suministradores (y consumidores) de agua potable en lo que respecta a que el nivel del tratamiento de purificación necesario para corregir las alteraciones antropogénicas de la calidad de las aguas subterráneas podrá reducirse con el tiempo y, en el mejor de los casos, eliminarse por completo. Esto puede conseguirse con medidas de protección de las aguas subterráneas (medidas que podrán aplicarse utilizando perímetros de protección) y con un seguimiento de la calidad de las aguas subterráneas sin tratar que demuestre las mejoras significativas y sostenidas (tendencias).

3.5 Calendario para el cumplimiento

Como ya se ha mencionado, las ZPAP deberán haber sido identificadas e incluidas en un registro a más tardar el 22 de diciembre de 2004.

La DMA no fija en su artículo 7.3 ningún calendario explícito que indique el momento en que debe iniciarse una evaluación de cualquier deterioro de la calidad de las aguas subterráneas y para cuándo deberán estar implantadas las medidas de protección necesarias.

Cuando se disponga de datos suficientes sobre el seguimiento actual de la calidad de las aguas subterráneas, para definir un nivel de calidad que sirva de base de referencia para la evaluación del deterioro, se recomienda que el punto de partida se base en dichos datos, al objeto de prevenir un mayor deterioro de la calidad del que fija la base de referencia. No obstante, cuando los datos existentes no sean suficientes, la evaluación podrá esperar hasta que se disponga de datos suficientes obtenidos de los programas de seguimiento que establece la DMA.

En la práctica, la recogida de datos suficientes para disponer de una imagen coherente de la calidad natural del agua en una masa de agua subterránea y de las tendencias de su calidad en los puntos de extracción de agua para el consumo humano podrá llevar algún tiempo. Para poder determinar de una manera fiable un deterioro de la calidad del agua sin tratar con respecto a los valores establecidos en un inicio (de hecho, se tratará de una tendencia adversa significativa y sostenida) pueden ser necesarios varios años.

Lo expuesto anteriormente no implica que la protección necesaria de las ZPAP y los perímetros de protección no deban implantarse en una fase anterior. En la mayoría de los casos, las medidas de protección adoptarán la forma de medidas para prevenir o limitar las entradas de contaminantes en aguas subterráneas. Son de aplicación la actual Directiva sobre Aguas Subterráneas (80/68/CEE), al igual que la nueva Directiva sobre Aguas Subterráneas (2006/118/CE) y otros actos de la legislación comunitaria que contribuyen a la protección de estas aguas. Los Estados miembros deben haber implantado programas sustanciales para la protección de las aguas subterráneas ya operativos, al objeto de cumplir estos requisitos; dichos programas deben mantenerse y ampliarse para cumplir los requisitos recogidos en la DMA y la DAS. De conformidad con los artículos 11 y 13 de la DMA, cualquier medida complementaria necesaria deberá establecerse y ser incorporada en los planes de demarcación hidrográfica a más tardar en diciembre de 2008 y ser aplicada en su totalidad a más tardar en diciembre de 2012.

	***¡Atención!*** **Deben mantenerse los programas existentes de protección de las aguas subterráneas para prevenir el deterioro de su calidad, al tiempo que se recogen datos de seguimiento suficientes y se realizan evaluaciones de la calidad de referencia y de las tendencias.**

3.6 Seguimiento y evaluación

Es fundamental que el seguimiento de las ZPAP esté integrado en los programas operativos y de vigilancia de las aguas subterráneas que son necesarios con arreglo a lo establecido en el anexo V de la DMA. Los pormenores de los requisitos de seguimiento de las ZPAP se indican en la guía sobre el seguimiento de las aguas subterráneas[2]. No obstante, a continuación se indican algunos de los temas más importantes.

La DMA establece en su **artículo 7.1** que:

"Los Estados miembros efectuarán un seguimiento, de conformidad con el anexo V, de las masas de agua que proporcionen, de acuerdo con dicho anexo, un promedio de más de 100 m^3 diarios."

El valor umbral de 100 m^3 diarios debe interpretarse como la suma de todas las extracciones destinadas al consumo humano en la extensión total de la masa de agua subterránea.

De acuerdo con el **artículo 7.2,** deberán cumplirse los objetivos de la DAP para el agua obtenida que se destine al consumo humano. Para ello puede ser necesario tener en cuenta la serie de parámetros que son evaluados con arreglo a esta Directiva a fin de valorar si en dichos parámetros existe algún riesgo de deterioro.

Utilizando las referencias a "contaminantes" y "contaminación" y sus respectivas definiciones, la mayoría de los objetivos de la DMA son aplicables únicamente a sustancias, lo que excluye los parámetros biológicos. No obstante, el **artículo 7.3** no hace referencia a los contaminantes, sino que se refiere en cambio a la "calidad". (*Observación: ésta es la razón por la que en el texto se utiliza en inglés el término "contaminants" (contaminantes) en lugar de "pollutants" (agentes contaminantes), ya que incluye parámetros microbiológicos, así como sustancias químicas y radiactivas).*

Los Estados miembros deberán evaluar la necesidad de hacer un seguimiento de los parámetros adicionales en el agua sin tratar a los que se refiere la DAP, que tenga en cuenta cualquier posible riesgo de deterioro en dichos parámetros.

La presencia de nuevos contaminantes para los que no exista una norma oficial aplicable al agua potable, pero que pueden repercutir en la utilización de aguas subterráneas para consumo humano, puede exigir un seguimiento y una evaluación complementarios, una vez que el riesgo haya sido identificado.

Cuando exista un riesgo procedente de fuentes de contaminación antropogénicas, los parámetros que se vigilan en el agua tratada deberían vigilarse asimismo en el punto de extracción de las aguas subterráneas sin tratar. En principio, esto podrá incluir los parámetros químicos, radiológicos y microbiológicos que son objeto de seguimiento con arreglo a la DAP.

El programa de seguimiento de las ZPAP no requiere necesariamente la misma intensidad de vigilancia que la que establece la DAP. Se recomienda que para las extracciones que estén sujetas a la DAP se haga un seguimiento de las aguas subterráneas sin tratar para todos los parámetros indicados en la DAP al menos una vez cada seis meses (el ciclo de planificación de la DMA). En el caso de parámetros en los que exista un posible riesgo de deterioro, el seguimiento debe hacerse con mayor frecuencia y de conformidad con las recomendaciones expuestas en la guía sobre el seguimiento de las aguas subterráneas[2]. A tal efecto podrán agruparse las extracciones, siempre que el seguimiento siga siendo representativo.

A la hora de determinar el alcance y la frecuencia de cualquier seguimiento necesario se tendrán en cuenta los probables riesgos de contaminación, cualquier impacto real en las aguas subterráneas y de superficie que tenga su origen en la actividad humana y las características hidrogeológicas de la masa de agua subterránea[2]. Por ejemplo, para un conjunto de captaciones podría ser adecuado hacer un seguimiento en una que sea representativa del conjunto además del seguimiento en aquellas donde el riesgo sea mayor.

3.7 Evaluación del nivel del tratamiento de purificación necesario

El tratamiento de purificación para cumplir los requisitos que establece la DAP o cualquier otro requisito para el agua destinada al consumo humano podrá instalarse en una captación de agua potable para corregir el deterioro por sustancias de origen natural así como por impactos antropogénicos.

En la práctica puede resultar difícil atribuir a un contaminante concreto los niveles actuales de tratamiento y poder evaluar en qué medida el aumento del grado del tratamiento obedece únicamente al componente antropogénico de dicho contaminante. Esto es especialmente aplicable a las sustancias frecuentes en el medio natural -p.ej. cloro, sulfato o arsénico-. También es complejo evaluar los sistemas de tratamiento.

Dado lo expuesto más arriba y teniendo en cuenta que el artículo 7.3 hace hincapié en evitar el deterioro de la calidad de las aguas subterráneas, es aconsejable que los Estados miembros centren sus esfuerzos en averiguar si se han producido cambios significativos y sostenidos en la calidad de las aguas subterráneas sin tratar en la captación, tal como determinan los programas de seguimiento. Si no se han producido dichos cambios, es razonable asumir que no habrá que modificar el grado de tratamiento necesario.

Si existen tendencias significativas y sostenidas [al aumento de la contaminación] y el sistema de tratamiento ya está instalado, lo más probable en la mayoría de los casos es que cualquier deterioro adicional repercuta con el tiempo en el grado del tratamiento (véase más abajo). Debe evaluarse el posible deterioro en un futuro y sus repercusiones en el tratamiento cuando aún no se sobrepasen las normas sobre el agua potable y aún no se haya instalado el sistema de tratamiento.

Observación: en este contexto, un cambio significativo en la calidad de las aguas subterráneas sin tratar supondría un cambio en un parámetro individual, cuya consecuencia sería, en la actualidad o en un futuro previsible (p.ej. en uno o dos ciclos de planificación con arreglo a la DMA), la necesidad de tratamiento de purificación para alcanzar las condiciones propias del agua potable.

El impacto del grado de tratamiento en la captación sólo deberá evaluarse cuando existan pruebas de cambios significativos en la calidad del agua sin tratar que puedan ser atribuidos al impacto antropogénico. De este modo se reducirá al mínimo la recogida y evaluación de datos adicionales.

Para evaluar los cambios en el "grado" de tratamiento será necesario conocer el proceso de tratamiento (incluyendo en su caso para qué parámetros se instaló el sistema de tratamiento, su alcance y la utilización de materiales consumibles, como sustancias químicas).

Resulta difícil ofrecer orientación sólida sobre la cuestión de qué constituye un cambio en el grado de tratamiento, pero se insta a los Estados miembros a que, de una manera individualizada, tengan en cuenta los siguientes factores:

- Durante cuanto tiempo será necesario en su caso incrementar el tratamiento - ¿se trata de un incremento temporal o a largo plazo?
- ¿Cuál es la tendencia general en lo que respecta a la utilización del tratamiento *in situ*?
- ¿Se requieren nuevas instalaciones?
- ¿Los cambios en las instalaciones o en las sustancias químicas pretenden incrementar el tratamiento o sencillamente hacerlo más eficaz? Los cambios en el proceso de tratamiento pueden ser un reflejo de los avances tecnológicos y no un incremento del grado del tratamiento como tal.

- En caso de mezcla del agua de diferentes fuentes, ¿cuál es su finalidad? ¿Es un indicador de que se ha producido un cambio significativo y sostenido en la calidad del agua sin tratar dentro de la ZPAP?

Debe recopilarse información sobre la modificación, el cierre y el abandono de captaciones existentes de agua potable como consecuencia de la contaminación antropogénica, con el fin de poder utilizar dicha información para reforzar el sistema de seguimiento; por mucho empeño que se ponga en ello, puede que no siempre se consiga detectar los incidentes de contaminación. Estos datos podrán utilizarse asimismo para evaluar si las medidas de protección necesarias están siendo eficaces.

Cabe observar que los cambios en la calidad de las aguas subterráneas pueden ser inducidos no sólo directamente como resultado de las entradas de contaminantes, sino también por los efectos de las extracciones. Estos efectos también deberán tenerse en cuenta.

3.8 Perímetros de protección

Como se ha dicho antes, el artículo 7.3 indica que los Estados miembros podrán establecer perímetros de protección que contribuyan a cumplir el requisito de garantizar la protección necesaria de las ZPAP. El establecimiento de dichos perímetros dependerá, por consiguiente, de la facultad discrecional de los Estados miembros.

Los perímetros de protección pueden utilizarse como un medio práctico de enfocar las medidas de protección en los puntos de captación de agua para el consumo humano. Dados el tamaño y el alcance de la mayoría de las masas de agua subterránea, se recomienda esta opción para que, en su caso, las medidas de protección específicas puedan dirigirse de modo que tengan el mayor efecto posible – en este caso, proteger las zonas de recarga de las aguas subterráneas (zonas de captación) en los puntos (fuentes) en los que se extraen aguas subterráneas para el consumo humano.

De esto se deduce que la extensión de los perímetros de protección puede ser en muchos casos mucho más pequeña que las masas de agua subterránea y que dentro de una masa de agua subterránea pueden existir varias zonas de este tipo. Sin embargo, en determinadas circunstancias como en los acuíferos kársticos, los perímetros de protección pueden ser bastante más extensos, como reflejo de la velocidad del flujo y la vulnerabilidad extrema de las aguas subterráneas. Incluso puede ser necesario ampliar los perímetros de protección hasta más allá de los límites de la masa de agua subterránea para que incluyan también las masas de agua superficial asociadas “aguas arriba”, que consideren las zonas de captación para la producción de agua potable. Por último, los Estados miembros podrán decidir establecer perímetros de protección que cubran todo el territorio nacional para proteger el suministro de agua potable (considerando 15 de la Directiva 2006/118/CE).

La extensión del perímetro de protección podrá variar, por consiguiente, en función de:

- las propiedades hidrogeológicas del acuífero. Por ejemplo, en un acuífero muy poroso, la zona de captación para la producción de agua puede ser relativamente pequeña, mientras que en un acuífero de baja porosidad, la zona de captación puede ser muy extensa;
- el volumen de la extracción para consumo humano;
- el tipo de contaminante y las fuentes de contaminación que requieran medidas de protección. En principio, podrían ser necesarios perímetros de protección de mayor extensión para contaminantes persistentes que tengan su origen en fuentes difusas extensas, en contraposición con los contaminantes ya atenuados procedentes de pequeñas fuentes puntuales;

- si se tomó como base del perímetro de protección el tiempo de tránsito hasta el punto de extracción, o la extensión de la zona de "captura". En principio, las zonas de "captura" son más adecuadas para enfocar las medidas destinadas a corregir los contaminantes persistentes, mientras que el tiempo de tránsito es más adecuado para contaminantes ya atenuados;
- la vulnerabilidad de los acuíferos. Por ejemplo cuando existe una zona superior de terreno de baja permeabilidad, cerca del punto de extracción, la zona de "captura" puede ser extensa y las zonas de mayor riesgo pueden encontrarse a cierta distancia del punto de extracción, donde la vulnerabilidad a la contaminación procedente de la superficie es mayor.

Muchos Estados miembros ya utilizan zonas de protección para las aguas subterráneas con distintos fines, partiendo de los principios expuestos más arriba. En el anexo 1 se exponen estudios de casos que ilustran su designación y utilización. La mayoría de los planes se centran en las captaciones de agua potable y, en particular, en aquéllas desde las que se suministra agua a los consumidores con arreglo a la DAP. Estos planes podrían adaptarse fácilmente para fines de designación de los perímetros de protección a efectos del artículo 7.3 de la DMA. Las zonas kársticas o aquéllas en las que existan grandes fisuras podrán necesitar consideraciones adicionales y métodos especiales a la hora de decidir sobre la designación de los perímetros de protección.

En particular, cuando el volumen extraído es muy pequeño (por ejemplo, para abastecer a viviendas aisladas o propiedades individuales), puede resultar difícil mantener en un lugar concreto un registro de todos los abastecimientos de este tipo, y tal vez no resulte práctico establecer medidas de protección específicas para la captación. Asimismo, puede resultar innecesario establecer medidas de protección de las aguas subterráneas aplicables a toda la extensión de la masa. Por ejemplo, la imposición de medidas de cautela a toda la masa de agua subterránea para un contaminante ya atenuado, podría impedir el desarrollo de muchas actividades humanas corrientes, lo que puede resultar innecesario para mantener la calidad del agua extraída para consumo humano.

Cuando se trata de designar los perímetros de protección, se sugiere a los Estados miembros un enfoque basado en el riesgo, para garantizar una protección de las captaciones para el consumo humano que sea lo más rentable posible, y recalcar a las partes interesadas que la protección de las aguas subterráneas tiene especial importancia en dichas zonas de producción de agua potable. En el cuadro 1 se ofrece un ejemplo de un plan de este tipo. El objetivo es relacionar la designación del perímetro de protección, tanto con la presencia de captación de agua destinada al consumo humano como con su tipo y el riesgo que la actividad humana puede suponer para la captación de agua en cuestión.

Cuadro 1: Ejemplo de un plan para designar perímetros de protección de captaciones individuales o grupos de captaciones a efectos del artículo 7.3 de la DMA

	Presiones antropogénicas	Seguimiento	Zonas y mediciones
Tipo 1 **Riesgo bajo** **Protección general**	Insignificantes, Por ej. designadas como no en riesgo durante la caracterización, baja densidad de población y de actividad humana en general.	Ningún seguimiento estratégico adicional. (Únicamente seguimiento operativo y control de vigilancia con arreglo a la DMA).	Zonas arbitrarias mínimas, por ej. medidas cautelares como códigos de buena práctica aplicados en un radio de 50 m en torno al punto de captación.
Tipo 2 **Riesgo moderado** **Protección cautelar**	Moderadas Por ej. la caracterización con arreglo a la DMA ha identificado riesgos, pero ninguna prueba de deterioro de la calidad de las aguas subterráneas.	Seguimiento de las fuentes de captación y posible seguimiento cautelar adicional dirigido a los riesgos identificados.	Considerar la posibilidad de establecer zonas en función del tiempo de tránsito y/o de las zonas de captura. Medidas cautelares adecuadas dirigidas a los riesgos identificados.
Tipo 3 **Riesgo alto** **Protección específica**	Altas Por ej. pruebas del deterioro de la calidad del agua.	Seguimiento específico en el perímetro de protección tanto de la captación como de las aguas subterráneas dentro de la zona. El seguimiento deberá diseñarse de modo que permita determinar la eficacia de las medidas.	Se recomienda calcular el tiempo de tránsito específico al lugar y/o zonas de captura. Medidas dentro de estas zonas específicas para atacar las fuentes de contaminación.

***Observación*: en todos los casos deberán tenerse en cuenta el volumen de captación y los riesgos dentro de la zona de captura/ tiempo de tránsito hasta la captación. Además, debe considerarse la vulnerabilidad del acuífero dentro de la zona.**

Anexo 1: Casos prácticos

ITALIA (Región de Emilia Romagna)

Identificación de zonas protegidas de aguas subterráneas y aplicación de medidas

Tipo de estudio: Cumplimiento de la normativa vigente en Italia

Enlaces de Internet:
http://www.camera.it/parlam/leggi/deleghe/testi/99152dl.htm
http://www.sogesid.it/allegati/accordo_conferenza_permanente_12_12_2002.pdf

Objetivo: protección y mejora de la calidad del agua potable

Referencia de la DMA: Protección de las aguas subterráneas para consumo humano.

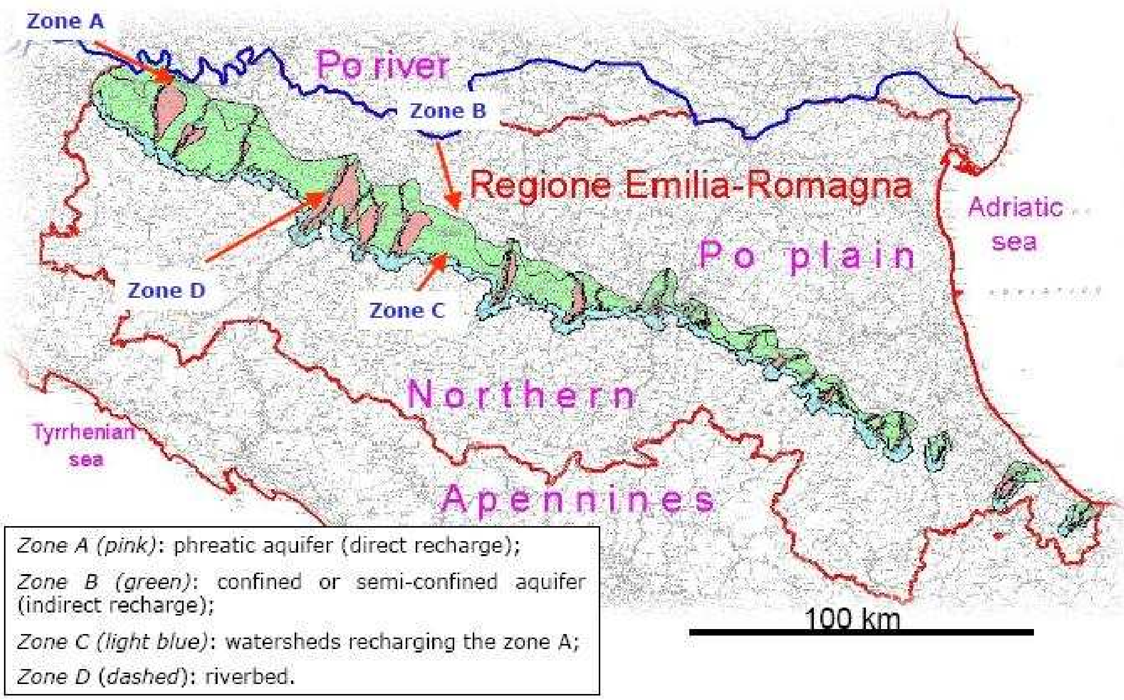
Contribuciones específicas: Definición de los perímetros de protección y de las zonas protegidas

Caracterización

La legislación italiana (D. Lgs. 152/99, art.21, apartado 1) establece que, para proteger y mejorar la calidad de los recursos de aguas subterráneas destinados al consumo humano, las Regiones (unidades administrativas italianas) especificarán perímetros de protección dentro de los cuales podrán aplicarse medidas y restricciones con objeto de garantizar la protección de las aguas subterráneas.

Los perímetros de protección se dividen en: 1. **"zona de protección absoluta"** (un área de 10 m de radio como mínimo en el entorno inmediato del punto de extracción); 2. **"zona respetada"** (el territorio que rodea la zona de protección absoluta, especificado por un tiempo de recorrido de entre 180 y 365 días, dependiendo de la vulnerabilidad y de las condiciones de peligro, o como mínimo de un radio de 200 m desde el punto de extracción); y 3. **"zonas de protección",** especificadas dentro de las zonas de recarga de las aguas subterráneas. La designación de zona de protección se basa en análisis hidrogeológicos, hidroquímicos e hidrológicos. También se tiene en cuenta la vulnerabilidad de la zona a la contaminación. Las zonas de protección se corresponden específicamente con toda la zona de recarga.

Las "zonas de protección absoluta" y las "zonas respetadas" ya están designadas en la mayoría de los casos, mientras que las Regiones establecen las zonas protegidas. En algunos casos, las zonas protegidas ya han sido designadas y son objeto de medidas de protección en vigor. La Región de Emilia Romagna ha designado las principales zonas protegidas de aguas subterráneas, que suponen más de 2.850 km^2 de los 22.000 km^2 (13%) que conforman el territorio de esta unidad administrativa, y está dividida en 4 subzonas que presentan características diferentes (Fig.1).



Zona A (de color rosa): acuífero freático (recarga directa);
Zona B (de color verde): acuífero confinado o semiconfinado (recarga indirecta);
Zona C (de color celeste): márgenes del río que recargan la zona A;
Zona D (rayada): lecho del río.
Figura 1: Zonas protegidas para la producción de agua potable en Emilia Romagna.

La llanura aluvial del río Po se extiende en la parte septentrional de la Región Emilia Romagna sobre más de 12.000 km². En esta llanura se han designado tres masas de agua subterránea diferentes, entre las que los “conos de deyección de los ríos de los Apeninos” podrían considerarse como las masas de agua subterránea prioritarias en lo que respecta a sus características químicas y cuantitativas. Las zonas de recarga están situadas a lo largo del margen meridional, donde los acuíferos son libres; hacia el norte, se convierten en acuíferos multicapa y confinados (Fig.2).

Las zonas protegidas para la producción de agua potable han sido especificadas en las zonas de recarga, como muestran la Fig.1 y el corte transversal esquemático de la Fig. 2. Las zonas de protección se extienden hasta más allá de los límites de la masa de agua subterránea e incluyen, aguas arriba, las cuencas impermeables de los conos que indirectamente pueden contribuir a la recarga de los acuíferos (zona C en la Fig.1).

Medidas de protección aplicadas

Las medidas de protección, organizadas en un Plan Regional, varían en función de las características de cada zona dentro de las áreas protegidas (A, B, C, D en la Fig.1). Dichas medidas van dirigidas a las actividades agrícolas y ganaderas (aplicación de estiércol y utilización de fertilizantes y pesticidas), explotación de canteras, urbanización (alcantarillados, impermeabilización), actividades industriales (también en relación con aspectos cuantitativos) y ubicación de vertederos. Las actividades peligrosas que guarden alguna relación con la calidad del agua deben ser autorizadas específicamente. Las medidas y normas han sido objeto de debate y de modificaciones a través de procesos participativos en los que han intervenido las partes interesadas públicas y privadas (compañías de abastecimiento de agua, asociaciones agrícolas, representantes de los sectores industriales y organizaciones de defensa del medio ambiente, entre otros).

Se han seleccionado indicadores de contaminación (p.ej. NO_3) y se han emprendido actividades de seguimiento en las zonas protegidas para comprobar la eficacia de las medidas adoptadas. Se ha previsto la posibilidad de introducir medidas correctoras durante la ejecución del Plan. Los órganos de administración están designando nuevas zonas protegidas para la producción de agua potable en la Región para las masas de agua subterránea de menor importancia.
Resultados obtenidos – Conclusiones – Recomendaciones La participación activa de las partes interesadas en la definición de las medidas y restricciones que deben adoptarse ha sido un componte esencial en la aplicación de zonas protegidas y ha propiciado una aceptación generalizada del Plan.
Accesibilidad a los resultados http://www.regione.emilia-romagna.it/geologia/ (en italiano e inglés) http://www.ermesambiente.it/PianoTutelaAcque/ (en italiano) **Siguientes pasos:** Otras Regiones de Italia están aplicando actualmente la normativa nacional y están designando zonas para la protección de las aguas subterráneas para el consumo humano. Las medidas que deberán aplicarse y los procedimientos de designación son competencias que han sido transferidas a las Regiones, mientras que los criterios generales y los objetivos son aquellos que establece la legislación nacional.

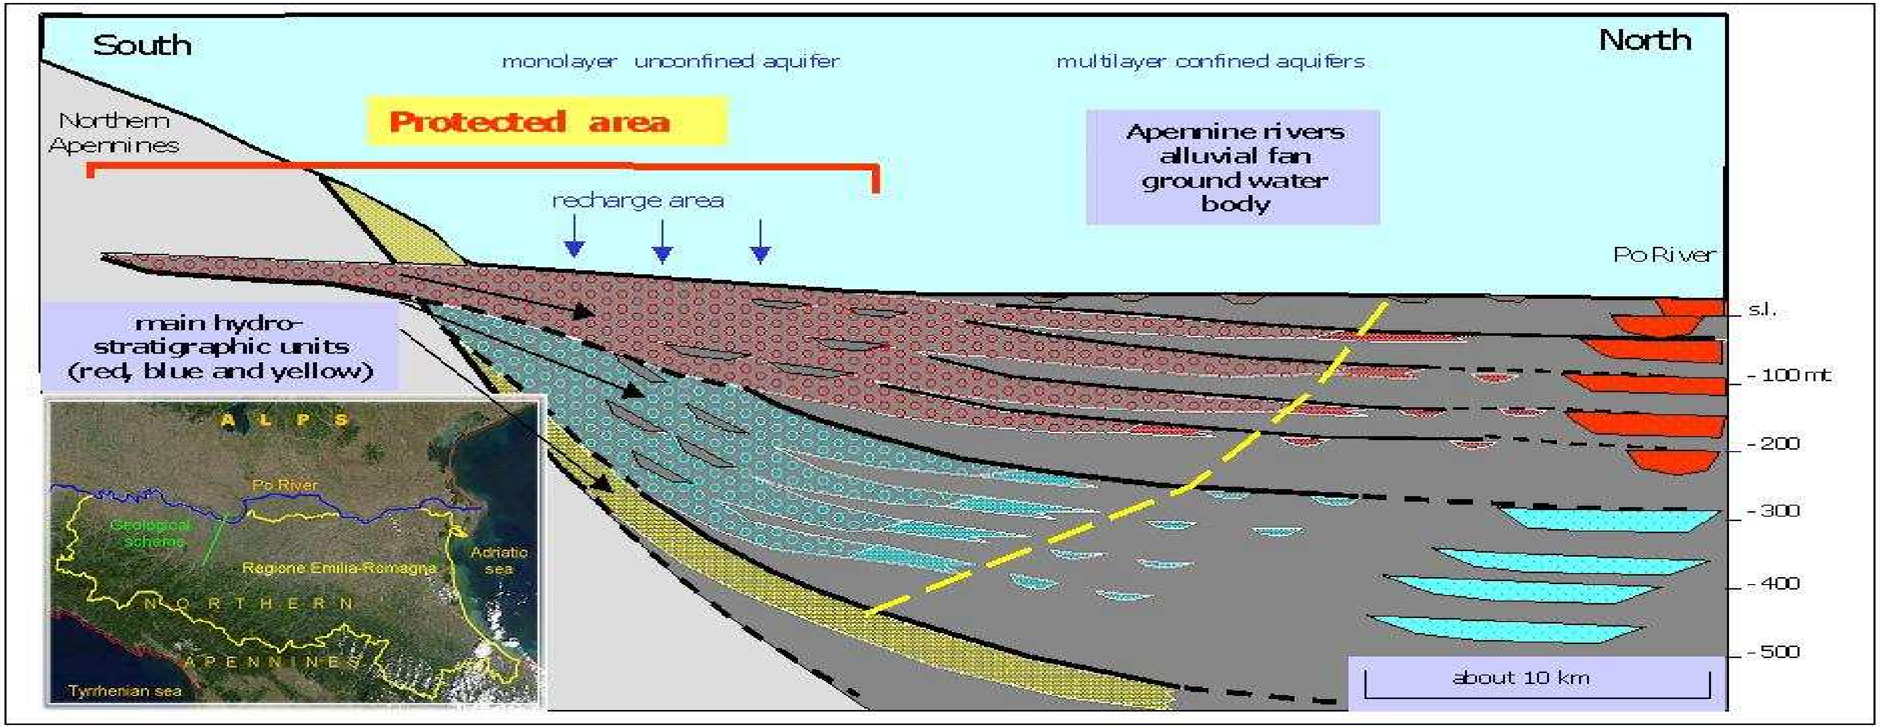


Figura 2: Mapa de ubicación y corte transversal esquemático de los acuíferos, en el que se indican las zonas protegidas para la masa de agua subterránea del "cono de deyección de los ríos de los Apeninos".

PORTUGAL Zonas de protección de las fuentes y medidas en torno al suministro público de agua en Golegã

Tipo de estudio: Especificación de las zonas de protección de aguas subterráneas y cumplimiento de las medidas.

Enlace de Internet: http://snirh.inag.pt/snirh.php?main_id=1&item=3.4&objlink=&objrede=

Objetivo: – indicar cómo se cumple la legislación portuguesa en materia de protección de la calidad del agua potable y la gestión del abastecimiento de aguas subterráneas en dos pozos situados en Golegã

Referencia de la DMA : Protección de las aguas subterráneas destinadas al consumo humano, seguimiento de las aguas subterráneas

Contribuciones específicas: garantía de la calidad de las aguas subterráneas, zonas de protección

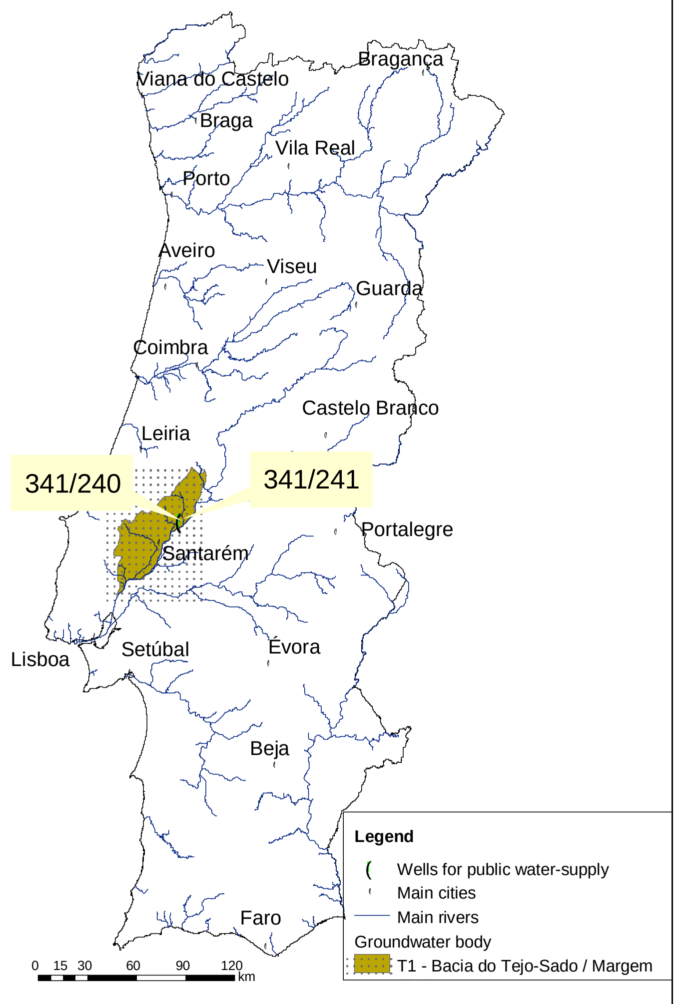
Caracterización

En el sistema de acuíferos porosos denominado “Bacia do Tejo-Sado / Margem Direita” existen dos pozos, identificados con el código nacional 341/240 (JK1) y 341/241 (JK2). Este es un sistema de acuíferos confinado y lo conforman arenisca alternada con arcilla. Los pozos JK1 y JK2 tienen una profundidad de 226,5 m y de 230,5 m respectivamente.

El flujo local de las aguas subterráneas discurre en dirección NNO hacia SSE. Esto significa que, **para tener en cuenta una posible expansión del cono**, las zonas de protección intermedias y exteriores deben tener una forma elíptica, desarrollada a lo largo de la dirección opuesta a la del flujo de las aguas subterráneas. La zona interior tiene forma poligonal.

En este caso se utilizó un método sencillo (Jacobs & Bear) para definir las zonas de protección de fuentes, principalmente la zona intermedia y la exterior. Deben conocerse la **transmisividad** (T), el caudal de bombeo (Q), el tiempo de residencia (t) (t=50 días en la zona intermedia y t=3500 días en la zona exterior), el espesor saturado (b), la porosidad efectiva (m_e) y el **gradiente hidráulico** (i). El tiempo de recorrido (t_R) se calcula mediante la fórmula:

$$t_R = \frac{2T^2 i^2}{m_e Q b} t$$

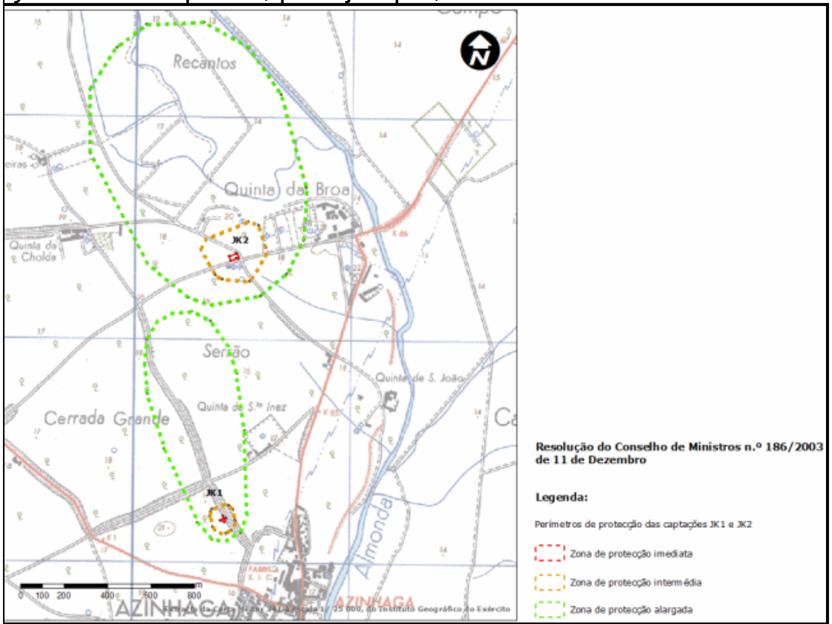


La zona interior, de forma poligonal, ya había sido definida por la autoridad competente para el suministro de aguas subterráneas. Se decidió mantenerla porque quedó demostrado que era una zona suficiente para proteger los pozos.

Las tres zonas de protección de las fuentes han sido designadas tal y como muestra el croquis *infra*: la línea roja marca la zona de protección interior; la de color naranja marca la zona intermedia y la verde, la zona exterior. La extensión para el pozo JK1 es como sigue; zona interior: 263 m^2, zona intermedia: 0,01 km^2, y zona exterior: 0,34 km^2; para el pozo JK2, zona interior: 780 m^2, zona intermedia: 0,06 km^2, y zona exterior: 0,95 km^2.

Una vez designadas las zonas, fue necesario establecer qué actividades o instalaciones debían quedar restringidas dentro de las diferentes zonas de protección para evitar la contaminación.

Para cada zona de protección, la norma portuguesa establece en su artículo 6 qué actividades o instalaciones están prohibidas o restringidas. En este sentido, en la zona interior están prohibidas todas las actividades o instalaciones, excepto aquellas destinadas a proteger el pozo. Ha sido necesario instalar un vallado. En la zona intermedia están prohibidos, por ejemplo, los desguaces, las fosas sépticas y las instalaciones aeronáuticas. La utilización de pesticidas persistentes y móviles, las carreteras, los ferrocarriles, las depuradoras, los cementerios solamente podrán darse dentro de esta zona de protección cuando se demuestre que no suponen ningún peligro de contaminación de las aguas subterráneas. En la zona exterior están prohibidos los vertederos, las fosas sépticas y las industrias químicas. Los lagos y los nuevos pozos, por ejemplo, han sido acondicionados.



Estos dos pozos pertenecen al Programa nacional de control de vigilancia. Cada seis meses se toman muestras de agua sin tratar. Se lleva un seguimiento de 48 parámetros diferentes.

Resultados obtenidos - Conclusiones - Recomendaciones

Las aguas subterráneas constituyen un recurso natural muy importante en Portugal porque de ellas se obtiene casi el 60% del abastecimiento de agua potable. La protección de su calidad y de su cantidad es una prioridad. Una de las estrategias utilizadas para proteger las aguas subterráneas para el suministro público de agua es la designación de zonas de protección de fuentes. Este marco es muy importante y debe integrarse en los programas de seguimiento y otras prácticas preventivas para conservar la buena calidad de las aguas subterráneas.

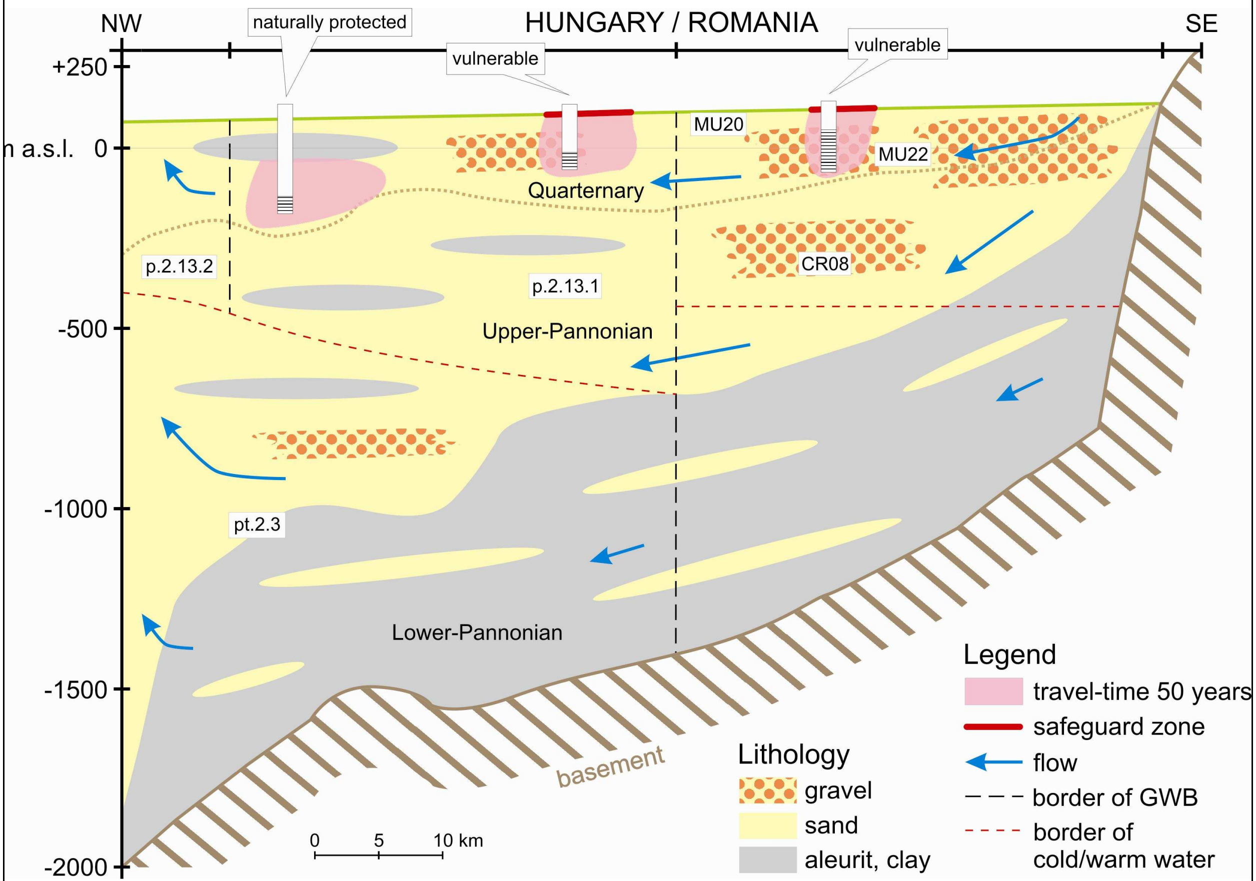
HUNGRÍA/RUMANÍA: Masas de agua subterránea transfronterizas - sistema de acuíferos multicapa del río Maros/Mureş

Información general
Título del estudio: Grupo de conos aluviales de las masas de agua subterránea transfronterizas – sistema de acuíferos porosos multicapa del río Maros/Mureş
Tipo de estudio: Ejemplo de protección de las aguas en las masas de agua subterránea transfronterizas entre Hungría y Rumanía (subregión – llanura aluvial del Maros/Mures: en parte central de la Llanura Occidental rumana y la parte sudoriental de la Gran Llanura húngara).
Enlaces de Internet: www.euvki.hu, www.inhga.ro, www.icpdr.org
Información general: El grupo de conos aluviales de las masas de agua subterránea del Mureş/Maros ha sido designado como una importante masa de agua subterránea transfronteriza en la cuenca del Danubio. Los conos aluviales del río Maros/Mures, donde los depósitos se remontan hasta el Mioceno, se extienden a ambos lados de la frontera húngaro-rumana. Es un importante recurso de agua potable para ambos países. Algunos de los abastecimientos de agua potable afrontan problemas de calidad considerables que se deben al alto contenido natural de arsénico, hierro, manganeso y amonio de estas aguas, especialmente en el lado húngaro. La masa de agua superior de Rumanía, y las aguas subterráneas poco profundas en la parte húngara son vulnerables a los contaminantes que se originan en la superficie.
Referencia de la DMA: Perímetros de protección de agua potable, zonas protegidas, masa de agua transfronteriza.
Contribuciones específicas: Designación de los perímetros de protección, protección de las fuentes de agua potable.
Caracterización: La cuenca, que comprende la parte sudoriental de la Gran Llanura húngara, se ha rellenado con más de 2000 m de sedimentos que datan de diferentes épocas. El enfoque húngaro para designar las masas de agua separa verticalmente el sistema de acuíferos multicapa con arreglo a las diferencias de temperatura (isoterma: HU 30 ºC, RO 23 30 ºC). Por consiguiente, la parte fría de las capas de la Alta Panonia y el Pleistoceno están unificadas verticalmente en Hungría, pero divididas horizontalmente por el característico flujo hacia abajo y de transición (Figura 1 - p.2.13.1) que las separa de la parte superior (p.2.13.2). En el lado rumano han sido designadas tres masas de agua, tomando como base la antigüedad de los estratos que separan el Alto Pleistoceno - Holoceno (MU20) del Bajo Pleistoceno – Pleistoceno Medio (MU22). La masa de agua subterránea MU20 alcanza una profundidad de 30 m, mientras que la MU22 se sitúa entre 30 y 150 m de profundidad, con su máximo espesor situado en la frontera. Debajo de la masa de agua subterránea MU22 existe otra masa de agua subterránea, la Arad-Oradea-Satu Mare (CR08), que data de la era Alta Panonia, contiene agua fría y se ha desarrollado a una profundidad de entre 150 y 400 m. Esta cuenca de agua subterránea es confinada, de tipo poroso permeable y la conforman arcilla y marga, con finas capas intermedias de arena, arenas arcillosas, con escasos guijarros o arenisca. Esta masa de agua ha sido explotada sobre todo en la cuenca del río Crişuri y su gestión ha sido asignada al Régimen de Aguas del Crişuri.

Las masas de agua se caracterizan desde el punto de vista litológico por guijarros, arenas y capas intermedias arcillosas, pero la parte superior y oriental es considerablemente más gruesa y su permeabilidad es mayor. La capa de cobertura está compuesta principalmente por entre 3 y 5 m de légamo arenoso y arcilla.

El acuífero superior es libre, mientras que los inferiores son confinados. El nivel freático en Hungría se sitúa a apenas 2-4 m por debajo de la superficie. La dirección principal del flujo de las aguas subterráneas va desde la zona de recarga hacia las zonas de descarga, o lo que es lo mismo, del ESE hacia el ONO. En condiciones naturales (sin extracción de aguas subterráneas), la principal zona de recarga se sitúa en Rumanía, por lo que el flujo lateral al otro lado de la frontera es un elemento importante del régimen de aguas de la parte húngara.

Figura 1: Corte transversal a través del grupo de conos aluviales del Maros/Mureş

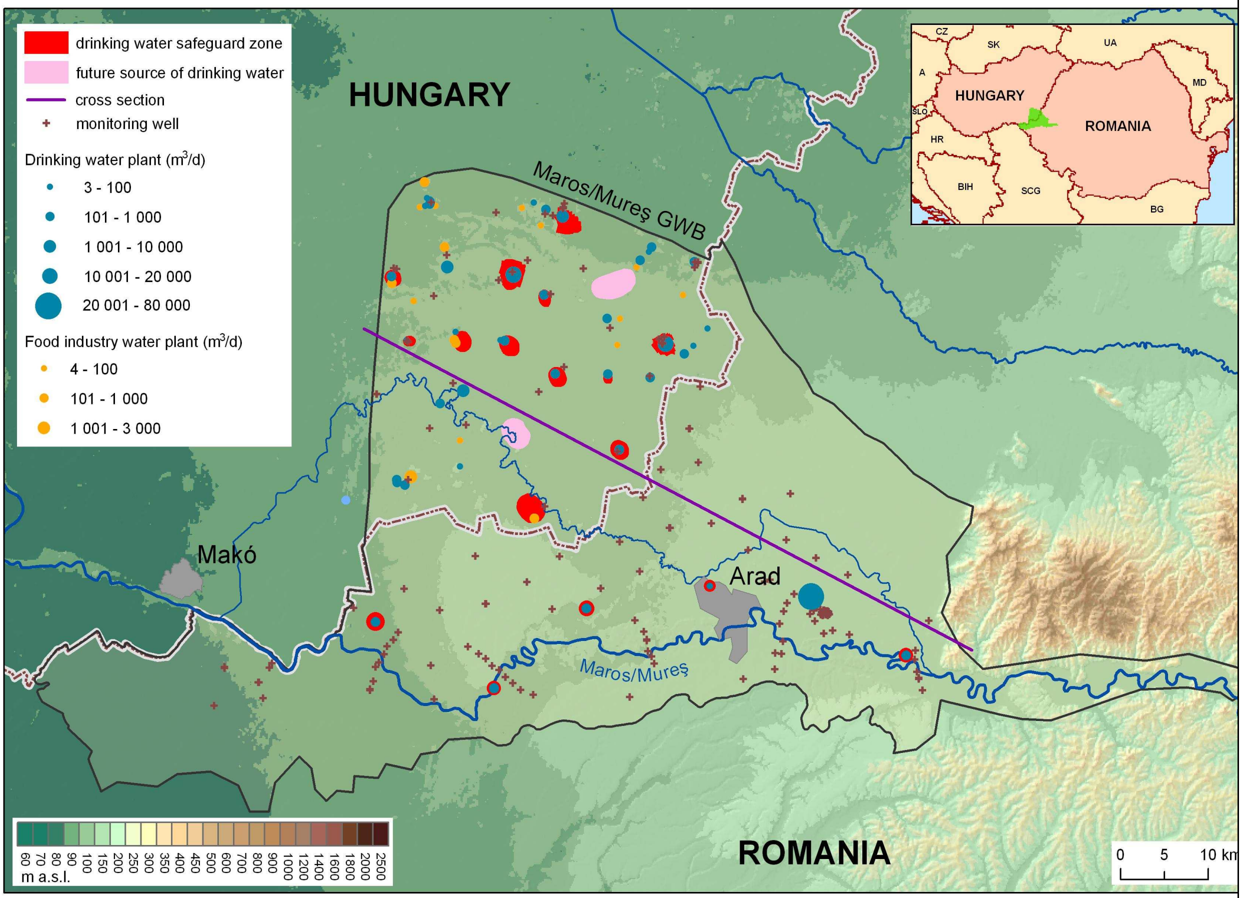


Resultados obtenidos - Conclusiones - Recomendaciones

En Hungría, el abastecimiento de agua potable depende casi por completo (96%) de los recursos de aguas superficiales. La legislación exige la protección de todas las fuentes de agua potable, con independencia de si están siendo explotadas o han sido designadas para su uso en el futuro. La metodología que se sigue para designar los perímetros de protección se basa en el Decreto Gubernamental nº 123/1997. (VII.18.). Los límites de los perímetros de protección se determinan con arreglo a las condiciones hidrológicas e hidrogeológicas, y la extensión de las zonas protegidas se basan en el factor tiempo de recorrido. Los tiempos de recorrido utilizados para las distintas zonas son como sigue: 20 días para la zona interior, medio año para la zona exterior y entre 5 y 50 años para las zonas hidrogeológicas protegidas. Estos perímetros de protección se establecen en las zonas de intersección.

La gestión del agua persigue designar perímetros de protección y evaluar un plan a la medida para restringir los usos del suelo y demás medidas necesarias para cada fuente vulnerable de agua potable. Como resultado de una investigación a escala nacional, todas las fuentes de agua potable han sido divididas entre grupos en los que existe protección natural y grupos vulnerables. Se considera que una fuente es vulnerable cuando la contaminación pueda llegar hasta ella en menos de 50 años. El modelo hidrogeológico es objeto de controles mediante el análisis químico de las aguas subterráneas, especialmente en lo que respecta a contaminantes de origen humano, p.ej. nitrato, pesticidas, hidrocarburos clorados, etc. Además se mide el contenido de tritio (3H). La detección de tritio significa que la edad del agua será de menos de 50 años, lo que significa que las aguas subterráneas son vulnerables.

En Rumanía, la designación de zonas de protección sanitaria y zonas de protección hidrogeológica se lleva a cabo de conformidad con la Decisión Gubernamental nº 930/2005. Las zonas de protección sanitaria tienen en cuenta un tiempo de recorrido de 20 días de una partícula de agua supuestamente contaminada desde el límite de la zona hasta el punto de extracción de agua, en el caso de una zona sujeta a un régimen riguroso, y un tiempo de recorrido de 50 días en el caso de una zona sujeta a un régimen de restricción. La designación de zona de protección hidrogeológica tiene en cuenta criterios geológicos y geomorfológicos.



Estos métodos cumplen los requisitos que la DMA recoge en sus artículos 6 y 7. En el caso de las fuentes vulnerables deben establecerse perímetros de protección que garanticen la protección necesaria de las fuentes de agua potable. La zona protegida de agua potable equivale a la extensión completa de todos los diferentes perímetros de protección. Las medidas no van encaminadas necesariamente a salvaguardar los recursos que ya cuentan con protección natural (acuíferos profundos), a los que no se les designa una zona protegida.

El seguimiento de la zona protegida de agua potable se efectúa en los pozos (de extracción y seguimiento).

En esta región se extraen de las aguas subterráneas unos 63 millones de m^3 de agua potable al año. La mitad de los recursos de agua potable son vulnerables. Las zonas de protección de agua potable abarcan cerca del 2% de la extensión total del cono fluvial del Maros/Mureş (4.038 km^2).

Accesibilidad a los resultados

Los organismos regionales responsables de los regímenes de aguas y el medio ambiente permiten el acceso a los resultados de las investigaciones que se llevan a cabo en cada una de las distintas instalaciones de abastecimiento de agua (solamente en húngaro). En Rumanía se puede acceder a estos datos en el Instituto Nacional de Hidrología y Gestión del Agua, así como en la Dirección General de Aguas del Mureş.

Siguientes pasos

En ambos países se está aplicando un programa nacional para la protección de fuentes de agua potable. El proceso de designación concluirá en 2009.

De conformidad con el nuevo acuerdo bilateral firmado en 2005, se elaborará un modelo hidrogeológico conjunto del cono aluvial del Maros/Mureş, para evaluar el régimen hídrico y obtener una base sólida para la gestión integral de las aguas subterráneas. Se están negociando las actividades necesarias para hacer un seguimiento bilateral.

ALEMANIA (zona de Lingen) Designación y utilización de perímetros de protección

Tipo de estudio: Redefinición de perímetros de protección en los alrededores de un campo de pozos de extracción
Objetivo: Protección y mejora de la calidad del agua potable
Referencia de la DMA: Protección de las aguas subterráneas para consumo humano.
Contribuciones específicas: Designación de perímetros de protección y zonas protegidas

Descripción

La ciudad de Lingen (57.000 habitantes) está situada a orillas del río Ems, a 30 km de la frontera neerlandesa, a una altitud de entre 20 y 65 m sobre el nivel del mar. Una parte considerable del agua potable que necesita la ciudad proviene de dos instalaciones de abastecimiento de agua. Dichas instalaciones tienen un derecho de extracción de 2,5 millones de m³ anuales. La más antigua de estas instalaciones se encuentra relativamente cerca del centro urbano y está rodeada de zonas de viviendas. A pesar de esta utilización del suelo y de la vulnerabilidad relativamente alta del acuífero, la calidad de las aguas subterráneas que se extraen es muy buena. Salvo la eliminación de hierro, no es necesario ningún otro tratamiento de purificación para garantizar la calidad del agua potable. Esto se debe principalmente a que la zona de captación goza de protección desde hace más de 30 años gracias al establecimiento de perímetros de protección del agua potable.

En 2003 se iniciaron amplias investigaciones hidrogeológicas con el fin de revisar y adaptar los perímetros de protección existentes. Las investigaciones han tenido como resultado el establecimiento y calibrado de un modelo tridimensional del flujo y del transporte transitorios de las aguas subterráneas. Utilizando el modelo como herramienta de gestión, el objetivo consistía en establecer nuevos perímetros de protección tomando como base las orientaciones DVGW W101 que utilizan las autoridades alemanas. De acuerdo con estas directrices debían establecerse tres perímetros de protección:

- Zona I: en las inmediaciones de los pozos de extracción (en un diámetro de 10 m)
- Zona II: Perímetro de protección más próximo (tiempo de recorrido de 50 días)
- Zona III: Perímetro de protección más amplio

La geología de Lingen la conforman arenas cuaternarias de 30 m de espesor, intercaladas con capas de légamo y arcilla, que crean una separación del acuífero en dos partes más o menos independientes, aunque existen orificios de comunicación (*hydraulic windows*) en varios puntos, que permiten una conexión limitada entre ambos. El acuífero inferior se utiliza como fuente para pozos de agua potable.

Al sureste de Lingen, la cuenca de captación está marcada por un saliente formado por depósitos glaciales, característico de las tierras bajas del norte de Alemania (Fig. 2). Las corrientes de aguas subterráneas desde este saliente siguen una dirección noroccidental hacia los pozos de extracción (Fig. 1). Para la cuenca de captación más amplia se estableció un modelo detallado tridimensional del flujo de elementos finitos en las aguas subterráneas.

Las mediciones de la corriente del agua superficial indican que existe un cierto grado de interacción entre las masas de agua superficial y el acuífero subyacente. Por ello el modelo incorpora asimismo las fugas desde los pequeños arroyos y ensenadas que van a parar al acuífero.

Tras haber calibrado con éxito el modelo, fue posible determinar la designación hidrogeológica de la cuenca hidrográfica a través de varias simulaciones (Fig. 3). La visualización del modelo de flujo simulado facilitó esta labor (Fig. 4).

La línea de demarcación del perímetro de protección más próximo, Zona II, se determinó utilizando el enfoque de modelo de transporte inverso (Fig. 5). Aquí se simula la migración de trazadores virtuales con respecto a la dirección del flujo durante un período de 50 días. El límite exterior, desde el que – con un 95% de probabilidades – el trazador puede llegar hasta los pozos de extracción en un intervalo de tiempo limitado, sirve como indicación para la designación del Perímetro de protección más próximo, zona II.

Medidas de protección aplicadas

Toda la zona protegida ha sido finalmente planificada tomando como base la cuenca hidrográfica y utilizando puntos de referencia, carreteras y lindes de propiedades (Fig. 6). Las restricciones de uso, definidas individualmente, en relación con, p.ej. obras de construcción, uso comercial y agrícola, están sujetas a las condiciones estipuladas localmente y están incorporadas en las directrices para la explotación de la zona protegida específica para la captación de agua.

Prólogo

Los Directores Generales del Agua de la Unión Europea (UE), los países de la Adhesión, los países candidatos y los países de la EFTA, han desarrollado conjuntamente una estrategia común para la implantación (ECI) de la Directiva 2000/60/CE, *"por la que se establece un marco comunitario de actuación en el ámbito de la política de aguas"* (Directiva Marco del Agua). Esta estrategia tiene como principal objetivo contribuir a una aplicación coherente y uniforme de la Directiva. La atención se ha centrado en las cuestiones metodológicas relacionadas con una comprensión común de las repercusiones técnicas y científicas de dicha aplicación.

En particular, uno de los objetivos de la estrategia es el desarrollo de documentos guía, de carácter práctico y jurídicamente no vinculantes, sobre varios aspectos técnicos de la Directiva. Estos documentos guía van dirigidos a los expertos que, directa o indirectamente, son los responsables de aplicar la Directiva Marco del Agua en las demarcaciones hidrográficas. En consecuencia, se ha adaptado la estructura, la presentación y la terminología a las necesidades de estos expertos, y, en la medida de lo posible, se ha evitado la utilización de un lenguaje formal y legalista.

En este contexto se elaboró un documento guía sobre "Análisis de Presiones e Impactos", aprobado por los Directores Generales del Agua en noviembre de 2002 (CIS Guidance Document nr. 3). Dicha guía sirve de referencia a los Estados miembros durante el proceso de análisis de presiones e impactos para la caracterización de las masas de agua subterránea, en el marco del desarrollo de los planes hidrológicos de cuenca requeridos por la Directiva Marco del Agua.

A modo de continuación y en el ámbito de aplicación de la nueva Directiva relativa a protección de las aguas subterráneas contra la contaminación y el deterioro, elaborada en cumplimiento del mandato del artículo 17 de la Directiva Marco del Agua, los Estados miembros han manifestado la necesidad de aclarar algunos aspectos relacionados con la evaluación del riesgo y con las medidas relativas a las "entradas ("inputs") directas e indirectas de contaminantes" en las aguas subterráneas. En 2004 se puso en marcha un proyecto para redactar un documento guía que complementase al anteriormente reseñado, y con ese objetivo se estableció un grupo de redacción (WG- C) bajo la supervisión del Grupo de Trabajo sobre Aguas Subterráneas de la Estrategia Común de Implantación. El grupo de redacción ha desarrollado su tarea bajo la coordinación de organizaciones de grupos interesados del sector industrial y de Países Bajos y con la participación de expertos de otros Estados miembros y de representantes de partes interesadas.

Este documento guía es el resultado de los trabajos de este grupo y contiene la síntesis de los resultados de los debates celebrados desde diciembre de 2004. Está basado en las aportaciones y las reacciones de una amplia variedad de expertos y partes interesadas que han participado en su elaboración a través de reuniones, talleres, conferencias y medios electrónicos, sin que por ello resulten vinculados en modo alguno con el contenido del presente informe.

"Nosotros, los Directores Generales del Agua de la Unión Europea, Noruega, Suiza y los países que han solicitado la adhesión a la Unión Europea, hemos examinado y aprobado el presente Documento guía en el transcurso de nuestra reunión informal bajo la Presidencia alemana (Dresden, 18-19 de junio de 2007). Deseamos expresar nuestro agradecimiento a los miembros del Grupo de Trabajo C y, en particular, a los responsables del grupo de redacción por la elaboración de este documento de gran calidad.

Creemos firmemente que éste y otros documentos guía elaborados en el marco de la Estrategia Común de Implantación tendrán un papel destacado en el proceso de implantación de la Directiva Marco del Agua y de la Directiva sobre la protección de las aguas subterráneas contra la contaminación y el deterioro.

Esta guía es un documento vivo que precisará de aportaciones y mejoras a medida que se procede a su aplicación y crece la experiencia en todos los países de la Unión Europea y en otros países. Hemos acordado, no obstante, que este documento se haga público en su forma actual con el fin de presentarlo al gran público como la base para seguir avanzando en su puesta en práctica.

Asimismo, nos comprometemos a evaluar y a decidir sobre la necesidad de revisarlo a la luz de los avances científicos y técnicos, así como de las experiencias acumuladas en la aplicación de la Directiva Marco del Agua y de la Directiva sobre la protección de las aguas subterráneas".

ÍNDICE

1 OBJETIVOS Y ALCANCE

1.1 Introducción

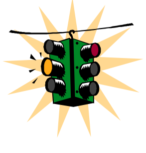
Las aguas subterráneas constituyen un recurso natural importante: si se deteriora, su restauración puede resultar difícil y costosa. En aras de la sostenibilidad, y por razones de carácter medioambiental y económico, parece apropiado disponer de un marco normativo para su protección eficaz que sea acorde con el principio de precaución y con el de “quien contamina, paga”. Este marco viene establecido en gran medida por la Directiva 2000/60/CE, de 23 de octubre, por la que se establece un marco comunitario de actuación en el ámbito de la política de aguas (Directiva Marco del Agua, DMA) que incorpora disposiciones contenidas en la Directiva 80/68/CEE, de 17 de diciembre de 1979, relativa a la protección de las aguas subterráneas, aunque su alcance es mucho mayor. Esta última directiva quedará derogada en 2013 y será reforzada y reemplazada por la Directiva 2006/118/CE, de 12 de diciembre, relativa a la protección de las aguas subterráneas contra la contaminación y el deterioro (DAS). Este marco normativo complementa asimismo otros aspectos de la legislación comunitaria relativos a medidas de protección de las aguas subterráneas, como la Directiva relativa a los nitratos y la Directiva relativa a la comercialización de productos fitosanitarios.

1.2 Objeto

Esta guía pretende servir de orientación para la aplicación de la DMA en lo relativo a las obligaciones de prevención o limitación de la entrada de contaminantes en las aguas subterráneas, tal y como especifica la DAS. La guía explica la relación que existe entre los objetivos de prevención o limitación y otros objetivos de la DMA y, en particular, aclara los requisitos relativos a las entradas directas o indirectas de contaminantes.

El documento debe leerse conjuntamente con las guías del Grupo de trabajo C sobre aguas subterráneas (WG C) de la Estrategia Común de Implantación (ECI) de la DMA, en particular la guía sobre el seguimiento de las aguas subterráneas[1].

La DMA brinda a los Estados miembros flexibilidad para que tengan en cuenta las circunstancias locales a la hora de establecer los criterios para valorar el buen estado químico del agua y cumplir los otros requisitos de la Directiva, incluidos los objetivos de prevenir o limitar la entrada de contaminantes en las aguas subterráneas. Estas circunstancias locales pueden incluir modos diferentes de enfocar la normativa y la protección medioambiental entre los distintos Estados miembros. En este sentido, el presente documento guía no tiene el propósito de recomendar medidas específicas que puedan adoptarse para prevenir o limitar las entradas de contaminantes en las aguas subterráneas, sino que se centra, en primer lugar, en explicar las definiciones y los requisitos contenidos en la DMA para que todos los Estados miembros entiendan por igual aquello que se les exige; y, en segundo lugar, ofrece ejemplos de cómo pueden cumplirse dichos requisitos. Se han incluido figuras y gráficos que explican, de la manera más precisa y completa posible, procedimientos, criterios, decisiones y otra información pertinentes. Debe tenerse presente, sin embargo, que no es posible incluir todas las situaciones específicas ni instrucciones pormenorizadas en estas presentaciones esquemáticas. No obstante, con la inclusión de estos esquemas se pretende facilitar información visual que permita la rápida comprensión de los aspectos clave de la DMA y la DAS sobre los temas tratados.



¡Atención! La metodología que propone esta guía deberá adaptarse a las circunstancias regionales y nacionales

La guía propone un enfoque pragmático global. Dada la diversidad de las circunstancias en la Unión Europea, los Estados miembros podrán aplicar la guía con flexibilidad para responder a los distintos problemas de las cuencas hidrográficas, subcuencas o masas de agua subterránea. Así pues, la guía se adaptará a las circunstancias específicas de cada caso.

[1] CIS Guidance Document No. 15 on Groundwater Monitoring. Diciembre de 2006.

1.3 Alcance

Esta guía forma parte de una serie de documentos que explican y analizan las disposiciones normativas de la DMA y de la DAS. Cada uno de ellos se centra en un aspecto diferente de las aguas subterráneas, -seguimiento[1], aguas subterráneas en áreas protegidas para la captación de agua potable[2] de acuerdo con la DMA, aplicación del término "entradas directas e indirectas", evaluación del estado químico y tendencias-, y en una metodología común para el establecimiento de valores umbral relativos a las aguas subterráneas.

En la práctica, estos diferentes requisitos están estrechamente relacionados entre sí y, en ocasiones, pueden solaparse. Cada documento guía tendrá su máxima utilidad en relación con un requisito específico de una directiva que, a menudo, sólo es pertinente en una parte concreta del sistema de aguas subterráneas. La figura 1 describe las partes del sistema de aguas subterráneas mencionado en las diferentes guías. En la figura se diferencian tres "áreas" principales de las aguas subterráneas, denominadas GWI, GWII y GWIII, para ilustrar el centro de atención principal de cada guía. No obstante, las áreas se solapan, dependiendo de las circunstancias locales y de los puntos específicos de atención -p.ej. en un área protegida las entradas pueden producirse en la zona no saturada, o, en caso de contaminación histórica, en la zona saturada-.

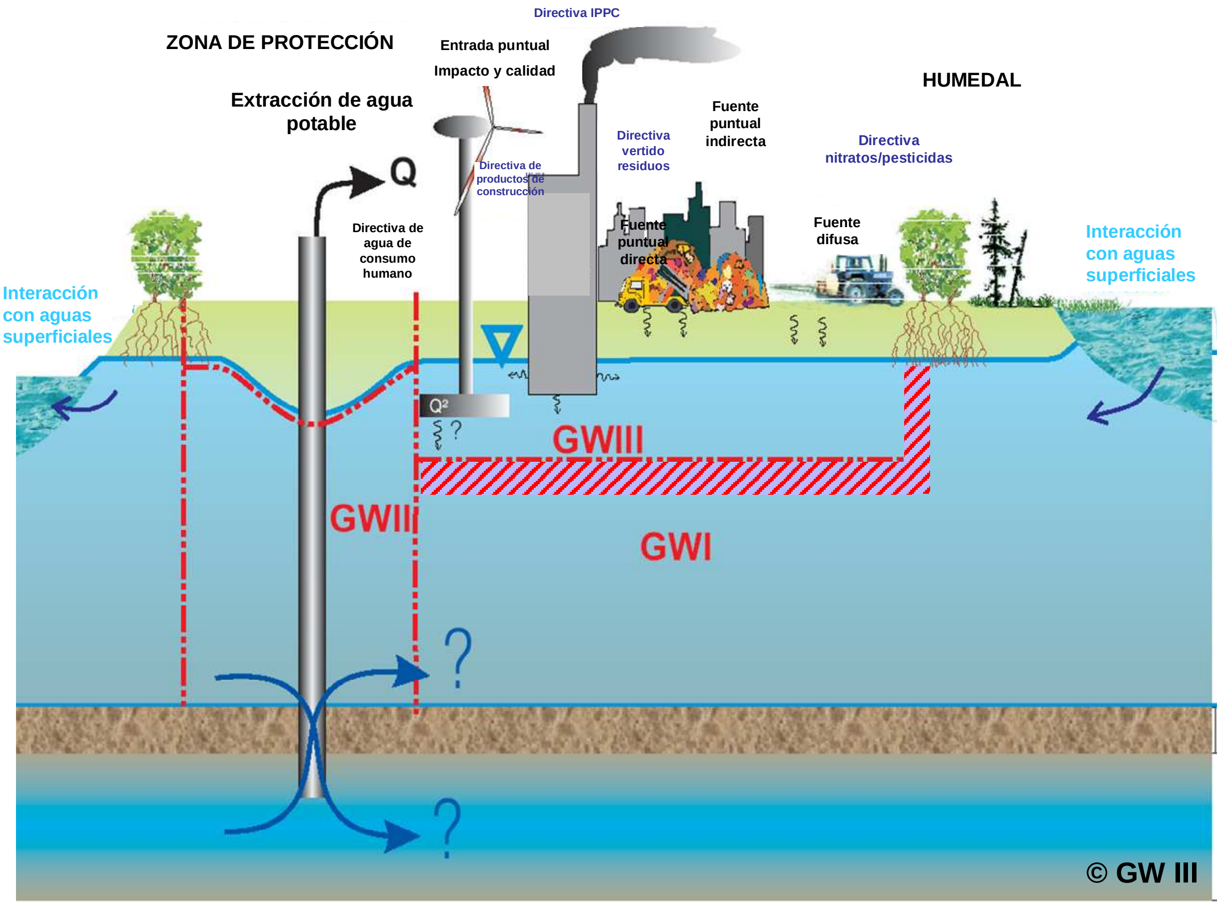


Figura 1: Enfoque de los diferentes documentos guía en el ámbito del sistema de aguas subterráneas (GWI-GWIII). Puede haber solapamiento de zonas y puntos de atención. GWI se refiere principalmente a "seguimiento", "estado químico y tendencias" y "valores umbral"; GWII trata principalmente de las "áreas protegidas" -p. ej. áreas protegidas de agua potable-; mientras que GWIII está relacionada principalmente con las "entradas directas o indirectas".

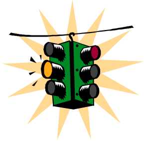
[2] CIS Guidance Document Nº. 16 on Groundwater in Drinking Water Protected Areas, July 2007.

La guía ofrece orientación sobre las entradas directas o indirectas de contaminantes en las aguas subterráneas. Las entradas pueden tener origen y formas diferentes. Por ejemplo, las entradas de carácter difuso pueden tener su origen en áreas urbanas o agrícolas, o en fuentes puntuales procedentes de la actividad industrial.



¡Atención! El alcance de los documentos guía puede solaparse

En ocasiones, para una situación determinada puede haber más de un documento guía pertinente. Es el caso de la entrada de contaminantes desde una fuente puntual directa, con el impacto correspondiente en la captación de agua potable o en un humedal.

2 ANTECEDENTES

2.1 Directiva relativa a las aguas subterráneas (80/68/CEE)

La Directiva 80/68/CEE relativa a las aguas subterráneas, en vigor hasta 2013, establece que los Estados miembros adoptarán las medidas necesarias, incluido un sistema de autorización especial, para *impedir* el vertido de sustancias de la “lista I” en las aguas subterráneas y *limitar* el vertido de sustancias de la lista II en las aguas subterráneas a fin de evitar su contaminación. Las listas I y II, recogidas en un anexo de la directiva, constan cada una de ellas de distintos grupos de sustancias. La lista I contiene sustancias de origen antropogénico, así como otras sustancias presentes en el medio natural, cuya introducción directa o indirecta en las aguas subterráneas por actividades antropogénicas supone riesgos relativamente altos para el medio ambiente, mientras que la entrada de sustancias de la lista II presenta riesgos relativamente moderados para el medio ambiente. El significado de “impedir o evitar” y “limitar” y también de “vertido directo” y “vertido indirecto” se trata más adelante en el presente documento.

2.2 Directiva Marco del Agua (2000/60/CE)

La DMA amplía los controles a las entradas de todos los contaminantes en las aguas subterráneas y establece objetivos medioambientales adicionales para las aguas subterráneas. A efectos de esta guía, las disposiciones más importantes son:

- Artículo 4.1,b),i), que establece que los Estados miembros habrán de aplicar las medidas necesarias para evitar o limitar la entrada de contaminantes en las aguas subterráneas. Este objetivo de evitar o limitar la entrada de contaminantes en las aguas subterráneas fue introducido en la DMA para garantizar la continuidad del sistema de protección de las aguas subterráneas que establece la Directiva 80/68/CEE a partir de su derogación en 2013;
- Artículo 4.1,b),ii), que establece que los Estados miembros habrán de proteger, mejorar y regenerar todas las masas de agua subterránea, con objeto de alcanzar un buen estado de las mismas, de conformidad con lo dispuesto en el anexo V de la DMA;
- Artículo 4.1.b),iii), que establece que los Estados miembros habrán de aplicar las medidas necesarias para invertir toda tendencia significativa y sostenida al aumento de la concentración de cualquier contaminante debida a las repercusiones de la actividad humana; y
- Artículo 11.3.j), que introduce la prohibición de *todos* los vertidos *directos* de contaminantes en las aguas subterráneas (sin perjuicio de determinadas excepciones). El artículo 2.32) define “vertido directo” como el vertido de contaminantes en el agua subterránea sin atravesar el suelo o el subsuelo. Véase asimismo el apartado 3.3 del presente documento guía.

2.3 Directiva sobre la protección de las aguas subterráneas (2006/118/CE)

La nueva Directiva sobre las aguas subterráneas incluye criterios para valorar el buen estado químico de las aguas subterráneas, así como para determinar las tendencias significativas o sostenidas al aumento y los puntos de partida para la inversión de la tendencia. Otro elemento que también se incluye es un marco para hacer operativo el objetivo de “evitar o limitar” que establece la DMA. En él se aclara cuáles son las sustancias cuya entrada en las aguas subterráneas deberá evitarse y cuáles limitarse, así como las excepciones al cumplimiento de este objetivo de evitar o limitar.

De conformidad con el artículo 22.2 de la DMA, la Directiva 80/68/CEE quedará derogada en diciembre de 2013, pero el nivel de protección que establece esta Directiva debe mantenerse y reforzarse en virtud de la DMA y la DAS.

2.4 Relación entre el objetivo de prevenir y limitar y los valores umbral

El objetivo de "prevenir o limitar" en la DMA y en la DAS protege las aguas subterráneas contra las entradas inaceptables de contaminantes. La protección abarca un amplio conjunto de receptores e incluye la contaminación a escala local.

Esto contrasta con los requisitos de buen estado químico, ya que la evaluación en este último caso se efectúa para la totalidad de la masa de agua subterránea. En la mayoría de las ocasiones, se tratará de un área bastante extensa. La evaluación se lleva a cabo en cada período del plan de cuenca y supone una revisión del estado de las masas de agua subterránea cada seis años. Esta evaluación determina si la masa de agua subterránea cumple con las condiciones de buen estado químico estipuladas en las DMA/DAS. La definición de ese buen estado se refiere solamente a algunos receptores y a circunstancias específicas, y no se traduce necesariamente en la protección de la calidad a escala local.

Para que se produzca una afección a un receptor, una entrada de contaminante debe desplazarse físicamente en el sistema de aguas subterráneas. Ese movimiento varía en función de las características físicas y químicas de los estratos geológicos. Y, más importante, el contaminante puede estar sujeto a procesos de dilución y atenuación en el trayecto hacia el receptor. En consecuencia, muchas entradas sólo tienen efectos localizados. Dichas entradas pueden producir una contaminación localizada, pero su efecto puede ser leve o nulo en los receptores reseñados en la definición del buen estado químico. Si se considera lo estipulado en las DMA/DAS, es muy posible que se produzca una contaminación de alcance espacial limitado en una masa de agua subterránea que se encuentre en buen estado químico. Sin embargo, cuanto mayor es la extensión de la contaminación, mayor será la probabilidad de que la masa se encuentre en mal estado químico. La contaminación localizada debería ser investigada –y suprimida en caso necesario- mediante la adopción de medidas de prevención o limitación.

En principio, las medidas de prevención o limitación constituyen la primera línea de defensa en la prevención de entradas inaceptables de contaminantes en las aguas subterráneas, consiguiendo así evitar la contaminación. La aplicación efectiva del objetivo de prevenir o limitar mediante medidas de carácter normativo debería asegurar la protección de la calidad de las aguas subterráneas. Dichas medidas pueden consistir en permisos, regulaciones de carácter vinculante o códigos de buena práctica para el control de actividades específicas en el uso del suelo. Las condiciones de los permisos y/o "valores límite" pueden utilizarse para asegurar que no se producen entradas inaceptables de contaminantes en las aguas subterráneas. Prescindiendo del tiempo necesario para que las entradas producidas en el pasado lleguen a degradarse o dispersarse, si todos los requisitos de prevenir y limitar se cumplieran en la totalidad de la masa de agua subterránea, la masa estaría en buen estado. El objetivo de prevenir o limitar y los requisitos de buen estado son así complementarios y, conjuntamente, proporcionan un marco efectivo para la protección de las aguas subterráneas en la Unión Europea.

Aunque los valores umbral que deben establecerse de conformidad con el artículo 3 de la DAS servirán para la evaluación del buen estado químico, esos valores, junto con el régimen de cumplimiento asociado, no serán frecuentemente apropiados para cumplir con los requisitos más estrictos del objetivo de prevenir y limitar.

Resulta conveniente resumir en este punto los diferentes propósitos y funciones de los valores límite y los valores umbral en la protección de las aguas subterráneas:

1. Escala de aplicación

   Los valores umbral establecidos para cumplir con los requisitos de los artículos 3 y 4 de la DAS no se aplican necesariamente en los mismos puntos de cumplimiento (PdC) que los valores límite reseñados en esta guía. La evaluación del estado se efectúa en las estaciones de la red de seguimiento o de la red operativa, que están distribuidos a lo largo de la masa de agua de agua subterránea. Las entradas se evalúan localmente en la proximidad de la fuente, en los puntos de seguimiento de la red diseñada para prevenir o limitar, y pueden ser reales o virtuales.

Con ello se consigue una protección más inmediata y completa del agua subterránea. Debe reseñarse que, en algunos casos, el punto de seguimiento de la red de prevención utilizado para evaluar la aceptabilidad de la entrada puede ser una estación de la red operativa donde se evalúa el estado, en cuyo caso el valor umbral constituye un valor límite apropiado.

2. Lugar de aplicación

   Debe utilizarse un valor umbral único en la totalidad de la masa, pero pueden utilizarse distintos valores límite en los distintos PdC. Además, los valores umbral sólo se aplican para las masas de agua subterránea, mientras que los valores límite sirven para cumplir con el objetivo de prevenir o limitar en las aguas subterráneas. Por ejemplo, el agua contenida en una terraza discontinua formada por gravas, o el agua "colgada" en una turbera situada sobre unas arcillas con bolos, son aguas subterráneas, y las entradas de contaminantes deben ser prevenidas o limitadas para asegurar que no se produce la contaminación de ningún receptor. Sin embargo, ninguno de esos depósitos geológicos es una unidad de gestión y, por tanto, masa de agua subterránea. No son objeto por ello de evaluación sobre el buen estado y no precisan de una designación de valores umbral.

2.5 Otras disposiciones pertinentes de la legislación comunitaria

Existen otras normas de la legislación comunitaria que garantizan cierto nivel de protección de las aguas subterráneas o facilitan información de referencia relativa a su protección. A continuación se citan las más importantes:

- Directiva relativa a la contaminación por nitratos (91/676/CEE). Contiene disposiciones sobre la designación de zonas vulnerables y sobre la actuación de los Estados miembros cuando la cantidad de nitrato que contienen las aguas subterráneas sobrepase o pueda sobrepasar el límite de 50 mg/l;
- Directiva Hábitats (92/43/CEE). Protege indirectamente las aguas subterráneas, en particular su estado cuantitativo. El requisito de mantener los hábitats que se nutren de aguas subterráneas implica la protección del flujo de aguas subterráneas en estas zonas;
- Directiva 91/414/CEE relativa a los productos fitosanitarios. Regula la autorización de la comercialización de productos fitosanitarios sobre la base de valoraciones exhaustivas de los riesgos para la salud humana y el medio ambiente. En lo que respecta a las aguas subterráneas, no se concederán autorizaciones cuando los usos que deben autorizarse sobrepasen (o pudieran sobrepasar) las concentraciones máximas admisibles de sustancias activas y metabolitos pertinentes, productos de degradación o de reacción, según lo establecido en la Directiva 80/778/CEE sobre el agua potable, sustituida por la Directiva 98/83/CE.
- Directiva sobre Biocidas (98/8/CEE), relativa a la autorización y comercialización para el uso de biocidas, similar a la Directiva 91/414/CEE,
- Directiva 91/271/CEE sobre el tratamiento de las aguas residuales urbanas. Tiene como objetivo proteger el medio ambiente de los efectos adversos de los vertidos de aguas residuales urbanas y de las aguas residuales procedentes de determinados sectores industriales. Esta Directiva es indirectamente pertinente para las aguas subterráneas (protección de las aguas subterráneas receptoras frente a aguas residuales que puedan estar contaminadas procedentes de fuentes de agua dulce).
- Directiva 96/61/CE relativa a la prevención y al control integrados de la contaminación (IPPC). Establece controles en la autorización de emplazamientos, con objeto de prevenir o reducir las emisiones al aire, al agua y al suelo procedentes de una serie de actividades recogidas en el anexo I de la Directiva.
- Directiva 99/31/CEE relativa al vertido de residuos. Su objetivo es establecer medidas, procedimientos y orientación para prevenir o reducir, en la medida de lo posible, las repercusiones negativas en el medio ambiente, incluidas las aguas subterráneas.
- Directiva 86/278/CEE sobre los lodos de depuradora. Intenta promover la utilización de los lodos de depuradora en agricultura y regular su utilización de tal manera que se eviten los efectos nocivos en el suelo, la vegetación, los animales y el ser humano.
- Directiva 89/106/CEE sobre los productos de construcción. Se centra en la conformidad de los productos de la construcción, teniendo en cuenta los posibles riesgos para el medio ambiente acuático, en particular el vertido de sustancias peligrosas a las aguas.

- Directiva 2006/21/CE sobre la gestión de los residuos de industrias extractivas. Instrumento jurídico independiente que exige minimizar los efectos para las aguas subterráneas derivados de los desechos de las industrias extractivas.
- Reglamento 1907/2006/CE relativo al registro, la evaluación, la autorización y la restricción de las sustancias y preparados químicos (REACH), por el que se crea la Agencia Europea de Sustancias y Preparados Químicos y se modifica la Directiva 1999/45/CE. Este Reglamento crea una estructura para la evaluación de las sustancias que se comercializan en el mercado de la UE y para facilitar información adecuada, entre otros, a los usuarios y las autoridades. Este Reglamento se basa en el principio de que corresponde a los fabricantes, importadores y usuarios intermedios garantizar que fabrican, comercializan o utilizan dichas sustancias de manera que no pongan en peligro la salud humana o el medio ambiente. Sus disposiciones están respaldadas por el principio de precaución. La evaluación de sustancias que deben hacer los fabricantes y otros organismos pertinentes incluye la protección de las aguas subterráneas. REACH deja amplio margen para la DMA y la DAS y para que las autoridades competentes evalúen las sustancias (como tales o contenidas en productos) con respecto a la protección del agua en general o en situaciones específicas.
- Directiva 2004/35/CE sobre responsabilidad medioambiental. Crea un dispositivo para prevenir y reparar la contaminación de aguas subterráneas.
- Directiva 80/778/CEE relativa a la calidad de las aguas destinadas al consumo humano, sustituida por la Directiva 98/83/CE. El objetivo de esta directiva es proteger la salud humana frente a los efectos nocivos de cualquier tipo de contaminación del agua destinada al consumo humano, garantizando su salubridad y su pureza.
- Directiva sobre la protección del suelo: La propuesta de directiva se centra en la protección del suelo frente a los procesos de degradación -sin incluir las aguas subterráneas- y a las amenazas –p.ej., la erosión, o el sellado, que deberán limitarse; deberán redactarse planes de acción y se adoptarán medidas cuando sea necesario. Comprende asimismo la contaminación del suelo, incluida la prevención, la detección de contaminación y la restauración o recuperación. Se limitará la introducción de sustancias peligrosas en el suelo (artículo 9).

La legislación mencionada anteriormente está recogida, en su mayoría, en la parte A del Anexo VI de la DMA como parte de las “medidas básicas” que los Estados miembros deben aplicar para lograr los objetivos de la DMA. Por consiguiente, dichas directivas son complementarias de la DMA, y sus requisitos deberán seguir cumpliéndose. Si los requisitos que establecen estas directivas en vigor no son por si solos suficientes para alcanzar los objetivos de la DMA, los Estados miembros aplicarán medidas complementarias.

2.6 Calendario para el cumplimiento de los objetivos de la DMA

A diferencia del logro del buen estado químico de las masas de agua, la DMA no establece plazos específicos para el cumplimiento de los objetivos en materia de prevención o limitación recogidos en el artículo 4 y complementados por el artículo 6 de la DAS. No obstante, el artículo 11 de la DMA estipula que, a más tardar en diciembre de 2009, los Estados miembros velarán por que se establezca para cada demarcación hidrográfica un programa de medidas con el fin de alcanzar los objetivos establecidos en esa directiva. Estos programas de medidas incluirán medidas para controlar los vertidos desde fuentes puntuales que puedan causar contaminación, medidas para prevenir o controlar la entrada de contaminantes procedentes de fuentes difusas que puedan generar contaminación, y la prohibición de efectuar vertidos directos de contaminantes en aguas subterráneas, sujeta a determinadas excepciones. Para poder determinar cuáles son las medidas necesarias es preciso conocer las presiones (entradas de contaminantes en aguas subterráneas), su impacto, cómo evitar o limitar dichas presiones y el coste de las medidas de prevención o limitación.

Estos programas de medidas deberán incluirse en los planes hidrológicos de cuenca, que también deberán presentarse a más tardar en diciembre de 2009.

2.7 Normativa de ámbito estatal

La DMA, la DAS y otras directivas de la EU establecen que los Estados miembros designarán las autoridades competentes que desempeñarán los cometidos y obligaciones estipulados. Las autoridades competentes establecerán definiciones del buen estado de las aguas superficiales y subterráneas, los métodos para evaluar el estado de las masas de agua, los valores umbral, los planes hidrológicos de cuenca, la concesión de licencias y otras medidas que puedan afectar a la entrada de contaminantes en las aguas.

Este requisito de designación de las autoridades estatales y de otras autoridades competentes significa que no es posible limitarse a describir las medidas generales que deben aplicarse respecto a actividades y productos que puedan provocar una entrada en las aguas subterráneas. Uno de los principales cometidos de las autoridades competentes es tener en cuenta las condiciones locales a la hora de especificar los criterios o, incluso, prohibir actividades o productos que puedan originar la contaminación de las aguas superficiales y subterráneas.

3 PRINCIPIOS GENERALES

Este capítulo trata sobre los principios fundamentales relativos a las “entradas”. Qué es “contaminación”, qué son “entradas” -directas o indirectas-, qué debe entenderse por “evitar o impedir” y “limitar”, y cómo pueden abordarse las entradas. La subdivisión en “entradas directas” y “entradas indirectas” se basa principalmente en las importantes diferencias en el modo de considerar las sustancias “peligrosas” -relacionadas principalmente con “evitar”- y las “no peligrosas” -vinculadas principalmente a “limitar”-.

3.1 ¿Qué es contaminación?

La finalidad de los objetivos de “evitar o limitar” que establecen la DMA y la DAS es prevenir la contaminación. En consecuencia, las autoridades competentes de los Estados miembros deben tener una comprensión clara de la base sobre la que se evalúa la “contaminación”. Para que exista contaminación, debe existir un efecto nocivo real o probable de la actividad humana en un receptor determinado.

La Directiva relativa a las aguas subterráneas (80/68/CEE), actualmente en vigor, define la contaminación como “…*el vertido de sustancias o de energía efectuado por el hombre, directa o indirectamente, en las aguas subterráneas y que tenga consecuencias que puedan poner en peligro la salud humana o el abastecimiento de agua, dañar los recursos vivos y el sistema ecológico acuático o perjudicar otros usos legítimos de las aguas.”*

La DMA y, en consecuencia, también la DAS, adoptan una definición más amplia de contaminación, a saber: “...*la introducción directa o indirecta, como consecuencia de la actividad humana, de sustancias o calor en la atmósfera, el agua o el suelo, que puedan ser perjudiciales para la salud humana o para la calidad de los ecosistemas acuáticos, o de los ecosistemas terrestres que dependan directamente de ecosistemas acuáticos, y que causen daños a los bienes materiales o deterioren o dificulten el disfrute y otros usos legítimos del medio ambiente*” (artículo 2.33) de la DMA). La DMA, por consiguiente, amplía los controles a todos los contaminantes (todas las sustancias que puedan causar contaminación, incluidas las sustancias radiactivas así como el dióxido de carbono o el agua calentada procedente de refrigeración), y no se limita al medio de las aguas subterráneas. La DMA no menciona los agentes microbiológicos.

La DMA define sustancias peligrosas como “*las sustancias o grupos de sustancias que son tóxicas, persistentes y pueden causar bioacumulación, así como otras sustancias o grupos de sustancias que entrañan un nivel de riesgo análogo*” (artículo 2.29). La DAS establece la necesidad de prevenir las entradas de estas sustancias en las aguas subterráneas (artículo 6.1,a). Se considerará que se han producido daños cuando los vertidos contengan sustancias peligrosas en cantidades apreciables que superen las concentraciones de fondo existentes de manera natural en las aguas subterráneas receptoras. El artículo 6.3 establece, sin embargo, excepciones a las entradas de contaminantes en determinadas circunstancias. En el caso de nuevos vertidos -p.ej. procedentes de un vertedero o de excavaciones para drenaje- no podrá tenerse en cuenta la dilución de estas sustancias por el flujo de aguas subterráneas a menos que esté cubierta por las excepciones, ni tampoco podrá alegarse que dichas sustancias pueden entrar en las aguas subterráneas porque éstas ya estaban contaminadas. En lugares en los que exista contaminación histórica del suelo y donde ya hayan penetrado sustancias peligrosas en aguas subterráneas, se considerará que ya se ha producido contaminación.

Las sustancias consideradas “no peligrosas” pueden, sin embargo, causar contaminación y producir efectos nocivos, dependiendo de cuál sea su concentración en las aguas subterráneas. En lo que respecta a estas sustancias, su mera entrada en aguas subterráneas o un ligero deterioro de la calidad de éstas no se considerará contaminación. La contaminación se producirá únicamente cuando la entrada o el deterioro estén relacionados con un efecto en un receptor. En este sentido, deberán tenerse en cuenta, junto con las aguas subterráneas, todos los receptores en el punto de entrada y “aguas abajo en la dirección del flujo subterráneo”. El término “receptor” se entenderá en su contexto más amplio, para que incluya no solamente los usos existentes de las aguas subterráneas, sino también todos los futuros usos y funciones plausibles a que podrían destinarse las aguas subterráneas, así como las propias aguas subterráneas. El término “usos” incluye la extracción de aguas subterráneas mediante bombeo y los receptores pasivos de aguas subterráneas como las fuentes, los ríos o los humedales.

3.2 ¿Qué son entradas?

La DMA no define el término “entrada” (“input”), utilizado en el contexto de evitar o limitar las entradas de contaminantes en las aguas subterráneas (artículo 4.1,b),i)). La DAS, por su parte, define “entrada de contaminantes en las aguas subterráneas” como “*la introducción directa o indirecta de contaminantes en las aguas subterráneas, como resultado de la actividad humana*”.

El término entrada es claramente diferente de vertido, utilizado en la Directiva 80/68/CEE, en el sentido de que abarca todos los contaminantes que entran en las aguas subterráneas, y no se limita a los casos de eliminación deliberada. Esto significa que el término entrada abarca un conjunto más amplio de hipótesis y situaciones, en los que las sustancias penetran en el subsuelo.

Las entradas pueden proceder de una fuente puntual, cuando se trata de un vertido/emisión/instalación único, o de fuentes de carácter difuso, derivadas de numerosas pérdidas o emisiones. La distinción entre ambas radica en el número de entradas y su magnitud.

Algunas de las actividades que pueden originar entradas son:

- En la industria: accidentes, derrames, fugas, almacenamiento, eliminación de residuos y vertederos.
- Actividades de gestión de residuos.
- En el tráfico: gases de escape, pérdidas de aceite o gasolina, abrasión de neumáticos, accidentes con pérdida de aceite, gasolina o carga; u otras partículas.
- Otros: materiales de construcción utilizados sobre o dentro del suelo -hormigón, pinturas-; instalaciones de almacenamiento y de aprovisionamiento de carburante, ya sean para uso particular o comercial -depósitos, estaciones de servicio-; campos de tiro; sistemas de evacuación de aguas residuales; almacenamiento de dióxido de carbono; entrada de agua de refrigeración en centrales geotérmicas.

Las entradas de carácter difuso se producen principalmente en explotaciones agrícolas, en suelos que contengan contaminantes procedentes de la precipitación atmosférica como consecuencia de las emisiones a la atmósfera procedentes de la industria, el tráfico, los incendios, etc., y en zonas “desarrolladas”, como grandes núcleos urbanos.

	***¡Atención! Una entrada es, por consiguiente:*** *cualquier introducción de una sustancia en las aguas subterráneas procedente de una actividad, ya sea accidental o deliberada, de una fuente puntual o difusa, que provoque la transferencia de un contaminante a las aguas subterráneas.*

Es necesario controlar las entradas en las aguas subterráneas porque pueden:

1. causar contaminación;
2. provocar o mantener un mal ***estado*** *q*uímico de la masa de agua subterránea;
3. tener como resultado ***tendencias*** significativas y sostenidas al aumento de la contaminación.

Por ello, la DMA establece el objetivo de evitar o limitar la entrada de contaminantes en las aguas subterráneas (véase capítulo 3.4) y la DAS introduce en su artículo 6 disposiciones complementarias.

3.3 Entradas directas e indirectas

Las entradas directas pueden identificarse mediante una de las siguientes propiedades:

- No se integran en el flujo en la zona no saturada del acuífero;
- La fuente de contaminación se sitúa en la zona saturada o afecta directamente a la zona saturada (masa de agua subterránea, MAS);
- Las fluctuaciones estacionales de la superficie piezométrica hacen que la fuente de contaminación entre ocasionalmente en contacto directo con las aguas subterráneas.

Estas tres situaciones se representan en la figura 2.

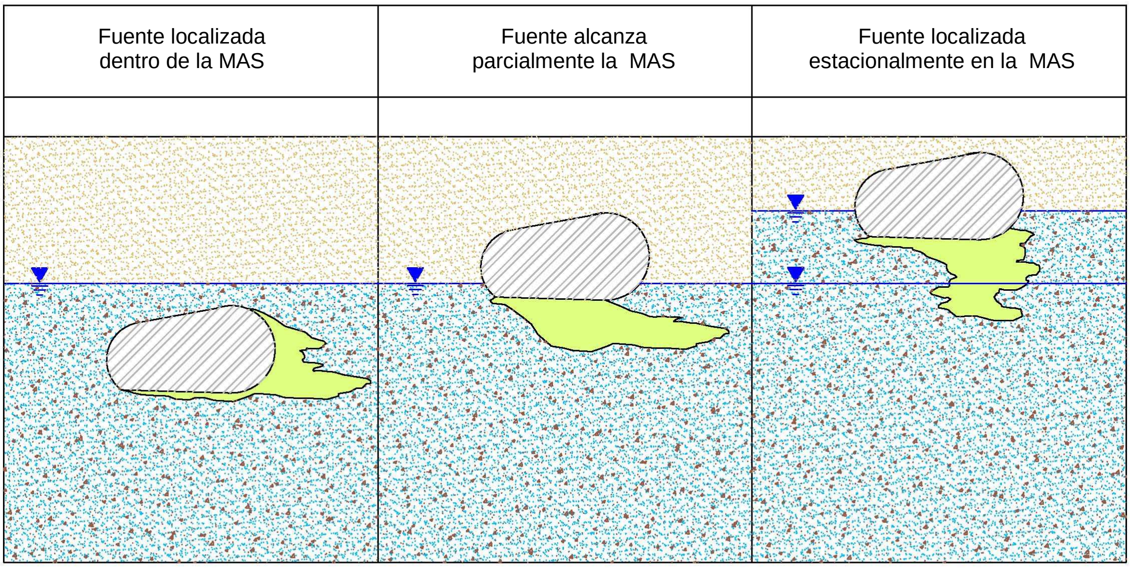


Figura 2: Entradas directas. La sección ovalada y sombreada, que representa una entrada, puede situarse permanentemente, en su totalidad o en parte, en la zona saturada, o puede situarse periódicamente en la zona saturada, cuando el nivel piezométrico asciende hasta la sección ovalada.

Las entradas indirectas se caracterizan por la incorporación a las aguas subterráneas tras haberse filtrado a través del suelo o el subsuelo (figura 3).

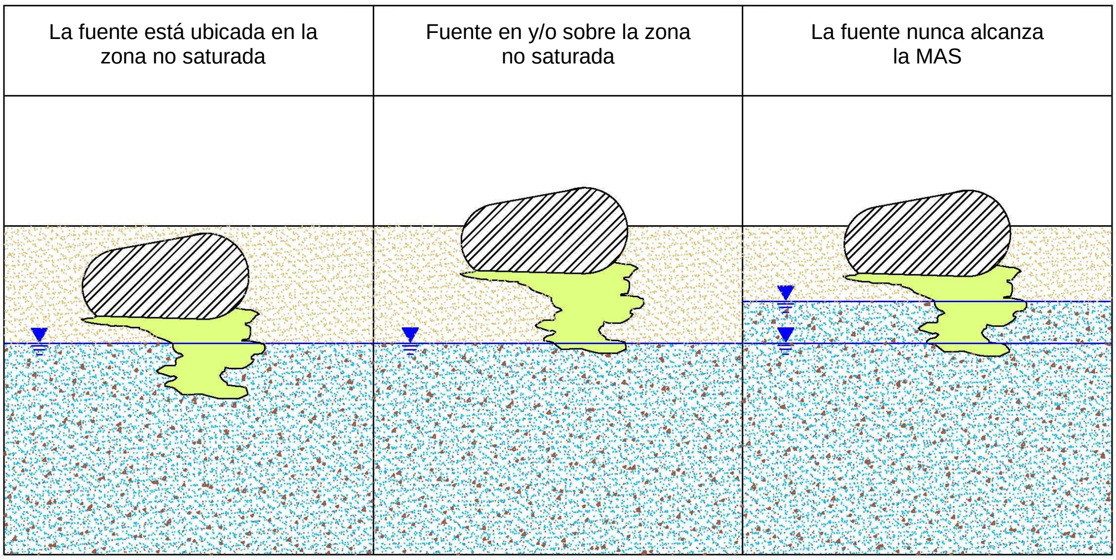

Figura 3: Entradas indirectas. La sección ovalada y sombreada, que representa una entrada, se sitúa permanentemente y en su totalidad por encima de la zona saturada, incluso en períodos de ascenso del el nivel piezométrico.

El anexo 1 ofrece algunos ejemplos de distintos tipos de entradas directas e indirectas.

3.4 ¿Qué se entiende por prevenir o limitar?

Según la DAS, las sustancias cuya entrada en aguas subterráneas hay que *prevenir o evitar* son aquéllas que los Estados miembros hayan identificado como *peligrosas* (Artículo 6.1,a)). En la identificación de tales sustancias, los Estados miembros tendrán en cuenta las sustancias peligrosas pertenecientes a las familias o grupos de contaminantes enumerados en los puntos 1 a 6 del Anexo VIII de la Directiva 2000/60/CE, así como las sustancias pertenecientes a las familias o grupos de contaminantes enumerados en los puntos 7 a 9 de dicho anexo, cuando se considere que son peligrosas. Las sustancias cuya entrada en aguas subterráneas hay que *limitar* de manera que no causen contaminación comprenden todos los demás contaminantes.

En el contexto de la DMA se entiende por "sustancias peligrosas" las sustancias o grupos de sustancias que son tóxicas, persistentes y pueden causar bioacumulación, así como otras sustancias o grupos de sustancias que entrañan un nivel de riesgo análogo. La DMA no define los criterios para designar una sustancia como tóxica, persistente y que puede causar bioacumulación. Los criterios para la definición de "peligrosa" se exponen, por ejemplo, en las Guías técnicas[3] adoptadas en la UE para apoyar la evaluación de riesgos de las sustancias. Podrán aplicarse estos criterios o cualquier otro procedimiento de evaluación adecuado por parte de los Estados miembros. Por consiguiente, no todas las sustancias incluidas en los puntos 1 a 9 del Anexo VIII de la DMA pueden clasificarse como "peligrosas". Obsérvese que al vincular las sustancias peligrosas a la cláusula de prevención, y todos los demás contaminantes a la cláusula de limitación, la DAS se aparta del planteamiento de las listas 1 y 2 de la Directiva 80/68/CEE. De hecho, de conformidad

---

[3] Guía técnica de apoyo a la Directiva 93/67/CEE de la Comisión por la que se fijan los principios de evaluación del riesgo de las sustancias objeto de nueva notificación, al Reglamento (CE) nº 1488/94 de la Comisión por el que se establecen los principios de evaluación del riesgo de las sustancias existentes, y a la Directiva 98/8/CE del Parlamento Europeo y del Consejo relativa a la comercialización de biocidas. (http://ecb.jrc.it/home.php?CONTENU=/Technical-Guidance-Document/sommaire.php). Véase también http://ecb.jrc.it.

con esta directiva, los Estados miembros adoptarán las medidas necesarias para evitar que las sustancias de la lista 1 entren en las aguas subterráneas, mientras que deberá limitarse la entrada de sustancias de la lista 2 para evitar la contaminación.

La ampliación de los controles de los contaminantes adoptada por la DMA, según se ha mencionado anteriormente, se ve ahora atenuada por la serie de excepciones que introduce la DAS (artículo 6.3). En realidad, no es técnicamente viable evitar todas las entradas de sustancias peligrosas, y algunas pequeñas entradas son insignificantes desde el punto de vista ambiental, por lo que no suponen riesgo de deterioro de las aguas subterráneas. Sin estas excepciones, el requisito de “prevenir” implicaría una tarea onerosa y, en ocasiones, inviable. Cada excepción es aplicable al objetivo de “prevenir y limitar” -tanto sustancias peligrosas como no peligrosas-, pero no invalidará otros requisitos más estrictos recogidos en otras normas comunitarias. Estas excepciones se detallan en el apartado 5.3.

“Prevenir" una entrada en las aguas subterráneas significa adoptar todas las medidas que se consideren necesarias y razonables para evitar la entrada de sustancias peligrosas en las aguas subterráneas y evitar un incremento significativo de la concentración en las aguas subterráneas, incluso a escala local. "Razonable" significa técnicamente viable, sin que entrañe costes desproporcionados. La definición de “costes desproporcionados” dependerá de las circunstancias locales.

A la hora de considerar la necesidad de adoptar medidas para prevenir la entrada *indirecta* de una sustancia peligrosa en las aguas subterráneas, podrá tenerse en cuenta la atenuación -fijación, degradación- de la sustancia en la *zona no saturada*. A tal efecto, se tendrán en cuenta todos los procesos geológicos, hidrogeoquímicos y biológicos, incluidos los cambios en la superficie piezométrica en un lugar determinado. Los procesos en la *zona saturada* no son pertinentes para evaluar las entradas de sustancias peligrosas, puesto que, como se reseña anteriormente, hay que evitar la entrada de estas sustancias en la zona saturada. Los procesos en la zona saturada son pertinentes únicamente cuando las sustancias peligrosas ya estén presentes en dicha zona (contaminación histórica). Los procesos ya no podrán evitar la entrada -puesto que ésta ya se ha producido-, pero son pertinentes para determinar las medidas necesarias -restauración, aislamiento, etc.- encaminadas a impedir que la contaminación se propague a través de las aguas subterráneas. Esto está relacionado con la disposición recogida en el artículo 5.5 de la DAS, que establece la necesidad de evaluar el impacto de los penachos de contaminación y de adoptar las medidas adecuadas.

En muchos casos no es posible evitar por completo la entrada de sustancias que ya están presentes en el medio ambiente -en la atmósfera, aguas superficiales, el suelo y en las obras de construcción- en las aguas subterráneas. Sin embargo, de conformidad con la DMA, la contaminación del medio ambiente por sustancias peligrosas podría ser objeto de una prevención más absoluta mediante la prohibición o eliminación gradual de determinadas prácticas o su prohibición/eliminación gradual total. Antes de poder tomar la decisión de prohibir/eliminar gradualmente, será necesario comprobar si es posible aplicar medidas razonables para evitar la entrada en las aguas subterráneas.

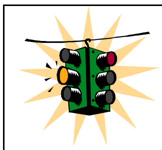
	***¡Atención! Prevenir o evitar la entrada en aguas subterráneas significa:*** *Que no debe producirse un incremento significativo de la concentración de contaminantes en las aguas subterráneas, ni siquiera a escala local. Deberán adoptarse todas las medidas que se estimen necesarias y razonables para evitar la entrada de sustancias peligrosas en las aguas subterráneas. Los Estados miembros podrán, bajo determinadas condiciones, eximir entradas de estas medidas, como se estipula en el artículo 6.3 de la DAS (véase apartado 5.3).*

La *limitación* es aplicable a todos los contaminantes no peligrosos. El artículo 6.1 de la DAS establece que los Estados miembros aplicarán las medidas necesarias para limitar las entradas en aguas subterráneas de manera que se garantice que tales entradas no causen deterioro del estado o tendencias significativas y sostenidas al aumento de las concentraciones de contaminantes en las aguas subterráneas.

Observación: aunque en el artículo 6.1 <u>deterioro</u> no se refiere específicamente al <u>estado</u>, el artículo 1 de la DAS así lo especifica de forma clara, y la Comisión Europea lo confirma como la interpretación correcta.

Aunque el artículo 6.1 de la DAS no lo especifica, se desprende claramente del resto de la Directiva que debe aplicarse el requisito de “limitar” para evitar la *contaminación*. Esto es necesario para mantener el nivel actual de protección de las aguas subterráneas amparado por la Directiva 80/68/CEE, cuando ésta sea derogada en diciembre de 2013.

A diferencia de la disposición relativa a “prevenir”, “limitar” significa que podrá permitirse un cierto incremento de la concentración por encima de los niveles de referencia de sustancias que pueden estar presente de manera natural, siempre que no cause el deterioro o una tendencia significativa y sostenida al aumento de las concentraciones de contaminantes (artículo 6.1,b) de la DAS). Asimismo, la DMA establece que la entrada no deberá entrañar una tendencia significativa y sostenida al aumento ni causar el deterioro del buen estado químico de las aguas. La DAS define “tendencia significativa y sostenida al aumento” como cualquier aumento significativo desde el punto de vista estadístico y medioambiental de la concentración de un contaminante, grupo de contaminantes o indicador de contaminación en las aguas subterráneas para el que se haya determinado la necesidad de una inversión de la tendencia, de conformidad con el artículo 5 (la guía nº 18 sobre estado y tendencias contiene un desarrollo más elaborado del tema). Los requisitos que establece la DAS de que las entradas no produzcan tendencias significativas al aumento y/o el deterioro del estado garantizan que las aguas subterráneas inalteradas y relativamente no contaminadas seguirán estando protegidas.



¡Atención! Limitar una entrada en aguas subterráneas significa:

Adoptar todas las medidas necesarias para prevenir la contaminación, al objeto de garantizar que:

1. *no se deteriora su estado; y*
2. *no se produce ninguna tendencia significativa y sostenida al aumento de las concentraciones de contaminantes en aguas subterráneas.*

La limitación de las entradas para prevenir la contaminación garantizará el mantenimiento de la concentración de sustancias por debajo del nivel en que pueda causar daños a un receptor o sobrepasar las concentraciones máximas admisibles y/o los niveles de calidad pertinentes de las aguas subterráneas.

Los Estados miembros podrán, bajo determinadas condiciones, eximir de estas medidas algunas entradas, de conformidad con el artículo 6.3) de la DAS. Para permitir dichas excepciones, los gestores de aguas subterráneas locales y las partes interesadas deberán presentar los oportunos argumentos. Los argumentos se describirán con transparencia, y el lugar idóneo para su exposición podrían ser los planes hidrológicos de cuenca (véase apartado 5.3).

A la hora de considerar qué medidas serían necesarias para limitar una entrada (véase la explicación de las medidas en el capítulo 5), también pueden tenerse en cuenta los procesos que producirán una atenuación en la zona no saturada así como en la zona *saturada*. En estos procesos se incluye la fijación de partículas al suelo, la degradación o la dilución, de manera que los receptores no sufran ningún daño ni se produzca una tendencia significativa y sostenida al aumento de la concentración. Deberá tenerse en cuenta asimismo la posibilidad de que la sustancia se transforme en una sustancia peligrosa. Si esto ocurriera, deberá *impedirse* que la sustancia entre en las aguas subterráneas.

3.5 Enfoque basado en el receptor frente al enfoque basado en compartimentos

Algunos Estados miembros difieren en su modo de gestionar la protección de las aguas subterráneas, aún cumpliendo los requisitos de la legislación comunitaria. Uno de los enfoques utilizados es el “basado en el receptor”, cuando los receptores que se tienen en cuenta al valorar si una entrada podría causar contaminación son todos los usos de las aguas subterráneas -los activos, p.ej. las extracciones, así como los pasivos, p.ej. las descargas de las fuentes en ríos y humedales-. Este enfoque es aplicable a aquellas sustancias que deben limitarse en aguas subterráneas. Respecto a las sustancias peligrosas, cuya entrada en las aguas subterráneas deberá evitarse, el receptor son las propias aguas subterráneas.

El enfoque alternativo es el “basado en compartimentos”, es decir cuando el receptor es el “compartimento” de aguas subterráneas en su conjunto[*], cualquiera que sea su utilización, y constituye el objeto de la protección. Este enfoque se aplica por igual, cualesquiera que sean las sustancias que intervengan. Son las propias aguas subterráneas las que hay que proteger de la contaminación.

3.6 Modelo conceptual

Para determinar si se ha producido o se producirá contaminación, es necesario desarrollar un modelo conceptual y conocer todas las relaciones entre fuentes, vías de propagación y receptores dentro de su enclave hidrogeológico más amplio (capítulo 3.6). Las consideraciones fundamentales son:

1. la naturaleza física y química del vertido o de la fuente de contaminación instalación o parte contaminada del subsuelo;
2. las características físicas y químicas del acuífero;
3. los procesos del subsuelo, p.ej. la dilución y degradación, que actúan sobre el contaminante a medida que éste desciende hacia la superficie piezométrica o se desplaza en la zona saturada;
4. el emplazamiento de todos los receptores y sus relaciones con el flujo de aguas subterráneas; y
5. las normas de calidad de las aguas que se aplican a los receptores y que permiten medir el daño, así como los criterios para el ecosistema de las aguas subterráneas.

El modelo conceptual constituye, por consiguiente, la esquematización de los procesos hidrodinámicos, hidroquímicos y biológicos fundamentales que actúan en una masa de agua subterránea. Esta caracterización es fundamental para comprender los procesos físicos, químicos y biológicos básicos que influyen en la calidad de las aguas subterráneas. Puesto que a menudo los contaminantes se desplazan a través de la zona no saturada hasta llegar a las aguas subterráneas, también deben incluirse, en su caso, los procesos que actúan sobre los contaminantes en la zona no saturada.

La esquematización del sistema y la cuantificación del proceso son partes necesarias del modelo conceptual, que permite determinar la calidad de referencia y cualquier variación de de la misma, y constituye una base fiable para futuras decisiones. Con respecto a las entradas directas e indirectas, el modelo conceptual es una pieza fundamental en la valoración básica de los mecanismos de atenuación que determinan el impacto de las entradas y la calidad de las aguas subterráneas.

Existen documentos guía sobre modelos conceptuales en inglés[4] y alemán[5].

---

[*] la acepción de “compartimento” es equivalente a acuífero o a masa.

4 CÓMO EVALUAR LAS ENTRADAS

4.1 Puntos de cumplimiento

Para evaluar si un vertido potencialmente contaminante es permisible, o determinar el nivel de limpieza necesario para el tratamiento de una contaminación histórica, es necesario establecer indicadores de evaluación de cumplimiento (véase recuadro) en uno o varios puntos de cumplimiento.

Los puntos de cumplimiento pueden ser de dos tipos:

1) Un punto teórico en un modelo que permita calcular una concentración de vertidos aceptable o el grado necesario de restauración de un lugar contaminado;

2) Un punto de seguimiento físico -p.ej. un sondeo de observación- que permita evaluar el cumplimiento de un permiso o de un régimen de restauración.

Un punto de cumplimiento puede estar ubicado, bien en el propio receptor, o bien en un punto situado entre el receptor y la fuente de contaminación; esto último podría ser necesario o más deseable por motivos prácticos. Cuando el punto de cumplimiento se sitúa entre el receptor y la fuente en cuestión, los valores de cumplimiento se basan en los efectos previstos de dilución y atenuación/degradación en el receptor “aguas abajo”.

A efectos de esta Guía, se pueden identificar cuatro puntos de cumplimiento (PdC) diferentes:

- PdC 0: situado en la base de la fuente en la zona no saturada, tanto en el caso de fuentes puntuales como de fuentes difusas. La finalidad del PdC 0 es poder evaluar si se produce contaminación, cuáles son los contaminantes y si podrían afectar a las aguas subterráneas;
- PdC 1: se sitúa en el punto más alto de la entrada en las aguas subterráneas -p.ej. en el caso de entradas indirectas, en la supeficie piezométrica, y en el caso de entradas directas, en el PdC 0- y sirve para verificar si los contaminantes alcanzan las aguas subterráneas. Si se trata de una entrada directa, el PdC 0 es el mismo que el PdC 1. Su función es, sin embargo, diferente, puesto que en el PdC 1 se tiene en cuenta principalmente la concentración real en las propias aguas subterráneas, mientras que en el PdC 0 se examinan principalmente las propiedades de la fuente, como se explicaba anteriormente;
- PdC 2: se sitúa “aguas abajo”de la entrada, entre el PdC 1 y el receptor. La finalidad de este punto de cumplimiento es servir de alerta temprana cuando el receptor pueda resultar afectado. También se utiliza durante el proceso de evaluación de riesgo para pronosticar el impacto potencial de la entrada. El PdC 2 puede situarse tanto en el sentido horizontal de dispersión como en el vertical;
- PdC 3: se utiliza para controlar si las aguas subterráneas alcanzan la calidad deseada y para vigilar el impacto en el receptor. Si una evaluación de riesgo indica que el contaminante sobrepasará el valor de cumplimiento en este PdC, es probable que la entrada provoque contaminación. Deberán efectuarse controles para eliminar este impacto o, de lo contrario, no debe permitirse la actividad.

Deben definirse las especificaciones en PdC 0, PdC 1 y/o PdC 2 para evitar que se sobrepasen los valores de cumplimiento en PdC 3.

Valores de cumplimiento y valores límite

Un **valor de cumplimiento** para una sustancia es la concentración y el régimen de cumplimiento asociado que, cuando no sea superado en el punto de cumplimiento, prevendrá la contaminación. ***Se mide en el punto de seguimiento de "prevención/limitación" (PdC 1, 2 ó 3).***

Un valor de cumplimiento sirve así de referencia para impedir que se sobrepase una norma medioambiental en un receptor. Los valores de cumplimiento suelen estar relacionados con la protección de los usos del agua, como el abastecimiento de agua para el consumo humano o el entorno natural de aguas superficiales. No deben, sin embargo, utilizarse automáticamente valores de otros regímenes legislativos -normas de calidad del agua potable o normas de calidad ambiental- sin antes tomar en consideración su pertinencia, en particular cuando el régimen de cumplimiento es diferente. La utilización inadecuada de dichas normas puede derivar en un exceso o en una falta de protección de los recursos hídricos subterráneos.

Los valores de cumplimiento son diferentes de los "valores límite" en cuanto al lugar de establecimiento y aplicación.

Un **valor límite** para una sustancia es la concentración y el régimen de cumplimiento asociado que, no siendo superado en la fuente, prevendrá la emisión inaceptable de un contaminante a las aguas subterráneas. ***Se mide en la fuente, es decir, en el punto de emisión (PdC 0).***

Los valores límite pueden expresarse como concentraciones o como carga contaminante aceptable. Pueden utilizarse como referencia para una autorización o servir como objetivo de recuperación en suelos contaminados.

Ejemplos.

1. Utilización o reutilización de materiales de construcción

Pueden definirse valores límites fijos para la emisión de sustancias procedentes de los materiales en el PdC 0. Estos valores pueden ser establecidos por los órganos competentes de conformidad con el correspondiente procedimiento de aprobación de los materiales de construcción –en caso de que exista como tal- o mediante la correspondiente disposición vinculante de carácter general. Si se ha confirmado en modelos de simulación y con base en experiencias anteriores que los lixiviados nunca producirán la superación de los valores máximos pertinentes -por ejemplo en un zona protegida para abastecimiento de de agua potable-, por lo general no será necesario designar puntos de vigilancia específicos. En caso contrario, los valores de cumplimiento podrán ser definidos en los puntos virtuales PdC 1, PdC 2 y/o PdC3 a fin de efectuar el seguimiento de las entradas y prevenir la contaminación.

2. Utilización de estiércol.

A los agricultores les resulta más práctico controlar los efectos de la utilización de estiércol mediante un seguimiento, por ejemplo, a un metro por debajo del nivel piezométrico (PdC 2). Si las aguas subterráneas descargan directamente en aguas superficiales -p.ej. en acequias- próximas a las tierras de labranza, podrá designarse un PdC 3 en los puntos de descarga en aguas superficiales. Los valores de cumplimiento pueden establecerse en cualquiera de estos PdC.

Respecto de las entradas históricas -p.ej. suelos contaminados o accidentes/derrames/pérdidas- en las que ya se ha producido la contaminación de las aguas subterráneas, incluidas sustancias peligrosas, la evaluación de las entradas debería determinar la necesidad de medidas paliativas adecuadas y su alcance para dicha situación. La ubicación de los puntos de cumplimiento seguirá siendo la misma.

Los PdC reseñados se muestran en la figura 4.

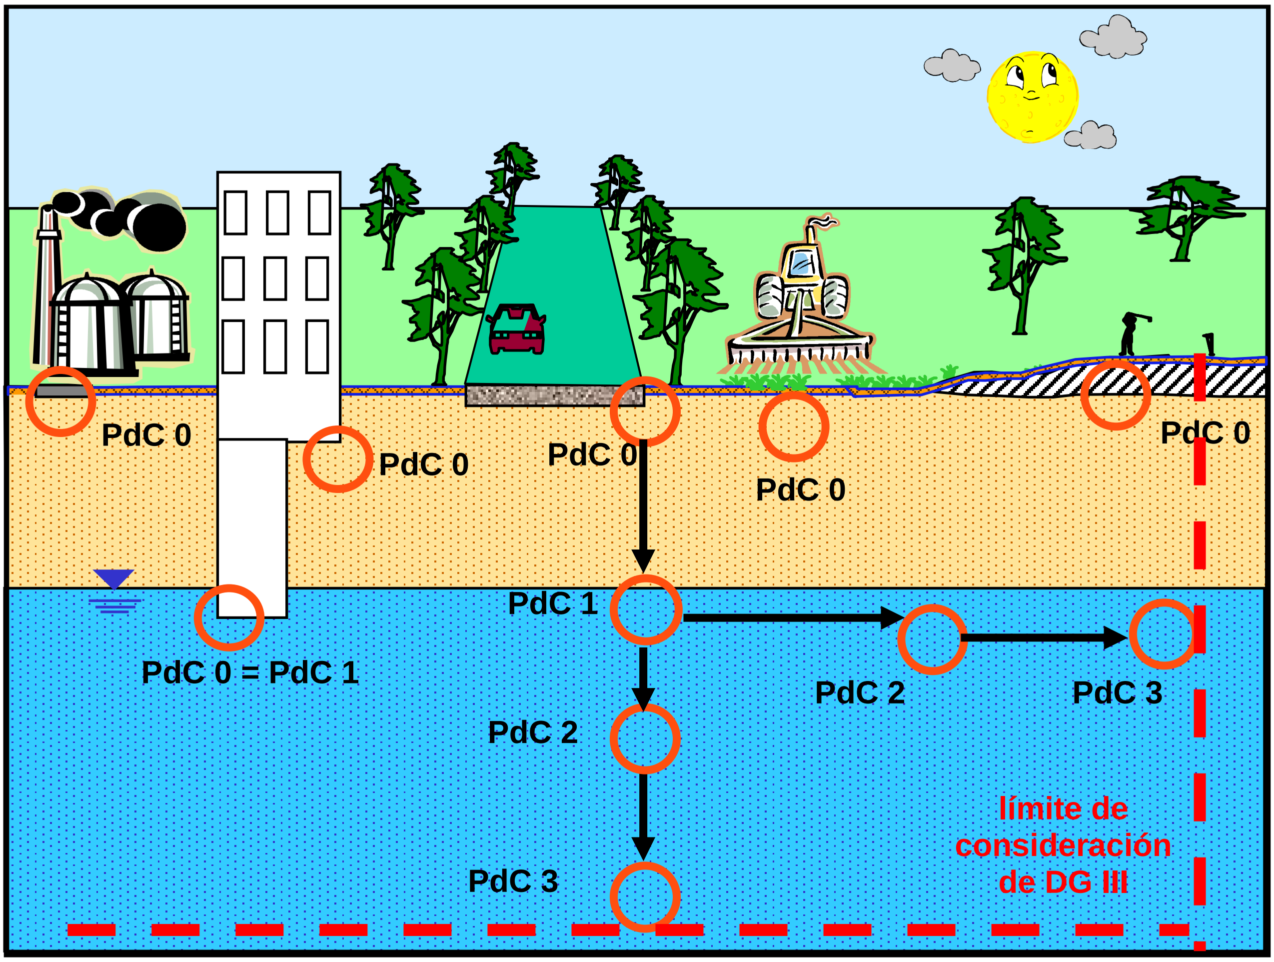

Figura 4: Puntos de cumplimiento (PdC)

Lo que sigue a continuación es un esbozo de las necesidades potenciales de datos para el PdC 0, para lo que se utilizarán los ejemplos de la figura 4. El primer PdC 0 de la izquierda está situado bajo una fábrica. El tipo de datos que podrían ser necesarios son:

- un inventario de las sustancias presentes en el suelo, en bidones, en depósitos, en camiones o en las tuberías, y que podrían llegar hasta el suelo debido a derrames, fugas, accidentes o vertidos previstos;
- sus propiedades: peligrosidad, comportamiento físico-químico -propensión a la degradación, evaporación, etc.-;
- las características de la mezcla total de sustancias y sus reacciones mutuas, -p.ej. la influencia que determina el p^H del suelo, el transporte por carbono orgánico disuelto (COD), la competencia entre sorbción y transporte de diferentes sustancias, etc.; y
- la probabilidad de que dichas sustancias penetren en el suelo -¿superficies selladas? ¿drenaje?-.

Si los cimientos de una edificación alcanzan las aguas subterráneas, la evaluación en un PdC 0 precisará de un inventario de las sustancias presentes en el material de cimentación, sus propiedades y su potencial de migrar desde el material hasta las aguas subterráneas. Cuando los materiales de construcción estén situados en la zona no saturada, las evaluaciones en el PdC 0 tendrán en cuenta asimismo la migración de sustancias desde el material, pero no incluirán la entrada en las aguas subterráneas, puesto que la migración a través de la zona no saturada es un paso que se evalúa en el PdC 1.

En vertederos, depósitos de suelos contaminados, residuos mineros, etc., el PdC 0 debe situarse en la interfaz entre la barrera de protección artificial, si la hubiera, y en el subsuelo.

En el caso de aplicación de sustancias para uso agrícola -plaguicidas, fertilizantes minerales, estiércol-, es prácticamente seguro que se producirá una ligera penetración de estas sustancias en el terreno debido a factores como la estructura abierta del suelo. En consecuencia, el PdC 0 debe situarse a una profundidad determinada, por lo general de un metro, donde puede considerarse que la presencia de las sustancias potencialmente contaminantes es un indicio de su potencial de adentrarse en el acuífero.

El tipo de entrada y las características hidrológicas, físicas y químicas del suelo y subsuelo en cuestión determinarán qué contaminantes cabe prever en la zona de interés, incluidos los productos de degradación.

En el anexo 2 se incluyen otros diagramas del emplazamiento de los PdC en diferentes tipos de acuíferos y en diferentes situaciones.

4.2 Directrices sobre la elección de receptores y puntos de cumplimiento

Las entradas procedentes de actividades presentes o previstas en el futuro o las derivadas de la presencia de suelos históricamente contaminados o derrames/accidentes/pérdidas, etc., deben ser objeto de tratamientos diferentes. En los siguientes apartados se exponen orientaciones al respecto.

4.2.1 Actividades previstas.

Como ya se mencionado anteriormente, deberá evitarse que los vertidos, emisiones y pérdidas que contengan sustancias peligrosas provoquen la entrada de estas sustancias en las aguas subterráneas. El receptor son las propias aguas subterráneas, por lo que todas las propuestas relativas a las sustancias peligrosas deben evaluarse en el PdC 1 (superficie piezométrica).

En lo que respecta a actividades previstas en las que intervienen sustancias no peligrosas, la evaluación deberá garantizar que las sustancias no sobrepasen los niveles aceptables de concentración en las aguas subterráneas, de manera que no se produzca contaminación ni una tendencia significativa y sostenida al aumento. Su cumplimiento debe evaluarse en el PdC 3, dependiendo del receptor; en el PdC 2 se definirán los valores de cumplimiento con arreglo a las características del acuífero, los contaminantes, los procesos en el suelo y las aguas subterráneas, asegurando así el cumplimiento en el PdC 3.

4.2.2 Entradas en lugares históricamente contaminados.

La limpieza de dichos lugares debe enfocarse de tal manera que se prevenga la entrada de cualquier sustancia peligrosa en las aguas subterráneas –PdC 0 y PdC 1-, a menos que sea aplicable alguna de las excepciones descritas en el artículo 6.3,a)-f) o que una evaluación del riesgo y del coste-beneficio demuestre que dicha prevención no es factible.

Cuando ya se haya producido la contaminación de las aguas subterráneas, la necesidad de restauración y su alcance, en lo que respecta a sustancias no peligrosas, vendrán determinados por los receptores que pudieran sufrir o hayan sufrido daños. El principal objetivo de la estrategia de restauración será prevenir que se produzca la contaminación o reducir el riesgo de que ésta se extienda por la expansión del penacho (artículo 5.5). La evaluación deberá efectuarse en PdC 2 y PdC 3.

Una vez emprendida la restauración adecuada, el resultado será, en muchos casos, un punto final estable en el que no se producirán nuevas entradas en aguas subterráneas. Podría, sin embargo, quedar aún un penacho de contaminación, porque a menudo es demasiado costoso o técnicamente no factible limpiar por completo las aguas subterráneas hasta restaurarlas a su estado inalterado. En tales circunstancias, no sería razonable exigir la adopción de medidas complementarias para eliminar por completo la contaminación; además, así lo permiten las excepciones a la prevención o limitación recogidas en el artículo 6.3 de la DAS (véase apartado 5.3). Esta acción requerirá de una justificación que resulte satisfactoria a los órganos competentes. Además, deberá efectuarse una evaluación de tendencias adicional del penacho contaminante remanente.

Las nuevas actividades previstas en lugares de contaminación histórica -p.ej. un depósito de petróleo ubicado sobre suelos contaminados en el pasado debido a fugas en tuberías e instalaciones industriales-, deberían diseñarse y ser objeto de mantenimiento de manera que no se produzca una nueva contaminación, teniendo en cuenta todos los requisitos sobre prevención y limitación reseñados en la DAS. Cualquier nueva entrada autorizada no debería impedir la futura mejora de la calidad de las aguas.

4.2.3 Limitaciones físicas en la ubicación de los puntos de cumplimiento.

Es posible que la decisión de situar un receptor en un punto más alejado de la vía de propagación de las aguas subterráneas del que se describe más arriba, se justifique en un momento dado por factores como los usos actuales y futuros del suelo, la propiedad de la tierra, la topografía o las limitaciones al desarrollo futuro de aguas subterráneas. Evidentemente, la escala es un factor a considerar. La duración de los efectos de un pequeño vertido puntual podría ser considerablemente menor que la de un vertedero o una zona industrial extensa, cuyo impacto podría prolongarse durante muchas décadas. La cautela deberá ser inevitablemente mayor en la elaboración de hipótesis sobre cuestiones como la propiedad de la tierra, en impactos importantes y a largo plazo.

4.3 Evaluación de nuevas actividades

A la hora de evaluar si son aceptables nuevas actividades que podrían originar entradas, es decir si se cumplen los requisitos que establece la DMA, habrá que responder a varias preguntas sobre cada una de las sustancias en cuestión, a saber:

- ¿Está contemplada la actividad en alguna de las excepciones existentes recogidas en el artículo 6 de la DAS o está prevista una excepción, p.ej. si la entrada es tan pequeña que puede descartarse cualquier peligro actual o futuro de deterioro de la calidad de las aguas subterráneas receptoras?
- ¿Es una entrada directa o indirecta?
- ¿Es una sustancia peligrosa o no peligrosa?
- ¿Es posible crear controles suficientes para evitar que la sustancia entre en aguas subterráneas o para limitar su efecto?

El diagrama de flujo de la figura 5 recoge de manera esquemática el procedimiento para efectuar dicha evaluación.

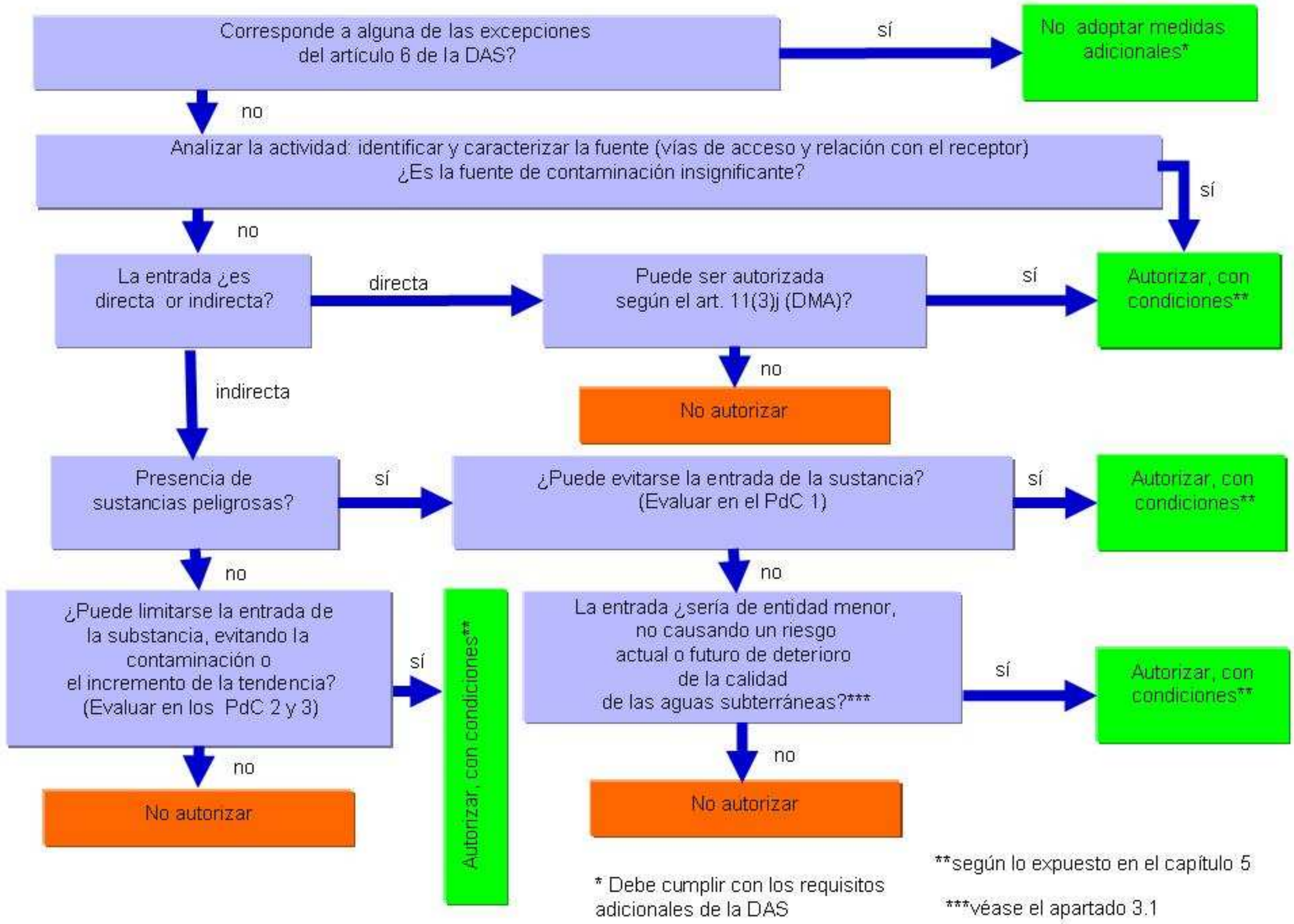

Figura 5: Evaluación de nuevas actividades

4.4 Evaluación de las fuentes de contaminación existentes

Cuando se haya puesto fin a la actividad que provocó la entrada y exista contaminación en las aguas subterráneas, o contaminación en el suelo que pueda contaminar las aguas subterráneas, carece de importancia que la entrada sea directa o indirecta. Habrá que evaluar si la contaminación ya ha alcanzado las aguas subterráneas, y qué nivel de limpieza será necesario. El procedimiento de evaluación se describe de forma esquemática en la figura 6. .

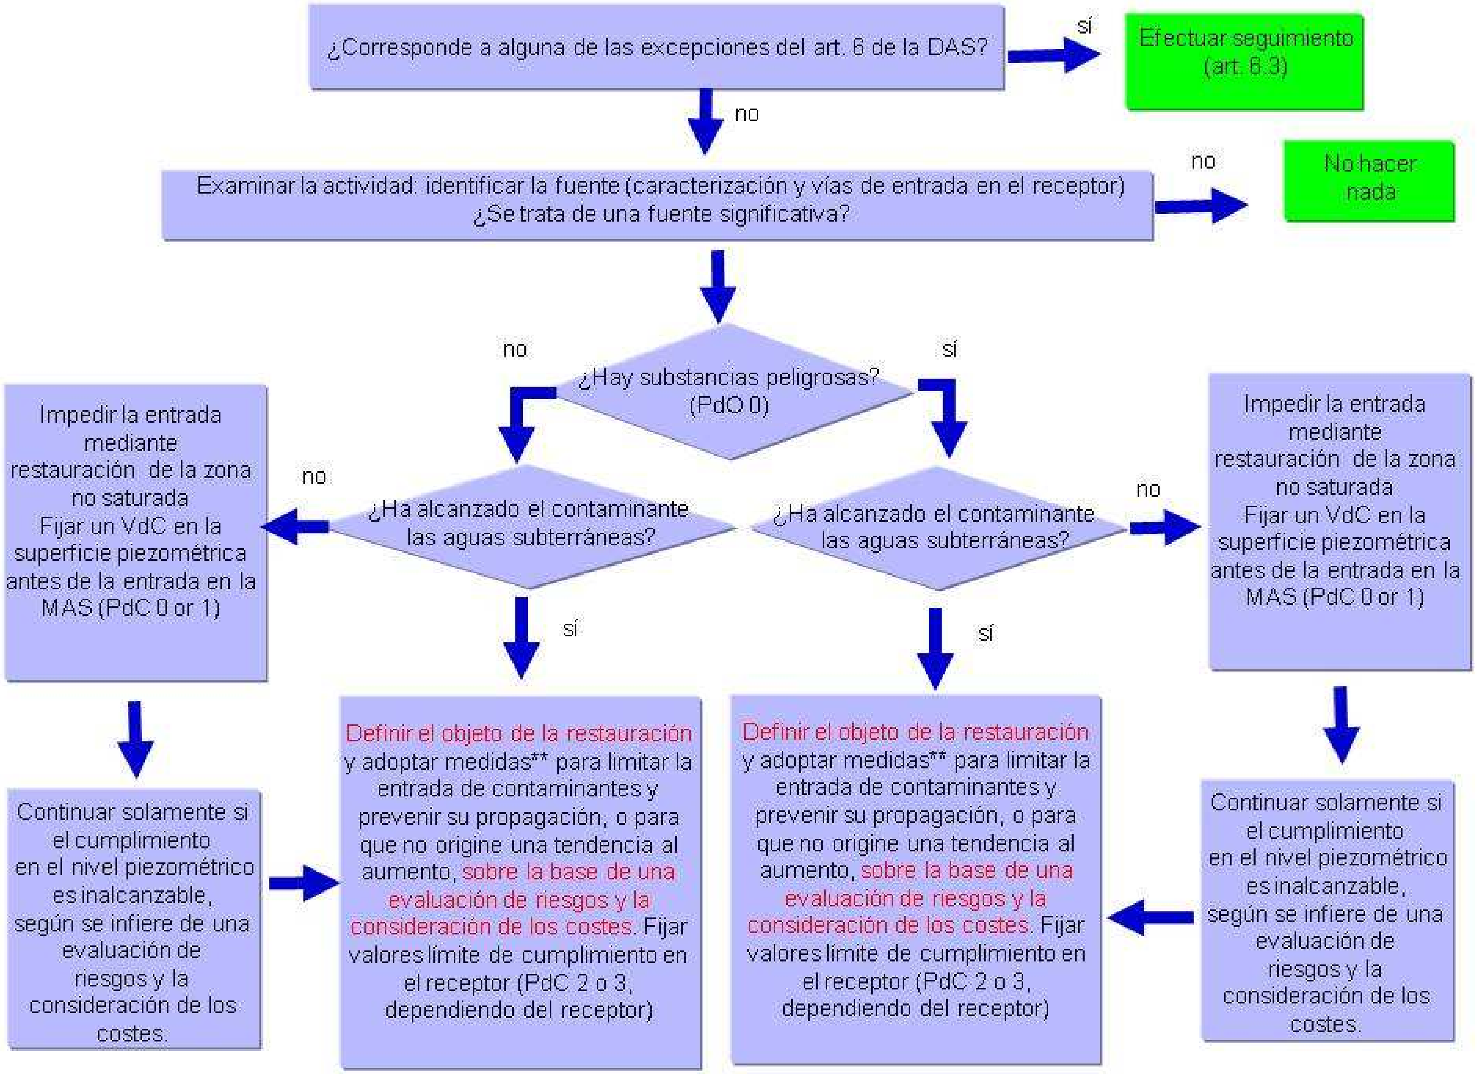

Figura 6: Evaluación de fuentes de contaminación existentes

4.5 Seguimiento preventivo de las entradas

El seguimiento al que se refiere esta guía es complementario al descrito en el documento guía nº 15 sobre seguimiento de las aguas subterráneas[1]. Dicho documento ofrece orientación sobre el establecimiento de los programas de seguimiento de las aguas subterráneas que exige la DMA, y se centra principalmente en las redes de control de vigilancia y de control operativo[6], es decir, el seguimiento estratégico necesario para caracterizar las masas de agua subterránea y determinar su estado.

Las medidas de planificación, ejecución y control para prevenir o limitar las entradas directas o indirectas requieren un modelo conceptual fiable (capítulo 3.6). La elaboración de este modelo puede requerir una estrategia de seguimiento más específica que aquélla necesaria para el seguimiento del estado de las masas de agua, porque deberá aportar información detallada sobre las interacciones del sistema. Estos puntos de seguimiento podrán formar parte más tarde del seguimiento relativo a la prevención y limitación de las entradas.

4.5.1 Finalidad del seguimiento de carácter preventivo

El seguimiento de la calidad de las aguas subterráneas es necesario para evaluar la eficacia de las medidas introducidas para prevenir o limitar las entradas de contaminantes y garantizar que no se ha producido o no se producirá contaminación y/o un deterioro del estado de las aguas subterráneas como resultado de las entradas. Aunque los programas de control de vigilancia y de control operativo van a contribuir de manera significativa a este fin, pueden ser necesarios programas de seguimiento específicos complementarios, que estén enfocados hacia las presiones desde fuentes puntuales y difusas. Este tipo de seguimiento es distinto del seguimiento estratégico -de vigilancia y operativo-, efectuado a escala de masa de agua subterránea. Véase, para más información, la citada guía sobre el seguimiento. El seguimiento de carácter preventivo debe basarse en un modelo o conocimiento conceptual del sistema de las aguas subterráneas correspondiente y en la interrelación de las entradas directas e indirectas con dicho sistema (véanse apartados anteriores).

Con este seguimiento preventivo se pretende principalmente garantizar el cumplimiento acorde con las condiciones del lugar o zona objeto de análisis y con las autorizaciones en los casos de actividades reguladas, o contribuir a la caracterización de impactos específicos en dicho lugar y elaborar y evaluar programas de acción correctora. Debe proporcionar información suficiente para evaluar si las entradas no tienen un impacto inaceptable en las aguas subterráneas. La aceptabilidad de las entradas viene determinada por la naturaleza de la sustancia, el tipo de entrada y si produce contaminación, con arreglo a la definición de la DMA, tal como se ha explicado en apartados anteriores.

4.5.2 Diseño de la red de seguimiento preventivo

En muchos casos, la necesidad de un seguimiento preventivo y su alcance vendrán determinados por la normativa vigente en materia de autorizaciones y medidas de recuperación de suelos contaminados. A diferencia del seguimiento estratégico a gran escala, este tipo de seguimiento suele situarse en un área reducida de la masa de agua subterránea. El seguimiento preventivo

---

- [6]Una **red de control de vigilancia** para: a) complementar y validar el procedimiento de evaluación de impacto; b) facilitar información para su utilización en la evaluación de las tendencias prolongadas como consecuencia de modificaciones de las condiciones naturales y de la actividad antropogénica, y c) determinar, conjuntamente con la evaluación de riesgo, si es necesario un seguimiento operativo. (Véase asimismo la guía de seguimiento de las aguas subterráneas, capítulo 2).
- Una **red de control operativo** para: a) determinar el estado químico de todas las masas o grupos de masas de agua subterránea respecto de las cuales se haya establecido riesgo; y b) determinar la presencia de cualquier tendencia prolongada al aumento de la concentración de cualquier contaminante. (Véase asimismo la guía de seguimiento de las aguas subterráneas, capítulo 2).
- **Seguimiento para prevenir y limitar:** su principal finalidad es garantizar el cumplimiento de las condiciones en el lugar y de las autorizaciones en el caso de actividades reguladas o de una investigación específica al lugar, es decir un control del cumplimiento, o para caracterizar los impactos específicos en el lugar y diseñar y evaluar programas de acción correctora, es decir, un control de investigación. (Véase asimismo la guía de seguimiento de las aguas subterráneas, capítulo 6).

siempre requiere una planificación caso por caso, que determine los parámetros, la frecuencia y la ubicación de los puntos de seguimiento.

A la hora de diseñar programas de seguimiento preventivo deberán tenerse en cuenta los siguientes aspectos:

- Seguimiento de una concentración cero (seguimiento aguas arriba y/o de referencia): Podría ser necesario informar sobre la situación inalterada/de referencia en el subsuelo antes de emprender una nueva actividad o aguas arriba de una fuente de contaminación existente;
- Los intervalos del seguimiento (frecuencia de muestreos) dependerán de evolución de los contaminantes conocidos –condiciones de flujo y transporte- y de sus productos de degradación;
- Las características técnicas de la construcción de las estaciones de seguimiento, y la profundidad a la que se efectúa el seguimiento en cada una, dependerán de la naturaleza de la entrada -p.ej. LNAPL/DNAPL[7]- y de las fluctuaciones estacionales del nivel del agua subterránea;
- Los métodos de muestreo, la conservación de las muestras y el método de análisis dependerán de la naturaleza de la entrada y de la concentración de contaminantes prevista;
- Los parámetros objeto del seguimiento en cada estación servirán para identificar el tipo de contaminante(s) y su impacto previsto. Podrían utilizarse posibles parámetros indicadores -oxidación-reducción, p^H, conductividad eléctrica, temperatura, sales disueltas- para simplificar las tareas de seguimiento;
- El coste-beneficio derivado de la comparación entre el número de estaciones de seguimiento y el nivel de información obtenido;

La configuración de la red de seguimiento va a depender de la definición de los puntos de cumplimiento que, a su vez, están condicionados en gran medida por las características de la masa de agua subterránea descritas en el modelo conceptual (capítulo 3.5) y por los requisitos de carácter normativo.

5 MEDIDAS Y EXCEPCIONES PARA PREVENIR O LIMITAR LAS ENTRADAS EN AGUAS SUBTERRÁNEAS

Este apartado tiene por objeto explicar los requisitos necesarios para que puedan adoptarse las medidas pertinentes para alcanzar los objetivos de "prevenir o limitar" las entradas en las aguas subterráneas previstos en la DMA y la DAS. Se describen asimismo las diferencias que existen entre estos nuevos requisitos y el sistema que establece la directiva en vigor relativa a las aguas subterráneas (80/68/CEE).

La Directiva 80/68/CEE será sustituida por la DMA en 2013, y el sistema que establece la primera se mantendrá y será reforzado en el marco de la DAS. El artículo 11 de la DMA establece que a más tardar en 2009 se establecerán programas de medidas, y que todas las medidas estarán operativas a más tardar en diciembre de 2012.

Esto supone que los permisos/licencias/autorizaciones concedidos deberán ajustarse a los requisitos que establece la DMA a más tardar el 22 de diciembre de 2012. Para poder lograrlo, será necesario un período de revisión de los permisos existentes a fin de garantizar que todas las medidas de prevención o limitación se ajusten a la DMA a más tardar el 22 de diciembre de 2012 y, por consiguiente, estén en conformidad asimismo con el nuevo sistema que establece la DAS antes de diciembre de 2013, fecha en que la directiva 80/68/CEE será derogada.

De conformidad con el artículo 11 de la directiva 80/68/CEE, "Las autorizaciones mencionadas en los artículos 4 y 5 sólo se concederán por un período limitado; las mismas serán reexaminadas al menos cada cuatro años. Se podrán prorrogar, modificar o revocar." Por consiguiente, a partir de

[7] LNAPL: líquido ligero de fase no acuosa; DNAPL: líquido denso de fase no acuosa

2009 este proceso de revisión de las autorizaciones existentes debe tener en cuenta el nuevo sistema de las directivas DMA y DAS, de manera que las autorizaciones que se renueven se ajusten plenamente al nuevo sistema a partir del 22 de diciembre de 2012.

De conformidad con el artículo 7 de la DAS, los nuevos permisos/licencias/autorizaciones que se concedan a partir del 16 de enero de 2009, al amparo de los artículos 4 y 5 de la directiva 80/86/CEE, deben tener en cuenta los requisitos que establece la DAS en sus artículos 3, 4 y 5.

Cabe reseñar por ello que, como resultado del paso del antiguo al nuevo sistema, podría ser necesario modificar las condiciones para la concesión de los permisos y/o los procedimientos de gestión. Por consiguiente, deberá actuarse durante este período de transición de una manera práctica y eficaz.

Resulta así evidente que deberán aplicarse los requisitos que establece la DMA y los sistemas de “prevenir o limitar” que establece la DAS antes de la derogación de la Directiva 80/68/CEE.

5.1 “Medidas básicas” que estipula la DMA

El artículo 4.1,b),i) de la DMA establece que “los Estados miembros habrán de aplicar las medidas necesarias para evitar o limitar la entrada de contaminantes en las aguas subterráneas”. El artículo 11 de la DMA establece que los Estados miembros velarán por que se establezca un programa de medidas con el fin de alcanzar los objetivos establecidos en el artículo 4, incluidos los objetivos de evitar o limitar las entradas en aguas subterráneas.

Se entenderá por medidas aquellos procesos y controles que deberán implantarse para alcanzar los objetivos medioambientales fijados para las masas de agua, incluida la prevención o limitación de las entradas de contaminantes en aguas subterráneas. En este apartado se pretende describir e interpretar los requisitos mínimos de las “medidas básicas” establecidas en el artículo 11.3, en lo que se refiere a evitar o limitar las entradas. Estas “medidas básicas” son las medidas mínimas que deberán incluirse en el programa de medidas en el marco de los planes hidrológicos de cuenca. Existen asimismo “medidas complementarias” que podrán adoptarse si se consideran necesario, pero este documento no trata sobre ellas.

Los apartados pertinentes son los siguientes (las letras de los apartados corresponden a las del artículo 11.3 de la DMA):

a) *las medidas necesarias para cumplir la normativa comunitaria sobre protección de las aguas, incluidas las medidas exigidas en virtud de los actos legislativos especificados en el artículo 10 y en la parte A del anexo VI;*

En el preámbulo de la DMA se hace referencia a un enfoque combinado en el considerando (40): “En relación con la prevención y el control de la contaminación, la política comunitaria de aguas debe basarse en un enfoque combinado a partir del control de la contaminación en la fuente mediante la fijación de valores límite de emisión y de normas de calidad medioambiental.”

El artículo 2.36) especifica que el “planteamiento combinado” significa el control de vertidos y emisiones en aguas superficiales de acuerdo con el enfoque expuesto en el artículo 10”. Este artículo 10 establece que los Estados miembros velarán por la aplicación de la legislación vigente para garantizar un planteamiento combinado para controlar las fuentes puntuales y difusas que pudieran originar vertidos en aguas superficiales. Esto debe lograrse mediante la creación de controles de emisión basados en las mejores técnicas disponibles, fijando valores límite de emisión pertinentes y, en el caso de impactos derivados de entradas difusas, siguiendo la mejor práctica medioambiental expuesta en la legislación comunitaria pertinente. Se incluyen aquí la directiva PCIC, relativa a la prevención y al control integrados de la contaminación, la directiva relativa al tratamiento de aguas residuales urbanas y la directiva relativa a los nitratos, aunque sin restringirse a las mismas.

El artículo 10 no hace referencia directa a las entradas en aguas subterráneas, pero sí a la aplicación de las directivas en vigor para reducir y/o eliminar los vertidos en aguas superficiales, lo que podrá suponer también en el control indirecto de las entradas en aguas subterráneas.

La parte A del anexo VI enumera las directivas cuyos requisitos deberán incluirse en los programas de medidas y que, por consiguiente, son complementarias para lograr los objetivos que establece la DMA.

Las principales directivas pertinentes para evitar o limitar las entradas de contaminantes en aguas subterráneas recogidas en el anexo VI son:

- La Directiva relativa a la comercialización de productos fitosanitarios, que establece un sistema de aprobación del uso de plaguicidas. En lo que respecta a la consideración de los efectos en aguas subterráneas, uno de los principios uniformes para la evaluación de los productos (anexo VI de la Directiva 91/414/CEE que es la Directiva 97/57/CEE) establece que debe procurarse que en las aguas subterráneas no se sobrepase la norma sobre agua potable de 0,1 mg/L de cualquier plaguicida, reproducida de la Directiva 98/83/CE. Mediante la aplicación de este principio, cada vez que se aprueben nuevos plaguicidas, se protegen, en cierto modo, las aguas subterráneas. Sin embargo, de la experiencia acumulada en toda Europa se desprende que, a veces, los plaguicidas aprobados penetran en el terreno hasta alcanzar las aguas subterráneas, incluso cuando se ha aplicado la mejor práctica, por lo que se precisaría de medidas adicionales para garantizar que los plaguicidas no llegan a las aguas subterráneas. Estas medidas podrían ser aquéllas expuestas en la parte restante del artículo 11.3, incluida la autorización previa de la utilización de los productos (véase la definición de los productos en el artículo 11.3,g) de la Directiva relativa a la comercialización de productos fitosanitarios);
- La Directiva relativa a los nitratos, que contiene disposiciones sobre la designación de zonas vulnerables y sobre la acción de los Estados miembros cuando la concentración de nitrato que contienen las aguas subterráneas sobrepasa o es probable que sobrepase 50 mg/L. Estos planes de acción se refieren únicamente al control de nitratos procedentes de actividades agrícolas y, por consiguiente, serán necesarias medidas complementarias para corregir las entradas procedentes de fuentes no agrarias;
- La Directiva relativa al tratamiento de aguas residuales urbanas, que indirectamente protege las aguas subterráneas al establecer que los núcleos urbanos de más de 2000 viviendas deberán estar conectados a una red de alcantarillado, en lugar de verter las aguas residuales al terreno o a las aguas superficiales.

d) *las medidas para cumplir lo dispuesto en el artículo 7, incluyendo las destinadas a preservar la calidad del agua con el fin de reducir el nivel del tratamiento de purificación necesario para la producción de agua potable;*

La interpretación de los requisitos del artículo 7 se puede encontrar en el documento guía nº 16 sobre zonas protegidas para la producción de agua potable[2]. Para cumplir con lo dispuesto en el artículo 7, lo más adecuado será probablemente que las medidas se centren en los “perímetros de protección” en el entorno de los puntos de captación de agua potable antes del tratamiento. Los controles podrán incluir restricciones o prohibiciones de la utilización de determinadas sustancias peligrosas en estas zonas o restringir la explotación y utilización del suelo a las actividades de bajo riesgo que los órganos competentes consideren apropiadas.

f) *medidas de control, con inclusión de un requisito de autorización previa, de la recarga artificial o el aumento de masas de agua subterránea. El agua que se utilice podrá obtenerse de cualquier agua superficial o subterránea, siempre que el uso de la fuente no comprometa la consecución de los objetivos medioambientales establecidos para la fuente o la masa de agua recargada o aumentada. Dichos controles se revisarán periódicamente y, cuando proceda, se actualizarán.*

Es un requisito que los Estados miembros dispongan de un sistema de concesión de autorizaciones o permisos para los sistemas de recarga artificial o aumento de acuíferos. Se trata de un control y una disposición similares a los que ya existen en la Directiva 80/68/CEE.

g) *para los vertidos de fuente puntual que puedan causar contaminación, un requisito de regulación previa, como la prohibición de la entrada de contaminantes en el agua, o el requisito de autorización previa, o de registro basado en normas generales de carácter vinculante, que establezca controles de emisión para los contaminantes de que se trate, incluyendo controles con arreglo a lo dispuesto en los artículos 10 y 16. Dichos controles se revisarán periódicamente y, cuando proceda, se actualizarán.*

Éste es un requisito para regular las entradas desde fuentes puntuales, una regulación que puede adoptar la forma de:

- prohibiciones, si la evaluación del impacto de la fuente puntual demuestra que, por ejemplo, no puede controlarse adecuadamente el riesgo de entrada de sustancias peligrosas en aguas subterráneas;
- autorizaciones, para garantizar que existen medidas preventivas de carácter técnico para cumplir los objetivos de “evitar o limitar”; o
- elaboración de normas generales de carácter vinculante, que cubran las actividades consideradas de bajo riesgo para las aguas subterráneas.

El artículo 11.3,g) no contiene ninguna restricción sobre los tipos de actividades o las sustancias que cubre esta medida. Este artículo ofrece mayor protección que el sistema de investigación y autorización previas que establece la Directiva 80/68/CEE, en la medida en que la DMA amplía estos controles a todos los contaminantes, y no se limita a las sustancias que figuran en las listas I y II de la Directiva 80/68/CEE. Por consiguiente, este requisito abarca todos los sistemas de autorización existentes y podría ser necesario desarrollar sistemas complementarios para controlar las sustancias adicionales que incluye la DMA. Desaparece el requisito de la Directiva 80/68/CEE de conceder autorizaciones únicamente por un plazo limitado, y aunque se podrá revisar la eficacia de estas autorizaciones, desaparece el calendario fijo para efectuar dichas revisiones. Lógicamente, la revisión deberá hacerse al menos una vez cada seis años en el marco de la revisión de los planes hidrológicos de cuenca, porque los programas de medidas están contenidos en dichos planes.

Además de incluir más sustancias, la DMA también establece un planteamiento más flexible que el formulado por la Directiva 80/68/CEE. Otorga a los Estados miembros la capacidad de crear normas y códigos de buenas prácticas reconocidos por la ley aplicables a sectores industriales de bajo riesgo. Se dispone así de la facultad discrecional para utilizarlos como alternativa a la autorización de actividades individuales.

Los artículos 10 y 16 de la DMA, a los que hace referencia el artículo 11.3,g), tienen como principal objetivo la protección de las aguas superficiales.

h) *para fuentes difusas que puedan generar contaminación, medidas para evitar o controlar la entrada de contaminantes; los controles podrán consistir en un requisito de reglamentación previa, como la prohibición de la entrada de contaminantes en el agua, el requisito de autorización previa o el de registro basado en normas generales de carácter vinculante, cuando este requisito no esté establecido de otra forma en la legislación comunitaria. Dichos controles se revisarán periódicamente y, cuando proceda, se actualizarán.*

Se trata de un requisito similar al del párrafo g), aunque es aplicable a entradas difusas que no sean fuentes puntuales. Esta medida de protección es más específica y clara que las que establece la Directiva 80/68/CEE, que se refiere a un sistema de autorización previa para las acciones de “eliminación o de depósito con fines de eliminación dichas sustancias”, lo cual resulta ineficaz en el caso de contaminación difusa. No especifica cuáles son las medidas adecuadas que deben adoptarse para evitar o limitar los vertidos indirectos de las sustancias enumeradas procedentes de otras actividades.

Las medidas adoptadas en este caso para controlar adecuadamente las entradas difusas serán aplicables sobre un área más amplia y a mayor escala que aquéllas para fuentes puntuales. Las medidas más eficaces son probablemente medidas de control tales como normas generales de carácter vinculante y códigos de buena práctica reconocidos por ley.

El artículo 11.3,j) contiene una prohibición específica relativa a las aguas subterráneas, así como excepciones a esta disposición, cuestiones que se tratan en el apartado siguiente.

5.2 Prohibición de vertidos directos en aguas subterráneas

La DMA incluye una prohibición específica relativa a las entradas en las aguas subterráneas. La medida básica contenida en el artículo 11.3,j) es la prohibición de todos los vertidos directos de contaminantes en las aguas subterráneas. Difiere de la Directiva 80/60/CEE, que exige la prohibición de todos los vertidos directos de las sustancias de la lista I, es decir, solamente las sustancias más peligrosas.

Esto significa que la DMA es más estricta que el sistema actualmente en vigor porque, en principio, dicha prohibición incluirá en el futuro todos los vertidos directos. La consecuencia es que los Estados miembros deberán garantizar, mediante un proceso de revisión, que las prácticas existentes se ajustan a esta nueva exigencia.

La DAS no establece por escrito ninguna prohibición similar a las “entradas”. Como ha quedado dicho en el presente documento, el término “entradas” comprende todos los contaminantes que entran en las aguas subterráneas, y no se limita a las eliminaciones deliberadas. Por ello se considera que la prohibición que establece el artículo 11.3,j) de la DMA debe ser aplicable a todas las entradas directas en aguas subterráneas.

El artículo 11.3,j) de la DMA contiene asimismo una serie de excepciones/disposiciones relativas a esta prohibición sobre las que trata el apartado siguiente. La DMA no establece ninguna prohibición específica relativa a las *entradas indirectas*. La DAS, sin embargo, prohíbe mediante su cláusula de prevención en el artículo 6.1,a) y sin perjuicio de las excepciones, todas las entradas, directas o indirectas, de sustancias que las autoridades competentes consideren peligrosas para las aguas subterráneas, mediante la aplicación de la cláusula de prevención del artículo 6.1a), sujeta a excepciones.

5.3 Excepciones

Salvo las disposiciones relativas a los vertidos directos, la DMA no contiene ninguna excepción explícita a la exigencia de evitar o limitar las entradas de contaminantes en las aguas subterráneas. Sin embargo, la DAS incluye excepciones, recogidas en su artículo 6.3.

Las excepciones que figuran en la DAS sustituirán a aquellas que recoge actualmente la Directiva 80/68/CEE. En la tabla que sigue se hace una comparación de las excepciones en ambas directivas. La DAS contiene más excepciones que la Directiva 80/68/CEE. La única excepción de la Directiva 80/68/CEE que se mantiene es la denominada disposición *de minimis* (letra b) en la tabla A). Debe reconocerse que las excepciones que establece la Directiva 80/68/CEE son excepciones a la propia directiva. Las excepciones presentadas en la DAS son excepciones solamente al apartado 1 del artículo 6, es decir a las exigencias de “prevenir o limitar”, y no a la directiva en su conjunto, cuyo alcance es mucho mayor que el de la Directiva 80/68/CEE.

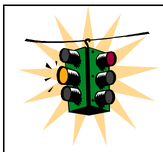
Tabla A: Excepciones incluidas en la DAS(2006) y en la Directiva 80/68/CEE

DAS - Artículo 6.3	**Directiva 80/68/CEE – Artículo 2**
Las entradas de contaminantes que: (a) sean resultado de vertidos directos autorizados de conformidad con la letra j) del apartado 3 del artículo 11 de la Directiva 2000/60/CE; (b) según las autoridades competentes, sean tan reducidas en cantidad y concentración, que excluyan todo peligro actual o futuro de deterioro de la calidad del agua subterránea receptora; (c) sean consecuencia de accidentes o circunstancias excepcionales de origen natural imposibles de prever, evitar o paliar; (d) sean resultado de una recarga artificial o aumento autorizados de	(a) los vertidos de efluentes domésticos que provengan de viviendas aisladas, no conectadas a una red de alcantarillado y situadas fuera de las zonas de protección de captación de agua destinada al consumo humano; (b) los vertidos respecto de los cuales la autoridad competente del Estado miembro afectado hubiere comprobado que contienen sustancias de las listas I o II en cantidad y concentración lo suficientemente pequeñas como para excluir cualquier riesgo de deterioro,

DAS - Artículo 6.3	Directiva 80/68/CEE – Artículo 2
conformidad con la letra f) del apartado 3 del artículo 11 de la Directiva 2000/60/CE;	presente o futuro, de la calidad de las aguas subterráneas receptoras;
(e) según las autoridades competentes, no sean técnicamente viables para prevenir o limitar sin la utilización de: (i) medidas que aumentarían los riesgos para la salud humana o la calidad del medio ambiente en su conjunto, o (ii) medidas con un coste desproporcionado para eliminar cantidades de contaminantes o para controlar su infiltración en suelos o subsuelos contaminados; o	(c) los vertidos de materias que contengan sustancias radiactivas.
(f) sean el resultado de actuaciones en las aguas superficiales con el objeto, entre otros, de paliar los efectos de inundaciones y sequías, así como para la gestión de las aguas y de los cursos de agua, incluidos los de ámbito internacional. Dichas actividades, que incluirán por ejemplo el corte, el dragado, el traslado y el almacenamiento de los sedimentos presentes en las aguas superficiales, se llevarán a cabo con arreglo a normas generales vinculantes, y, cuando sean aplicables, con permisos y autorizaciones concedidos sobre la base de las normas que hayan desarrollado al respecto los Estados miembros, siempre que esas entradas no pongan en peligro la consecución de los objetivos medioambientales que se hayan fijado para las masas de agua correspondientes a tenor de la letra b) del apartado 1 del artículo 4, de la Directiva 2000/60/CE.	

5.4 Ejemplos de excepciones

A continuación se citan textualmente las excepciones, seguidas de una explicación y de algunos ejemplos.



¡Atención!

Los ejemplos que figuran a continuación no constituyen una lista exhaustiva ni tampoco deben entenderse como los casos de excepciones más comunes.

El artículo 11.3,j) de la DMA, que comprende la prohibición general de vertidos directos, contiene asimismo una serie de excepciones en las que, en determinadas circunstancias, se permitirán los vertidos directos, siempre que hayan sido autorizados con condiciones o que se realicen con arreglo a las normas generales vinculantes desarrolladas para un determinado sector de actividad o industrial. Estas autorizaciones deben garantizar que no ponen en peligro la consecución de los objetivos medioambientales fijados para la masa de agua subterránea. Estas disposiciones son las siguientes:

1. *Los Estados miembros podrán autorizar la reinyección en el mismo acuífero de aguas utilizadas con fines geotérmicos.*

También podrán autorizar, indicando las condiciones para ello:

2. *la inyección de aguas que contengan sustancias resultantes de las operaciones de exploración y extracción de hidrocarburos o actividades mineras, así como la inyección de aguas por razones técnicas en formaciones geológicas de las que se hayan extraído hidrocarburos u otras sustancias, o en formaciones geológicas que por razones naturales no sean apropiadas, de manera permanente, para otros fines. Tales inyecciones no contendrán sustancias distintas de las resultantes de las operaciones antedichas,*
3. *la reinyección de aguas subterráneas bombeadas procedentes de minas y canteras o asociadas a la construcción o al mantenimiento de obras de ingeniería civil,*

4. *la inyección de gas natural o de gas licuado de petróleo (GLP) con fines de almacenamiento en formaciones geológicas que por razones naturales no sean apropiadas, de manera permanente, para otros fines,*
5. *la inyección de gas natural o de gas licuado de petróleo (GLP) con fines de almacenamiento en otras formaciones geológicas en las que haya necesidad imperiosa de garantizar el abastecimiento de gas y cuando la inyección se haga de manera que se evite cualquier riesgo actual o futuro de deterioro de la calidad de todas las aguas subterráneas receptoras.*
6. *obras de construcción, ingeniería civil y edificación y actividades similares sobre o dentro del terreno que esté en contacto con aguas subterráneas. A dicho efecto, los Estados miembros podrán determinar que dichas actividades se traten como si hubieran sido autorizadas siempre y cuando se lleven a cabo de conformidad con las normas generales de carácter vinculante establecidas por los Estados miembros relativas a dichas actividades,*
7. *vertidos de pequeñas cantidades de sustancias con fines científicos para la caracterización, protección o restauración de las masas de agua limitadas a la cantidad estrictamente necesaria para los fines en cuestión.*

Aunque la mayoría de las actividades descritas en los puntos 1 a 7 son autoexplicativas, hay descripciones generales, como “inyección de aguas por razones técnicas...”, (véase el punto 2 precedente), que podrían precisar de una explicación. Un ejemplo concreto es la inyección de salmuera, resultante de la desalación de aguas subterráneas salobres mediante la filtración a través de una membrana. La salmuera se reinyecta en un acuífero salino de mayor profundidad no utilizado. Situando debidamente los puntos de extracción y de reinyección puede expandirse la porción de una masa de agua que contiene agua dulce y agua salobre que puede ser utilizada de manera sostenible para la producción de agua potable. Mediante la filtración a través de una membrana sin sustancias adicionales, la actividad cumple la condición que establece la disposición 2): “Tales inyecciones no contendrán sustancias distintas de las resultantes de las operaciones antedichas”.

La excepción 6) incluye la condición previa de que las actividades se lleven a cabo de conformidad con las normas generales de carácter vinculante establecidas por los Estados miembros. Una de las finalidades de estas normas será la de prevenir la utilización de materiales de construcción y auxiliares o técnicas que causen filtraciones inaceptables de sustancias contaminantes en las aguas subterráneas. A pesar de que la excepción se refiere a “actividades”, es evidente que incluye también la *presencia* de materiales de construcción autorizados que entren en contacto con las aguas subterráneas una vez finalizada la obra.

Los Estados miembros podrán eximir, de conformidad con el artículo 6.3 de la DAS, las entradas con determinadas características de los requisitos de “prevenir y limitar”, sin perjuicio de otros requisitos más estrictos recogidos en otros actos de la legislación comunitaria. Las entradas exentas se enumeran en las letras a) a f).

a) las entradas que sean *el resultado de vertidos directos autorizados de conformidad con la letra j) del apartado 3 del artículo 11 de la Directiva 2000/60/CE;*

Esta disposición garantiza la coherencia de la DAS con el artículo 11.3,j) de la DMA que se describe más arriba.

b) las entradas que *las autoridades competentes consideren que son tan pequeñas en cantidad y concentración que no suponen ningún peligro actual o futuro de deterioro de la calidad de las aguas subterráneas receptoras;*

La Directiva 80/68/CEE incluía una disposición *de minimis* similar. Reconoce que existen pequeñas entradas respecto a las cuales las medidas de prevención o limitación no son razonables porque el efecto de dichas entradas en la calidad de las aguas subterráneas sería poco significativo o nulo si no se controlara la actividad. A pesar de que la excepción relativa a “los vertidos de efluentes domésticos que provengan de las viviendas aisladas, no conectadas a una red de alcantarillado” que establece la Directiva 80/68/CEE no está contemplada en la DAS, el caso de una vivienda aislada o un asentamiento muy pequeño cuyo efecto sea poco significativo seguirá estando exento de conformidad con la disposición *de minimis*.

La disposición *de minimis* podrá aplicarse asimismo a las entradas residuales de poca importancia procedentes de vertederos. Los vertederos han de cumplir ciertos requisitos encaminados a minimizar las filtraciones. Con el paso del tiempo podrá producirse un pequeño flujo de contaminantes hasta alcanzar las aguas subterráneas, pero si el impacto se evalúa como poco significativo -p.ej. mediante modelos de simulación- y se confirma mediante un seguimiento, será aplicable la excepción.

En general, la excepción se refiere también a entradas residuales de menor relevancia procedentes de materiales de construcción que hayan sido autorizadas por la autoridad competente para determinadas aplicaciones. Por lo general resulta materialmente imposible prevenir por completo los flujos de carácter difuso procedentes de los materiales de construcción en las aguas subterráneas circundantes. Entre los componentes del material puede haber sustancias consideradas peligrosas. No obstante, la autorización del material de construcción supone que las filtraciones previstas “sean tan reducidas en cantidad y concentración, que excluyan todo peligro actual o futuro de deterioro de la calidad del agua subterránea receptora”. Autorizar la utilización de tales materiales es también la finalidad de la excepción 6 con arreglo al artículo 11.3,j) de la DMA, mencionada más arriba.

c) las entradas que *sean consecuencia de accidentes o circunstancias excepcionales de origen natural imposibles de prever, evitar o paliar;*

El texto no especifica si se refiere a accidentes de origen natural o accidentes en general -p.ej. los accidentes durante el transporte terrestre de sustancias químicas-. Es razonable, sin embargo, suponer que la excepción no sea aplicable a los accidentes que causen contaminación que hubieran podido evitarse mediante la eliminación con un coste razonable.

Podrían considerarse como circunstancias excepcionales de origen natural inundaciones, sequías, incendios forestales, terremotos y erupciones volcánicas. El alcance del requisito de “prevenir y limitar” excluye, evidentemente, los efectos naturales que se producen con independencia de la actividad humana. No obstante, si pudieran preverse dichas circunstancias -p.ej. inundaciones o terremotos-, deberían adoptarse medidas preventivas, a menos que los efectos sean de poca importancia o que dichas medidas no sean viables por los motivos expuestos en las excepciones b) y e).

Las inundaciones pueden provocar la contaminación de las aguas subterráneas, en particular cuando afectan a instalaciones, como vertederos o lugares de almacenamiento y manipulación de sustancias químicas. El efecto directo es la contaminación de las aguas superficiales, pero la contaminación puede llegar con el tiempo hasta las aguas subterráneas mediante la filtración de las aguas superficiales en el suelo o la deposición de suelo contaminado, desde donde los contaminantes pueden filtrarse hasta las aguas subterráneas. La aplicabilidad o no de la excepción c) dependerá de la valoración que se haga respecto a si razonablemente podrían haberse adoptado medidas para evitar estos accidentes o paliar sus consecuencias. En principio, los accidentes deben prevenirse mediante construcciones seguras o restricciones en zonas inundables o, en caso de inundaciones, mediante sistemas de alerta y protocolos. La aplicación de tales medidas debe formar parte del programa de medidas al que se hace referencia en el artículo 6.1 de la DAS y en el artículo 11 de la DMA. Un razonamiento similar es aplicable a los accidentes de gran alcance, como los que pueden causar los terremotos.

d) las entradas que *sean resultado de una recarga artificial o aumento autorizados de conformidad con la letra f) del apartado 3 del artículo 11 de la Directiva 2000/60/CE;*

El artículo 6.3,d) de la DAS establece de manera explícita la coherencia entre el artículo 6 de la DAS y el artículo 11.3 de la DMA, reseñado en el apartado 5.1

La disposición que establece el artículo 11.3,f) de la DMA es clara y no requiere explicación. La recarga artificial o el aumento se denominan asimismo "infiltración artificial".

e) entradas que *según las autoridades competentes, no sean técnicamente viables para prevenir o limitar sin la utilización de:*

i) medidas que aumentarían los riesgos para la salud humana o la calidad del medio ambiente en su conjunto; o

ii) medidas con un coste desproporcionado para eliminar cantidades de contaminantes o para controlar su infiltración en suelos o subsuelos contaminados;

Un ejemplo de "medidas que aumentarían los riesgos para la salud humana o la calidad del medio ambiente en su conjunto" podría ser el tratamiento de suelo contaminado mediante trabajos de excavación que alteraran las capas impermeables del suelo, que protegen las aguas subterráneas profundas que se utilizan para la producción de agua potable.

Puede ocurrir que en algunos casos el suelo contaminado o los sedimentos produzcan una entrada de contaminantes en aguas subterráneas que sea significativa -al menos a escala local-, por lo que no será aplicable la excepción b); sin embargo, la restauración (recuperación) completa causaría más daños que beneficios al medio ambiente. Dicha restauración puede, por ejemplo, causar ruido que perturbe la vida silvestre, puede necesitar cantidades desproporcionadas de energía u otros recursos, etc. En algunos casos serán posibles otras soluciones que garanticen una restauración parcial. Es posible que en algunos casos la restauración de sedimentos contaminados depositados en el fondo de aguas superficiales no sea posible sin que se produzca una “resuspensión” considerable del material contaminado, lo que originaría daños ecológicos o sería perjudicial para la calidad del agua de baño o para la utilización de aguas superficiales para la producción de agua potable. Podría ser conveniente aplicar una técnica de restauración más cuidadosa, pero si su coste fuera desproporcionado, sería aplicable la excepción ii). En general, la restauración/recuperación de suelos contaminados o de sedimentos que entrañe unos costes desproporcionadamente altos en comparación con el beneficio medioambiental sería un motivo para la excepción ii). Lo que debe entenderse por "desproporcionado” se determinará mediante evaluaciones individualizadas que, de conformidad con el artículo 14 de la DMA, deberán hacerse con la participación de todas las partes interesadas y sobre las que se informará con transparencia.

f) las entradas que *sean el resultado de actuaciones en las aguas superficiales con el objeto, entre otros, de paliar los efectos de inundaciones y sequías, así como para la gestión de las aguas y de los cursos de agua, incluidos los de ámbito internacional. Dichas actividades, que incluirán por ejemplo el corte, el dragado, el traslado y el almacenamiento de los sedimentos presentes en las aguas superficiales, se llevarán a cabo con arreglo a normas generales vinculantes, y, cuando sean aplicables, con permisos y autorizaciones concedidos sobre la base de las normas que hayan desarrollado al respecto los Estados miembros, siempre que esas entradas no pongan en peligro la consecución de los objetivos medioambientales que se hayan fijado para las masas de agua correspondientes a tenor de la letra b) del apartado 1 del artículo 4, de la Directiva 2000/60/CE.*

Otros ejemplos en los que es aplicable esta disposición son el mantenimiento de la profundidad del canal fluvial para embarcaciones, y la excavación de un canal adyacente en la llanura de inundación de un río para reforzar la protección contra las inundaciones. Estas actividades generan grandes cantidades de sedimento o suelo que deberán depositarse en algún lugar. El material podría utilizarse, por ejemplo, en la construcción de diques. Otra solución sostenible y rentable es el depósito en excavaciones profundas para extracción de arena o grava dentro o en las inmediaciones del sistema fluvial. Estas excavaciones se llenan de agua, pero debido a su gran profundidad creada de manera artificial no forman un hábitat ecológico natural. La mayoría de los sedimentos están contaminados en cierta medida. La concentración de sedimentos muy esparcidos en la zona de la excavación reducirá probablemente la entrada global de contaminantes en las aguas superficiales y subterráneas, así como la exposición del medio ambiente a la contaminación. No obstante, podría producirse un flujo local de contaminantes en las aguas subterráneas. Éste podría ser un motivo para la excepción b) -poco significativo-; sin embargo, la excepción f) permite un planteamiento basado en la aplicación de normas generales de carácter vinculante. Dichas normas deberían evitar que las obras como las expuestas anteriormente tuvieran un efecto significativo en la calidad de las aguas subterráneas. Cuando una obra se ajusta a dichas normas generales, ello debería significar que el órgano competente ha considerado que el flujo potencial de contaminantes en aguas subterráneas es lo suficientemente pequeño como para no poner en peligro el logro de los objetivos medioambientales establecidos con arreglo a la DMA para las masas de agua subterránea en cuestión. Aunque puede aducirse que el depósito de suelo o sedimentos estaría permitido, asimismo de conformidad con la excepción e), ii), la excepción f) hace una referencia más clara a los casos como los que aquí se describen.

5.5 Condiciones para la aplicación de excepciones

El considerando 18 de la DAS reza: *"En determinadas circunstancias, los Estados miembros deben autorizar la concesión de excepciones a las medidas destinadas a impedir o limitar la entrada de contaminantes en las aguas subterráneas. Toda excepción debe basarse en criterios transparentes y justificarse en los planes hidrológicos de cuenca."* El artículo 6, 3) de la DAS define las actividades o situaciones específicas que pueden estar exentas bajo determinadas condiciones. Por tanto, para eximir una entrada de la exigencia de prevenir o limitar, el órgano competente debe, en primer lugar, decidir si es aplicable alguna de las descripciones recogidas en el artículo 6.3. Los criterios para tomar dicha decisión deben ser transparentes y deberán facilitarse los pormenores pertinentes en el plan hidrológico de cuenca. Para dilucidar si es aplicable una o más de las excepciones recogidas en el artículo 6, 3), deberá describirse la actividad o el incidente causante de la entrada que debe eximirse de las medidas. Evidentemente, en el caso de actividades o incidentes que tengan un carácter similar, bastará con una la mera descripción general en el plan hidrológico, o una referencia a otro documento que contenga dicha descripción. Esto es aplicable, por ejemplo, a las actividades que se ajusten a las normas vinculantes desarrolladas a tal efecto.

El artículo 6.4 de la DAS establece que para poder llevar a cabo la notificación a la Comisión, previa solicitud de ésta, las autoridades competentes deben realizar un inventario de las excepciones. El artículo 6.4 no especifica el nivel de detalle que debe contener el inventario ni tampoco exige que el propio inventario forme parte del plan de cuenca. El inventario podría ser un anexo del plan, que incluya todos los argumentos relacionados con las excepciones o que haga referencia a otros documentos que contengan dichos argumentos. Otra posibilidad sería que el plan de cuenca indicara dónde puede encontrarse el inventario. Es poco razonable mantener un inventario de cada excepción individual con una descripción detallada, especialmente cuando se trata de entradas que se producen con frecuencia y que proceden de obras de construcción o fosas sépticas. Por lo tanto convendría desarrollar soluciones prácticas para la elaboración de dichos inventarios; en caso de existir normativa o códigos de buena práctica para autorizar la utilización de materiales de construcción con el fin de garantizar que la entrada residual sea aceptable, es decir, que pueda quedar exenta, podría bastar con incluir en el inventario la correspondiente la norma general vinculante.

Según la última frase del artículo 6.3 de la DAS, las exenciones sólo podrán otorgarse previa comprobación por las autoridades competentes de los Estados miembros de que se realiza el seguimiento de las masas de agua subterránea implicadas, a tenor del punto 2.4.2 del Anexo V de la Directiva 2000/60/CE, u otro seguimiento pertinente. El seguimiento, de conformidad con el punto 2.4.2 del Anexo V de la DMA, sobre el que se trata en la guía de seguimiento de las aguas subterráneas, probablemente no establezca mediciones lo suficientemente detalladas para determinar los efectos de los casos individuales en los que se aplican exenciones. Las autoridades competentes deben decidir sobre la necesidad de un seguimiento adicional para verificar que es aceptable la evaluación, subyacente a la conclusión, de los efectos de una entrada exenta; por ejemplo, en el caso de un material de construcción que haya sido autorizado para utilizarlo en el suelo o en aguas subterráneas a pesar de contener una sustancia peligrosa, la autorización implica que la filtración se considera de poca importancia. Naturalmente no es necesario hacer un seguimiento de la calidad de las aguas subterráneas en todos los lugares en que se deposite el material. Bastará con los tests del material presentados para obtener la autorización. Es posible que otros tipos de entradas dispersas candidatas a la excepción deban ser objeto de seguimiento en varios puntos representativos.

El artículo 6.3 comienza con la condición "Sin perjuicio de cualquier requisito más estricto establecido en otros actos de la legislación comunitaria". La aplicación de una exención, por ejemplo, no debería tener efectos adversos sobre una zona Natura 2000 ni en la producción de agua potable. Si desde el lugar en cuestión se produce una escorrentía subterránea hacia otros lugares en los que otros actos de la legislación comunitaria establecen objetivos más estrictos, debe demostrarse que aún así, se prevé la consecución de los objetivos citados. Dichos razonamientos podrán requerir una evaluación experta de los gestores de las aguas subterráneas y de las partes interesadas -las partes interesadas deben participar, de conformidad con el artículo 14 de la DMA sobre participación pública-.

5.6 Cómo desarrollar las medidas

El desarrollo de medidas, esquematizado en la figura 7, se basa en las características de la entrada (capítulo 3.2 y 3.3), y en el tipo de actividad (capítulo 4.3 y 4.4). Esto constituye la base para comprobar si es aplicable una de las exenciones de la DAS (capítulo 5.3 y 5.5). En ambos casos, -nuevas actividades y fuentes existentes-, debe tenerse en cuenta el planteamiento del punto de cumplimiento (PdC, capítulo 4.1), a fin de evaluar el impacto de esas actividades y determinar las acciones necesarias para asegurar que se alcanza el objetivo de prevenir y limitar de la DMA.

Respecto a nuevas actividades, la figura 5 ofrece asesoramiento detallado sobre cómo proceder. Para las fuentes existentes, el planteamiento del PdC conduce a un desarrollo por etapas de las medidas necesarias para prevenir o limitar la entrada de contaminantes en aguas subterráneas. Comienza con el seguimiento y establece líneas de actuación concretas en caso de que deban adoptarse medidas más rigurosas específicas al lugar. La concepción de las medidas citadas debe basarse en una evaluación de los riesgos para el receptor/compartimento (capítulo 3.5) siguiendo el proceso descrito en la figura 6.

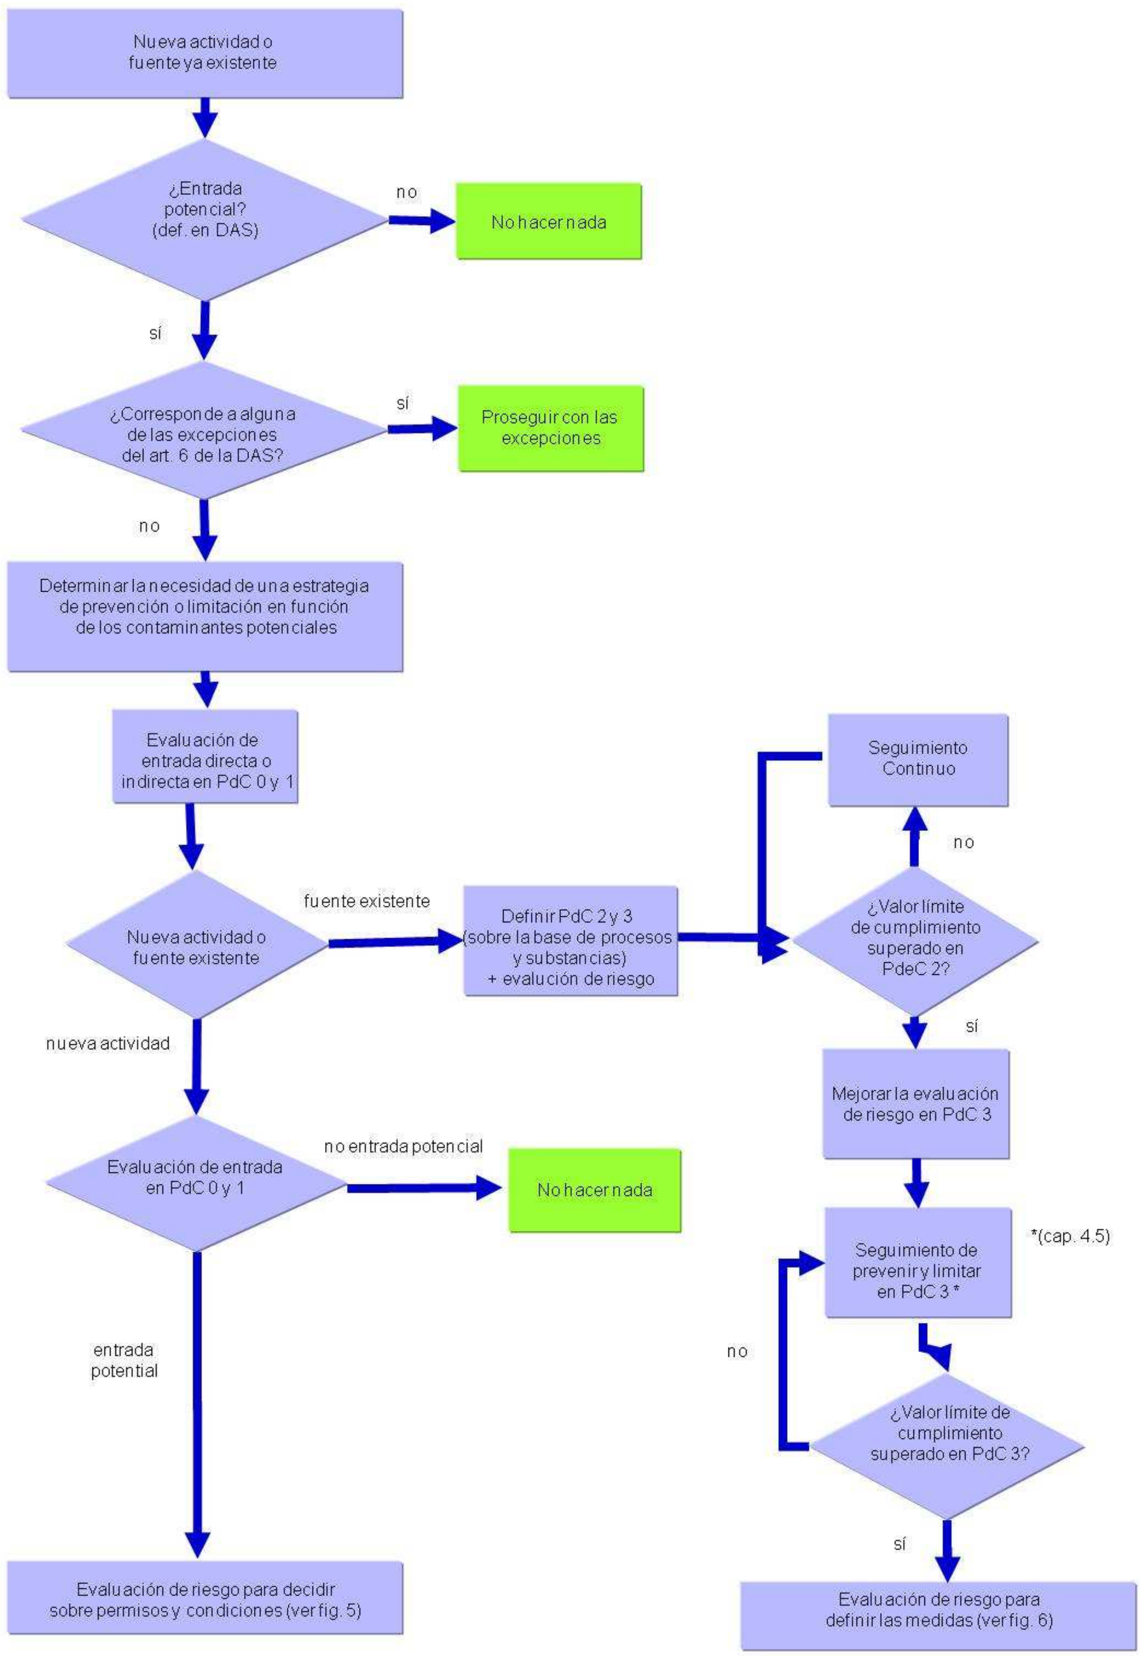


Figura 7: Esquema de cómo llegar hasta las medidas

Anexos

Anexo 1 Ejemplos de entradas

	Tipos de fuentes y entradas	Ejemplos	Tipo de entrada habitual :directa o indirecta	Propiedades de las entradas	Tipo de fuente: puntual o difusa (*)
1	Fuentes puntuales; vertidos líquidos a través de conducciones	- Infiltración desde estación depuradora de aguas residuales industriales - Fosa séptica-infiltración desde el sistema - Infiltración de agua de lluvia desde tejados, carreteras, etc.	- Indirecta o directa - Indirecta - Indirecta	Entrada continua	puntual
2	Lixiviado de materiales sólidos	- Materiales de construcción - Vertederos - Madera tratada - Objetos metálicos	Todas: Indirectas o directas	Entrada única (**); Disminución habitual del lixiviado con el paso del tiempo	puntual
3	Difusión	- Plaguicidas - Estiércol, Fertilizantes, Compost - Lodos de aguas residuales - Tratamiento antihielo en carreteras	Todas: Indirectas	Entrada de repetición periódica	difusa
4	Infiltración	- Recarga artificial - Para abastecimiento de agua potable - Para almacenamiento de energía - Fugas desde balsas para almacenamiento de residuos líquidos, etc. - Inyección/eliminación de fluidos derivados de la producción de petróleo y gas	- Directa o indirecta - Directa o indirecta - Directa - Directa o indirecta - Directa	- Entrada continua - Entrada continua - Entrada continua - Entrada continua o fortuita - Entrada continua	puntual
5	Entradas atmosféricas	- (Antiguas) industrias locales - Accidentes industriales - Por la calidad del aire en general	Todas: Indirectas	-Entrada continua -Entrada fortuita -Entrada continua	difusa
6	Contaminación existente en el suelo y en aguas subterráneas	- Zona de suelo contaminado - Gran extensión de suelo contaminado - Zona de aguas subterráneas contaminadas - Gran extensión de aguas subterráneas contaminadas	Todas: Directas o indirectas	Acción única (**); lenta propagación habitual a las aguas subterráneas y a través de éstas.	-puntual -difusa -puntual -difusa
7	Fugas por accidentes	- Depósitos, tuberías, perforaciones petrolíferas, - Sistemas de almacenamiento de energía	Todas: Directas o indirectas	Acción única (**); Propagación lenta o rápida	puntual

Observaciones

(*) varias fuentes puntuales en una misma zona pueden constituir una fuente difusa, cuando se las considera conjuntamente.

(**) única = cada entrada es una acción única. No obstante, es posible repetir la acción en el mismo lugar con materiales iguales o distintos que puedan liberar sustancias. En tales casos puede tratarse como una entrada de tipo continuo en dicho lugar.

Prólogo

Los Directores Generales del Agua de la Unión Europea (UE), los países de la Adhesión, los países candidatos y los países de la EFTA, han desarrollado conjuntamente una estrategia común para la implantación (ECI) de la Directiva 2000/60/CE, *“por la que se establece un marco comunitario de actuación en el ámbito de la política de aguas”* (Directiva Marco del Agua). Esta estrategia tiene como principal objetivo contribuir a una aplicación coherente y uniforme de la Directiva. La atención se ha centrado en las cuestiones metodológicas relacionadas con una comprensión común de las repercusiones técnicas y científicas de dicha aplicación.

En particular, uno de los objetivos de la estrategia es el desarrollo de documentos guía, de carácter práctico y jurídicamente no vinculantes, sobre varios aspectos técnicos de la Directiva. Estos documentos guía van dirigidos a los expertos que, directa o indirectamente, son los responsables de aplicar la Directiva Marco del Agua en las demarcaciones hidrográficas. En consecuencia, se ha adaptado la estructura, la presentación y la terminología a las necesidades de estos expertos, y, en la medida de lo posible, se ha evitado la utilización de un lenguaje formal y legalista.

En este contexto, los Directores Generales del Agua elaboraron y aprobaron una serie de documentos guía relativos a las aguas subterráneas. Dichos documentos deben servir de referencia a los Estados miembros en temas tales como identificación de masas de agua –documento guía nº 2- análisis de presiones e impactos –documento guía nº 3-, y seguimiento (“monitoring”) –documento guía nº 7-, en el marco del desarrollo de los Planes Hidrológicos de Cuenca.

A modo de continuación y en el ámbito de aplicación de la nueva Directiva relativa a las aguas subterráneas (Directiva 2006/118/CE), elaborada en cumplimiento del mandato del artículo 17 de la Directiva Marco del Agua, los Estados miembros han manifestado la necesidad de aclarar algunos aspectos relacionados con las aguas subterráneas. En respuesta a dicha solicitud se redactaron nuevos documentos que ampliaban la serie, relativos a aspectos cubiertos por ambas directivas, concretamente sobre seguimiento de las aguas subterráneas –documento guía nº 15-, zonas protegidas para el abastecimiento de agua potable –documento guía nº 16-, y prevención de entradas directas e indirectas de contaminantes –documento guía nº 17-. Como complemento a estos tres documentos guía se tomó la decisión de redactar recomendaciones sobre el estado de las aguas subterráneas y la evaluación de tendencias de contaminantes, sobre la base de la experiencia y mejora del conocimiento adquiridas en el proyecto BRIDGE, referente a criterios de referencia para la identificación de valores umbral en las aguas subterráneas y financiado bajo el 6º Programa Marco, y en el desarrollo del Informe Técnico sobre aspectos estadísticos de la identificación de tendencias en la contaminación de las aguas subterráneas y de la agregación de los resultados del seguimiento (2001). Con dicho objetivo se estableció un grupo de trabajo dependiente del Grupo de Trabajo WG-C de la ECI sobre aguas subterráneas. Este grupo de trabajo ha sido coordinado por Austria, Francia, Reino Unido y EuroGeoSurveys, y ha contado con la participación de expertos procedentes de otros Estados miembros y de organizaciones de grupos interesados.

El presente documento guía es el resultado de los trabajos de este grupo y contiene la síntesis de los resultados de los debates celebrados desde diciembre de 2004. Está basado en las aportaciones y las reacciones de una amplia variedad de expertos y partes interesadas que han participado en su elaboración a través de reuniones, talleres, conferencias y medios electrónicos, sin que por ello resulten vinculados en modo alguno con el contenido del presente informe.

“Nosotros, los Directores Generales del Agua de la Unión Europea, Noruega, Suiza y los países que han solicitado la adhesión a la Unión Europea, hemos examinado y aprobado el presente Documento guía en el transcurso de nuestra reunión informal bajo la Presidencia francesa (París, 24-25 de noviembre de 2008). Deseamos expresar nuestro agradecimiento a los miembros del Grupo de Trabajo C y, en particular, a los responsables del grupo de redacción por la elaboración de este documento de gran calidad.

Creemos firmemente que éste y otros documentos guía elaborados en el marco de la Estrategia Común de Implantación tendrán un papel destacado en el proceso de implantación de la Directiva Marco del Agua y de la Directiva relativa a las aguas subterráneas.

El presente documento guía es un documento vivo que necesitará aportaciones y mejoras continuas a medida que avanza la aplicación y crece la experiencia en todos los países de la Unión Europea y en otros países. Hemos acordado, no obstante, que este documento se haga público en su forma actual con el fin de presentarlo al gran público como la base para seguir avanzando en los esfuerzos de aplicación en curso.

Asimismo, nos comprometemos a evaluar y a decidir sobre la necesidad de revisarlo a la luz de los avances científicos y técnicos, así como de las experiencias acumuladas en la aplicación de la Directiva Marco del Agua y de la Directiva relativa a las aguas subterráneas."

INDICE

LA ESTRATEGIA COMÚN DE IMPLANTACIÓN (ECI) DE LA DIRECTIVA MARCO DEL AGUA

La Directiva Marco del Agua (2000/60/CE)[1] (DMA) es una norma jurídica de ámbito comunitario que establece, *inter alia*, objetivos de “buen estado” para todas las aguas de Europa. La DMA requiere una gestión sostenible e integrada de las demarcaciones hidrográficas incluyendo objetivos vinculantes, plazos claramente establecidos y un programa global de medidas basadas en análisis científicos, técnicos y económicos, que incluya la información y la consulta del público. Desde la fecha de adopción de la DMA se puso de manifiesto el reto que supondría lograr su aplicación con éxito para todos los países, instituciones y partes interesadas.

Para afrontar los retos de modo cooperativo y coordinado, los Estados miembros, Noruega y la Comisión Europea (CE) acordaron establecer una Estrategia Común de Implantación (ECI, CIS en las siglas inglesas) de la Directiva Marco del Agua. Además, los Directores Generales del Agua subrayaron la necesidad de implicar a los actores interesados, a las ONG y a la comunidad investigadora en este proceso conjunto, y de asegurar la participación de los países candidatos.

En la primera fase de la ECI se redactaron una serie de documentos guía, cuya aplicación práctica se sometió a prueba en cuencas hidrográficas piloto europeas en 2003 y 2004. En el Programa de Trabajo 2005/2006, los cuatro Grupos de Trabajo -Estado ecológico, Gestión Integrada de Cuencas Hidrográficas, Aguas Subterráneas e Informes (Reporting)- han seguido ocupándose de las cuestiones clave para la implantación. Además, los nuevos grupos de trabajo -DMA y Agricultura, Sistemas de Información Geográfica y Seguimiento del estado químico- están compartiendo sus experiencias en este ámbito, y una nueva red de cuencas hidrográficas piloto está apoyando las actividades técnicas de todos los grupos de trabajo.

El Grupo de Trabajo sobre aguas subterráneas (WG C) de la ECI desarrolla actualmente la tercera fase de los trabajos (2007-2009)[2], centrada en la aplicación de la nueva Directiva sobre aguas subterráneas y en los elementos relativos a las aguas subterráneas dentro de la DMA, junto con los principios de la ECI. En particular, el objetivo principal del WG C de cara a la preparación del primer Plan Hidrológico de Cuenca (PHC) es el desarrollo de una metodología común para el establecimiento de valores umbral para las aguas subterráneas y un documento guía sobre el estado del cumplimiento y la evaluación de las tendencias. Más adelante se centrará la atención en las mejores prácticas relacionadas con programas de medidas y recomendaciones para la evaluación y la gestión integrada de riesgos relativos a las aguas subterráneas, incluyendo modelos conceptuales.

Simultáneamente a este trabajo, la Actividad de Seguimiento Químico (CMA en sus siglas en inglés) se ha centrado en desarrollar una guía sobre el seguimiento del estado químico. Esto ha dado como resultado un proyecto de directiva de la CE sobre las especificaciones técnicas de los análisis químicos y el seguimiento del estado de las aguas[3]. Incluye las aguas superficiales y las aguas subterráneas. En la preparación de esta guía se han tenido en cuenta las nuevas especificaciones.

[2] Mandato del Grupo de Trabajo sobre Aguas Subterráneas. Estrategia común de implantación de la Directiva marco del Agua. Programa de Trabajo 2007-2009 (2006).

[3] Proyecto de directiva de la Comisión de (día, mes, 2009) que establece, de conformidad con la Directiva 2000/60/CE del Parlamento europeo y del Consejo, especificaciones técnicas para el análisis químico y el seguimiento del estado de las aguas. (Directiva QA/QC) 10575/08 ENV 365.

1 OBJETIVOS Y ALCANCE

Esta guía se ha redactado como respuesta a un mandato del Grupo de Trabajo de Aguas Subterráneas de la DMA -WG C-, que se concreta en el desarrollo de guías prácticas y especificaciones técnicas para la determinación de valores umbral y para la evaluación del estado del cumplimiento. El documento se basa en las guías de la DMA y las complementa[4]. Esencialmente se centra en los requisitos de la DMA y de la nueva Directiva de Aguas Subterráneas[5] (DAS), y en especial en las obligaciones contenidas en el Anexo V de la DMA y en los artículos 3 y 4 y los Anexos II y III de la DAS.

La DMA y la DAS requieren a los Estados miembros la identificación de las tendencias de las concentraciones de contaminantes, y la evaluación de esas tendencias para determinar en qué medida son significativas para el medio ambiente. Cuando existan tendencias significativas al aumento deben invertirse mediante la aplicación de programas de medidas que garanticen que no se incumplan en el futuro los objetivos medioambientales. El punto de partida establecido en la DAS para la inversión de la tendencia coincide con el momento en que la concentración del contaminante alcanza un porcentaje del valor umbral o norma de calidad (75% por defecto).

Este documento constituye una guía práctica para el cumplimiento de cada uno de los requisitos descritos anteriormente. Así:

- establece una metodología para la determinación de los valores umbral;
- establece criterios para la evaluación del estado químico y del estado cuantitativo;
- establece un método para la identificación de tendencias significativas desde el punto de vista medioambiental;
- reitera los requisitos de la DMA en materia de información;
- aporta ejemplos en forma de casos prácticos que ilustran la aplicación de la guía en los Estados miembros.

Durante la redacción de esta guía se han tenido en cuenta los resultados de distintos proyectos de I+D así como el contenido de otras guías publicadas anteriormente. En cuanto a los valores umbral para las aguas subterráneas, el método que se describe en este documento se basa en los resultados del proyecto BRIDGE[6]. Para la evaluación del estado químico se han consultado las especificaciones técnicas relativas al análisis químico y al seguimiento del estado de las aguas, que ha desarrollado la Actividad de Seguimiento Químico (CMA, en sus siglas en inglés) de la UE, así como la Directiva de la Comisión[7] sobre la materia. En cuanto a la evaluación de las tendencias y la inversión de las tendencias, se ha prestado una atención especial al Informe Técnico elaborado por el grupo de trabajo 2.8 de la Estrategia Común de Implementación de la DMA[8] .

El objetivo de este trabajo es proporcionar un enfoque práctico que apoye a los Estados miembros en la aplicación y la consecución de los requisitos de la DMA y de la DAS. El documento es fruto de numerosas consultas con expertos en aguas subterráneas de toda Europa, y representa un enfoque

basado en las mejores prácticas del momento. La guía no tiene carácter jurídicamente vinculante y los Estados miembros son libres de adaptar las directrices que aquí se presentan, a la luz de las características de las masas de agua subterránea, y/o las estrategias y normativas nacionales o regionales para la gestión de las aguas subterráneas. Asimismo, es justo reconocer que la experiencia puede aportar mejoras a las metodologías propuestas.

2 PRINCIPIOS GENERALES

2.1 Modelos conceptuales

Para la aplicación de la DMA y la DAS, y para la gestión eficaz de las aguas subterráneas, se requiere una comprensión clara de las condiciones medioambientales necesarias para el logro de los objetivos medioambientales, y del modo en que éstas pueden verse afectadas por la actividad humana. Esta comprensión se apoya en el desarrollo de un **modelo conceptual o comprensión conceptual** del sistema de aguas subterráneas, en el que se definen el esquema general de las condiciones de flujo y de transporte, y el de las características hidrogeoquímicas. Los modelos conceptuales no son necesariamente modelos numéricos, y constituyen una comprensión de las relaciones funcionales en el sistema geológico e hidrogeológico objeto de estudio. No obstante, pueden utilizarse los modelos numéricos para apoyar o confirmar algunos elementos del modelo conceptual, cuando proceda.

No sólo la evaluación de riesgo, sino también el seguimiento, deben basarse en principio en un modelo conceptual del sistema de aguas subterráneas. Los datos obtenidos en los programas de seguimiento de la DMA deben utilizarse para verificar, validar y afinar los modelos conceptuales. La información sobre los tiempos de tránsito, caudal, velocidad de transporte y/o distribución de edades de las aguas subterráneas puede ser también una aportación útil para el diseño del modelo conceptual, así como para su validación.

Una masa de agua subterránea es tridimensional. Por ello, la concentración de contaminantes y los niveles de referencia de las sustancias presentes de modo natural pueden experimentar variaciones significativas en dirección vertical y lateral. Esto debe tenerse en cuenta cuando se establezcan valores umbral así como en el procedimiento de evaluación del estado y de las tendencias.

La importancia de los modelos conceptuales se describe ya en otra guía de la CIS[9]. El capítulo 3.1 de la guía “Groundwater Monitoring”[10] formula los principios y las relaciones del modelo conceptual con el programa de seguimiento. En el mandato del grupo de trabajo WG C se incluye el desarrollo de criterios y procedimientos adicionales sobre modelos conceptuales. Los modelos conceptuales se consideran actualmente como un instrumento fundamental para apoyar la aplicación de todas las disposiciones de las directivas DMA y DAS en materia de aguas subterráneas.

2.1.1 Modelos conceptuales y establecimiento de valores umbral

El anexo II.A de la DAS formula las siguientes orientaciones para la determinación de valores umbral:

- los valores umbral deberían basarse en el alcance de las interacciones entre las aguas subterráneas y los ecosistemas acuáticos y ecosistemas terrestres dependientes,
- los valores umbral deberían partir de los usos legítimos actuales o potenciales (a saber, abastecimiento de agua potable, regadío, etc.) o en las funciones de las aguas subterráneas,
- la asignación de valores umbral debería incluir a todos los contaminantes que caracterizan las masas de agua subterránea como masas en riesgo de no cumplir los objetivos del artículo 4 de la DMA,
- los valores umbral deberían basarse en las características hidrogeológicas de la masa de agua subterránea, incluida la información sobre las concentraciones de referencia derivadas de los procesos naturales hidrogeológicos e hidrogeoquímicos,
- la determinación de los valores umbral debería tener en cuenta el origen de los contaminantes, su posible existencia natural, su toxicología y tendencia a la dispersión, su persistencia y potencial de bioacumulación,
- la determinación de los valores umbral debería tener en cuenta la calidad de los datos y la precisión de las determinaciones analíticas.

La multiplicidad de aspectos que deben tenerse en cuenta para establecer valores umbral explica la necesidad de utilizar modelos conceptuales de flujo subterráneo y de características hidroquímicas de la masa de agua subterránea.

[9] Guidance Document No. 3: Analysis of Impacts and Pressures – WG 2.1 IMPRESS (2003)
Guidance Document No. 7: Monitoring Under the Water Framework Directive – WG 2.7 Seguimiento (2003);

[10] Guidance Document Nº 15: Groundwater Monitoring (2007)

2.1.2 Modelos conceptuales y evaluación del estado

En cada fase del procedimiento de evaluación del estado es importante considerar los resultados de la evaluación de riesgo, el análisis de presiones -por ej. el uso del suelo-, la vulnerabilidad de los acuíferos y los resultados del seguimiento.

Para la evaluación del estado químico de las aguas subterráneas, la DAS considera el modelo conceptual de una masa de agua subterránea como un componente integral y hace referencia al mismo en puntos específicos:

- el anexo III, 3, propone apoyar, en caso de necesidad, la evaluación de estado por medio de estimaciones de concentraciones basadas en un modelo conceptual.
- el anexo III, 4, afirma que junto con los datos objeto de seguimiento, un modelo conceptual adecuado debería permitir a los Estados miembros evaluar si el estado químico es bueno.

El modelo conceptual también desempeña un papel importante en la evaluación del estado cuantitativo, sirviendo de ayuda para la evaluación del impacto de los cambios en el nivel piezométrico en la masa de agua subterránea, en el nivel de las aguas superficiales y en su caudal, y en los ecosistemas dependientes de las aguas subterráneas.

2.1.3 Modelos conceptuales y evaluación de tendencias

Para evaluar las tendencias y la inversión de tendencias, el papel que desempeña el modelo conceptual es clave en las circunstancias siguientes:

- cuando se consideran las características temporales físicas y químicas, incluyendo las condiciones de flujo de las aguas subterráneas, las tasas de recarga y el tiempo de percolación a través del suelo o del subsuelo.
- cuando se decide la ubicación de los puntos de control y la frecuencia de medidas, para proporcionar la información necesaria que garantice que las tendencias significativas al aumento puedan distinguirse de las variaciones naturales con un nivel adecuado de confianza y precisión.
- cuando se establecen los puntos de partida para la inversión de tendencias que difieran del 75% de la norma de calidad de las aguas subterráneas o del valor umbral, que dependerán de las características del acuífero y de la capacidad para impedir del modo más rentable que se produzca cualquier cambio que perjudique seriamente la calidad de las aguas subterráneas.

2.2 Ecosistemas terrestres dependientes, pertinentes para la evaluación del estado y las tendencias

De conformidad con la definición establecida en la guía sobre humedales[11] en la página 22, los ecosistemas terrestres pertinentes que deben considerarse en la evaluación del estado de las aguas subterráneas y el establecimiento de valores umbral son los enclaves Natura 2000 que dependen directamente de las aguas subterráneas y otros ecosistemas terrestres dependientes de las aguas subterráneas -ETDAS, GWDTE en sus siglas en inglés- cuyo valor ecológico y socio-económico sea suficiente para que el perjuicio que produzcan en ellos las alteraciones del agua subterránea pueda ser considerado como significativo, en función de su gravedad.

2.3 Concentraciones de sustancias presentes de forma natural. Niveles de referencia

El considerando 10 de la DAS establece que "*Las disposiciones relativas al estado químico de las aguas subterráneas no se aplican a las situaciones en que se dan niveles naturales elevados de sustancias o iones, o de sus indicadores, contenidos en una masa de aguas subterránea o en masas asociadas de aguas superficiales, debidos a condiciones hidrogeológicas específicas no incluidas en la definición de "contaminación"*.

De conformidad con el artículo 2.5 de la DAS, "nivel de referencia" es "*la concentración de una sustancia o el valor de un indicador en una masa de agua subterránea correspondiente a condiciones no sometidas a alteraciones antropogénicas o sometidas a alteraciones mínimas, en relación con condiciones inalteradas";*

Los niveles de referencia pueden ser muy elevados[12] para algunos parámetros y algunos tipos de aguas subterráneas, por lo que es fundamental que el primer paso de la evaluación del estado y de las tendencias consista en su identificación. Además, tal como señala la DAS (anexo II.A.1.d), "*Al establecer los valores umbral, los Estados miembros atenderán a […]: las características hidrogeológicas, incluida la información sobre niveles de referencia."*

Como han puesto de manifiesto los proyectos BaseLine y BRIDGE[13], en Europa existen condiciones hidrogeológicas e hidroquímicas muy variadas. Los niveles de referencia son el resultado de varios factores, como las interacciones entre el agua y la roca, los procesos químicos y biológicos en la zona no saturada, el tiempo de permanencia, la lluvia, las relaciones con otros acuíferos (transferencias). Por este motivo, cada masa de agua subterránea es diferente y posee una composición química natural única. Además, es frecuente que dentro de una masa de agua subterránea se observen variaciones espaciales de los niveles de referencia. Con todo, es posible definir la horquilla de valores para cada parámetro y para cada tipo de acuífero.

Para la identificación de los niveles de referencia, los Estados miembros son libres de aplicar su propio enfoque, dependiendo de los estudios existentes y los modelos conceptuales de las aguas subterráneas. El proyecto BRIDGE ofrece una metodología para el cálculo de los niveles de referencia que puede aplicarse a todas las sustancias, tanto aquellas de origen puramente antropogénico –derivado de la actividad humana- como las que ocurren tanto de modo natural como derivadas de la actividad humana. Cuando los conocimientos existentes sean demasiado escasos, se propone un enfoque sencillo que utiliza tipologías de acuíferos como punto de partida para el establecimiento de los niveles de referencia.[14]

2.4 Concentraciones por debajo del límite de cuantificación

El tratamiento de los valores que están por debajo del límite de cuantificación (LC) requiere una atención especial cuando se comparan los datos dentro de una zona o en un plazo de tiempo. La DAS establece procedimientos específicos para la evaluación del estado químico y para la evaluación de las tendencias y de la inversión de la tendencia.

---

[11] Guidance Document No. 12: The Role of Wetlands in the Water Framework Directive (2003)

[12] Pauwels *et al* (2006)

[13] Edmunds *et* Shand (2003); Pauwels *et al*., (2006)

[14] Müller *et al* (2006)

Del mismo modo, deberían tenerse en cuenta y aplicarse las disposiciones de la Directiva de la Comisión QA/QC, en particular el artículo 5.[15]

2.4.1 Evaluación del estado químico

Para la evaluación del estado químico, se recomienda que todas los valores registrados inferiores al límite de cuantificación se sustituyan por valores iguales a la mitad del LC (LC/2) excepto para los plaguicidas totales, de conformidad con el artículo 5 del Proyecto de Decisión de la Comisión QA/QC. Para los plaguicidas totales, la nota al pie (2) del anexo I de la DAS especifica que: *Se entiende por "total" la suma de todos los plaguicidas concretos detectados y cuantificados* […]" lo que significa que al calcular la suma sólo deben considerarse las concentraciones cuantificadas, y no los valores por debajo del límite de cuantificación.

2.4.2 Evaluación de tendencias

En la evaluación de tendencias, las concentraciones de parámetros individuales inferiores al LC deberían sustituirse por la mitad del valor del LC más elevado registrado en la serie temporal que sea objeto del análisis (anexo IV A, 2d) de la masa de agua subterránea. Este requisito reconoce que los límites de cuantificación pueden variar a lo largo del tiempo y pueden producir sesgos en la evaluación de tendencias.

La excepción es "plaguicidas totales", en cuya evaluación solo deberían considerarse concentraciones cuantificadas, porque el uso de la norma de sustitución podría dar lugar a un sesgo. Así pues, "plaguicidas totales" debe ser la suma de todos los plaguicidas individuales, incluyendo los metabolitos pertinentes, los productos de degradación y de reacción que se detecten y cuantifiquen (anexo I de la DAS, 1 (nota al pie)).

Además de los requisitos anteriores, para no introducir tendencias artificiales, todos los valores inferiores al LC más elevado deberían sustituirse por ese LC/2. Si las series temporales son suficientemente largas, los Estados miembros deberían decidir si suprimen los datos antiguos -datos consecutivos antiguos y no mediciones separadas dentro de la serie temporal- que presenten LC elevados. Esto garantizaría que se sustituyera por los LC/2 más altos un número inferior de datos medidos, para no perder de este modo información valiosa.

Si en una serie temporal la proporción de valores inferiores al LC es elevada, se puede producir un sesgo importante en la evaluación. En esta situación, no debería llevarse a cabo el test de tendencia si se considera que la influencia de los valores por debajo del LC es demasiado significativa[16].

***Nota:** En el futuro tal vez puedan utilizarse concentraciones por debajo del LC en la evaluación de tendencias. No obstante, estos datos no están disponibles en muchos casos, y se considera que su uso rutinario plantea dificultades. A la luz de los progresos científicos y técnicos del futuro, la DAS puede ser objeto de modificaciones, de conformidad con el artículo 8.*

2.5 Informes (Reporting)

El anexo V de la DMA y la DAS especifican cómo tienen que informar los Estados miembros en los planes hidrológicos de cuenca sobre el estado químico y cuantitativo y las tendencias. La información que debe figurar en los informes es la siguiente:

- valores umbral y un resumen de la metodología utilizada para determinarlos. Esto debe tener en cuenta los requisitos del artículo 3.5 y del anexo II Parte C de la DAS. El establecimiento de valores umbral de las aguas subterráneas debe considerar como mínimo la lista de sustancias que figura en el anexo II Parte B de la DAS.
- los resultados del estado químico y la metodología utilizada para clasificar las masas de agua subterránea de conformidad con el anexo V 2.5 de la DMA.

---

[15] Proyecto de Directiva de la Comisión de (día, mes, 2009) que establece, de conformidad con la Directiva 2000/60/CE del Parlamento europeo y el Consejo, especificaciones técnicas para el análisis químico y el seguimiento del estado de las aguas (Directiva QA/QC) 10575/08 ENV 365.

[16] Technical Report No. 1: Aspectos estadísticos de la identificación de las tendencias a la contaminación de las aguas subterráneas y agregación de los resultados del seguimiento – WG 2.8 Estadísticas (2001)

- los resultados de la evaluación de tendencias y de la inversión de la tendencia y la metodología utilizada, de conformidad con el artículo 5.4, 5.5 y el anexo IV, Parte A, punto 3, de la DAS. El anexo V 2.4.5 exige que figure en los mapas que presentan el estado químico de la masa de agua subterránea la indicación de las tendencias y la inversión de la tendencia con sus códigos de color.

Todos los requisitos en materia de informes se consideran dentro de la serie de "*Reporting Sheets*", que desarrolló el grupo de trabajo D (Informes, Reporting en su acepción en inglés). Los informes sobre el primer plan hidrológico de cuenca deben presentarse en 2010.

Para las masas de agua transfronterizas se solicita información sobre las medidas adoptadas para coordinar el establecimiento de los valores umbral, la evaluación de estado y la evaluación de tendencias para las aguas subterráneas transfronterizas.

2.5.1 Valores umbral de las aguas subterráneas

Los Estados miembros pueden establecer varios valores umbral para cada MAS y/o cada parámetro, dependiendo de los receptores que estén en riesgo (aguas superficiales, ETDAS, usos…)

Tal como exige el artículo 3.5 de la DAS, los valores umbral deben establecerse por primera vez el 22 de diciembre de 2008, y publicarse en los planes hidrológicos de cuenca. De conformidad con el anexo II Parte C de la DAS, los Estados miembros realizarán un resumen del modo en que han llevado a cabo el procedimiento establecido en la Parte A del anexo II de la DAS, incluyendo, cuando resulte factible:

- información sobre el número de masas o grupos de masas de agua subterránea caracterizadas en riesgo, y sobre los contaminantes e indicadores de contaminación que contribuyen a tal clasificación;
- relación entre las masas de agua subterránea y las aguas superficiales asociadas o los ecosistemas terrestres directamente dependientes (ETDAS);
- valores umbral (VU) para cada parámetro e indicador de los contaminantes que contribuyen a la clasificación de riesgo y nivel al que se aplican los VU -masa de agua subterránea, demarcación hidrográfica, parte de la demarcación hidrográfica internacional, territorio del Estado miembro-;
- relación entre los valores umbral y niveles de referencia para los parámetros presentes de forma natural; y
- relación entre los valores umbral y los objetivos de calidad medioambiental y otras normas.

Los Estados miembros proporcionarán la información y los valores respectivos -valores umbral medioambientales y/o valores umbral de uso, dependiendo de los receptores-, de conformidad con las respectivas "*Reporting Sheets*" de la DMA.

2.5.2 Estado de la masa de agua subterránea

De conformidad con el anexo V de la DMA, los Estados miembros deben proporcionar mapas con códigos de colores en los planes hidrológicos de cuenca, que muestren el estado cuantitativo y químico para cada MAS. El color verde indica un buen estado y el color rojo indica un mal estado.

El anexo III.5 de la DMA establece que los Estados miembros no sólo deben elaborar mapas de conformidad con las secciones 2.4.5 y 2.5 del anexo V de la DMA sino que "…*además indicarán en esos mapas todos los puntos de control en los que se han excedido las normas de calidad para las aguas subterráneas y/o los valores umbral, siempre que sea pertinente y factible*."

Conviene reseñar que no todos los valores umbral son relevantes en todos los puntos de control, dependiendo de los receptores y de su ubicación en la MAS. Se propone por ello indicar en el mapa sólo los puntos de control en los que se ha superado el valor umbral pertinente más estricto, sin necesidad de incluir aquellos puntos de control en los que no se haya determinado un valor umbral, o el valor umbral no se haya excedido.

Este procedimiento estaría en consonancia la DAS, que dispone que *"se indiquen los casos en los que se ha superado… siempre que resulte pertinente y factible"*, y dirigiría la atención hacia los problemas específicos de cada masa de agua subterránea.

De acuerdo con el artículo 4.4 de la DAS, debe publicarse en los planes hidrológicos de cuenca un resumen de la evaluación del estado químico de las aguas subterráneas. Este resumen debe incluir una explicación sobre cómo la evaluación final se refiere a los incumplimientos de las normas de calidad de las aguas subterráneas o de los valores umbral registrados en las diferentes estaciones de control.

2.5.3 Evaluación de tendencias

De conformidad con el anexo V, 2.5 y 2.4.5, los resultados de la evaluación de tendencias y de la inversión de la tendencia deben reflejarse en un mapa. Las MAS que experimentan una tendencia significativa y sostenida al aumento de las concentraciones de cualquier contaminante como resultado del impacto de la actividad humana, deben indicarse en el mapa con un punto negro. Cuando se ha logrado la inversión de una tendencia ascendente debe indicarse mediante un punto azul.

Tal como establece el artículo 5(4) de la DAS, y de conformidad con el artículo 13 de la DMA y el artículo 5(5) de la DAS, el resumen que los Estados miembros deben publicar en los PHC debe indicar asimismo:

- de qué modo ha contribuido la evaluación de tendencias en los puntos de control dentro de una masa o de un grupo de masas de agua subterránea a identificar que las masas citadas están sujetas a una tendencia significativa y sostenida al aumento o a una inversión de esa tendencia; y
- la justificación de los puntos de partida definidos para la aplicación de las medidas de inversión de la tendencia, y
- cuando proceda, los resultados de la evaluación de los impactos de los penachos existentes, en particular la verificación por medio de evaluaciones de tendencia adicionales, de que los penachos existentes de suelos contaminados no se extienden, no deterioran el estado químico de las masas de agua subterránea y no presentan un riesgo para la salud humana y el medio ambiente.

3 EVALUACIÓN DEL ESTADO

De conformidad con la DAS, la evaluación del estado sólo debe llevarse a cabo en masas de agua subterránea que se hayan identificado como masas en riesgo y en relación con el receptor y cada uno de los contaminantes que contribuyen a esa caracterización de la masa de agua subterránea (anexo III, 1). Las MAS que no están en riesgo se clasifican automáticamente como masas en buen estado.

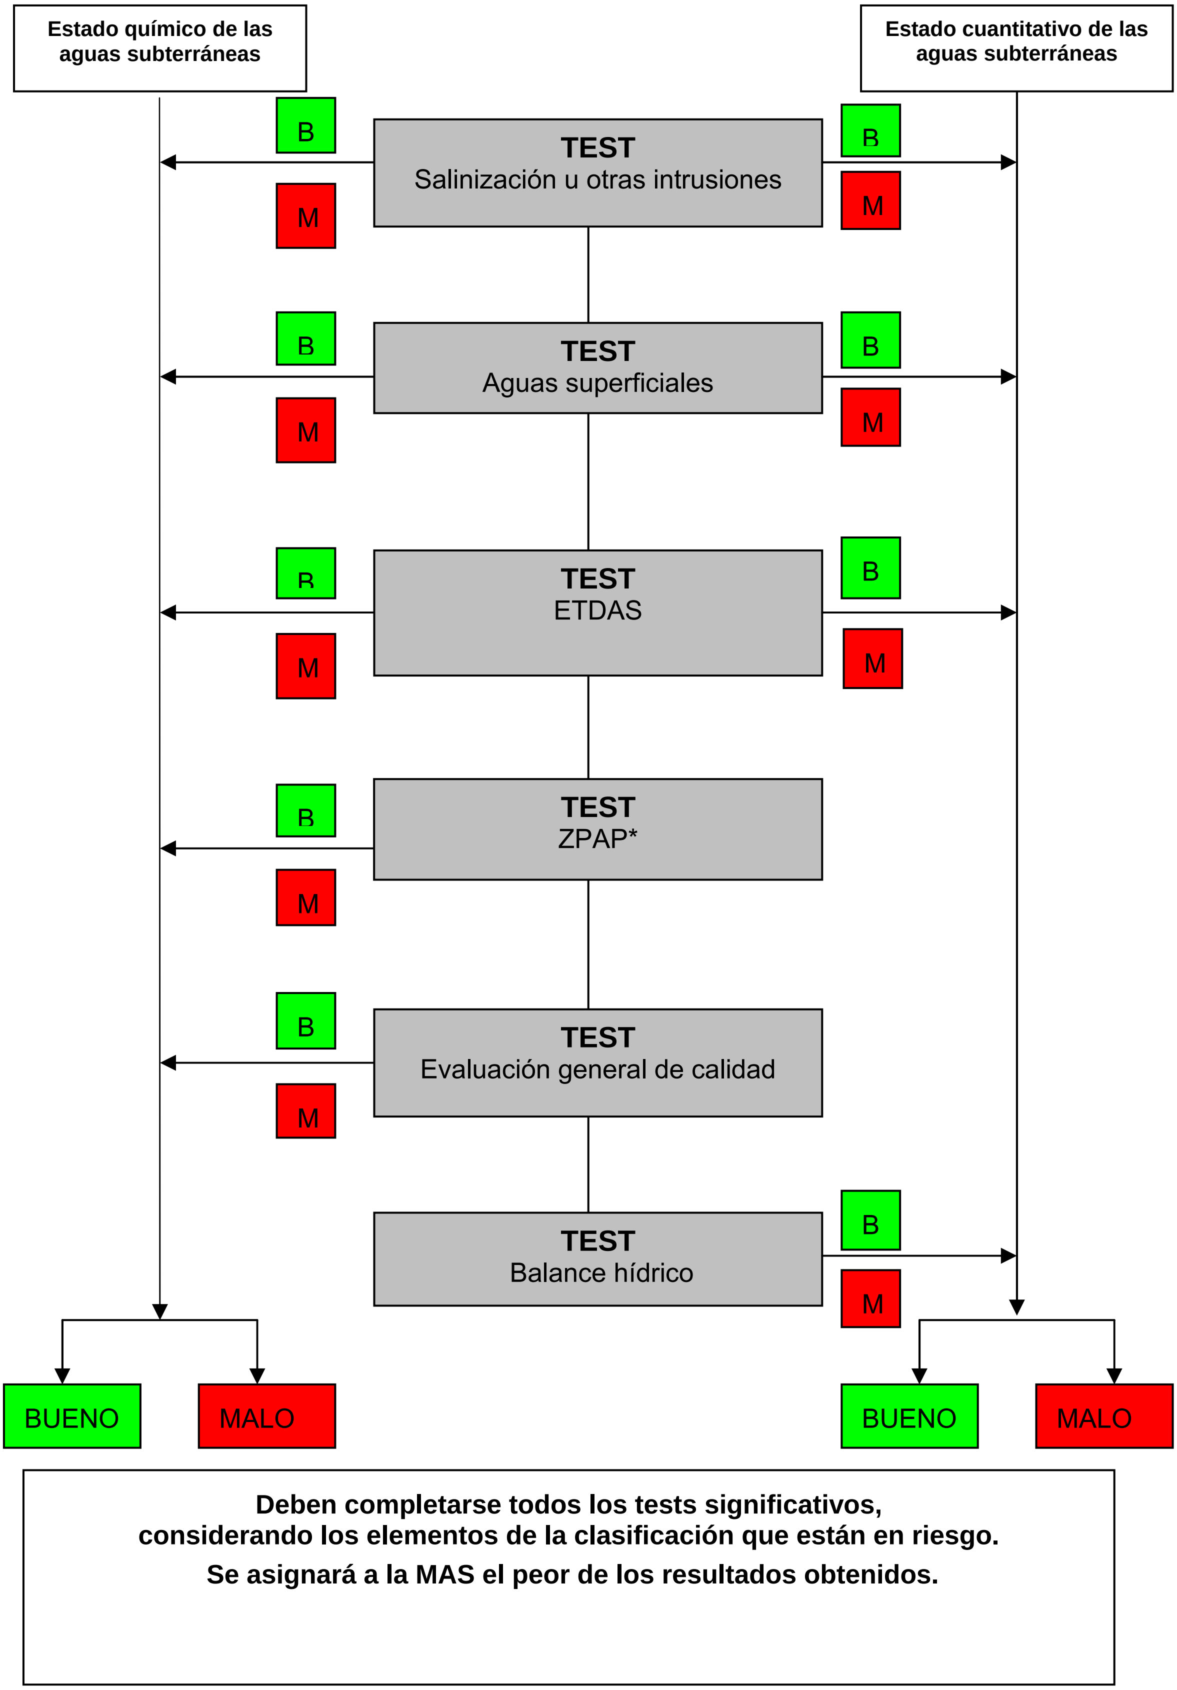
La evaluación del estado se lleva a cabo utilizando los datos de control operativo y de vigilancia disponibles recogidos durante el periodo del PHC. Debe producirse al final del PHC, para que permita evaluar la eficacia de los programas de medidas adoptados previamente.

El mapa que muestra los resultados de la evaluación del estado de las aguas subterráneas es parte integral del PHC. El proyecto de PHC se somete a participación pública un año antes de ser operativo, por lo que se recomienda que se realice una evaluación del estado antes de la publicación del proyecto de PHC para que puedan incluirse los resultados/mapas.

3.1 Tests de clasificación

Alcanzar un buen estado de las aguas subterráneas implica el cumplimiento de una serie de condiciones que se definen en las directivas DMA y DAS. Para evaluar si esas condiciones se cumplen, se ha desarrollado una serie de tests de clasificación para el estado cuantitativo y químico, que se ilustran en la Figura 1. Existen cinco tests químicos y cuatro cuantitativos con algunos elementos comunes a los dos tipos de evaluaciones. Cada uno de los tests, considerando los elementos de clasificación que estén en riesgo, debe llevarse a cabo de modo independiente y los resultados combinados deben aportar una evaluación global del estado químico y cuantitativo de la masa de agua subterránea (véase el capítulo 4.4 y la figura 4).

El peor resultado en la clasificación resultante de los tests químicos se establece como el estado químico global de la masa de agua subterránea, y el peor resultado de clasificación de los tests cuantitativos se establece como el estado cuantitativo global de la masa de agua subterránea. Si alguno de los tests da como resultado un mal estado químico o cuantitativo entonces la clasificación general de la masa será mala. Todos los tests pertinentes deben llevarse a cabo en todas las masas de agua subterránea. El proceso de evaluación del estado no debe detenerse aunque el resultado de uno de los tests indique el mal estado de la masa de agua subterránea.



* ZPAP: Zonas protegidas para la captación de agua potable

Figura 1: Procedimiento global para los tests de clasificación para la evaluación del estado de las aguas subterráneas

3.2 Evaluación de riesgo frente a evaluación de estado

Debe diferenciarse claramente la validación del análisis de presiones e impactos -evaluación del riesgo- del artículo 5 de la DMA al comienzo del ciclo de un PHC, de la evaluación del estado de una masa de agua subterránea al final del ciclo de un PHC -evaluación del cumplimiento-.

Al principio de cada ciclo, la evaluación del riesgo tiene en cuenta las presiones y los impactos, y lleva a cabo una estimación del estado en el que se encontrará la MAS al final del ciclo. Esta estimación se convalida con los datos de control recientes procedentes del control de vigilancia y con cualquier otra evaluación de tendencia que se considere adecuada. Si no puede confirmarse que una masa de agua subterránea estará en buen estado al final de un ciclo PHC, será necesaria una caracterización adicional, así como el establecimiento de valores umbral, seguimiento operativo y un programa de medidas.

Los valores umbral y los programas de medidas están sujetos a informes dentro del PHC. Al final de cada PHC, deberá llevarse a cabo una clasificación del estado para evaluar si la masa de agua subterránea se halla en buen estado y el programa de medidas ha sido efectivo.

Es posible que las dos evaluaciones -evaluación del riesgo y evaluación del estado- se lleven a cabo prácticamente a la vez, pero son procesos paralelos separados; la evaluación del riesgo se centra en el futuro, hacia el final del próximo ciclo del PHC, y la evaluación del estado es retroactiva, referida a los resultados obtenidos durante el último ciclo del PHC (véase la figura 2).

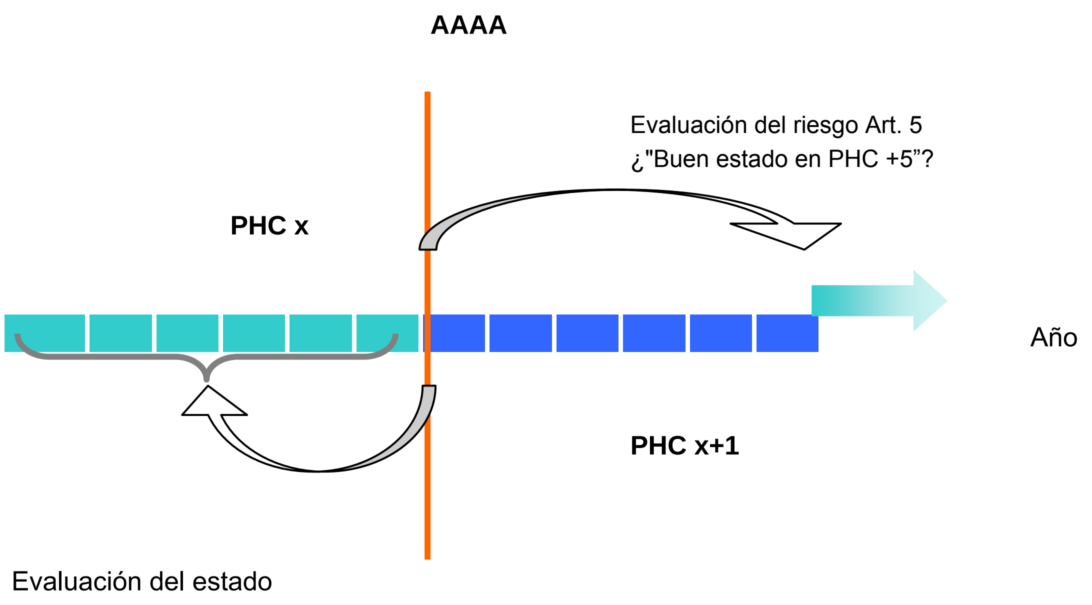


Figura 2. La evaluación de riesgo se centra en el futuro, mientras que la evaluación del estado se basa en los resultados anteriores.

3.3 Confianza en la evaluación

De conformidad con el anexo V 2.4.1 de la DMA *"[…] En el plan se ofrecerá una apreciación del nivel de fiabilidad y precisión de los resultados obtenidos mediante los programas de control."*

4 EVALUACIÓN DEL ESTADO QUÍMICO

4.1 Definición de buen estado químico y fundamentos legales

La definición del estado químico figura en el anexo V 2.3.2 de la DMA. Se alcanza un buen estado químico de las aguas subterráneas cuando:

"*La composición química de la masa de agua subterránea es tal que las concentraciones de contaminantes:*

- *como se especifica más adelante, no muestran los efectos de la salinización o de otras intrusiones,*
- *no exceden las normas de calidad aplicables según otros actos de la legislación comunitaria, de conformidad con el artículo 17 de la DMA*[17]
- *su naturaleza no es tal que pueda producir la imposibilidad de lograr los objetivos ambientales especificados de conformidad con el artículo 4 para las aguas superficiales asociadas ni ninguna disminución significativa de la calidad ecológica o química de estas masas ni ningún daño significativo a los ecosistemas terrestres que dependen directamente de la masa de agua subterránea.*

Los cambios en la conductividad no indican que exista salinización ni ninguna otra intrusión en la masa de agua subterránea".

La DAS reitera que la evaluación del estado químico debe llevarse a cabo para todas las masas de agua subterránea que estén en riesgo de no cumplir los objetivos del artículo 4 de la DMA, en relación con cada uno de los contaminantes que contribuyen a esa caracterización de la masa de agua subterránea (anexo III, 1 de la DAS). Esto se aplica a aquellas MAS que se identificaron en 2004 como masas en riesgo, de conformidad con los requisitos del artículo 5 de la DMA, así como cualquier otra que se identificara con posterioridad a raíz del trabajo de actualización de la evaluación de riesgo utilizando los nuevos datos de seguimiento. El artículo 4(2) de la DAS dispone que una masa de agua subterránea o un grupo de masas tiene un buen estado químico cuando:

- cumple las condiciones del anexo V 2.3.2 de la DMA,
- no excede ningún valor umbral (artículo 3 y anexo II de la DAS) ni norma de calidad (anexo I de la DAS) en ninguno de los puntos de control, o
- aunque ha excedido el valor umbral o la norma de calidad en alguno de los puntos de control, se ha demostrado mediante investigaciones adecuadas (anexo 3 de la DAS) que:
    - i. las concentraciones de contaminantes no presentan un riesgo medioambiental significativo, teniendo en cuenta, cuando proceda, el alcance de la masa de agua subterránea que se ve afectada;
    - ii. se cumplen las demás condiciones para un buen estado que figuran en el anexo V 2.3.2 (DMA), con arreglo al párrafo 4 del anexo III de la DAS;
    - iii. no hay deterioro de la calidad de las aguas para consumo humano (ZPAP) de conformidad con el párrafo 4 del anexo III de la DAS; y
    - iv. no hay deterioro significativo de la capacidad de la masa para atender los diferentes usos.

El anexo V, 2.4.5 de la DMA estipula las especificaciones siguientes para el procedimiento de evaluación del estado químico de las aguas subterráneas:

"Al evaluar el estado, los resultados de cada punto de control en una masa de agua subterránea se globalizarán para la totalidad de la masa. Sin perjuicio de las Directivas correspondientes, para que una masa de agua subterránea alcance un buen estado, en lo referente a los parámetros químicos para los que se han fijado normas de calidad medioambiental en la legislación comunitaria:

– *se calculará el valor promedio de los resultados del control obtenidos en cada punto de la masa o grupo de masas, y*

[17] Esto corresponde al requisito de la DMA que condujo a la adopción de la DAS

– *de acuerdo con el artículo 17, dichos valores promedio se utilizarán para demostrar la conformidad con el buen estado químico de las aguas subterráneas […]"*

La DAS dispone a continuación que de conformidad con el anexo III 2 c): *"Los Estados miembros deberán tener en cuenta […] c) cualquier otra información relevante, incluida una comparación de la concentración media anual de los contaminantes pertinentes en un punto de control con las normas de calidad de las aguas subterráneas […] y con los valores umbral […]."*

De conformidad con el anexo III, 3 de la DAS, en cuanto a i) y a iv) los Estados miembros efectuarán una estimación de la porción de la masa de agua subterránea cuya concentración media anual de un contaminante supera la norma de calidad o el valor umbral.

En lo relativo a ii) e iii), los Estados miembros evaluarán:

- el impacto de los contaminantes sobre la masa de agua subterránea
- la cantidad y las concentraciones de contaminantes que se están transfiriendo o pueden transferirse desde la masa de agua subterránea hacia las aguas superficiales asociadas o los ecosistemas terrestres directamente dependientes, y los posibles impactos resultantes
- el alcance de toda posible salinización o intrusión de otro tipo en la masa de agua subterránea
- los riesgos derivados de los contaminantes en la masa de agua subterránea para la calidad del agua captada o que pueda ser captada para el consumo humano

Los tests de clasificación química que se indican en esta guía se derivan de los requisitos mencionados con anterioridad.

4.2 Elementos de la evaluación del estado químico

En la evaluación del estado químico de las aguas subterráneas deben considerarse los siguientes elementos:

- **los criterios** para la evaluación del estado químico de las aguas subterráneas -*normas de calidad y valores umbral-* que se describen con detalle en la sección 4.3.
- la necesidad de **agregación** de los datos
- **el alcance** del incumplimiento de las normas de calidad o de los valores umbral
- **la localización** de los puntos donde se han superado las normas de calidad o los valores umbral
- **la confianza** en la evaluación

4.2.1 Agregación de los datos

Como se ha reseñado anteriormente, varios artículos y anexos de las Directivas DMA y DAS hacen referencia a la agregación de los datos. Se trata de la evaluación de los siguientes aspectos:

- los riesgos ambientales significativos derivados de los contaminantes presentes en una masa de agua subterránea,
- que no exista deterioro significativo de los diferentes usos,
- la disminución de la calidad ecológica y química de las masas de aguas superficiales asociadas,
- los daños a las ETDAS,
- que no haya deterioro de las aguas para el consumo humano.

Se propone adoptar la norma de considerar los datos de control recogidos en los dos últimos años, lo que posibilita el cálculo de un valor medio aunque solo se realice una medición al año. Puede elegirse un periodo medio más largo -hasta de 6 años- cuando el modelo conceptual y los datos de control indiquen que es necesario evitar la influencia de las variaciones de calidad a corto plazo, que no indican la repercusión real de las presiones.

4.2.2 Alcance del incumplimiento de las normas de calidad o de los valores umbral
